- Planning and design should be thorough. Sustainable design is "front loaded" compared with traditional design. Early decisions have the greatest impact on energy efficiency, passive solar design, daylighting, and natural cooling.
- Sustainable design is more of a philosophy of building than a prescriptive building style. Sustainable buildings do not have any particular look or style.
- Sustainable buildings do not have to cost more, nor are they more complicated than traditional construction.
- Integrated design, that is design where each component is considered part of a greater whole, is critical to successful sustainable design.
- Minimizing energy consumption and promoting human health should be the organizing principles of sustainable design. Other than the above elements for sustainable designs are energy saving architectural features, energy conserving building envelope, and energy-efficient and health-promoting mechanical, electrical, and plumbing systems.

The main objectives of sustainable design are to avoid resource depletion of energy, water, and raw materials; preventing environmental degradation caused by facilities and infrastructure throughout their life cycle; and to create built environments that are livable, comfortable, safe, and productive.

3. Energy conscious design in Sri Lankan context

To achieve sustainable development, one of the major contributions has given through designing energy efficient buildings. Therefore practicing and developing the energy conscious design enhance to produce more energy efficient buildings. This research is aimed to find the practice in the energy efficient design in building industry in Sri Lanka. Due to the broad scope of energy efficient design, this initial research is focuses on identifying energy conscious design discipline of architectural and services designers from the building sector and considering mainly commercial building in the Sri Lankan industry. The aim of this research will be addressed:

- To identifying the energy conservation techniques and design tools and other measures to achieve energy conscious design.
- To identifying the measures taken to achieve the energy conscious design and their impediments factors.
- To investigate the level of consideration on the energy efficient design by the designers.
- To recognize what areas should be developed in the industry towards crafting energy efficient buildings.

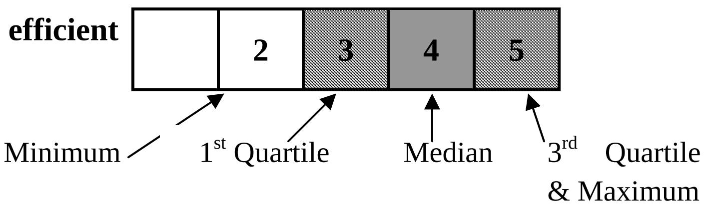
4. Research Methodology

The research methodology for this study adopted was quantitative. Initially the pilot study was conducted by telephone interview to find out the designer's consideration to the energy efficient design and the usage of energy analysis design tools. Then detailed survey was conducted within that closed questionnaires used. It includes fixed responses option as Likert scales. This was used to identify what extent that energy conscious design has been practised and what level it has considered in current context. Unstructured interview was not suitable since the scope of study is limited to find the level of practised and not in detail in depth as case studies. Structured questionnaire survey is conducted with selected thirty samples which included in the pilot study sample. Fifteen number of professionals related to Architectural designs had been interviewed, and the rest of the fifteen professionals were interviewed in Services Design such as Electrical and Air Conditioning discipline.

Descriptive statistical method was used for the analysis of data which were collected from structured interview. The levels of responses incorporated with the statements were given weightages to convert this ordinal set of data to numerical figures. Further for descriptive statistical measures, viz. the minimum, maximum, median and the quartiles were used in analysis. A graphical box diagram as given in following example is used to present this parameters for easy comprehension (Figure 1):

What do you think about energy efficient design?

Figure 1: Box Diagram



Explanation: This box diagram can be interpret as, 50 percent of the responses have considerable knowledge in energy efficiency design. Less than 25 percent of the designers have some idea on that and at least one of the designers would have heard about the energy efficient design. Further there were some designers who have thorough knowledge in the energy efficient design.

Further Mann-Whitney U test have been used to identify the significant differences between two independent groups of sample as Architects and Services Engineers.

5. Research Findings

5.1 Results from the designers

The analysis of the responses of the designer reviled the following results.

Q1	What do you think about energy efficient design?		2	3	4	5
Q2	Do you think that is practical to achieve?			3	4	5
Q3	To what extent client consider through out the design phase?	1		3	4	5
Q4	Does the client allocate sufficient funds for energy efficient designing?	1	2	3	4	
Q5	Do you think that clients are not sufficiently aware of issues such as renewable energy and energy efficient buildings?	1		3	4	

According to the diagram Q1, it can be seen that at least 50 percent of the designers have some idea regarding energy efficient design. The 25 percent of the designers have considerable more knowledge on that. And every designer has at least heard about energy efficiency design. And there are designers who have thorough knowledge in energy efficiency design.

According to above diagram Q2 shows that all the designers somehow believe that it can be practically achieved and 50 percent of designers have confident that energy efficiency can be achieved frequently at operational stage which would be anticipated in the design stage.

According to above diagram Q3 shows, 50 percent of the designers believe that some how client consider energy efficiency measures throughout the design phase without concerning only at the initial stage.

The above diagram Q4 shows that, more than 50 percent of the designers reflect that the client rarely allocates sufficient funds for the energy efficient design at the design stage and at least 25 percent of the designers state that client never allocate sufficient funds for energy designing.

From above diagram Q5 it represents that, more than 50 percent of the designers responds that only some of the clients does not have average awareness on issues such as relevant to energy efficient designing and renewable energy. Its specially need to consider that none of the designers said that all the clients do not have sufficient knowledge on energy related issues. So which can be interpreted as most of the clients have considerable awareness related to the energy efficient issues.

From above diagram Q6, it explains that 50 percent of designers believe that some clients are voluntarily adopting the energy efficiency measures without any financial incentives and nearly 25 percent of the designers express that client are less likely to adopt energy efficient measures without financial incentives and education on the costs and benefits.

Q7. Do you think that the followings will be required to insist clients and designers to consider the energy efficient designing?

a.	New building regulations or legal enforcement are required.			3	4	5
b.	New mechanisms and incentives are		2	3	4	5

required to encourage clients to invest in

		1	2	3	4	5
c.	Provide sufficient information and knowledge to client and designer regarding the energy efficiency.			3	4	5
d.	Provide enough access to the resources, products, information and skilled assistance regarding energy.			3	4	5
e.	Provide training and education to state and local officials, private industry, and consumers.			3	4	5

According to this diagram Q7 represents, that 75 percent of the designers considerably agree that new building regulations or legal enforcement; provide sufficient information and knowledge; increase the availability of the energy efficient products; provide training and education will be required often to insist to consider energy efficient designing. Further 50 percent of the designers expressed that new mechanism and new incentives often insist the client and designer to go for energy efficient design.

Every designers express that these above factors are much more needed to insisted to clients as well as designers to proceed with the energy efficient designing. Most of the designers expressed that statutory requirements will help level of playing field for developers and builders as energy-conscious designers and building professionals will not have to compete with others who achieve construction cost savings by eliminating or ignoring energy-efficient features in their design. Some architects believe that mandatory standards limiting the design freedom and innovations if the Building Energy Standards are not comprehensive and flexible enough.

Q8	Do you think that time taken for design is high for achieve clients energy efficient requirement?	1	2	3		
Q9	Do you think that design cost is high for achieve clients energy efficient requirement?	1	2			

According to the diagram Q8 and Q9 it shows that, only 25 percent of the designer’s states that design time is never long for energy efficient designs and when compare with design cost more than 50 percent of the designers stated that design cost was never high. And none of them states that design cost and time duration of the energy efficient design were always high.

Q10	Do you think that time taken is long for constructing energy efficient buildings?	1	2	3		
Q11	Do you think that integration design process by using in-house professionals will enhance the energy efficient design?	1		3	4	5

According to the diagram Q10, it shows that 25 percent of the designers states that construction time is never long as well as 50 percent of the designers expressed rarely time increased for construction of the energy efficient buildings.

As per the diagram Q11, it shows that the 50 percent of the designer's states that the integration design process by using in-house professionals will sometimes enhance the energy efficient design. Only 25 percent of the designers states that it often enhance the energy efficient design. Further it is found that, some of the designers described that it depends on the availability of communication modes in the organization. Even though the professionals are separated the design process will be enhanced by proper communication system between these professionals.

Q12	Do you set energy performance goal?	**1**	**2**			
Q13	Do you follow any checklist to achieve this goal?	**1**	**2**			
Q14	Do you use any technique to evaluate energy efficient design?	**1**	**2**			
Q15	How often the proposed alternative designs has been agreed by the client?	**1**		**3**	**4**	**5**
Q16	How often the proposed alternative designs has been agreed by the other design professionals?	**1**			**4**	**5**

From the box diagram Q12, Q13 and Q14 represents, that the similar responses obtained for to above three facts. Where more than 75 percent of the designers are do not use any check list to achieve energy efficient design goal; do not set energy performance goal and do not use any technique to evaluate their design.

From the box diagram Q15 and Q16 represents, 75 percent of the designers states that the alternative designs proposed by them has been agreed by other professionals but it is 50 percent in case of client. In case of energy efficient designs the clients is the most influence on decision making process in case of alternating the proposed designs.

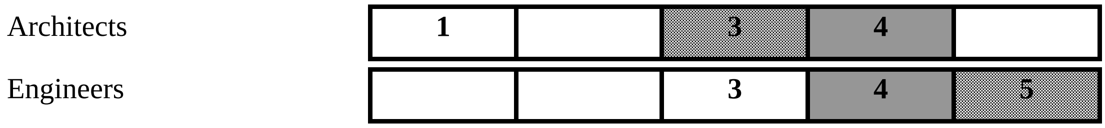
5.2 Results from the Engineers and Architects

1. Do you think that there is sufficient energy saving technologies available in the current market?

Architects	**1**	**2**	**3**	**4**	
Engineers	**1**		**3**	**4**	**5**

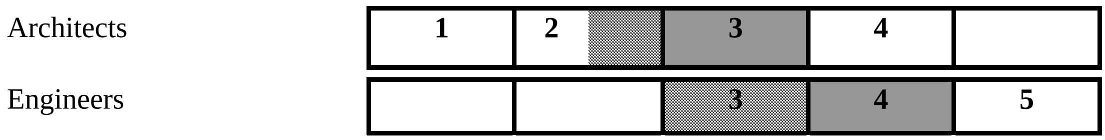
According to this diagram, more than 50 percent of the Architects state that the energy saving technologies are rarely available in the current market. However, 50 percent of the Engineer states that energy saving technology available often in the market. Some of the Engineer states that there are always sufficient energy saving technologies available in the market but in the other case of none of the Architects mentioned as it is.

2. To what extend energy efficient requirement of the client succeeded?



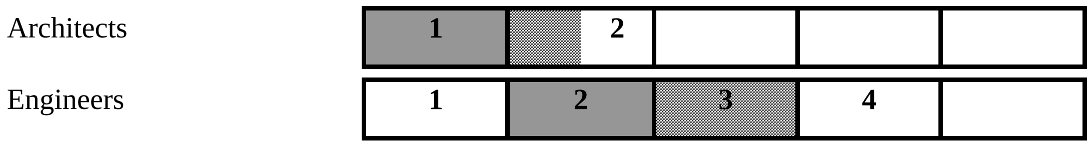
According to the Box diagram, the more than 75 percent of the Architects states that client succeeded with his requirement very often. But there were no Architects who response as always it is succeeded. But in the case of Engineer it was found that more than 25 percent of respondents state always the client succeeds with his initial requirement. At least every Engineer has a confident that energy efficient design was considerably succeeded with the client initial requirement.

3. Do you think that construction cost is high for energy efficient buildings?



From the above diagram it represents as, 50 percent of the Architects states that sometimes the construction cost is high for the energy efficient building. In meantime, within the Engineer states at least for somehow construction cost is high.

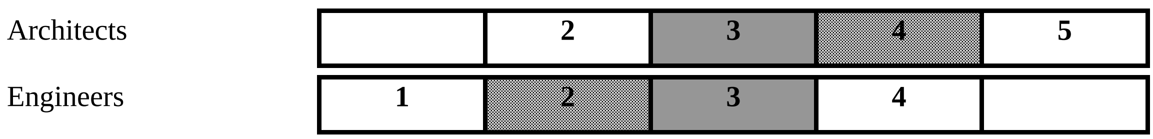
4. Does designer follow any guidelines to achieve energy efficient designing?



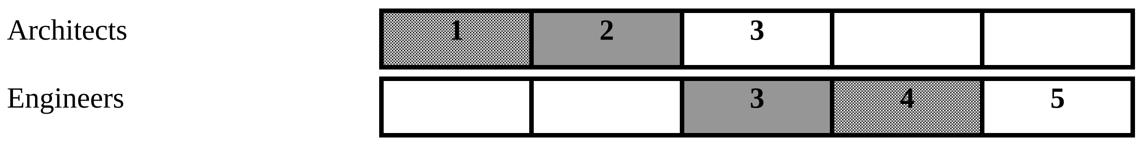
From the diagram it can be found that more than 50 percent of the architects have never follow any guidelines related to energy efficient design. At the same time, 50 percent of the Engineer has somehow follow guidelines such as Energy Efficient Building Code (EEBC) in their design. While their questioning it was found that EEBC was not popularize among the design professionals especially Architects.

5. What extent the designers use following techniques to achieve energy efficient building?

a. Incorporate solar passive techniques in a building design to minimize load on conventional systems

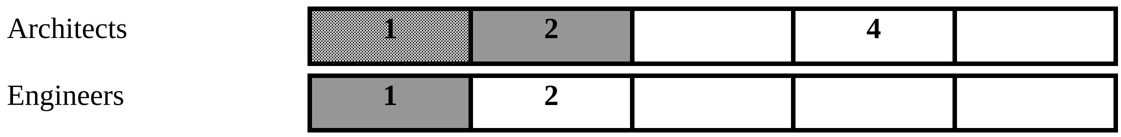


b. Design energy efficient lighting and HVAC systems



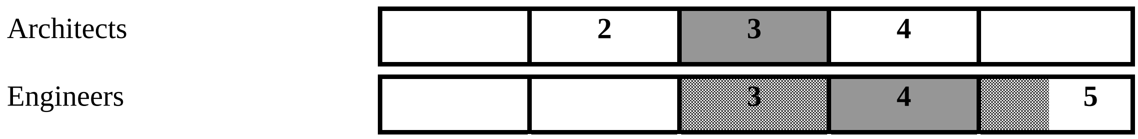
From above two diagrams that it clearly shows that Architects and Engineers have different level of knowledge on techniques used to achieve energy efficient building. Its clear that more than 50 percent of the Architects have some idea on that solar passive techniques in a building design to minimize load on conventional system when compare with the Engineers, who have less than 25 percent. It is vice versa in the case of designing of energy efficient lighting and HVAC system. From this its obvious that the Engineers have considerably high knowledge on HVAC system.

c. Use low energy materials and methods of construction & reduce transportation energy (reducing embodied energy)



When we consider the technique of using low embodied energy materials to achieve energy efficient in the building, none of the professionals have through knowledge on that. Especially 50 percent of the Architects have less knowledge on that but in the case of Engineers have no idea about it.

d. Use renewable energy systems (Solar photovoltaic systems/ solar water treating systems) to meet a part of building load.



The above diagram indicates that more than 50 percent of the Engineers have considerable knowledge on the use of renewable energy systems to achieve energy efficient in the buildings. But more than 75 percent of the Architects have some idea on that.

6. Conclusions

This study was conducted to identifying the designers concern towards the energy responsive design in building industry. Nowadays the world focuses on sustainable development. Hence the designers focusing more on the sustainable design with respect to the construction industry. The awareness regarding the energy efficient design is very important in the present day design scenario. Most of the designers should consider it not only by considering the benefit of the clients but should need to consider the society’s benefit as well.

As an initial measure to reduce the demand side energy was taken by introducing EEBC as voluntary guidelines to the Sri Lankan Building industry in the year 2000. However till now it has not developed and the implementation of that code is very rare in present day industry. Most of the designers expressed that the mandatory guidelines must needed to construct more energy efficient buildings in the future. They further expressed that the present EEBC should need to be updated and revised before it is practiced as a mandatory guideline. This should be implemented as soon as possible. This will encourage more designers and engineers to craft their design as energy conscious design in future.

