Integration of Motion Capture into 3D Animation Workflows

Introduction

Motion Capture (MoCap) is a technique for gathering data of the movements of the human body. With the intention of using this information to drive the movements of 3D models in computer generated animation, MoCap offers significant advantages for producing natural and believable movement in 3D animation and opens up the possibility of bringing to ear acting and live direction in the animation process.

Some major Animation studios expect an output from their animators of around 1-2 seconds of footage per day. So any enhancement to the animation production workflow would result in a reduction of the labour intensive and very highly skilled process of manually animating 3D characters. However it is wishful to think that MoCap can replace animators with actors.

Our group set out to test and evaluate this technology on a live CG animation project and discover how it can actually contribute to the animation production workflow. The project is Called “Icarus” and it is a short animation produced entirely CG. It is a fantastic retelling of the myth of Icarus.

There are several methods of motion capture.

There are optical methods, such as Vicon, where white spots are applied to the body at the joints. Their movement across a camera or tracked and analyzed computationally in order to define a motion path for each joint in 3D space. This is widely used in the industry, but has the significant disadvantages of producing noisy data and being limited to movements that take place with the frame of a static camera or set of static cameras.

There are mechanical methods that are attached to the body and measure the rotation of the joints. This is a fairly accurate method of data capture but has the unfortunate effect of influencing the actual movements of the actor since the sensors are visible to the camera.

The method we used is based on the Xsense motion capture suit which uses inertial sensors attached to the body. This method avoids the major problem of the other methods. It is relatively unobtrusive to the actor movement allowing a large range of movement at both the infinite scale and the large scale up to a radius of 150 metres. The disadvantages are the sensor is affected by electromagnetic interference and absorption. So the data produced is effected by incidental topical noise. Also physical disturbance of the sensors causes errors in the data. e.g. if they are knocked out of position in vigorous actions. These problems aside the Motion Capture suit method appears to offer the most flexible system for acquiring natural movements.

The limitations of the MoCap suit are that it records only the limbs and spine movements, there is no data for finger movement or facial movement. The Xsense suit does not log any information in the vertical dimension relative to the ground. This is widely used in the industry, but has the significant disadvantages of producing noisy data and being limited to movements that take place with the frame of a static camera or set of static cameras.

In Practice

In practice, we required three people- the actor and a minimum of two people to tend the kit and operate the software. Setting up the suit took time and a certain amount of understanding of how it is supposed to work. The sensors must be in the right locations and well settled before calibrating the suit.

The MoCap software provided the makers of the suit gets live feedback of the data readings. The data from the sensors is transmitted wirelessly and represented on screen as a standard animation skeleton. Calibration involves the actor taking up predetermined poses and performing controlled predetermined gestures. This allows the software to calculate the relative positions and relative rotations of the sensors. This is further confirmed by manually inspecting the physical dimensions of the actor. In the first sessions this process took several hours; but with practice we gained an intuition for how the software was calibrating and the process could be completed in a few minutes.

The animation process meant that we had to plan the capture session quite carefully. In a process that is quite similar to a simplified film shoot. We produced a list of movements that were needed to tell our story. This scene was set up using improvisation props to match the movements described by the content of the scene. An actor also had to be aware of the layout and ground plans of the scene so that the actor’s movements in real space match the architecture of the 3D model etc.

The degree of freedom offered by the Xsense MoCap suit allowed a lot of latitude for improvisation in the use of space. e.g. we used the underside of table to simulate the character climbing upside down a ladder.

The gathered of these acting sessions is remarkably sensitive, seeing the representation of the movements on the skeleton reveals how subtle our movements are and how consciously we are aware of what we are doing. There are small rotations of the joints. This is a subtlety of movement that gives the uncanny sense of believability that is missing from much computer animation.

The Clean Up

The data in raw form contains errors of various types.

- There are spikes in the motion curve caused by radio frequency interference.
- Enormous static rotations caused by the sensors slipping out of place after the calibration.
- Fluctuations in the motion path, caused by signal interference.
- Interpretation errors, caused by inappropriate interpolation of data by the MoCap software in uncertain instances of signal failure.

Many of these errors are just a few frames in length and can be fixed quite simply skimming off data held on the problematic frames and creating an appropriate interpolation between the good data the surroundings it. This is a painstaking and labour intensive process. Longer errors not worthwhile repairing as it is less work to re-shoot the shot or manually animate later on in the process.

The MoCap data is re-integrated onto a control rig which is standard forward kinematic and inverse kinematic rig in Motion Builder software. This means the rotations and translations are applied to the rig. Thus applied, the errors in the data are more easily read and corrected. This is an industry standard animation control rig for driving 3D characters. This rig offers control over more parts of the body including fingers, jaw, eye etc. The MoCap data drives to movement of the parts of the animation rig that it has data for and leaves the rest unchanged. These will be animated manually later on.

The animation control rig then has a 3D character model applied to it. The model is moved by the rig and the rig is used in animation software to drive and adjust the final movements of the designed characters.

Conclusion

With a small amount of experience and practice it is possible to produce very good quality motion capture data from the Xsense Mark 3 kit in 3D animation.

The product of the Motion Capture data processing is a partially driven character rig, which gives a base animation that is re-fined by the animators to fit with the creative intent of the story. This is a significant aid in accelerating the process of 3D CG animation.

It also has the beneficial effect of educating animators about the subtlety of natural movement and how movement convey messages as the sensitivity of the system reveals minute gestures and movements that we do not perceive with the naked eye. Seeing the movements on the skeleton, stripped of the context of the personality aids the animator in gaining an objective view on the whole figure and enables a focus on the communicative gestures.
