Abstract

A cross correlation filter – a half period of sinusoidal waveform sequence (p_T period), is applied to filter the topographical signal (p period) of 1D arbitrary-form grating against positions. It, as a template, cross-correlate with the signal and the noise that coexists with signal is eliminated if $p_T \approx p$. After filtering, the distance between any two adjacent waveform peaks along the direction perpendicular to 1D grating lines is one pitch value, the peak-detection (PD) method. In this method, the pitch average and uniformity can be calculated.

1. If present pitch evaluation methods meet noise?

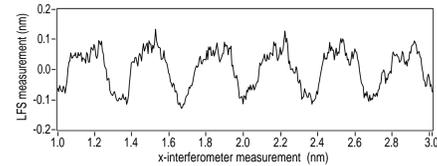

Figure 1. A grating position related topographical signal with noise and irregular waveforms. In such situation, centre-of-gravity (CG) evaluation method is difficult to be applied to calculate the pitches. Fourier-Transform-based (FT) method can be used, but it cannot decide the pitch uniformity.

2. 1D sinusoidal grating-probed signal filtering

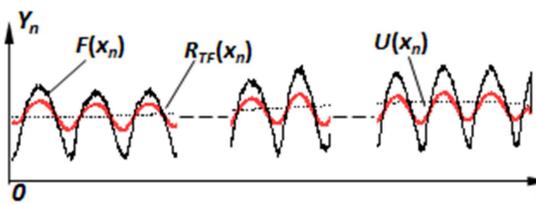

Figure 2. 1D sinusoidal grating position-related signal $F(x_n)$ probed by an AFM. It consists of sinusoidal $f(x_n)$, noise $W(x_n)$ and a tilt drifting $U(x_n)$ signals:

$$F(x_n) = f(x_n) + U(x_n) + W(x_n) = A \sin\left(\frac{2\pi}{p}x_n\right) + \sum_{n=0}^K H \cdot n^K + \frac{1}{M}, \quad 0 \leq n < M-1 \quad (1)$$

A cross correlation filter:

$$T(x_n) = B \sin\left(\frac{2\pi x_n}{p_T}\right), \quad 0 \leq n < N-1 \quad (2)$$

After cross-correlation filtering, the signal:

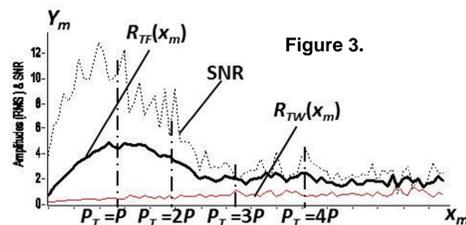

$$R_{TF}(x_m) = R_{TF}(x_m) + R_{TU}(x_m) + R_{TW}(x_m) \quad (3)$$

where $m = -(N-1), -(N-2), \dots, -1, 0, 1, \dots, M-2, M-1$.

Simulation experiment results [1] 1:

1. Cross correlation tilt signal $R_{TU}(x_m)$ is still a tilt component;
2. Cross correlation sinusoidal signal $R_{TF}(x_m)$ is sinusoidal;
3. Signals are in same period of p , with phase shift ϕ .

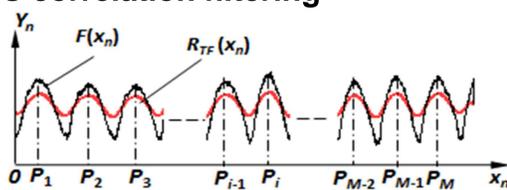

Illustrated by figure 3, simulation experiment results [1] 2:

$p_T = p$	$p_T < p$	$p_T > p$
1. Cross correlation signal $R_{TF}(x_m)$ has max. amplitude;	Noise can't be totally suppressed	$R_{TF}(x_m)$ drops as small as $R_{TW}(x_m)$ so that SNR is too low to distinguish periodical signal from noise.
2. Cross correlation noise $R_{TW}(x_m)$ is nearly to zero;		
3. Signal to noise ratio (SNR) has maximum amplitude.		

3. Pitch evaluation after cross-correlation filtering

Figure 4. Signals before and after cross-correlation filtering, where low frequency tilt signals are eliminated in figure 2.

