Abstract:

The ISO standards for the Geometrical Product Specification and Verification (GPS) define an internationally uniform description language, that allows expressing unambiguously and completely all requirements for the geometry of a product with the corresponding requirements for the inspection process in technical drawings, taking into account current possibilities of measurement and testing technology. The practice shows that the university curricula of the mechanical engineering faculties often include only limited classes on the GPS, mostly as part of curriculum of subjects like Metrology or Fundamentals of Machine Design. This does not allow students to gain enough knowledge on the subject. Currently there is no coherent EU-wide provision for vocational training (VET) in this area. Consortium, members of which are the authors of this paper, is preparing a proposal of an EU project aiming to develop appropriate course.

1. Introduction

The ISO standards for the Geometrical Product Specification and Verification (GPS) define an internationally uniform description language, that allows expressing unambiguously and completely all requirements for the micro and macro geometry of a product with the corresponding requirements for the inspection process in technical drawings, taking into account current possibilities of measurement and testing technology. This avoids ambiguities and inconsistencies during the planning of manufacturing and inspection processes and in addition costs through time-consuming arrangements between the client and suppliers. GPS is a subject that is relevant to a growing number of sectors of industry throughout the EU. The standardization works are very intensive in the scope of GPS. Currently there are 60 standards under development, for which the total number of pages is ca. 2500.

Well trained staff in this subject is necessary for effective and wide implementation of new GPS tools. Currently there is no coherent EU-wide provision for vocational training (VET) in this area. A consortium of partners, members of which are the authors of this paper, prepares a proposal of an EU project aiming to develop appropriate course. It is of vital importance that this dearth of knowledge at a vocational level is addressed to ensure EU industry competitive advantage in a global marketplace. Due to accessibility of the course though the internet it's easy to use in any place and suitable time. Duration of the learning is controlled by the user. Learner can also control the level of the gained knowledge through the comprehension tests provided. A significant number of real life examples and illustrations makes the understanding of the material much easier. The final version of the prepared didactic material and curriculum can be a base for an EU wide course in the proposed subject that leads to skills that are relevant and timely for industry.

2. Importance of the subject

Engineering drawings without geometrical tolerances and datums or datum systems are in most cases incomplete and ambiguous and therefore not unambiguously interpretable. The incomplete, ambiguous tolerancing of components in engineering drawings causes not only increased production and inspection costs but also makes impossible reasoned complaints of shortcomings and ultimately lead to an incalculable liability risk in the case of legal disputes. Therefore the designers and metrology engineers must have good knowledge on the Geometrical Product Specifications (GPS) and verification methodology which ought to be given during studies or refreshed and supplemented by specialized training courses on the new standards. The practice shows that the university curricula of the mechanical engineering faculties often include only limited classes on the GPS, mostly as part of curriculum of subjects like Metrology or Fundamentals of Machine Design. This does not allow students to gain enough knowledge on the subject.

The problem of ambiguous specification of product geometry requirements relates primarily to distances. Examples can be the
distance between two integral features facing opposite directions (Fig. 1a), linear step dimensions (Fig. 1b) and distance between an integral and a derived feature (Fig. 1c) which are specified on the drawing as tolerated dimensions. This problem is raised in ISO 14405-2 [1].

Fig. 1. Example of ambiguous specification of manufacturing accuracy by means of linear distance: a) distance between two integral features facing opposite directions, b) linear step dimension, c) distance between axis and plane [1]

Another example of ambiguous geometry specification is dimensioning of radii (Fig. 2) and chamfers (Fig. 3) [1].

Fig. 2. Example of ambiguous specification of radius [1]

Fig. 3. Example of ambiguous specification of chamfer [1]

3. Most important GPS standards concerning macro-geometry of products

The most important GPS standards concerning macro-geometry of products are definitely ISO 1101 [2], ISO 5459 [3], ISO 14405-1 [4], ISO 14405-2, ISO 2768-1 [5], ISO 2768-2 [6], ISO 5458 [7], ISO 13715 [8], ISO 10579 [9] and ISO 2692 [10]. The standards include many tools for proper (unambiguous) requirements specification – one just needs to use them. Geometrical tolerances, and especially tolerance of position [1, 2], give possibility of unambiguous definition of requirements. Fig. 4a presents three examples for replacing tolerated linear dimension from Fig. 1 with position tolerance. It’s worth to mention that the ways of specification are directly connected with the possible measurement strategies (Fig. 4b).