Furthermore clients have been very reluctant to go for energy conscious design. Because most of the clients have misconception that construction cost was high for energy efficient construction by only considering the initial cost. However it is not real in the present scenario. When considering the long run of the building it is found that energy efficient building is more economical than the traditional energy non-conscious buildings. Some of the designers have considerable knowledge on life time benefits of the energy efficient design and they have a high responsibility to convince client to go for energy conscious design.

In the Sri Lankan building industry, certain energy efficient design concepts are in practice such as solar gain control, efficient lighting, power factor correction etc. but technique like passive design techniques were not much familiar among the designers. Moreover it is found that technique to achieve energy efficient building, by using low embodied energy material, is not well-known among the designers. Most of the designers' state that due to non-availability of material and technologies in the market are also one of the main obstacles to go for energy conscious design.

However, in general most of the designers are not considerably concern in related to the energy efficient designs in their design discipline. In addition to that the knowledge regarding energy analysis tools also lack within the designers. And most of the designers believe that it is not practicable to use in Sri Lankan context. Hence providing education and training and other measures to familiarize the energy conscious design will be much more needed in the present day industry. In addition to the designers, the parties of the stakeholders such as local officials, private and public clients and consumers also necessary to be aware on the energy efficient aspects to save energy and provide vital economic and ecological benefit to the country like Sri Lanka.

Management Plans And State of Environment Reports Prepared And Implemented By Local Councils In Nsw: Problems And Potential for Biodiversity Conservation

Dr Andrew H Kelly
Faculty of Law, Institute for Conservation Biology and Law, University of Wollongong, NSW, Australia.
(email: andrewk@uow.edu.au)

Abstract

The *Local Government Act 1993* (NSW) demands every local council in NSW to prepare, inter alia, a 'management plan' and a 'state of the environment report'. This paper critically examines both mechanisms and the relationship between them. Discussion is underpinned by the context of biodiversity conservation at the local level. Whilst good intentions lie behind the legislative requirements, their environmental benefits are questionable. They are often recognised as little more than bothersome bureaucratic hurdles. Although overdue legislative and policy change is forthcoming, concern is raised about loss of focus on the conserving biodiversity.

Keywords: local government, environmental law, management plans, state of environment reports, biodiversity conservation, policy change.

1. Introduction

There are almost 700 local councils across Australia, including 252 'general councils' in the most highly populated state, New South Wales (NSW). They differ widely on various scales. But one common feature is that the Federal Constitution fails to recognise local government, which is therefore a creature of State Parliaments. An issue of greater concern is local government's lack of financial resources in meeting functional expansion and community expectations. Dealing with the natural environment provides a ready example. This article considers two legislative requirements of councils in NSW. The first is preparation of the 'management plan', which extends far beyond the traditional 'corporate plan'. The second is the local 'state of the environment report' (SoER), which is exclusive to NSW [1]. The commentary illustrates the nature, benefits and problems of both mechanisms, including their statutory linkages. It then briefly moves on to current State Government policy change. The broader notion underpinning the paper is that statutory mechanisms designed for environmental monitoring do not always play the conservation tune.

2. The Management Plan

Councils in NSW that embark on major new projects, including conservation works, must engage in the *management plan* process. As described by the NSW Department of Local Government (DLG), this is the 'central mechanism … by which councils allocate their resources and prioritise their activities' [2]. The legislation – namely the *Local Government Act 1993* (NSW) (LGA 1993) - requires every council to endorse a management plan every year. Similar plans under different names are required in all six Australian States. In theory, the plan is the vehicle through which a council determines how it will exercise its broad service powers. Mandatory consultation provisions illustrate how the management plan is a potential instrument for community participation and accountability [3].

The legislation directs that the management plan contain details about a council's proposed 'principal activities' for, at least, the following three years. It must identify such actions that the council intends to carry out, as well as 'statements' on (at LGA 1993, s 403):

- the objectives and performance targets for each such activity;
- the means by which a council proposes to achieve those targets;
- the manner in which a council proposes to assess its performance in respect of each specified activity; and
- any matters prescribed by regulation (i.e. the *Local Government (General) Regulation 2005* (NSW) (LGGR)).

The extent to which the above matters are addressed is variable. Of the 25 plans studied by Marshall and Sproats in 1997/98, six included 'no performance indicators at all' [4].

'Principal activity' is not defined. Instead, the legislation lays down a non-exhaustive list of matters that, if carried out, the management plan must address. It refers to traditional municipal functions in wide terms such as 'capital works projects' and 'services'. Whilst some conservation projects, such as street tree planting, may fall into one or more of these categories, the list also makes specific reference to 'activities to properly manage, develop, protect, restore, enhance and conserve the environment in a manner that is consistent with and promotes the principles' of Ecologically Sustainable Development (ESD). In accordance with the LGGR, these are known as 'environmental protection activities' (EPAs) (cl 199(2)). It would appear that the formula is broad enough to extend well beyond physical conservation works, such as providing financial and technical assistance to voluntary conservation groups. But it is clear that the legislation does not *compel* councils to undertake EPAs. It only requires councils to detail such activities in the prescribed manner should any be undertaken. Whilst it may be argued that the focus is on procedure rather than outcome, the statutory openness nevertheless reflects the subsidiarity principle. The State Government plays no role in approving the management plan.

In addition to the general consultation requirements as discussed later, a council must, under the LGGR, 'consult' and 'involve' the community, including 'environmental groups', in developing ‘environmental management strategies’ for EPAs (cl 199). The legislation is silent on how a council should meet these obligations. Even the term ‘environmental strategy’ is undefined. Of course, the extent to which councils engage their local communities will vary. In its guidelines on preparing management plans, the DLG provides a brief list of possible approaches, such as ‘community workshops’ and ‘issue based research & reporting’. Yet it presents scant detail [5]. Furthermore, the LGGR requires a council, when preparing that part of the draft management plan relating to EPAs, to ‘apply’ the principles of ESD. An explanatory statutory note simply states that councils are to ‘take into consideration’ the principles of ESD. This is scarcely onerous. In the case of resource-poor or uninterested councils, ESD is likely to receive nothing more than lip service. Such councils are unlikely to engage in any EPAs in the first place.

The weakness of the regime becomes even more apparent in the case of principal activities falling *outside* the EPA umbrella. Apart from the provisions relating to EPAs, the LGA 1993 does not expressly demand the factoring of any environmental concerns into the decision-making equation. For instance, a council might decide to construct a new road through native woodland. As the activity comprises a ‘capital works project’, various statements must be provided in the plan. The concern, however, is that the information may relate to engineering issues alone. There is no express requirement that environmental issues be confronted. The situation is not helped by the LGGR in which the provisions relating to ESD apply to EPAs alone. This is ludicrous. It suggests that ESD has been saved only for those activities already intended to conserve or improve the environment. It is also inconsistent with the DLG’s own guidelines, which state that ‘ESD principles apply to *all* of the activities of the council’ [6]. This aspect of the LGGR is likely to be invalid in view of the statutory object relating to ESD in the primary Act at section 7(e) which, on its face, is not restricted to a particular subset of a council’s activities. Whilst the courts may rely on this and other introductory provisions to ensure that ESD is at least *considered* by councils in relation to *all* their activities, it is still unfortunate that section 7(e) suffers from lack of supportive, substantive provisions throughout the remainder of the Act. This provides an example of the weakness of the legislature to provide clean and workable frameworks for achieving ESD [7].

There is one qualification to the apparent limitations of the management plan provisions. Local citizens may use the public consultation process to demand that appropriate environmental objectives are injected into the management plan [8]. Public involvement in local conservation policy depends on community awareness of the process, neighbourhood dedication to indigenous biodiversity and the extent to which a council seeks feedback beyond formal public procedures. The DLG urges councils to pursue a more ‘proactive and targeted approach’ beyond the bare requirements, noting that mere exhibition at the end of the plan-making process ‘does not, in itself, provide for adequate community and stakeholder input’ [9]. Whilst Brown et al assert that whilst council/citizenry partnerships is obligatory, they lament that ‘the baseline of real partnership’ identified by their empirical research is ‘low’ [10].

If there is sufficient commitment to biodiversity conservation, the management plan has enormous potential. It provides opportunity for councils to integrate conservation principles across the entire spectrum of their actions by incorporating them into their adopted ‘objectives’ and ‘performance targets’ for every principal activity. In terms of biodiversity conservation, this will be more effective than the occasional one-off project to help protect a special place. It should also help minimise inconsistent actions between different departments of a council. A commitment to desired environmental objectives must *permeate* council activities in order to achieve an integrated approach [11]. The problem is that many celebrated local environmental projects tended to work in isolation away from other spheres of council activity [12].

Whilst the management plan process may promote strategic co-ordination *within* a council, co-ordination *between* councils is another matter altogether. A particular council might actively pursue biodiversity conservation through its management plan whilst its neighbour may follow different priorities. The regional dimensions of environmental management mean that without effective cross-boundary cooperation, the good work of one council can be undermined by another. The system provides little encouragement for councils to work towards common regional goals through their individual management plans. A small exception is found in the required ‘particulars’ for matters prescribed by the LGGR to be addressed in management plans. The scheme demands that management plans include certain information on ‘any proposed council activity relating to the management’ of ‘stormwater’, ‘coasts and estuaries’, ‘sewage’ and ‘waste’ (cl 198(1)). Details are also required on ‘the relevant characteristics of the area, catchment or region’ as well as council membership on relevant bodies and ‘any action to be taken jointly with other councils or bodies’ (cl 198(2)(d)). These provisions may encourage councils to turn their minds to opportunities for cooperative action, not only with their neighbours but also with other authorities, especially at the State level. It is a rare statutory example of pushing councils, as described by Smith, into ‘creat[ing] networks … with other agencies’ and attempting to ‘persuad[e] other agencies to achieve prescribed ends’ [13].

The reference to ‘coasts and estuaries’ in particular may prompt councils to develop biodiversity policy for these aspects of the environment, preferably at a regional scale. Such places are special to the community and are creating pressure for growing populations. But the statutory nudge relates only to a discrete component of the environment. It does not extend to non-coastal environments unless affected by stormwater discharge and the like. Even within their narrow ambit, these clauses hardly enjoy a high profile, tucked away in subordinate legislation.

Drawing the material together, despite wide opportunity presented by the management plan mechanism, there is a danger that for some councils, a combination of limited outlooks, conflicting priorities, resource shortcomings, pre-occupation with procedural management and perhaps uninterested neighbours will ensure that effective biodiversity conservation remains in the realm of empty talk, if addressed at all in the management plan. SoERs, however, may assist to drive innovative environmental directions.

3. SoERs and Linkages to Management Plans

The LGA 1993 requires each council to prepare an annual report. In terms of general bureaucratic culture, this is no surprise. The legislation is very specific as to what it must address. For instance, it must contain information 'as to [a council's] achievements with respect to the objectives and performance targets set out in its management plan'. It thereby provides a layer of environmental accountability with respect to a council's 'principal activities' depending on the extent to which environmental concerns have been infused into the 'objectives and performance targets' in the management plan. By enabling the outcomes of all proposals to be evaluated and reported upon, the management plan goes beyond being a merely descriptive document. Moreover, the annual report *must* include the SoER.

The SoER concept is scarcely restricted to local government. Measures were adopted on a global basis in the mid-1990s by the Organisation for Economic Co-operation and Development (OECD) to address environmental concerns on a 'pressure-state-response' model [14]. A series of national SoERs for Australia commenced in 1996, now demanded by Commonwealth legislation. Adoption of SoER obligations by individual State/Territorial jurisdictions has also arisen, pushed by four out of six states in addition to the Australian Capital Territory. As noted earlier, NSW is the only state where every council must prepare its own SoER. This places any council that is struggling financially in an invidious position.

Introduction of the SoER requirement created a bombshell. It was inserted in the Local Government Bill 1993 by the then Opposition, with the support of independent members, but opposed by the then Government. Mr J Turner, who had chaired a special Parliamentary committee to oversee development of the bill, warned that the costs would be 'crippling' [15]. The NSW Local Government Association, interestingly, despite initial chagrin, later decided to support the SoER concept subject to State Government assistance. But no monetary help has ever arisen [16]. In other words, the SoER requirement was simply dumped upon a largely unprepared local government. The only substantial support councils have received is written guidelines. The resource-intensive nature of SoER preparation has been softened slightly, however, by provisions introduced in 1997 allowing for four-yearly 'comprehensive' SoERs updated by annual 'supplementary' SoERs.

The original 1993 list of themes to be addressed in council SoERs included, *inter alia*, 'areas of environmental sensitivity', 'important wildlife and habitat corridors' and 'any unique landscape and vegetation'. Such vague descriptions must have promoted subjectivity, inconsistency and potentially unsympathetic environmental management. For instance, when might a corridor have been sufficiently 'important' or a landscape 'unique' to warrant attention in the SoER? Following a Ministerial discussion paper [17], in 1997 the NSW Parliament rewrote section 428(2)(c) LGA 1993 by adopting the following 'sectors' that a SoER must address (including 'biodiversity') [18]:

I. land,
II. air,
III. water,
IV. biodiversity,
V. waste,
VI. noise,
VII. Aboriginal heritage
VIII. non-Aboriginal heritage,
IX. with particular reference, with regard to each such environmental sector, to:
X. management plans relating to the environment,
XI. special council projects relating to the environment,
XII. the environmental impact of council activities.

In 1997, the then Minister for Local Government noted unsurprisingly that the quality of reports varied widely [19]. There is still evidence of resistance to SoERs. Whilst councils at least recognise the statutory obligation to prepare SoERs, this does not necessarily translate into utilising them as effective environmental management tools. An invaluable contribution SoERs may provide is to alert councils to the need for appropriate responses to existing or foreseeable environmental problems. For example, a SoER might reveal a particular area to be more ecologically significant than previously believed. The council might then, for instance, choose to use the information to support an amendment to an instrument under the land use planning legislation to protect it. Or it might decide to negotiate with landholders to encourage on-ground environmental management. Alternatively, it may choose to carry out environmental protection works itself. Clearly, SoERs can do far more than prsent interesting data and gather dust.

The legislation provides strong linkages between SoERs and the management plan. First, one of the items listed under s 403(2) LGA 1993 (in relation to the required 'particulars' for proposed 'principal activities' to be addressed in management plans) refers to 'activities in response to, and to address priorities identified in, the council's current comprehensive report as to the state of the environment and any other relevant reports'. This is crucial. Second, the LGA 1993 requires each council, when compiling its SoER, to address each of the eight specified 'environmental sectors' in the context of 'management plans relating to the environment' (see s 428(2)(c)(ix) above). This widens the net for all identified principal activities to be assessed against a variety of environmental criteria, including biodiversity. It makes good sense [20], and was recognised in some quarters well before 1997 [21]. The notion is championed by the DLG which recommends an optional 'environmental management plan' (EMP) as a 'sub-plan linked to the management plan' [22]. By bringing local environmental problems to the attention of elected representatives, a SoER may therefore influence the types of 'principal activities' that a council may decide to engage in. In turn, a later SoER may be utilised to evaluate the environmental outcomes of such actions. In other words, the SoER may be seen as an *extension* to the management plan process by addressing essential follow-up action. The DLG commends a 'management planning/annual reporting cycle' [23]. The concept is attractive but empirical research is needed to help check the extent to which such potential falls into the realm of rhetoric.