Individual pitch is calculated by:

$$\begin{cases} P_1 = (p_2 - p_1) \cdot \cos \alpha \\ P_2 = (p_3 - p_2) \cdot \cos \alpha \\ \dots \\ P_{M-1} = (p_M - p_{M-1}) \cdot \cos \alpha \end{cases} \quad (4)$$

$$\text{Pitch Average: } \bar{p} = \frac{1}{M-1} \sum_{i=1}^{M-1} P_i \quad (5)$$

$$\text{Pitch Uniformity: } \delta = \frac{1}{M-1} \sqrt{\sum_{i=1}^{M-1} (P_i - \bar{p})^2} \quad (6)$$

where, $p_1, p_2, p_3, \dots, p_M$ – detected peaks; α – angle between x-axis and direction which is perpendicular to the 1D grating lines.

To decide the tilt angle α [2]:

$$\begin{cases} X = (fsx + lx + fex) \cdot p / \sin \alpha \\ Y = (fsy + ly + fey) \cdot p / \cos \alpha \end{cases} \quad (7)$$

$$\alpha = \arctan\left(\frac{Y}{X} \cdot \frac{lx + fsx + fex}{ly + fsy + fey}\right) \quad (8)$$

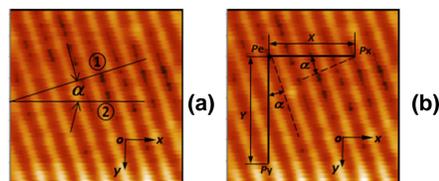

Figure 5. A tilt angle α between perpendicular line ① and displacement direct ② is shown in (a) and the diagram on evaluation of tilt angle α is shown in (b).

where, lx, fsx and fex are integer periods, fractional parts at beginning and end in x-axis; ly, fsy and fey are integer periods, fractional parts at beginning and end in y-axis.

4. Application of cross-correlation filter to signal of 1D, p-periodic and arbitrary-structured grating

It can be written as a Fourier sine series: $f(x_n) = \sum_{k=1}^{\infty} A_k \cdot \sin\left(\frac{2k\pi x_n}{p}\right)$ ($0 \leq n \leq N-1$) (9)

$$\text{where } A_k = \frac{4}{p} \int_0^{p/2} f(x_n) \cdot \sin\left(\frac{2k\pi x_n}{p}\right) dx_n, (k=1, 2, 3, \dots) \quad (10)$$

When it cross-correlated with a half sinusoidal waveform template of p -period,

$$R_{TF}(x_m) = C_1 \cdot \sin\left(\frac{2\pi x_m}{p} + \phi_1\right) + C_2 \cdot \sin\left(\frac{2\pi x_m}{p_2} + \phi_2\right) + \dots + C_k \cdot \sin\left(\frac{2\pi x_m}{p_k} + \phi_k\right) + \dots \quad (11)$$

where $p_k = p/k, (k=2, 3, 4, \dots)$, and C_k – proportional to A_k

C_k decreases considerably with k increasing, 1st fundamental item in (11) nominates.

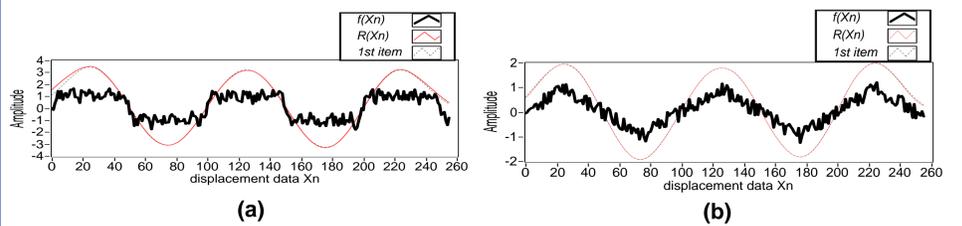

Figure 6. Simulations of 1D rectangular and 1D triangular grating position-related signals in legend $f(x_n)$ and their cross-correlation signals in legend $R(x_n)$ are shown in (a) and (b) respectively.

5. Experiments and results

5.1 Agreement between evaluated pitch and true pitch value

Table 1 Simulation results of average of pitch deviations and variations (arbitrary units)

Pitch evaluation method	Noise level	sinusoidal		rectangular		triangular	
		Deviation average	Variation (STD)	Deviation average	Repeat ability	Deviation average	Variation (STD)