Fig. 4. Three examples of possible unambiguous specification using position tolerance (a) and associated ways of measurement (b)

Fig. 5 presents three examples for replacing linear dimension used on Fig. 1c. In this case position tolerance with single datum can be used (Fig. 5a and b) or datum system (Fig. 5c) [2, 3].

Possible way of requirement specification for radius using profile any line/surface and chamfer is depicted on Fig. 6 (a – for radius, b – for chamfer).

In order to connect geometrical product specification with appropriate measurement procedures, the standard ISO 14405-1 [4] introduces possibility of specification of type of dimension (Fig. 7).

The term “type of dimension” is directly connected with the possible way of performing the measurement.

Some types of dimensions received their designation:
• two-point size – LP,
• local size defined by a sphere (ball size, spherical size) – LS,
• least-squares association criterion (least-squares size) – GG,
• maximum inscribed association criterion (maximum inscribed size) – GX,
• minimum circumscribed association criterion (minimum circumscribed size) – GN,
• circumference diameter – CC,
• area diameter – CA,
• volume diameter – CV.

Further types of dimensions like section size and portion size are pointed out on the drawing by other tools like e.g. symbol “ACS” which stands for “any cross section”.

Fig. 5. Three examples of possible unambiguous specification of distance between hole axis and a plane using position tolerance: a) datum is plane, b) datum is axis of the hole, c) the hole position is defined in respect to 2 datum system

Fig. 6. Examples of unambiguous specification of: a) radius, b) chamfer, c) interpretation of chamfer tolerance
Moreover, for local two-point size it’s possible to specify so-called rank-order sizes including 5 types of dimensions:

- maximum size (maximum measured value) - SX,
- minimum size (minimum measured value) - SN,
- average size (average of measured values) - SA,
- median size (median of measured values) - SM,
- mid-range size (mean of maximum and minimum measured values) - SD

and 1 characteristic describing dispersion of dimension:

- size range (difference between maximum and minimum value) – SR.

Examples of use of the designation of dimension type are depicted on Fig. 7.

Introduction of modifier CZ (common zone) enables specification of requirements for common axis (Fig. 8) or common plane.

Additionally, in ISO 5459 new tools for datum specification are included. Of particular note is the possibility of specifying moveable datum target (Fig. 9).

ISO 5459 [3] introduces also other new modifiers, e.g.:

- [CF] - contacting feature,
- [DV] - variable distance (for common datum),
- [PT] - situation feature of type point,
- [SL] - situation feature of type straight line,
- [PL] - situation feature of type plane,
- \(<<\) - modifier „for orientation constraint only“ (Fig. 10),
- direction feature (Fig. 11),
- collection plane (Fig. 12),
- intersection plane (Fig. 13),
- orientation plane (Fig. 14),
profile (P) parameter, 4’ concepts associated with operations on geometric elements such as integral feature, derived feature, feature of size, etc. There are such new terms as skin model, geometrical feature, situation feature, etc. [38].

Zone can be used to expand the tolerance of size dimension. “Savings” resulting in incomplete use of the geometrical tolerance to expand the geometrical tolerance zone, and in some cases the “savings” resulting in incomplete use of the tolerance of dimension can be used for reciprocity requirement [10]. This is due to the fact that the “savings” — maximum material requirement, least material requirement and requirements specification — may include many important details (Fig. 15), especially information on filtering parameters.

4. Standards concerning surface roughness

The most important standards for surface roughness include:

- for 3D measurements: ISO 25178 (a few parts) [20-25].

It may be noticed that the attention is brought to the precise requirements specification — standard surface structure designation includes many important details (Fig. 15), especially information on filtering parameters.

5. Standards concerning coordinate measuring technique

Coordinate measurements are commonly used measuring technique. Together with its introduction a new philosophy of measurements and terminology are introduced. Many aspects of this technique are presented in standards ISO 14660-2 [26], ISO 17450-1 [27], ISO 17450-2 [28], ISO 22432 [29], ISO 25378 [30], ISO 12180-1 [31], ISO 12180-2 [32], ISO 12181-1 [33], ISO 12181-2 [34], ISO 12780-1 [35], ISO 12780-2 [36], ISO 12781-1 [37], ISO 12781-2 [38].