Literature suggests that the potential of SoERs is not being reached. Senior municipal personnel interviewed by Brown et al in 1998 cited the SoER as ineffective and merely something to complete under the legislation [24]. Whittaker similarly refers to managers complaining of difficulties in interpreting SoERs, with some asserting that they 'have not seen, let alone read [the SoER] for their council' [25]. Brown et al's findings are especially disturbing as they involve councils at Sydney's periphery with relatively large budgets and, presumably, far more environmental expertise than remote resource-poor authoritives. Such comments reflect, arguably, managerialist trends that emphasise cost-cutting rather than long-term environmental improvement. But the SoER is a very different mechanism to the traditional budgetary reports with which council executives are familiar. As Brown et al note, the SoER 'has as its central reference point the whole environment … rather than council's activities in that area' [26]. It deals with broad issues such as biodiversity decline, which are difficult to reduce to financial statements. A narrow perception of SoERs means a minor role in shaping municipal agendas.

The LGGR demands that comprehensive SoERs apply the 'pressure-state-response' model in analysing data, identifying appropriate indicators for each sector and presenting results. It therefore corresponds with the OECD model. The 'response' component is especially noteworthy by identifying 'the response of councils, government agencies, industry and communities to the pressures on, and state of the environment' (LGGR cll 14-15). Not only do the provisions require a council to canvas its own approaches, if any, but those of other bodies. They arguably encourage a council to adopt the role of environmental steward by considering a full range of issues affecting its area, including matters beyond its conventional jurisdiction. A SoER may, for example, address the impact of other authorities' policies on biodiversity. For instance, it might contain information on reserves, such as national parks managed by State government located within one or more local government areas. In theory, consideration of such matters may lead to lobbying by councils and/or development of inter-agency partnerships.

The architecture of the legislation illustrates that councils are expected to *respond* to issues raised in their SoERs. In addition, the LGGR requires a council, when preparing that part of its management plan dealing with EPAs, if any, to 'consider' its most recent comprehensive SoER (cl 219). This further encourages the management plan/SoER 'cycle', providing a third link between the two mandatory mechanisms. The *National Local Government Biodiversity Survey* reports that a 'high proportion' – more specifically, 45% – of surveyed councils in NSW had 'incorporate[d] biodiversity objectives into their corporate/operational plan [27]. In view of the statutory linkages with their specific references to the environment, the figure is disappointing, suggesting that more than half of the councils had paid minimal, if any, attention to the requirements relating to biodiversity accountability and ongoing management. More recent survey analysis would reveal if the problems have declined further.

Public involvement may influence the direction of SoERs. In preparing their SoERs, councils must consult with their communities, including 'environmental groups', and also involve people in 'monitoring changes to the environment' (LGGR cl 220). But again, there are no details on how this is to occur. Terms such as 'environmental group' are undefined. Brown et al found the desired council/community partnership to be 'almost non-existent' amongst the authorities surveyed, with three managers viewing the community as ‘irrelevant and/or disinterested’ [28]. Such analysis is troubling, especially in view of increasing pressure on local communities in view of limited municipal finances. A Commonwealth Parliamentary report issued in 2003 has warned councils against entering costly functional territory [29].

No public comprehensive review of SoERs has been undertaken to test the extent to which they influence council on-ground policy. Whilst there is widespread recognition of the fragile and limited extent of vegetation remnants, the emphasis appears to be on the need to gather more information rather than setting down concrete responses. Yet many SoERs do not reflect the opportunities, let alone obligations, imposed by the LGA 1993 and LGGR. In many cases, the detailed statutory rules appear to have been disregarded. Of course, there is scope for SoERs to *evolve*. But biodiversity will continue to diminish whilst we wait. Importantly, such comment is not intended to overlook those councils that are head and shoulders above others. Sutherland Shire and Randwick City provide immediate examples. Both are located in the Sydney metropolitan area rather than remote NSW.

There is also the issue that environmental sectors that SoERs must address, including biodiversity information, can clearly transcend municipal borders. They may be ill-suited to be dealt with on a piecemeal, council-by-council basis. This raises the idea of *regional* SoERs. In their review of early SoERs, Brown and Greene observed that ‘[m]any issues were … more appropriate for regional or catchment treatment’ [30]. In an effort to minimise costs for individual member councils, but also in recognition of the sheer common sense in adopting a regional perspective, some voluntary ‘regional organisations of councils’ (ROCs), or other strategic alliances, have promoted regional approaches. In 2000, the Western Sydney Regional Organisation of Councils (WSROC) published its Regional SoER, described by Parissi as ‘the first regional [SoER] in Australia … based on sustainability principles’ [31]. But such an example does not remove the statutory requirement that each council must prepare its own individual SoER. In the 1997 discussion paper on SoERs, Minister Page acknowledged wide support for regional SoERs but remained steadfast in his commitment to individual SoERs [32]. This was unfortunate. From an ecological management viewpoint, SoERs prepared on a bioregional basis would make far more sense than many unconnected SoERs of varying quality.

The law-makers do not dismiss regional dimensions of SoERs altogether. In introducing the 1997 amendments, Minister Page promised that regional reporting would ‘be encouraged where environmental issues are best addressed at that level’ [33]. Clause 39(1) LGGR requires a council to include in its SoER ‘information relating to the general region’ if analysis of any of the factors listed under LGA 1993 section 428(2)(c) ‘cannot be met’ solely by reference to the local municipal area. A council must then observe all the statutory requirements for SoER reporting, such as adopting the ‘pressure-state-response’ model, in the ‘regional’ part of its SoER. Information on biodiversity would be a willing contender for regional attention. Yet the LGGR fails to define ‘region’. There is no statutory requirement, nor even a suggestion in the DLG’s guidelines, for a uniform approach to regional information. As for WSROC’s regional SoER, Parissi raises many concerns raised by council staff but concludes ‘that a strengthened foundation is needed’ [34].

The picture is again one of unfulfilled opportunity. Any success of the SoER as a conservation tool relies on a combination of political commitment, sufficient resources and regional willingness. As far as politics are concerned, many councils will already have other priorities cemented by tradition. Cowra Shire Council's 1998/99 SoER provides an example. Under the 'biodiversity' heading, it suggests that conservation be restricted to 'rocky outcrops of land which can not be cultivated' because the floor of the Lachlan Valley 'is too valuable ... to *not be* cleared and put into intensive agricultural production' [35]. This Council's priority was clearly on boosting the local economy grounded in agriculture. It would be interesting to check if a wider commitment to biodiversity has since emerged.

4. Current Policy Change and Conclusion

At the time of writing, it is likely that the two major mechanisms discussed above will be substantially changed, if not deleted. In late 2006, the DLG issued an 'Options Paper' regarding the future of, inter alia, management plans and SoERs [36]. Of the three options put forward, it appears from that the third alternative is supported by the DLG. Significantly, it does not embrace continuation of either the management plan or SoER. Instead, at the top of the hierarchy is a 'Community Strategic Plan' (CSP), which is designed to serve the community rather than the council itself. It will address four themes: social, environmental, economic and governance. The CSP will last for ten years, after which time scales will depend on individual council decisions. Below the CSP there is to be a 'delivery plan' for every four year electoral term, an annual operational plan and the annual report, which will influence the CSP. The failure to include an improved, well articulated and community-based structure for the SoER demands reconsideration. Further investigation into regional cooperation is crucial. Although SoERs will be optional, and most likely not mentioned at all in the revised scheme, those councils devoted to maintaining the concept can apply their own emphases. This would not only match the subsidiarity principle but encourage regional scales where warranted. But retention of SoERs, or structurally different devices dealing with the environment, will not be universal. Whilst the legislative and policy review by the DLG was well overdue, we do want to see the biodiversity baby being thrown out with the administrative bathwater.

Abstract

South Africa has a diverse and cultural society with a tradition of colonialism, cultural interaction, separatism and democracy. To conserve buildings influenced by South African history, a sympathetic approach to all its cultures is needed to ensure conservation, showing merit in diversity.

To this end tourism in Southern Africa plays a major role in respect of sustainability of cultural and historic buildings.

This paper will demonstrate how this was done in the past and how future conservation will play a major role in showing the cultural history of the Southern African heritage. The paper will be strongly supported by visual images of the South African built environment.

Keywords: Diversity, tourism, cultural heritage, conservation, built environment

1. Background

South Africa has a tradition of colonialism, cultural interaction, separatism and democracy within a diverse and cultural society. To conserve buildings influenced by South African history, a sympathetic approach to all the cultures is needed, one that will ensure conservation showing merit in diversity.

Tourism in Southern Africa plays an important role in respect of sustainability of cultural and historic buildings.

Southern African conservation in the past and how future conservation will play a role in its cultural heritage is demonstrated in this paper.

2. Early architecture: expression of culture and art

Ancient trading patterns are indications of social and cultural interaction between the people of Southern Africa, Europe and the countries on the Indian Ocean rim and from even further east. Commerce between the people of the Horn of Africa, the Arabian Kingdoms, and the ancient cultures of India and China influenced the Iron Age people of Africa (Bizzell, 2002: 3).

Many examples of South Africa's early building heritage exist and can be visited to appreciate the history and diversity. Some examples are:

- Buildings of the late Iron age. Corbelled dome-houses were very small with tiny entrances built from local stone without any cement or painting (Hartdegen, 1988: 3).

- The Vlakfontein Tswana Iron Age settlement: This settlement in the Transvaal is sometimes called the lost city, it shows remnants of a wonderful early culture. Unfortunately, very few examples of complete structures remain (Hartdegen, 1988: 4).

- Thulamela town, inhabited about five centuries ago, shows the building material of the area and the circular walls, a reminder of the Zimbabwe ruins (Nussey, 1997: 17).

- Masorini is an accurate reconstruction of an African iron-smelter's village that existed in the Kruger Park area during the 18^{th} Century (Nussey, 1997: 17). The traditional Xhosa hut, grouped together to form kraals, have their own style built with stone, mud-bricks and mud-plaster with white washed walls. The white walls and black thatched roofs stand visually pleasing amongst the green hills of the Transkei (Hurford, 1997: 74-75).

- The Sotho hut with it's brilliant and subtle decoration and style, usually done by the women of the tribe, is part of South Africa's beautiful architectural heritage (Hurford, 1997: 46), and is now being protected in a cultural village where people find enjoyment and proudly share their tradition, style and culture with visitors, in a manner that conserves some of the Sotho culture tradition. One example of such a village is found in the Golden Gate National Park.

3. The beginning of the Western influence

In 1488 the Cape of Good Hope was said to be discovered by Bartholomeu Dias when he was sailing around the southern most tip of Africa. For the people of Europe the history of South Africa had begun. Since then the view of South African history has broadened to include the evidence of science, archaeology and palaeontology and, in fact, the history of this region stretches back to the dawn of man. Three ships belonging to the mighty Dutch East India Company sailed into the bay of the Cape of Good Hope on 6 April 1652. On board was the first group of white settlers willing to occupy and establish a trade outpost. Previously, survivors from wrecked ships had ascertained that the Cape soil was fertile and that the inhabitants were not cannibals as many Europeans feared (Hartdegen, 1988: 5).

The Portuguese, English, French and Dutch voyagers called at the Cape purely to take on fresh water, fish and game which would sustain them for the remainder of their arduous voyage to Asia (Hartdegen, 1988:5).

4. The Cape Dutch influence on the built environment

The arrival of the Dutch settlers in 1652 brought another architectural influence to South Africa and today many Cape-Dutch buildings still exist especially on farms. Some of these are amongst the Cape's best attractions, open to tourists where the wine and fruit produce can be enjoyed. Some good examples of Cape-Dutch architecture can be seen at the following places:

- Groot Constantia: The original manor house was developed for Simon van der Stel in 1692 (Hartdegen, 1988:26) (See photograph 1 in addendum).

- Meerlust: The estate belongs to the Myburgh family since 1757. The typical Cape-Dutch style homestead was built in 1776 with material imported from Holland and Batavia, while indigenous timber like yellowwood and stinkwood were used for doors and floors (Hartdegen, 1988: 26).

- Boschendal: A white-washed H-shaped Cape-Dutch homestead, built against the backdrop of the Groot Drakenstein Mountains. Tourists may enjoy and experience the style and culture of an earlier century (Hurford, 1997: 138).

The legal practices of the Dutch in the 17th and 18th centuries led to the development of racial order, which in turn led to migration to find some Promised Land where people might follow their own cultural practices. This led to inland development. There were a few cultural changes especially regarding language (Thompson, 1990: 68).

5. Architecture and the British influence

The British occupation of South Africa brought further change to South African architecture and roofing styles. Among the 1820 settlers were trained potters who started producing pan-tiles, which were extensively used as roofing material in the Eastern Cape (Hartdegen, 1988: 48). Amongst buildings built in the British architectural style in South Africa are:

- The Tulbagh town house now known as Mount Bijou: Built between 1812 and 1822 follows the Cape style but with a new English aesthetics of classical symmetry and proportion (Hartdegen, 1988:54) (See photograph 2 in addendum).

- Other examples that still exist are the Union buildings designed by Englishman Sir Herbert Baker in 1910 (incorporating Cape-Dutch, English and Italian renaissance influences), Pretoria station (1908), and St Andrews College in Grahamstown (1913) (Hartdegen, 1988: 99, 114, 120, 121, 129).

6. European tradition in the 19th Century

One should be careful not to judge European architecture as foreign to Africa. European architecture has influenced Africa's culture and expression of life to a great degree. The question that needs to be asked is whether European style is sympathetic to Africa or does it, in it's contrast, make a mockery of Africa's own heritage.

Most developments in respect of services, railways, infrastructure and development of towns in the colonial times, especially after the British Settlers arrived in 1820, took place. Great Britain dominated activities in the Cape of Good Hope for many years (Thompson, 1990: 66).

Examples of architecture that find their place in sympathy with the South African environment are found mainly in church buildings and are based on European styles. These punctuate towns and environments in recognition of our temporary habitation and dependence. Among these are:

- Holy Trinity Anglican Church in Port Elizabeth (1866). A free-standing Gothic revival construction, with pointed stonework and plastered dressing. A building with lovely flowing lines (Herholdt, 1994: 109) (See photograph 3 in addendum).

- The Graaff-Reinet Dutch Reformed Church (1887) is a focal point of this historical town with more than 200 national monuments. The church was modelled (like many others in South Africa) on its English counterpart, the Salisbury Cathedral, but adjusted to the South African culture, environment and needs, and stands as an example of faith and tradition (Hurford, 1997: 100 - 101).

Port Elizabeth shows examples of imported styles brought to the area by settlers during the 19th century. Today these buildings add to the character of the city. Styles were adjusted to suit the conditions of the new country, examples of these are:

Late Georgian style: Simplicity, chimneyed gables and symmetrical façade (See photograph 4 in addendum).

Early Victorian with classical decorations, decorated barge board and convex veranda sheeting.

High Victorian: A style with strong colours and vertically stressed in the building form.

Regency. A style showing full pane windows grouped in pairs (Theron, 1983: 4-5, 10, 11).

Dramatic changes occurred in many parts of South Africa under the impact of both external and internal influences. Most of the capital investment in the mining industries came from overseas. Kimberley, city of diamonds, and Johannesburg, city of gold, developed and grew.

Johannesburg grew to contain the largest concentration of people in the entire region (Thompson, 1990: 110).

7. Independent republics

During the period of independence of the two inland republics (Orange Free State and the Transvaal) some interesting buildings were built. Examples of these are:

- The Presidency in Bloemfontein (1886) (See photograph 5 in addendum).
- The Fourth Raadsaal (Government building) in Bloemfontein (1893).
- The "Twin Tower Church" in Bloemfontein (1880). A building in the Romanesque Gothic style.
- Church Square Buildings: Pretoria (1890 – 1910). (Hartdegen, 1988: 282-285)

8. 20th century architecture

This century may be divided into various phases in the political life of South Africa and its influence on architecture, the Union of 1910, the world wars, the Republic of South Africa in l961, the apartheid era, and the democracy in 1994. Some examples of these eras are:

- Grootte Schuur hospital in Cape Town (1937).
- Tudor style theatre in Natal (1935).
- Libertas, official residence of the State President.
- Black housing with its box type units to establish the apartheid cities.
- The building boom of the sixties: The University of the North as an example of architecture for black universities; the Civic Centre in Kimberley.
- The Diamond House in Johannesburg is an example of classic architecture of the late twentieth century.
- The Bloemfontein Civic Centre (Hartdegen, 1988: 282, 214, 226, 260, 264, 284, 286) (See photograph 6 in addendum).

9. Rural areas – the built environment and sustainability

Sustainability in the Southern African context is also linked to the wealth of communities in both rural and urban environments. Sustainability relates closely to environment and the built-environment that establishes the physical environment and a sense of place where people live and have to make a living.

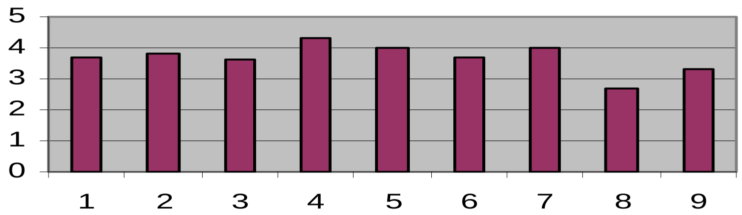
9.1 Rural areas

Sustainability in rural regions is seen as part of the building blocks for environmental protection, upliftment and economy.

To establish the stability of these building blocks, a study relating to the rural areas of the Free State region was done by the University of the Free State (UFS). Professionals working in rural areas were contacted to test their opinions on the sustainability of their areas. The study showed that tourism will and has already played an important role in sustainability.

Physical projects aimed at manufacturing, tourism, infrastructure development and state spending should contribute to 'economical and financial sustainability' (Graph 1).

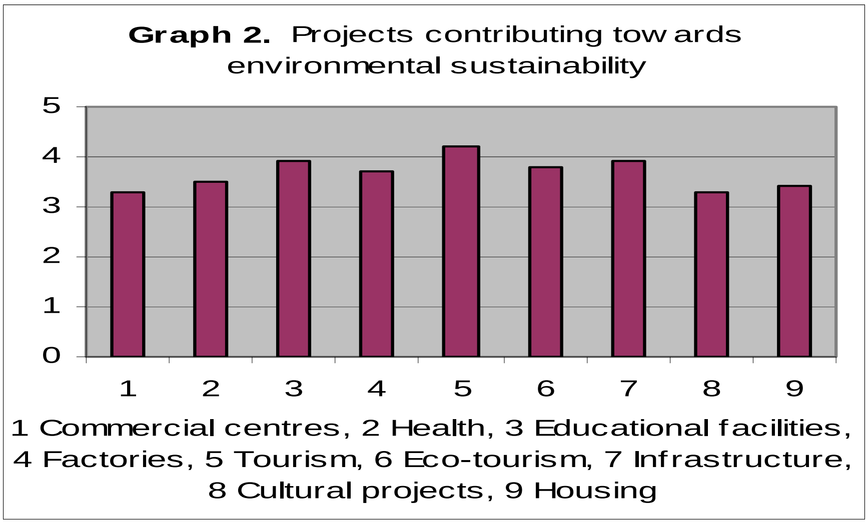
Graph 1. Physical developments which positively contribute towards economy and financial sustainability



1 Commercial centres, 2 Health, 3 Education facilities, 4 Factories, 5 Tourism, 6 Eco-tourism, 7 Infrastructure, 8 Cultural projects, 9 Housing

(Source: Department of Quantity surveying and Construction Management, University of the Free State (UFS))

As far as the 'environment' is concerned, tourism, eco-tourism, infrastructure, development and state spending will have a substantial positive influence on 'financial sustainability' (Graph 2).



(Source: Department of Quantity surveying and Construction Management, University of the Free State (UFS))

The most pressing problems of rural areas were pointed out as being, the economic situation, urbanisation, limited physical projects and state spending (Verster and Berry, 2004).

The question that should also be answered, in the context of this paper is: what influence does architectural heritage play in the establishment and growth of the tourism industry?

The proposition is that architectural history and heritage help to tell the story of a country, of its pain and achievement, and establishes a sense of culture, art and society, and that tourism helps to relay the country's story and heritage.

If the proposition holds true it establishes the theory that the protection and heritage of architecture will positively influence the economic position of urban as well as rural communities. The sustainability of rural communities is specifically important in the South African context.

9.2 Rural needs and the professions

Designers and planners should also have a keen sense of cultural diversity and steps should be taken to make a community interesting and wonderful to experience:

- Open spaces, bars and cafés to foster and develop the night-life economy.
- Council-owned properties to assess their feasibility as arts or cultural venues.
- A youth cultural policy and a circuit for popular activities.
- Conversation and arts initiatives, linking the greening of local areas to culture.

- Attention to street design, furniture and sculptures (Montgomery, 1990: 23).

A further proposition in respect of architecture and the conservation thereof may follow from Montgomery’s opinion that examples of architectural heritage punctuate an environment, telling the story of a culture and it’s sympathy towards history and the present.

By conserving, rebuilding, and actively promoting South Africa’s architectural heritage, this may further enhance the country as a tourist destination.

10. Present buildings focusing on the South African architectural heritage

10.1 New approaches

The Peoples Parliament in Kimberley is an example of how Africa’s organic architectural heritage and the concept of the people’s square or “Patello” finds its way into the present built environment as interpretation of traditional response to shelter, open space, ceremony and celebration. The language of Africa’s architecture is further developed in this manner while maintaining consciousness of location.

10.2 New trends

Another reason why South Africa’s architectural heritage should be protected, is due to the negative influence of foreign style or rather ‘fake’ style that has found it’s way into the South African architectural production system. As Lipman in (Le Roux, 2005: 6) calls it “fake foreign fads” (Le Roux, 2005: 16). This refers to Tuscan, Italian and Georgian styles that have found their way into commercial and residential architecture. In defence of South Africa’s European architectural style such as Cape-Dutch, Georgian- or Transvaal-regionalism, Van der Vyver (in Le Roux, 2005: 17) holds that these styles were adapted to local climate, availability of material and craftsmanship.

Joubert (in Le Roux, 2005), argues that Africa has produced some notable Afropean buildings that “...celebrate our socio-economic and environmental peculiarities, while respecting the integrity of Eurocentric design premises.” The Mpumulanga government buildings in Nelspruit and the new Constitutional court building in Johannesburg are some notable examples (Le Roux, 2005: 17).

11. Socio-cultural impact of tourism

Any meeting of people has a rub-off effect on those involved in the encounter. In some cases, when two people have a similar cultural background and knowledge of each other's language, the communication is verbal. In most cases it is a silent dialogue. Communication, by a look, a gesture and a general manner of behaviour. This most universal kind of communication is particularly related to tourists and the natives of the region they visit, for the impact of their meeting is usually brief and superficial. In spite of this, however, tourists carry away powerful images of the places they visit and the native resident receives a strong impression of the tourist and his ethos (Theobald, 1994: 92).

11.1 Mass tourism

Culture and building heritage in this sense, is of course, one of the main motives for travel from the time of the Grand Tour until the time of mass travel. Classical history, Bible history, Egyptian history and the Renaissance were motivations for most tours and the claim to consider oneself a cultured person. The arrival of mass travel made the pursuit of pleasure the main motivation for a holiday (Theobald, 1994: 99 – 100).

Desirable types of tourism that have some or all of the following characteristics are:

- Tourists behave differently to mass tourists.
- They have different attitudes towards the resources they use compared to mass tourists.
- Tourism is usually small scale (low numbers of tourists).
- The local community (hosts) has more control over tourism (Burton, 1998: 138).

The cultural heritage in South Africa needs constant attention and the conservation of buildings to ensure continuous growth of awareness of this heritage attracts the above types of tourism.

11.2 Community based tourism

Community-based tourism is a form of tourist development characterised by the participation of the local community in the decision-making process at an early stage. It has been advocated in Western democracies and widely debated and experimented with, for example, in the United Kingdom in the 1970's in the context of education, housing and leisure planning. It re-emerged to become a fashionable concept in tourism planning in the 1980's, both in the Western democracies and as advocated for third world countries. This was due to the recognition that the costs and benefits of tourism development were distributed unequally between the local host populations and 'outside' interests (e.g. national governments, multi-national development companies), where the local community often suffered more of the costs and experienced less than their fair share of the benefits (Burton, 1998: 139).

Community tourism, where local people participate in the decision-making, is seen as a remedy to these perceived disadvantages. The common assumptions behind the community approach are usually:

- That a unified view of what is locally acceptable can be found.

- Local communities will put a high preference on environmental quality when tourism development decisions are made (Burton, 1998: 139).

12. Conclusion and recommendations

This paper aims to show examples of the wonderful architectural heritage of South Africa as well as the variety of styles, history, materials used, culture and time periods. It also proposes that the protection of this heritage will enhance South Africa’s image as a tourist destination.

Historical architecture is important for sustainability and should focus on value at these entities to attract tourism, especially the up-market industry. Research clearly shows the importance of tourism towards sustainability (refer to Graph 1). A country and its citizens must protect architecture to ensure the attraction of tourism for sustainability.

Figure 1 proposes a model of the main elements and links that should influence conservation of the built environment in the South African context, to ensure sympathy for the country's building heritage.

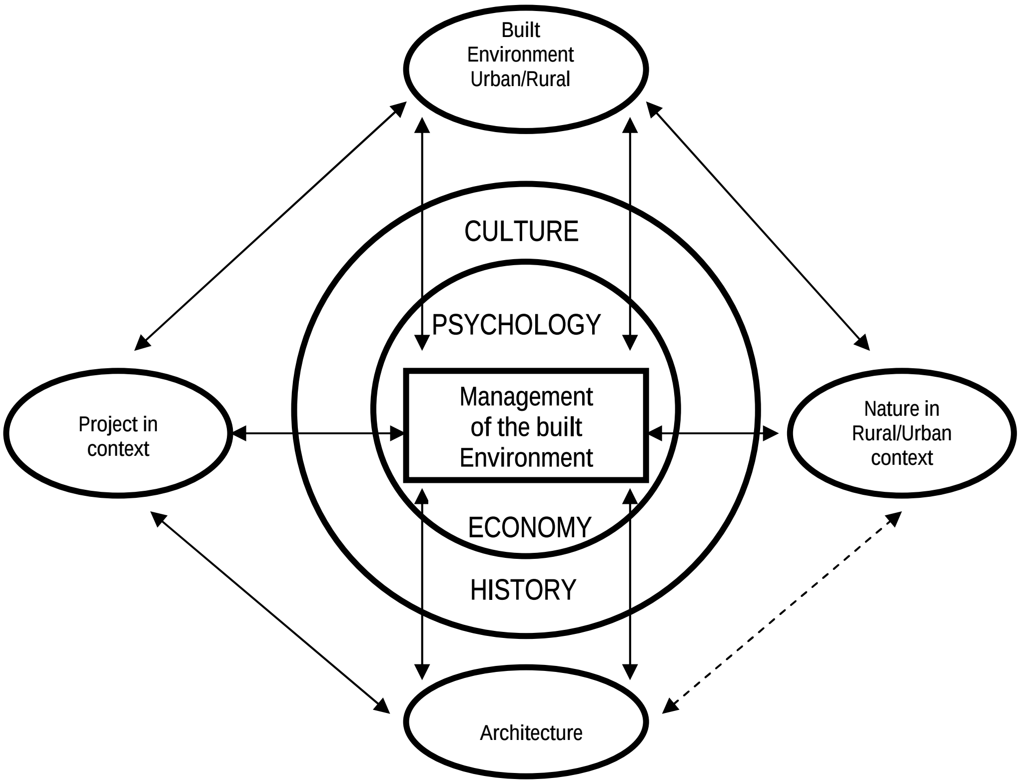


Figure 1- Main elements of conservation of the built environment (Source: Adapted from Verster, 2004)

South Africa has an interesting heritage of building architecture, objects and structures that inherently depicts the people of the country, their culture, politics and inter-relationships. New, Africa-centred architecture that may delight visitors to the country has now begun to evolve.

A New Village in Sri Lanka:

Learning Lessons There, Sharing Lessons Here

Abstract

When the Indian Ocean tsunami hit Sri Lanka, it destroyed the 190-person village of Kalametiya. Eleven people were killed and every building was ruined.

In March 2005, the first two authors helped to "catalyze" the reconstruction of the town under the direction of Sri Lankan architect Madhura Prematilleke and with Ball State University faculty colleague Nihal Perera and 21 students from the U.S. These efforts, along with those of many local citizens and relief workers, built one of the country's first post-tsunami permanent villages, known today as Minsiripura.

Responding to such extreme local circumstances can challenge existing knowledge, if one is prepared and open. For example, when building with no electricity on-site, participating in auspicious moments, sharing tea with adults, and playing with children, the need to respond to local conditions becomes magnified, especially to an outsider. When working with limited resources under an unyielding sun, it is immediately obvious that buildings, builders, and architects must be "smart" regarding the climate, available materials, and culture. And when heeding the plans and advice of others, one comes to understand that letting go—believing that a good way to change the world is to be open to changing yourself—can reveal something wonderful that was previously unimaginable. Such circumstances provide a test, of sorts, regarding what is known and what needs to be known, and represent a classic epistemologic reordering, what Maxine Greene refers to as 'wide-awakeness' in contrast to sheer attentiveness, in which a person is fully present in the contextualized moment before him or her.

This paper reflects on our shared experiences in Kalametiya and discusses how lessons learned there have influenced recent works completed by the authors and their students, including a construction in Halifax, Nova Scotia, Canada and deconstructions in Flint, Michigan, USA. Both projects question conventional 1-2-3 sensibilities (which assume that knowledge flows

primarily if not exclusively from the First World to the Third World) and instead promote a 3-2-1 awareness--that there is much to be learned in the developing world.

1. Background

When the Indian Ocean tsunami hit Sri Lanka on December 26, 2004, more than 40,000 lives were lost and another 2.5 million were displaced. Among these large numbers of people directly impacted by this natural disaster was the 190-person village of Kalametiya. Eleven people were killed and every building was ruined.

Four months later, in March 2005, under the direction of Sri Lankan architect Madhura Prematilleke and with our Ball State University faculty colleague Nihal Perera and 21 students from the U.S., the first two authors helped “catalyze” reconstruction of a new village. [2] These efforts, along with those of relief agencies, relief workers, many local citizens, and the Kalametiyans themselves, built one of the country’s first post-tsunami permanent villages, known today as Minsiripura.

With this paper the co-authors Wes and Tim reflect upon the lessons we learned in Sri Lanka and suggest how our experiences there effected and continue to effect the lessons we share with students and colleagues here in the U.S. and North America. The involvement of Thalia, a Ball State University faculty colleague in our university’s Department of Education Studies, is an effort to add depth to this consideration of our immersive and/or active learning experiences as part of a postcolonial pedagogy.

Reflexivity is a process in which a researcher continuously reflects on how the action research process changes his or her perspectives. Autoethnography adds a critical dimension to the process. There are two different understandings of autoethnography. In the first and most common approach, “autoethnography is understood as ‘the process by which the researcher chooses to make explicit use of [their] own positionality, involvements and experiences as an integral part of ethnographic research.’” In the second approach, autoethnography “is not something researchers do that they may want to study. . . The intent is to strategically alter the way an audience of dominant outsiders understands the subordinate group, and beyond that, to push back to some extent, against the shove of domination." [3]

What follows are some examples of how we have approached the process of reflexivity and our current efforts at reconsidering a specific Sri Lankan experience in early 2005 now, nearly three years later. While we will rely on self-reflection which, by definition, places us at the center of the stories that we are constructing, we will also offer instances in which the locals "pushed back" against the outsiders, even as the Kalametiyans welcomed us into their village, lives, and futures. By displacing ourselves, we seek to complicate conventional 1-2-3 sensibilities (which assume that knowledge flows primarily if not exclusively from the First World to the Third World) and instead offer our early insights into a 3-2-1 view that argues that there is much for the developed world to learn from the developing world.