The standards dealing with coordinate measurements include such new terms as skin model, geometrical feature, situation feature, integral feature, derived feature, feature of size, etc. There are concepts associated with operations on geometric elements such as partition, extraction, filtration, association, collection, construction, reconstruction, reduction, evaluation, transformation. There is term characteristic (single property defined from one or more geometrical feature(s)) of different type like intrinsic or situation (Fig. 16).

6. ISO 14638

The standard ISO 14638 [39] systematizes the work in the range of GPS by introducing classification of the GPS standards into 3 groups (fundamental, general, complementary), and its scope includes nine types of geometrical property (size, distance, form, orientation, location, run-out, profile surface texture, areal surface texture, surface imperfections). The former edition of the standard distinguished fourth group (global) and more types of geometrical property (size, distance, radius, Angle, form of a line independent of datum, form of a line dependent on datum, form of a surface independent of datum, form of a surface dependent on datum, orientation, location, circular run-out, total run-out, datums, roughness profile, waviness profile, primary profile, surface imperfections and edges).

Particular standards are assigned to so called chain links, designated with letters A to G (previously with numbers 1 to 6):

A. Symbols and indications (this consists of ISO GPS standards defining the form and proportions of symbols, indications and modifiers and the rules governing their use).

B. Tolerance characteristics and specification limits (this consists of ISO GPS standards defining tolerance characteristics, tolerance zones, constraints and parameters; this would include standards defining geometrical characteristics, size properties, surface texture parameters, the shape, size, orientation and location of tolerance zones, and the definitions of parameters).

C. Feature properties (this consists of ISO GPS standards defining the characteristics and conditions of features on a workpiece; this would include standards defining operations of partitioning, extraction, filtration, association, collection and construction).

D. Conformance and non-conformance (this consists of ISO GPS standards defining the requirements for comparison between specification requirements and verification results; this includes...
standards defining default values, rules for conformance and non-conformance and standards dealing with uncertainty).

E. Measurement (this consists of ISO GPS standards defining the requirements for measuring feature characteristics and conditions).

F. Measurement equipment (this consists of ISO GPS standards defining the requirements for equipment used for measurement).

G. Calibration (this consists of ISO GPS standards defining the requirements for calibration and calibration procedures for measurement equipment).

7. ISO 8015

The standard ISO 8015 [40] is of key importance. Many years ago it introduced concept of independency principle – currently it sets out general principles binding in GPS, namely:

- invocation principle,
- principle of GPS standard hierarchy,
- definitive drawing principle,
- feature principle,
- independency principle,
- decimal principle,
- default principle,
- reference condition principle,
- rigid workpiece principle,
- duality principle,
- functional control principle,
- general specification principle,
- responsibility principle.

With this standard, there is, among others, legal basis for resolving conflicts between supplier and customer.

8. Standards concerning measurement uncertainty

The problems of measurement uncertainty in GPS are considered in: ISO 14253-2 [41], ISO 16015 [42] in relation to conventional measurements and in ISO 15530-3 [43] and ISO 15530-4 [44] in relation to coordinate measurements. ISO 14253-2 provides a classification and detailed list of error sources. It references the parent documents concerned with uncertainty evaluation, namely JCGM 100 [45] and JCGM 101 [46], distinguishes black and transparent box model of uncertainty estimation and provides comprehensive examples of uncertainty evaluation. ISO 16015 is completely devoted to the temperature errors evaluation.

ISO 15530-3 [43] deals with uncertainty evaluation of coordinate measurements according to the procedure using calibrated workpiece. This method can be easily implemented in automotive industry (Fig. 17).

The technical specification ISO/TS 15530-4 [44] deals with evaluation of uncertainty of coordinate measurements by analytical methods, and especially with use of Monte Carlo simulation. These methods are now-a-days used mainly by calibration laboratories.

9. Standards concerning calibration of measuring equipment

Following standards concern requirements and calibration of conventional measuring equipment:

10. Standards concerning specific machine parts

Rules for specification requirements as well as verification of products geometry for specific machine parts like threads, gears, splines, cones, etc. can be found in following standards:

- threads – ISO 965-2 [66], ISO 1502 [67],
- gears – ISO 1328-1 [68], ISO 1328-2 [69] and ISO 1340 [70],
- splines – ISO 4156-3 [71],
- cones – ISO 3040 [72],
- wedges – ISO 2538-2 [73].