2. Prior Knowledge

Sri Lanka was not an unfamiliar place to us. Our faculty colleague, Nihal Perera, is a native Sri Lankan. He is also the originator and director of CapAsia, a unique field study program that brings U.S. students to south Asia every other spring semester for eleven weeks of study. [4] Wes is the co-director of CapAsia and had visited Sri Lanka in 2001, 2002, and 2003. In 2003, on CapAsia III, Nihal and Wes collaborated with Madhura, Vijitha Basnayake, and Varuna de Silva and led sixty Sri Lankan and CapAsia students in the design and construction of two pavilions on the Moratuwa campus. With the successful completion of this project and the growth of our friendships, trust grew in each other. [5] Nihal and Wes had some, admittedly limited, experience with a natural disaster in south Asia. Both were in Delhi with students in 2001 when the Bhuj earthquake hit. And in 2005, before bringing the CapAsians to Sri Lanka, Nihal took the students to Bhuj, where they visited some of the areas devastated in 2001, in order to see what developments had occurred since the earthquake.

The tsunami struck as CapAsia IV was about to depart for south Asia. We anticipated a planned construction program with the architect Laurie Baker in Thiruvananthapuram. The day after the tsunami, Nihal and Wes spoke of the need to change the field study's itinerary, based on the belief that with our active knowledge of Sri Lanka we might be among the best positioned U.S.-based university programs to offer our services to those effected by the great wave. Using our local connections in Sri Lanka, we diverted our students away from the pre-arranged building project in India and towards the fishing village of Kalametiya.

3. CapAsia IV, 2005, Kalametiya

Pre-tsunami, Madhura was planning a resort near the village of Kalametiya, approximately twenty kilometers east of Tangalle and just south of Hungama. Not wanting to overwhelm the lives of the villagers with the new facility, he took the time to get to know the people believing this could help mediate the resort's impact on the lives and livelihoods.

Post-tsunami, Madhura volunteered his services and time to the village's reconstruction. The original village had been situated along the coast in a beautiful palm grove. The site for the new village, as ordered by the national government, was moved four kilometers inland on a sun-baked site to the north of the Kalametiya Bird Sanctuary.

Madhura encouraged us to help in any of four areas: 1) permanent house construction, 2) restoration of livelihoods, i.e., repairing fishing boats, 3) cleaning up house debris, and 4) social engagement. In particular, he wrote, "The frustration among [the villagers] is growing under these very difficult circumstances and social engagement with groups at different levels will be very useful to ease some of this frustration. Opportunities include play activities with the young kids, sport with the young men – volleyball or cricket, or even board games; cook-outs with the women, camp-fires etc."

Once we arrived, our plans to begin constructing immediately were derailed: in keeping with charts that were done of the stars, the village's auspicious moment would occur two days after our arrival. We had to wait. We had to set aside our schedule and, for the moment, our ambitions and take time to get to known the people and place.

As a result, our group spent part of one day assisting locals in cleaning up the remnants of the village swept into a lagoon by the tsunami, making neat piles of the torn remains: coconut wood framing members and tree branch posts, corrugated tin sheets tumbled into misshapen globes by the water wall, and aluminum cabling. Household items too--lamp bases, plastic chairs, insulated coolers, curtains, and tablecloths--the stuff of people's lives. Fishing nets, floats, and a boat hull tossed by the vengeful water. Pile after pile. And Wes found a passport in the sand, number K0538847, and imagined its owner before, during, and after the tsunami.

We then visited the temporary village, a U-shaped arrangement of approximately thirty 3-meter by 3-meter shelters constructed by Oxfam. The fishing families, who lived their entire lives under palm trees on a beach washed by ocean water and breezes, found themselves living in wood boxes sealed with corrugated tin roofs, all baking in the hot equatorial sun. A local woman named Rasika said to Nihal and Wes: "Now we are the dried fish."

At the auspicious moment--shortly after 8:00 AM on March 6, 2005--three young monks chanted as milk was boiled and a foundation stone set. As work began on the foundation trench for the first house, the leaders of CapAsia intended to complete one "demonstration" house that the villagers and builders could use as a model in completing the other twenty-nine houses. We came to a somewhat painful realization that this would be impossible. The hard-packed earth and hand tools slowed our progress.

In keeping with something Madhura said in an earlier conversation, we began to rethink our role as one that could provide great energy to begin the entire rebuilding of the village—to "catalyze" the construction of houses for everyone. We could get the big work going. And as we had come in "under the radar"—not associated with any large funding or supervisory agencies—we might be able to push forward even is some official permissions were missing or on the way.

We decided to spread the student group across the site, staking out foundations for the entire village, and beginning their trenches too. When we departed one week later, all the house foundations were dug, the majority of the trenches had a concrete pad poured in them on which the granite foundation would be built, and the first house had its granite foundation completed.

While on-site in Sri Lanka, flying back to the United States together, and teaching at Ball State University, Wes and Tim spoke of their shared experiences in Kalametiya, sometimes in direct reference to the project--“Could you figure out who was managing the construction site?”--sometimes more abstractly--“I’m more and more interested in simple tools” and “Maybe it’s time to do a project in which you’re not afraid to fail.” These questions, found or addressed while in Sri Lanka, provided us with a number of lessons that came and continue to influence our teaching.

4. Lessons

4.1 Lesson 1: Waking up

The CapAsia participants were time travelers, moving through air, space, and countryside at different speeds and in different orbits, to a place destroyed in an instant, where the survivors lived disjointed lives even as they waited patiently for a new beginning and a new rhythm for their days.

Our experiences on the ground brought a rawness, an immediacy, and a heightened awareness of how long a simple task might take to begin or complete, a feeling that one’s strong young body was being underutilized, a sense of wonder at the different rituals and beliefs that framed our efforts, and a desire to do something immediately for people whose lives had been completely upended, if not nearly ended.

Among the most notable comments on this aspect of the project was one by Tim, who arrived in Sri Lanka several days after the other CapAsians. Wes met Tim at the Negombo airport (after a long series of pan-Pacific flights) and escorted him to Kalametiya through a long night’s drive along the Coastal Highway, arriving at the construction site just as the auspicious moment rituals began. In a state of both exhaustion and euphoria--tired from the long trip and ready to help in whatever way he could--days later Tim said he “woke up in Sri Lanka with a pick in his hands.” For the students, this “waking up” was an especially difficult negotiation between their desire to make a difference and the anxiety they felt as they were awakened from their long middle class sleep by new challenges, insights, and pains they did not know and could not anticipate.

Locals “pushed back” at our plans. We had to wait for the auspicious moment. Many of the village men and some of the local villagers paid by relief organizations to work did no work.

Instead, they sat in the shade, watching. Persons who had lost a family or family member in the tsunami remained in a state of shock. In a sense, our "waking up" was tied to their "waking up." A local European provided alcohol to the village's men and kept them occupied, for reasons we could not determine. In this, there was a multi-layered local "sleep" as well, one we could not shake. [6]

4.2 Lesson 2: Not knowing

We adopted a way of working that not only took cues from the locals, but looked to them to provide leadership. While the plans gave us some sense that we knew where the project was headed, still, there was a great deal we did not know. From another vantage point, it can be said that we had no choice in the roles we assumed. Wes and Tim did not speak one word of Sinhalese (the local language), had never swung mamotties (the local hand tools used for digging), and were not expected to be in-charge of the building site. We came to understand the need to trust the others to know what to do and what was best. We followed the lead of men working on the construction site often in sandals and sarongs, and of women on the site as well whose intimate understanding of the local tools and conditions allowed them, at times, to outwork even our strongest CapAsian men.

While we had some knowledge, still, we did not know. For example, once the granite foundation wall was completed, we knew from the drawings that a concrete bond beam would be built to rest on top of it. We did not know, exactly, how it would be constructed on site. We didn't know how they planned to build the frame to hold the wet concrete of the bond beam until it was built. What wood was to be used? How was it to be assembled? How would it to be connected to the granite? There were many such moments when our existing knowledge gave us some notions, but provided limited insight.

At the same time, on a site where agents of various international, national, and local agencies and funding sources had their own interests, one could see that our inability to find logic within the system of construction was caused not only because we were foreigners. We got the sense that the Sri Lankans themselves did not understand how to organize the site—truckloads of granite blocks were being dumped with no on-site direction, masons were working without any direct supervision by the architect, water tanks were being placed without any consultation.

We could not direct, only respond. Letting go provided the chance to see the limits and relevance of our cultural and architectural knowledge. Was what we knew or learned about construction in North America even relevant on this piece of land in southern Sri Lanka, and if not, WHY? What did it feel like to let go, to work for others, and in not knowing, find even greater success? We could help, but it was, in the end, their job site and in a very positive sense, their village.

4.3 Lesson 3: Living now

We had no choice but to connect to the place and people. The ground in and on which the village was to be built was stubborn and did us no favors. We came to know its color, texture, and taste. The sun was hot and relentless. We sweated profusely, drank great amounts of water, and longed for the coolness of the ocean breezes. Our bodies were fully engaged--hands blistered immediately, we had grit in our teeth, and our backs ached. Still, with bandaged hands and smiling faces, we continued to work.

Even as we were caught in the immediacy of the moment, some of the Kalametiyans sought to extend friendship and connections into the future. They kept us in the "now" even as their engagements with us—working and playing with us, inviting into their homes, for example—suggest their efforts to break the immediacy of our involvement. Months later, one family sent Tim a Christmas card, and some of our students also remained in communication with the villagers. In the "now," they joined us in attempting to extend our bonds into the future. They "pushed back" at us by offering their friendship and thanks.

4.4 Defining success

Our week in Kalametiya was just that--seven days. Maybe the villagers saw us as an ephemeral presence--we were there for a short time, they enjoyed and appreciated our efforts, and then we were gone, too soon.

We had come to Kalametiya expecting to complete a "model" for others to follow, to impart our knowledge and expertise. In short time, we had to shift our expectations and follow the fluid course of events. There was little coordination on site. There was not any obvious animosity or anger, but no shared understanding of the project either. The masons kept to themselves and to their own pace.   We never worked in the cool of the evening. In this, there was little urgency and not much big energy, except among some of the villagers themselves.

We came to a different understanding of the successes of the project. Our building site was among the first to begin reconstruction, four months after the disaster. Visitors told us that this was the only reconstruction site in the area that had Sri Lankan locals working alongside westerners. By the time of our departure all thirty houses had been started. We came to appreciate this accomplishment as a greater success than completing just one. As we departed among hugs, tears and glasses of thick, sweet tea, we saw our role as that of a catalyst for both healing and reconstruction, and with that altered perspective understood our involvement as a great success.

We departed, of course, with much work left to do, from a construction site where we contributed little knowledge, had almost no input, and did not understand even the most basic of tasks, intervening in lives that had been through tragedies we couldn't imagine. We didn't get to start the project when we wanted to, didn't accomplish our objective, and stopped with just a small percentage of the work completed. And we left behind friends and a place we had grown close to and had been a part of, a place with which future contact would be difficult (it was out of the range of mobile phone service and the mailing address was a city several kilometers away).

It was, we came to understand, enough to help begin, enough to complete one house foundation, and more than enough to be very sad when we departed.

4.5 Lesson 5: Shifting innovation

The architect Sheila Kennedy speaks of the "shifting geography of innovation." In this, she challenges the widespread belief that we, in the developed West, innovate and give to or share our technology with those in developing economies and settings.   She argues that a 1-2-3 (first world to third world) exchange fails because the innovation often cannot adapt to the local culture. [7]

Working alongside the masons, the local citizenry, and the Kalametiyans shifted our perspectives. We learned by participating in their means and methods, which grew directly out of the place. We watched a mason lay out a foundation plan in twenty minutes with one piece of string--an assignment that two of our graduate students took two hours and numerous pieces of string to complete. We checked to make sure the top of the foundation was of a uniform height not with a laser or even a level, but with a simple garden hose filled with water. And our young, strong students did their best to match the digging skills of local men and women, but could not.

In this, we learned practical and technical lessons related to technique and local intelligence. Maybe more importantly, we learned humility, that "our" way is just one way, and might not always be the best way. In this, we found that a 3-2-1 flow of knowledge, from third world to first world, has much to offer. We learned, again, the need to listen. [8]

In one of our small architectural contributions, Tim suggested that a construction detail of the foundation needed further attention. Specifically, a metal "tie" was needed to mechanically join the granite blocks to the beam that rested on top of them. This was a detail not shown in the architect's drawing and not being constructed by the masons. We telephoned the architect who said his office had forgotten to show the "tie." Then, Wes instructed the masons on-site, without a word of shared language, to include such a "tie" in the future. In a sense, our "push back" improved the constructed quality of the houses. More importantly, it established the relevance of shared knowledge, of both following and questioning within the project.

5. Case Studies

Two recent projects suggest the ways in which our experiences in Kalametiya inform both our practices with students and our attempts to alter the ways in which we, the dominant group, understand the subordinate group.

5.1 Project 1: Halifax, Nova Scotia, Canada

Each summer the Department of Architecture at Dalhousie University in Halifax, Nova Scotia (Canada) runs a series of FreeLAB studios that must result in a full scale built construction of some type. As the name implies, the projects are largely determined by individual instructors who are invited from around the country and the world. Tim was invited to lead a FreeLAB in the summer of 2006, two years after participating in the reconstruction of Kalametiya.

The Light Sail Installation was intended to reveal the unique qualities of its site, located adjacent to the historic grain silos at the Halifax waterfront. The piece is composed of a grid of light reflectors salvaged from the site. In this, the work invests both the reflectors and the silos with a new life and reveals the beauty of the site itself. The reflectors are suspended from a custom fabricated steel frame and when activated by the breeze they pivot independently, creating a brilliant dance of light. The work is interactive--participants are able to both rotate the assembly and affect the projection of light through the screens and onto the massive wall of the grain silos.

Tim considers the result of the short (15-day) FreeLAB among the most successful of his design-build efforts with students, of which there are many. He found himself reflecting on how his experiences in Kalametiya might have influenced his approach to the project in Halifax:

On the long drive out to Halifax I "woke up" to the fact that I had no idea what I was going to build or where I was going to build it. I had a familiar tool—a 120-volt welder--in the back of the truck and a fair assortment of my own tools, something I could count on. I had never gone into a project feeling quite this exposed. I needed to lead but I also needed to be open to the flow of events. I needed to let go and follow. Had my experience in Kalametiya prepared me for this?

Prior to leaving for Canada I had discussed my work with Wes in a friendly conversation and he suggested I needed to have a "grand failure," a comment I took in jest at the time but found myself thinking about often on the long drive to Nova Scotia. A grand failure? Letting go of control? Pushing boundaries? What exactly was he getting at?

Upon my arrival in Halifax (after a three-day drive) I found myself having dinner at the home of my hosts and meeting some of the other FreeLAB instructors (six labs run concurrently) for the first time. This dinner was my first stop in Halifax and the FreeLAB was to begin the following morning, lasting for just over two weeks. This is an ambitious schedule for a construction project of any kind. I intended to do a site-specific installation but had no idea what to build or where to build it. I had very little money for the construction. And I wanted to do something derivative of a place that I was visiting for the first time.

Over dinner I discovered that the other instructors did have specific ideas of what they would build. Most had external funding and some were familiar with the place. A grand failure? I thought to myself that Wes would be very pleased as I felt I had set myself up for just that.

To "not know" Halifax and FreeLAB was to see both the workshop and my work with the clarity of fresh eyes, new people, and a new place experienced for the first time. The short deadline, very limited funding, and negotiating within the bureaucracy of a new university created their own anxious pressure. Complementing these concerns were the luxury of complete focus and no distractions. There was just the project, the students, and the place. The temporary nature of the work intensified the experience and focus of the moment. In this sense, to speak of "living now" is to understand that the completed project had a life of exactly one day. There was an opening, an event, and a bright short life full of magic, energy and pride. I left town the next day on a journey toward home over 1500 miles away. The Light Sail was dismantled and put into storage.

Had placing myself in that uncomfortable situation of not knowing, not planning, contributed to the project's success? Does organizing a project to guarantee a good result in some ways constrain the potential for a great one? Could I have taken this chance prior to "letting go" in Kalametiya?

Finally, to write of the shifting geography of innovation, the Light Sail took its cues from the leftover, the derelict, the industrial backyard of the city, and in that ragged mix found beauty and elegance. The project began with an inventory of the discarded contents of an old warehouse, finding inspiration in the unlikely, in the "rubbish" of the place itself. We approached the project with a willingness to quietly listen and to learn from this unlikely place as well as a willingness to let the investigation and the process define the response. Shop technicians were consulted and became participants in the design of the project, even as they worked as enthusiastic facilitators from separate (competing) departments.

In retrospect, listening, including, and enabling were central to the success of the project. Were these lessons I had learned while sweating alongside the local masons in the dusty red earth under the hot sun of Kalametiya? One is never sure where prior knowledge ends and new knowledge begins, or where one may find beauty in the unexpected. The temporary nature of the project and the abstraction of distance and time allow one to be open in ways he or she might normally be closed. It's hard to define what one takes from such events, but in the end I've discovered perhaps that the true magic lies in letting go.

5.2 Project 2: Flint, Michigan, USA

General Motors was founded in Flint one hundred years ago. The city and its worker-citizens rode the company's rise to a position of global primacy. At its peak in the 1960s, Flint was home to 190,000 persons and 80,000 General Motors' jobs, and prepared for a population of 250,000. Today, with the U.S. auto industry in free-fall, Flint's population is at 120,000 and 17,000 GM jobs remain. No one is sure if the bottom has been reached or is even in sight.

As Flint shrinks, houses are abandoned. Comprehensive numbers are difficult to establish, but a demolition crew chief told Wes that 4,000 houses need to be torn down "today" and another 10,000 will need to be torn down in the future. Crews tear down two to seven houses every working day. The quantity of demolition waste produced in Flint is significant: 200 cubic yards of waste/house x 5 houses/day (+/-) x 5 work days/week x 52 weeks = 260,000 cubic yards/year. That's equivalent to a 15-story building the size of a soccer field. Every year.

  

In 2006 Wes was commissioned to determine if it is possible to deconstruct houses in Flint so as to reduce, even slightly, the amount of waste produced when a house is torn down. Ultimately, in this radically extreme setting, three recommendations were made. The first, "soft strip," suggested the need to pull elements off and out of the houses that were most easily removed—gutters, downspouts, handrails, aluminum siding, and more. [9]

Waking up in Flint is to be in a place with almost no hope--you're a time traveler with no sense of time as there is no movement forward. To work in Flint, you have to let go of much of what was and is known. Living now, in Flint, is to acknowledge that the bottom has not been reached, that there are problems that can't be solved, that one needs to be humble in order to understand the depth and breadth of the distress. Living now in Flint is also to engage house teardown processes that are well-practiced--thousands of houses have been torn down using essentially the same backhoes, fire hoses, large dump trucks, bulldozers, landfill, and people. Living in Flint today is also to run into untold numbers of liquor stores, squatters, unemployed persons, and others in distress. This is the "now" of a shrinking city. To work in Flint, today, as an architect is to have to redefine one's sense of success. How does one "succeed" in such a setting? Can you find a place for your architectural knowledge? And Flint is not alone. Cities are shrinking throughout the Rust Belt in the United States, in the former Soviet Union, and in the older societies in Europe. In shifting to these places of innovation, issues arise that challenge our sense of responsibility and knowledge.

There was tremendous "push back" by the various actors. Too many abandoned houses, a well practiced and rough teardown process, limited funding to support teardown efforts, a desire to reduce landfill deliveries, scavengers and squatters, a lack of support from the State of Michigan, thousands of lost jobs, and more. Each, essentially, is part of a setting in which their combined "shove" overwhelms the efforts of any others.

6. Conclusions: New Modes of Practice and Design

To address the title of her own article "Can Architects be Socially Responsible?" Margaret Crawford replied: "[A]s the profession is presently constituted, no. Both the restricted practices and discourse of the profession have reduced the scope of architecture to two equally unpromising polarities: compromised practice or esoteric philosophies of inaction." However, Crawford offered two avenues for further exploration: "existing material conditions rather than . . . idealistic projections of future technical capabilities" and "compelling stories about social needs" (such as the homeless, communities threatened by decay; elderly, poor, minority groups, and more). [10]

The projects profiled herein evidence significant overlap among Crawford's proposals and the authors' interests. "Existing material conditions" were central aspects of the works. "Compelling stories" were engaged both in the ways in which Wes and Tim, as Maxine Greene might say, were "wide-awake" and fully present themselves, and in the ways that local people assumed, expected, and demanded participation and presence. [11]

In this version of immersive learning, constructional projects are grounded in local building cultures, immediate settings, and real lives; these moments are conceived as learning venues for all.

That said, basic questions arise. Who is the building educator? Who is the building student? Who is the building community? Absent "answers," even as old and new concerns for power and position swirl around us, our search for new modes of practice and design will continue.

Development of low-cost fly ash bricks

Andreas Nataatmadja
School of Urban Development, Queensland University of Technology
(email: a.nataatmadja@qut.edu.au)

Abstract

Fly ash is produced in vast quantities as a by-product of the burning of fossil fuels for the thermal generation of electricity. At present 10-15% of the fly ash produced in Australia is utilised in cement manufacturing and concrete industry, with the remaining majority requiring costly disposal processes. Due to growing environmental concerns and the need for cleaner production, the management of fly ash has become an important issue facing the power generation industry. For that reason, many researchers are actively working to find new and improved methods of combating the fly ash waste disposal problem, particularly by establishing its useful and economic utilisation. One such example that is gaining considerable interest in many parts of the world is the utilisation of fly ash in brick manufacturing.

This paper examines the potential for using Class F fly ashes from Queensland as major constituents in the manufacture of common residential building bricks. Scaled-down pressed bricks were made by varying proportions of fly ash, sand, hydrated lime, sodium silicate and water. Both fired, oven-dried and air-cured bricks were tested for their properties including compressive strength, tensile strength, water absorption, and durability. In the paper, the test results are analysed and effects of variables discussed. Recommendations and conclusions as to whether or not the fly ash bricks can perform adequately alongside the clay bricks are included.

Keywords: Construction material, Brick, Fly ash, Sodium silicate, Masonry

1. Background

Housing shortages in many developing countries have stimulated efforts to develop construction methods that use cheap and durable local materials. It is essential to develop technologies that use minimal resources because of the increasing shortage of energy and raw materials. In this regard, the International Development Research Centre (IDRC) in Canada [1] noted that one of the most promising building materials for many countries is the fired clay brick. Traditionally produced in a cottage industry setting, fired clay brick production plays a major role in the informal economy of such countries. However, it is hampered by a number of problems:

Brick makers have little training;

The quality of bricks produced is low, and supply is irregular;

Great quantities of firewood are needed for production while energy loss (in the form of heat) is high at 40-50%; and

The process is damaging to the environment.

On the other hand, in many countries, electricity is often supplied by coal-powered generators. In the power stations, approximately 80-90% of the ash formed from burnt coal is carried out of the furnace, then extracted from the flue gas and is known as fly ash. Large quantities of fly ash produced as a by-product of coal-based power stations have been viewed as a serious environmental problem. It is not surprising that with growing environmental awareness, there has been considerable interest in the use of fly ash in the brick manufacturing industries. At present, India has been leading the way in fly ash brick manufacturing.

The use of fly ash in brick manufacturing is not new. Sloanaker [2] studied class F fly ashes from the USA to produce fired bricks for construction. It was indicated that fired bricks made from feeds of 72% fly ash, 25% bottom ash, and 3% sodium silicate met commercial specifications. In India, Rai [3] was able to produce calcium silicate type bricks using fly ash, sand and lime mixtures, while in Australia, Kayali [4] patented a new process to produce bricks from 100% fly ash which has a compressive strength of more than 40 MPa using a kiln with a firing temperature of 1000°C - 1300°C. In addition, it is worth noting that the possibility of developing non-fired (air-cured) fly ash bricks was studied in Israel [5].

This paper describes an experimental investigation into the use of fly ash in making pressed fly ash bricks by firing, oven-drying and air-curing. Tests were carried out to determine the strength characteristics and water absorption properties of the bricks.

2. Materials

In the current investigation, pressed bricks were made using fly ash and other materials such as sand, lime and sodium silicate of various proportions, wherein the amount of fly ash was at least 50% by mass.

A dry processed “fine-grained” ash from Queensland, namely the Tarong fly ash, was chosen as the main constituent in this investigation. The ash is classified as a low iron mix with more than 75% of constituents as oxides of Silica and Alumina (see Table 1).

Table 1: Main Constituents and Properties of Tarong Fly ash

CaO	SiO_2	Al_2O_3	Fe_2O_3	MgO	SO_3	Na_2O	K_2O	TiO_2	Mn_2O_3
0.1%	70%	25%	1%	0.1%	0.01%	0.1%	0.5%	1.6%	0.03%
Note: pH = 4 Particle density = 2.14 Loss on ignition = 1.5									

Fly ashes are pozzolanic materials, i.e. they react with water with the addition of lime (CaO) to form cement materials. Some fly ashes have a sufficient amount of "free lime" such that they have self-cementing characteristics. However, Queensland fly ash contains low (< 4%) CaO contents (i.e. class F fly ash) and hence, it does not show appreciable self-cementation behaviour.

To improve the mix gradation and workability, two types of sand were used in this study, namely:

- Silica sand: this sand is normally used for the manufacture of domestic glass and has a silica content of about 98%.
- River sand: common sand normally used in concrete manufacture.

Liquid Sodium Silicate (LSS) Grade 42 (SiO_2 : Na_2O = 3.22, total solids = 39.3%, pH = 11.2) was used as an additive in this investigation. This material, also known as water-glass, is generally considered to be non-hazardous although skin contact should be minimised to avoid irritation. It is expected that by adding water-glass, silicon-oxygen anions found in fly ash go into solution and form polymers which begin to coagulate in the liquid during curing [5]. The alkali of the sodium silicate then reacts with silica present in fly ash in the glass phase, strengthening this process of polymerisation and coagulation, ending with the generation of a water-stable silica gel. Dehydration of the silica gel and consolidation of the structure subsequently produces an increase in the strength of the bonds, resulting in the creation of a hard, solid material.

Commercial building lime (hydrated lime) was used to trigger the pozzolanic reaction of the class F fly ash (and hence improve the strength and durability of the bricks). Care was taken to avoid "scumming" and after trial and error testing, each fly ash brick was prepared with a constant amount of lime (5% of total mass). This additional lime did not seem to cause any "scumming" after firing.

3. Specimen preparation

There were four major steps involved in producing the test specimens. These included, proportioning of constituents, mixing, moulding/pressing of green bricks and followed by firing, oven-drying or air-curing.

Initially, three different combinations of fly ash and sand (i.e. primary raw materials) were used, namely, 50/50, 70/30 and 90/10. Liquid Sodium Silicate (5, 10, 15 and 20%) and hydrated lime (5%) contents were added to the mix with proportions calculated by multiplying the percentages in parenthesis by the total mass of primary raw materials.

The mixing of constituent materials was performed in two stages. First, the dry materials (ash, sand, lime) were mixed thoroughly using a 15 litre mechanical mixer. The second stage

involved the addition of LSS and water (as required). This was done gradually until the mixture was of a uniform and mouldable consistency.
A steel mould with moveable top and bottom platens was used to produce the green bricks. With the bottom platen supported by four springs, the mould assembly was placed on a hydraulic press machine (Figure 1). It was found by trial and error that 150 grams of mix, moulded using pressure of around 10 MPa would produce a test brick of approximately 78 mm x 38 mm x 27 mm; the ratio of these dimensions are similar to those of a common house building brick (225mm x 105mm x 75mm).

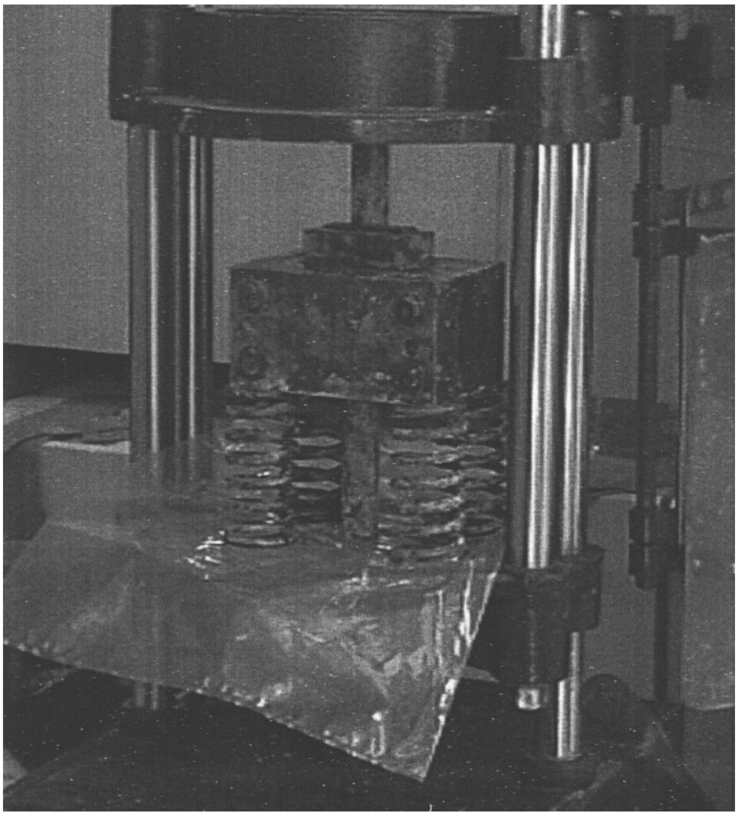

Figure 1: Brick Casting Using a Hydraulic Press Machine

To produce fired bricks, a high temperature oven was used. An initial study carried out to find the effect of firing temperature indicated that a firing temperature of 555°C was adequate. The green bricks were placed in the oven with an initial temperature of 25°C. This was increased gradually to 555°C in 120 minutes and subsequently kept at 555°C for 100 minutes. Thereafter, the oven temperature was dropped back to 35°C over 100 minutes and the bricks were then cooled to ambient temperature with the oven door ajar. The brick specimens were subsequently removed, weighed, measured and visually inspected.

In addition to the above, a number of non-fired bricks were studied in the present investigation. The first was air-cured bricks, which were placed in airtight plastic bags for 28 days before testing. The use of airtight bags was intended to reduce the effects of carbonation, which is a problem known to affect concretes high in fly ash and lime content. Other bricks were cured in a standard oven at 105°C for 24 hours, and a limited number of bricks were cured in open air prior to testing.

4. Testing and results

4.1 Fired bricks

It was observed that bricks with high moisture content values usually developed hairline surface cracks after firing. Excessive moisture contents were associated with gross shrinkage, leading to the development of severe cracks and loss of strength, and hence moisture contents were kept below 30%. Test results generally indicated that to achieve optimum performance, the moisture contents of both fly ash/silica sand and fly ash/common sand mixes had to be within the range of 25±2%.

The dry density of the green bricks is proportional to the densities of the brick constituents and primarily the moulding pressure used to form the bricks. The moulding pressure used was 10 MPa, a value commonly used in clay brick production. This produced brick specimens having dry densities ranging from approximately 1.15 t/m^3 to 1.65 t/m^3. For optimum performance, however, bricks made from fly ash/silica sand and fly ash/common sand would need dry densities of approximately 1.40 t/m^3 and 1.60 t/m^3, respectively. Compared to dry densities of 2.25 t/m^3 to 2.8 t/m^3 for clay bricks, the proposed fly ash brick was remarkably lighter.