11. Proposal of EU project

In 1999-2001 some of the consortium members participated in the project carried out under Leonardo da Vinci programme, which output was the book "Geometrical Product Specification - course for Technical Universities" which was published in English [74], German
The importance of the GPS as well as e-learning with use of the Internet is underlined in many publications [78-90].

The authors propose to develop and implement a coherent learning system for higher-level vocational training concerning the GPS, which can also be a supplement for existing curricula of engineering studies bridging a gap in the education of engineers. The courses are delivered by means of basic and specialized continuing e-training systems offering on-demand e-learning modules, as well as assistance systems that incorporate permanent participation in a ubiquitous e-learning community of experts. Necessity of assistance systems that incorporate permanent participation in training systems offering on-demand e-learning modules, as well as courses are delivered by means of basic and specialized continuing e-learning systems. The courses are designed to provide a unified standard learning offer, but still profiting from the diversity of learning and teaching constraints in different countries as well as to the equipment of specific training providers.

The intended approach combines eLearning materials defining a uniform standard of generally available information with individually designed presence-based offers. The teaching material will be implemented by an international cooperation of universities and metrological institutes and assessed in a pilot implementation in all participating countries, thus assuring the European dimension of the training offer and taking provisions for the later on transfer to further countries. During the further use, it will be possible to enhance the cooperation and communication of learners from different countries, unified by a basic standard learning offer, but still profiting from the diversity and individual strength of each specific learning environment.

The learning resources of the project will also be accessible at the workplace. It will include attractive links, small training tasks and self-assessment questions that should encourage users to broaden their learning, to go into greater depth and to take a more systematic learning path that, originating from a problem of practical relevance - will automatically retain its orientation towards application.

As those e-learning resources are constantly available, and as users are always able and encouraged to customize the direction and profoundness of their competence acquisition process, also those who were less active in a continuous process of work-related retraining in the past may be motivated towards entering a real lifelong learning path. These aims - towards application orientation and lifelong learning - require all learning resources, including instructional media, access to source material, all elements of the learner support and tutoring system, and the peer-learner virtual learning community have to be strictly available over the Internet and configurable for intranets, utilizing standard browser functionalities. Consortium also plans to enable offline use of the material, however in this case some interactive functionality may be lost, but still useful and required by some users.

Although, the university students are not the target group of this project they also can benefit from the outputs as the partners from different European Universities plan to use the developed material also in their lectures where GPS subject is included.

This course aims to bridge the gap in understanding that exists in the area of GPS, a vital component of manufacturing and quality management, such that knowledge in this area is accessible and immediate at the front line of industry. The contents of the course will be high quality product covering the up-to-date state of knowledge in the area of GPS. Transfer and implementation of this knowledge by the learners in the industry should lead to increasing the quality their products and rising the competitiveness of the enterprises.

The draft curriculum content is divided among partners according to their competences in particular field and necessary resources for preparation of the learning material. It’s planned to develop following modules of the course:

1. Geometrical characteristics and ISO system of limits and fits
2. Tolerances of form
3. Datums
4. Tolerances of orientation
5. Tolerances of location
6. Tolerances of any line/surface
7. Tolerances of runout
8. Principle of independency and other requirements
9. General tolerances
10. Complex geometrical features
11. Roughness, waviness, primary profile 2D/3D
12. Measurements with use of conventional measuring devices
13. Measurements with use of measuring machines
14. Measurements with use of coordinate measuring systems
15. Measurements of form deviations
16. Measurements in micro- and nanoscale
17. Measurements of surface roughness
18. Inspection by gauges and decision rules for proving conformance or non-conformance with specifications
19. Measurement uncertainty
20. Tolerancing of assemblies, dimensional chains
21. Calibration of measuring equipment

12. Conclusions

Globalization and the ensuing dissipation of the production of machine parts require precise formulation of requirements for geometrical accuracy products. From the side of standardization problem is to a large extent solved. However, there is a significant gap in the education of engineers, which - if the problem is not solved - may be a barrier in the development of new, finer design. According
to the authors problem can be solved by developing and widely providing high-quality teaching materials. Due to the widespread use of English in enterprises materials do not need to be translated into other languages in most cases.