Compressive strength is the only mechanical property used in normal brick specification; it is the failure stress measured normal to the bed face (as the majority of brickwork only experiences vertical compressive loads due to the self-weight of the brickwork and bearing loads). Three specimens were tested for each batch of bricks in accordance with AS/NZS4456.4.

For each tested specimen, the failure load was noted and recorded to estimate the uniaxial compressive strength; given by Equation 1 below.

$$\sigma_c = K_a(1000P/A) \qquad (1)$$

Where σ_c = uniaxial compressive strength (MPa),

P = failure load (kN),

A = net cross-sectional area (mm^2), and

K_a = aspect ratio factor (to allow for height-to-thickness ratio), in this case 0.61.

The results, as shown in Table 2, indicate that the compressive strength of the fired bricks under investigation increased rapidly with the amount of LSS up to approximately 15% by mass. It can also be seen that for bricks containing silica sand, higher proportions of fly ash to sand tend to exhibit greater strengths.

Additions of LSS in excess of 15% by mass lead to high moisture content values in the green bricks made with 50/50 and 70/30 fly ash/silica sand. Consequently, these bricks experienced more shrinkage/cracking, which caused a weakening of microstructural bonds and ultimately a decrease in compressive strength. Bricks made with 90/10 fly ash/silica sand, however, continued to increase in compressive strength with additions of LSS up to twenty percent. It can be seen from the results that compressive strengths greater than 20 MPa were easily achieved by all mixes containing silica sand and 15% LSS, and strengths >25 MPa could be achieved with the 90/10 fly ash/silica sand mixture incorporating 20% LSS.

Table 2: Uniaxial Compressive Strength (Average Values)

	COMPRESSIVE STRENGTH, σ_c (MPa)	
% LSS by mass	WITH SILICA SAND	WITH COMMON SAND
50/50 FLY ASH/SAND		
5%	8.57	9.37
10%	7.55	15.41
15%	23.49	30.82
20%	12.29	-
70/30 FLY ASH/SAND		
5%	8.25	8.11
10%	11.40	11.72
15%	26.98	25.91
20%	24.31	-
90/10 FLY ASH/SAND		

5%	10.01	7.56
10%	16.66	12.72
15%	24.29	24.10
20%	27.81	-

For bricks containing common sand, it was also found that the compressive strength increased rapidly with the amount of LSS up to approximately 15% by mass. As with the bricks made using silica sand, the bricks containing common sand also became saturated when amounts of LSS were increased to 20% by mass to an extent that the raw mixture was non-workable; rendering moulding, extraction and handling impossible. Hence, mixtures containing 20% by mass of LSS were discarded as being unviable.

At 15% LSS, the 50/50 fly ash/common sand mixture performed differently than bricks made with silica sand; the former clearly exhibited the highest average strength (>30MPa). However, with the objective being to maximise fly ash utilisation and the fact that the 70/30 mixture of fly ash/common sand produced the most consistent results averaging around 25MPa with 15% LSS, it could be selected as the most viable mixture alternative.

For the indirect tensile strength, the testing method was in accordance with AS/NZS4456.14. The test simply involves applying a line load to a brick, supported by a linear reaction in the plane of linear loading to cause the brick to fail/split.

The failure load is indirectly related to the tensile strength of the brick (Equation 2).

$$f_s = 2F_s/(3.142bh) \qquad (2)$$

Where f_s = tensile strength (MPa),

F_s = maximum splitting load (N),

b = width of chosen cross-section (mm), and

h = height of chosen cross-section (mm).

The average results, as shown Tables 3, indicate that the indirect tensile strength of the bricks tends to increase with increased additions of LSS. Increasing the amount of LSS from 5% to

15% by mass brought about an increase in tensile strength from less than 1 MPa to something close to 2 MPa.

The mixture of 70/30 fly ash/silica sand with 15% LSS produced consistent results averaging around 2.3 MPa. In general, compared to the tensile strength of common clay bricks, the tensile strength of the fly ash bricks was lower (2 to 3 MPa less).

The water absorption of a brick is the percentage increase in mass of a dry brick when it has been saturated. The test for water absorption properties was performed in accordance with AS/NZS4456.14. Two types of water absorption tests were performed, i.e. cold water 24-hour immersion test and 5-hour boiling water test. The results are shown in Table 4.

It can be seen from Table 4 that the experimental bricks exhibited distinct water absorption characteristics with respect to their constituent proportions of fly ash, sand and LSS content.

The water absorption of all brick mixes decreased with increasing LSS content. This was expected as increasing the LSS content, produces more impermeable bricks and hence, the potential for capillary action reduces, subsequently decreasing the water absorption capacity of the product.

The percentage water absorption of all bricks increased with increased fly ash content. The 90/10 fly ash/sand brick exhibited the greatest water absorption characteristics, whereas the 50/50 fly/sand brick exhibited the lowest and most promising water absorption characteristics, and the 70/30 fly ash/sand brick exhibited water characteristics between the two mentioned extremes.

In comparing cold and boiling water absorption results, it is evident that little difference exists between these properties. This is due to the fact that the testing method period was lengthy enough for the test bricks to become saturated during both testing procedures.

The results achieved for the bricks made with silica sand are slightly irregular when compared to those of the bricks made with common sand. The tendencies described above still apply but are not as distinct to the eye as those derived for bricks with common sand.

The optimum blends of 70/30 fly ash/sand showed distinct differences in water absorption properties for the different sand types used. The bricks made with silica sand exhibited unacceptable water absorption as compared with those of the bricks made with common sand. The latter averaged approximately 13% water absorption, when 15% LSS was used, which can still be considered comparable to that of typical clay bricks.

Table 3: Indirect Tensile Strength (Average Values)

FLYASH/SAND RATIO	% LSS BY MASS	TENSILE STRENGTH, f_S (MPa) WITH SILICA SAND	WITH COMMON SAND
50/50`	5	0.66	1.01
	10	0.75	1.86
	15	1.66	2.69
	20	1.57	0
70/30	5	0.73	1.64
	10	1.63	1.15
	15	2.30	1.95
	20	2.76	-
90/10	5	0.94	1.17
	10	2.71	0.99
	15	1.68	1.93
	20	2.69	-

4.2 Non-fired bricks

As mentioned earlier, Freidin & Erell [5] reported the results of an experiment whereby air-cured bricks were made from fly ash, slag and water-glass. If air-cured bricks could perform adequately, it would certainly be the most economical option. In the present investigation, it was decided to prepare non-fired bricks with 70/30 fly ash/sand ratio. Only common sand was used with either 0 or 5% lime and with either 12% or 15% sodium silicate. Table 5 shows the results from air-cured and oven-cured bricks (tested in moist, dry and wet conditions), along with those shown in [5].

It is seen that, in general, the results from the present investigation agree with those from [5]. Curing in a sealed bag produced the worst performing bricks, especially when tested in moist conditions. Curing in open air for 28 days produced much better performance when testing was carried out after oven drying the bricks (at 105°C) to a constant mass. The best performance was achieved when green bricks were placed in an oven (105°C) for 24 hours before testing; the results were comparable to, if not better than, those of the fired bricks. In general, the addition of lime improved the brick's performance. It should be noted that whilst bricks cured in open-air have reasonably high dry compressive strength, the strength completely disappeared after 48-hours soaking.

Table 4: Water Absorption Results

		COLD WATER ABSORPTION (%)		BOILING WATER ABSORPTION (%)	
FLY ASH/SAND RATIO	% LSS BY MASS	With Silica Sand	With Common Sand	With Silica Sand	With Common Sand
50/50	5	25.00	22.73	20.37	22.73
	10	24.07	20.91	21.30	20.91
	15	18.97	-	15.52	-
	20	17.69	-	15.04	-
70/30	5	33.66	31.37	29.70	31.37
	10	25.00	28.85	21.00	27.88
	15	22.93	13.16	19.27	14.04
	20	19.64	-	17.86	-

90/10	5	34.38	36.73	30.21	35.71
	10	20.00	31.96	17.89	30.93
	15	26.73	20.56	22.77	20.56
	20	25.25	-	21.21	-

5. Conclusions

The results of this investigation suggest that it is possible to produce lightweight bricks from fly ash at a firing temperature of around 550°C. In particular, with proper proportioning, these bricks can produce compressive strengths comparable to those of common clay bricks. Although their tensile strength is somewhat below the typical values of clay bricks, the absorption characteristics may be comparable to those of clay bricks.

There appears to be an optimum composition for the fly ash bricks studied. A combination of 70/30 for fly ash/common sand with 15% liquid sodium silicate and 5% lime would produce the best performing brick in terms of strength, mouldability and water absorption.

As compared with fly ash bricks containing silica sand, it was found that fly ash bricks containing common sand performed better in terms of water absorption while their strength characteristics were not significantly different. It is obvious that common sand would be a much better choice in terms of cost.

Table 5: Results from Non-Fired Bricks (Average Values)

* With slag ** Without slag # Oven dry at 105°C for 24 hrs

^^ Tested after oven-drying to a constant mass

^ Tested after soaking in water for 48 hrs

The possibility of developing oven-dried fly ash bricks has also been explored and the results show that it is possible to simply dry green bricks at 105°C to obtain performance similar to that of the fired fly ash bricks. Translated into the conditions found in many developing countries, this could mean an affordable small/home industry with low energy requirements and minimal energy losses. More than that, the process is making use of waste material (fly ash) in large quantities and hence, is more environmentally acceptable.

It is difficult to provide a cost estimate for the manufacture of fly ash bricks since it depends on the availability and cost of the raw materials (fly ash, sand, sodium silicate). However, the above results suggest that aside from material and transportation costs, it is possible to manufacture the bricks using a much cheaper and simpler technique and hence, compete directly with clay bricks.

6. Acknowledgment

The paper has been based on the work carried out by Messrs. M.D. Chester and A. Jobbins under the Author's supervision.

Sustaining Cultural Heritage in South And Southeast Asia: integrating Buddhist philosophy systems theory and resilience thinking to support sustainable conservation approaches.

Jamie MacKee
Lecturer, School of Architecture and Built Environment, University of Newcastle, Australia.
(email: jamie.mackee@newcastle.edu.au)

Abstract

The World Heritage Convention, based on euro-centric principles espoused in the Venice Charter, provides a mechanism for listing and protecting tangible and intangible heritage in many countries. The World Heritage List is wide-ranging but not all-encompassing representing selected examples of indigenous heritages. However, there is an extensive collection of heritage that falls outside this safety net of recognition and protection, particularly in developing countries of Asia.

Many cultural heritages of Asia have their roots in the cultural traditions of the sub-continent developing independently to those of Europe. As a result the traditional view is that the cultural systems of the sub-continent are based on spiritual values, norms and beliefs, communalism, and holism. However western culture has evolved towards the development of values founded on the reality of the material world or materialism, and rationalism. Tangible and intangible heritages values have had a distinctive role in presenting the differences between the western mode of thinking and that of Asia.

This paper proposes that any sustainable approach to the conservation in South and Southeast Asia must be based on the cultural and philosophical traditions that have underpinned the formation of the cultural heritage. Through a review of literature synergies between systems theory, resilience thinking, based on holism, and the philosophical traditions of the region, particularly Buddhism are established. Focusing on a case study of non-secular built heritage in Sri Lanka it is argued that systems theory provides the foundation for an alternative paradigm supporting an original approach to sustainable conservation and protection of cultural built heritage in South and Southeast Asia. Outcomes presented in this paper indicate such an approach highlights the uniqueness of cultural traditions, notions of spirituality, place-making and spatial relationships particularly of non-secular monuments. Sound preconditions for sustainable cultural heritage conservation outside the institutional protection provided by the World Heritage Convention and euro-centric approaches.

Keywords: Sustainability, cultural heritage, Buddhist philosophy, systems theory, conservation theory, resilience thinking.

1. Introduction

1.1 Background

This paper explores the interconnections between Buddhism, resilience thinking and systems theory in the context of developing a sustainable approach for the conservation of non-secular built heritage in the South and Southeast Asian region. The non-secular built heritage is conceptualised as a complex system within the larger system of the culture in which it resides; thus providing the development of a theoretical basis for then constructing a conceptual framework (MacKee 2007). The functions and elements of systems theory are discussed to evaluate its usefulness as an approach to the conservation of non-secular built heritage. The paper reinforces and explores the links made between systems theory and Buddhist philosophy as developed by Chao and Midgley (2007a, 2007b), Midgley and Chao (2007), Macy (1991a, 1991b, 1976), Khisty (2006a, 2006b), Churchman (1968) and Ellis and Ludwig (1962). A discussion of these two overlapping worldviews is crucial to be able to propose systems theory as a credible framework for an Asian approach to conservation of non-secular monuments.

The essential proposition of this paper is that the current theories and representative wealth of charters and guidelines that govern conservation practice are the “tip of the iceberg”. Beneath lie an immense body of cultural philosophical and religious thought and traditions that underpin the whole sphere of Western approaches to conservation (MacKee 2007). This research poses a fundamental question: How would the rich and unique cultural built heritage of the Asian region be interpreted and conserved if the theories and guidelines that were to underpin it were based on the cultural and philosophical traditions of the region?

For the reasons discussed here, this research postulates a new paradigm supported by a conceptual framework for conservation of non-secular monuments in South and Southeast Asia, based on the cultural and philosophical traditions of the region. This is represented by the philosophical foundations of Buddhism that has widespread acceptance throughout Asia and a number of key similarities with other philosophies in the region, predominately Hinduism. Buddhism forms the basis of the study for this reason; however it doesn’t provide a coherent foundation for the development of a conceptual conservation framework. For this purpose a search for an appropriate sound methodology was undertaken. From the literature review, the work of Joanna Macy (1991a, 1991b, 1976), a Buddhist and systems theorist, provided the initial links between Buddhism and systems theory which has since been supported by a number of others (Chao and Midgley 2007a, 2007b, Midgley and Chao 2007, Khisty 2006a, 2006b, Checkland 1999, Schmithausen 1997, Capra 1996, Churchman 1968, Ellis and Ludwig 1962).

Macy (1991a, 1991b, 1976), establishes links between Buddhist philosophy and systems theory based on the synergies and similarities between the Buddhist universal law of causality and the cyclical process of cause and effect and can be related to the notion of feedback loops in cybernetics and systems theory (Macy 1991a, 1991b, Schmithausen 1997). In Buddhism the concept of the universal law of causality is central to the notion of *karma*. *Karma* is an important notion in the context of a cyclical view to life processes, that is birth-death-rebirth, as

opposed to a linear view and is a common theme amongst the religions/philosophies of the sub-continent (Harvey 2003, Kalupahana 1976). Macy's (1976) other key links relate to holism, as she perceives Buddhism as providing a holistic view to life and empiricism. In Macy's view, the Buddha is essentially an empiricist as he developed a philosophy based on his experiences and observation of life and has avoided all metaphysical arguments. She supports these further similarities by detailing the empirical basis of systems theory and how systems theory relies primarily on empirical data as a means of dealing with problems (Macy 1991a, 1991b, 1976).
The established synergies between the philosophy of Buddhism and those of philosophical traditions of the region as proposed primarily by Macy in her work has been reinforced in the recent work of Khisty (2006a, 2006b) writing on systems theory; Kumar and Sankaran (2006) writing on management and systems theory; Capra (1996, 1982) writing on systems theory and changes in Western thought, and one of the early proponents of systems theory in management, Churchman (1968). Churchman's links are implicit in a much broader discussion on spirituality. For Khisty (2006a, 2006b), while his connections broadly reinforce those of Macy, he further elaborates on the idea of Interbeing as proposed by the Venerable Thinh Nacht, a contemporary Buddhist priest, which is along similar lines to Macy's proposal. Interbeing is a term that covers the Buddhist concepts of interdependence, interconnectedness and interrelatedness. Khisty (2006a) equates this with the idea of holism in systems theory and that all systems are interrelated, avoiding separation and reductionism in traditional management and problem solving. Kumar and Sankaran (2006) provide strong links with Hinduism and Checkland's (1999) Soft Systems Methodology. Their starting point is the notion of context sensitivity and the concept of the flexibility of truth in the Indian context and how within this Indians react to their own context, and then act rather than accept the general abstract formulation of law applicable to all (Kumar and Sankaran 2006). This relates to the idea of a lack of a hard reality and how this is conceptually similar with Checkland's Soft Systems Methodology. Checkland's Soft Systems Methodology is situation driven and always iterative wherein a person internalises what they see, understands and then act according to their understanding of the situation (Hutchings and Cassar 2006, Checkland 1999 1990).

In the context of this research these issues are relevant predominately because they offer an organic, holistic, pluralistic ontology of aspects that may guide the conservation and preservation of non-secular built heritage in the South and Southeast Asian region. This would ensure that all aspects of the uniqueness of the monuments and indigenous beliefs are taken into account in a sustainable context.

2. Systems Theory

The history of scientific investigation in the context of western enquiry has been based on a rationalist empiricist approach to problem solving (Capra 1996, Laszlo 1972, Van Bertalanffy 1968). Descartes' methodology for solving scientific problems has proved influential (Dicker 2003, Arrington 2003). His idea of reducing or "pulling apart" the problem into its parts, solving the parts and then reassembling them has been used to solve a range of issues (Du Plessis 2000, Capra 1996, Flood and Jackson 1991). Such reductionism has been predicated on the belief that any whole or problem can be described or defined by the sum of its parts. In science there has been the tendency to adopt this approach, and in fact, many of the theories that we apply today are based on this foundation thinking. By way of an example of reductionist thinking, we can explore the issues and 'solutions' of the problems of public transport, these solutions are often then proposed as the panacea for a range of urban problems (Checkland 1999, Flood and Jackson 1991). Local authorities or public utilities that manage these systems may look at timetables, routes or quantities without looking at the complex issues of the total system that include all modes of public and private transport and their interrelationships to obtain a successful public transport system. Instead there has been a tendency to focus on the issues of the parts in isolation, rather than the connections that link the parts (Checkland 1999, Laszlo 1972, Churchman 1968).

This paper argues that the non-secular monuments of South and Southeast Asia, inclusive of all tangible and intangible heritages, need to be considered as part of a larger whole of the Asian region, society and culture in which they exist. This is particularly true in the situation of South and Southeast Asia where global Euro-centric conservation theories have been applied to complex and unique systems of heritage-cultural-societal interrelationships, quite different in conceptual foundations to those from where the conservation theories were developed in the first place (MacKee and Hartig 2007, MacKee and Hartig 2006, MacKee and Briffett 2000).

2.1 The application of systems theory in sustainable development

Historically, there has been a search for a better way to understand the complex relationships that make up the human-nature interface. Many authors (Khisty 2006a, 2006b, Eckersley 2004, 1992, Capra 1996) argue that is has been the commitment to a mechanistic worldview and reductionism that has resulted in significant environmental problems. The prevailing worldview for our (western) understanding of the environment has also been one of anthropocentrism, whereby humans are the centre of moral concern. The anthropocentric view has in part been reinforced by Judaeo-Christian teachings that humans are made in the image of God and have dominion over nature, which has been the orthodox interpretation of the Biblical account of creation (Passmore 1980). The work of many philosophers both pre and post-renaissance support this, for example Descartes is identified (Dicker 2003) with providing the philosophical basis for setting humans apart from the natural world (Khisty 2006a, 2006b, Dicker 2003, Rockmore 2003). 'Dualism' is the term given to this worldview and it also supported anthropocentrism and provided a theological cornerstone for philosophical dualism (Dicker 2003). The environmental degradation that has resulted from the Cartesian view is well documented and requires no detailed investigation (Cooper 2003). However, the contemporary claim that human domination of nature has been destructive has been accompanied by new scientific and theological paradigms that rethink the validity of strong anthropocentrism (Cooper 2003).

Rachel Carson's Silent Spring (1962) is considered to be the beginning of the ecological revolution and a counter to strong anthropocentrism. Ecocentrism (Eckersley 2004, 1992) is a position that argues that the whole of nature should be given moral consideration. It has similarities with deep ecology (Naess 1989, 1986, Sessions 1995, Devall and Sessions 1985) where "biocentric egalitarianism" is forwarded as a counter to the idea that humans are at the top of the hierarchy of creation or evolution. The roots of the deep ecology movement can be found in the early writings of Thoreau Roszak and Mumford (Devall and Sessions 1985). Deep Ecology also has its origins and influences stemming in part from the writings of Spinoza and Zen Buddhism (Khisty 2006b, Devall and Sessions 1985). Khisty's insights into deep ecology are useful here because of the links to Buddhism in the form of Zen Buddhism. Among many other things, what has arisen from the debate between the advocates of anthropocentrism and ecocentrism is the contested notion of stewardship. Stewardship is the view that through divine intervention or evolution, humans are endowed with particular skills and talents that provide them with a level of consciousness and comprehension that allows them the responsibility to make moral decisions about the rest of creation/life, (Khisty 2006b, Passmore 1980). Where the anthropocentric movement put humans above nature, value was seen as residing in humans with nature only given instrumental value (Capra 1996). In contrast, deep ecology, which could be considered as a truly holistic environmental philosophy, considered human beings as an intrinsic part of nature, a unique strand in the fabric of life (Khisty 2006b, Capra 1996). Khisty (2006a, 2006b) sees deep ecology as an extension of spiritual systems, particularly that of Buddhism.

The discussions on spirituality and natural systems can be applied to the way in which we deal with environmental protection and our relationship with the environment to systems theory. This direction is supported by the notions of holistic thinking, that is the basis of systems theory, by looking at the idea that the natural-social-economic divide is actually one complete system of which each subsystem with very subtle relationships and links, communication loops, is related to the whole. The work of Du Plessis (2005, 2001, 2000, 1999) has focused on the application of systems theory to sustainable development for this reason, especially in the context of African cultures. Khisty's (2006a, 2006b) work, while providing strong links to Buddhist philosophy, has linked the environmental movement with systems theory through the tenets of deep ecology. The idea of systems in the context of the environment relates to a notion of natural systems that places humans within the emergent complexity along with all other aspects of the larger ecosystem. Once we understand the relationships between the various subsystems of which humans are only one of many, it is hoped that we can move towards a more environmentally sustainable future.

2.2 The concepts of Complex Systems and Resilience Theory

Earlier discussion has shown how, in general, systems are holistic, strongly connected, operate cyclically and to support the cyclical processes that rely on feedback loops (Macy 1991a, Laszlo 1972, Bertalanffy 1968). In studying the changes that occur in natural eco-systems research has led to the notion that these systems are invariably very complex (Walker and Salt 2006). The highest level of complexity is evident in social-ecological systems, that is the relationship between human systems and ecological systems (Walker and Salt 2006, Berkes, Colding and Folke 2003, Berkes and Folke 1998). Understanding the complexity of these co-evolving systems; their interrelationships, change dynamics and transformation has provided the rich foundation for looking at the 'resilience' of these systems (Walker and Salt 2006, Berkes, Colding and Folke 2003, Berkes and Folke 1998). At the heart of resilience thinking is the very simple notion of coherence despite change and the idea that to ignore change is to increase our vulnerability and forego emerging opportunities (Walker and Salt 2006, pp 9-10). In resilience thinking humans and nature are considered as elements of the one system, as they are interdependent. To think of one in isolation of the other is to come up with only a partial solution (Walker and Salt 2006). In essence, Resilience, defined by Walker and Salt (2006) is a systems capacity to absorb disturbances without a regime shift and they see it as the key to sustainability (Walker and Salt 2006, p38).

One link between resilience theory and this research is Redman's (2005) discussion of the notion of resilience thinking in archaeology. He postulates that "...resilience thinking looks at change transformation and adaptive cycles and archaeology provides the opportunity to study not only one completed cycle but multiple completed cycles " (Redman 2005, p70). Redman's contention is that the study of persistence and change in systems is at the heart of resilience thinking and can be verified by archaeology in the study of many systems historically over time. In so doing archaeology confirms the notions of adaptive cycles of change and transformation and the dynamic changes that occur over time in social-ecological systems (Redman 2005). Redman's study has implications for the current research in that, as with archaeology, the conservation of monuments and specifically non-secular monuments is about dealing with persistence despite change and transformation. This changes the temporal, utilisation and management contexts. The research argues that culture; heritage and built heritage can be considered as systems that are interconnected and interdependent. The application of resilience thinking to the conservation of built heritage provides the opportunity to understand and deal with the persistence and survival of heritage against the ongoing forces physical, social and natural change. That is, resilience thinking engages in a trans-disciplinary way the dynamic interconnections and interdependencies amongst the key systems.

Another link between resilience and the current research is the notion of interdependence mentioned earlier in the context of considering human and natural systems as one, the social-ecological system. Buddhism also has a holistic view of the human and natural systems in that they are seen as one system, yet interdependent and interconnected to one another (Khisty 2006b, Macy 1991a).

Resilience thinking provides the opportunity to extend the ideas presented in this paper to the next level of exploring the concept of resilience in the context of a broader range of heritage issues. Systems theory provides a foundation from where to establish parameters as no other research has attempted this alternative interpretation of non-secular built heritage.

3. Eveloping an Asian Approach To Conservation: Integrating Systems Theory And Buddhist Philosophy

The discussion to this point has attempted to coalesce the disparate links between the cultural and philosophical traditions of the region under study and develop a viable theory. With its links to Buddhism specifically, Hinduism and Asian culture more broadly, it is proposed that systems theory provides a foundation to develop a viable theoretical framework. The literature reveals the notion of two worldviews existing, that of the West and East and classified the differences in terms of mechanistic and systemic worldviews (du Plessis 2005, 2001, 2000, 1999). This mechanistic worldview is goal-orientated, the systems worldview is process orientated (Du Plessis 2000, 1999). As briefly discussed earlier in the introduction, the conservation theories, practices, guidelines and policies of the West arise from a mechanistic worldview drawing on the philosophical heritage of the West/Europe. Based on doctrines of rationalism and empiricism, the tools of conservation are observation, measurement and rational analysis lying within a linear causal framework. Determining the authenticity, significance and the values within the monument, it is argued here, are the "goals" of Euro-centric based conservation. To achieve one, a number, or all of the goals is the aim of conservation. It is the processes mentioned here that are used to protect heritage on the World Heritage list and other heritage outside the scope of the list, by default, as no other formal mechanism exists.

3.1 The development of a systemic conceptual framework

The essential principles of current global conservation practice are based on the test of authenticity, the significance of the monument, and the values that are contained within the monument. These principles have been formulated within the mechanistic worldview sustained by the rationalist and empiricist philosophical supported by a reductionist model. For example, the essence of these principles has sought to assess the monument by the "reduction" to a set of nine criteria3 (Jokilehto 2006). These criteria seek to analyse the monument in a rationalist framework, concerned with components seen in isolation rather than in a holistic sense. Concepts that define the monument or cultural built heritage (CBH) within very rationalist boundaries (Munjeri 2004) are in contradiction to Asian values and philosophies. Different values require very different conservation approaches. As the systemic approach has been linked to the cultural traditions and values of the east, any approach to conservation developed within this milieu would recognise the uniqueness of South and Southeast Asia. In this context the protection and conservation of the cultural built heritage would be seen as a system within the larger complex system of the cultural and philosophical systems of South and Southeast Asia. In this way it is necessary to view the whole larger system in which the CBH is a subsystem, and not reduce the system to its smaller components such as authenticity, significance or its various values and look at these in isolation. The subsystems encompass questions of spirituality, naturalistic sensibilities (Seung-Jin 2005, 1998) the cultural landscapes (Taylor and Altenburg 2006, Taylor 2004) along with values, norms and societies (Munjeri 2004) that may form part of the larger system. These proposed subsystems are those that demonstrate the differences between Asian and Euro-centric conservations approaches.

This paper has briefly discussed the philosophical and cultural traditions in an attempt to synthesise the foundation for an Asian approach to the conservation and protection to the cultural built heritage in Asia. It has been argued that systems theory has strong associations with Asian cultural and philosophical thought, particularly Buddhism, and could be appropriate as the foundation from which to build a framework for the conservation of monuments in Asia.

3.2 The components of a framework based on systems theory

There are a number of key principles of Buddhism; including impermanence, karma, dukkha, the eightfold path and the four noble truths (Macy 1991a, 1991b, 1976, Kalupahana 1976). As argued above, three principles of Buddhism that provide strong links with systems theory are universal interconnectedness, radical interdependence and mutual conditioning (Khisty 2006a, 2006b, Macy 1991a, 1991b, 1976). It has been argued that these principles provide the methodology for describing intra- and inter-systems relationships that would be the basis for determining what is important about the heritage, how is it important, and how it could be conserved. These are then three key relational qualities of heritage, chosen because they explain the complex multiple reciprocal relationships (Munjeri 2004) between heritage, communities, societies, tangible and intangible values that provide a basis for developing a theoretical framework for conservation in South and Southeast Asia. Table 1 provides the description of the elements of the framework while Figure 3 summarises the process of the framework.

Table 1: The three key relational qualities of heritage systems within South and Southeast Asia (Source: The Author).

Key Relational Quality	**Description**
Interconnectedness	The quality where interconnections exist between one system and another.
Interdependence	The quality where one system is dependent upon another.
Mutual conditioning	The quality where one system conditions another, one system must have existed for the other to come to exist.

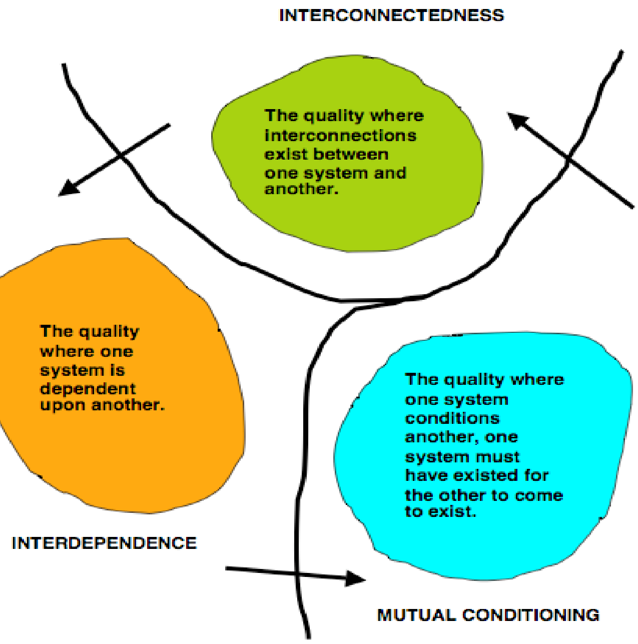

Figure 3: This figure summarises the process of the framework and how this would be operationalised (Source: The Author).

The concept of universal interconnectedness relates to fact that everything is a part of everything else, not only spatially but also temporally. Society is situated in an intricate order, and thus everything is interconnected with other aspects of a larger society or culture (Khisty 2006a, 2006b). Society along with all other things, is embedded in a context, within the universal system (Khisty 2006b). For non-secular heritage the implications are that since its creation there has been a continuum that ties the non-secular heritage to each period in time as much as the previous and the future, implying that there is a relevance to all people at various points in time. This suggests that heritage is interconnected to each period and relevant to each period in equal proportions. At another level it implies that there is interconnectedness between the heritage and those that initially created the heritage. However, there is also interconnectedness with those who consume the heritage through time. Within the heritage object there is interconnectedness between the various elements that in sum are the total of the heritage. This encompasses material elements, spiritual, values, norms, and other intangible values that can be identified. In Sri Lanka, for example, Ruwanweliseya Stupa encompasses these elements because of its place in peoples spiritual. The interconnectedness described demonstrates that heritage is dynamic with relevance continuing through time. In relation to the systems that have been developed in this research, interconnectedness can be traced between the various systems, from the primary system of culture to the subsystems of heritage and non-secular heritage. Within subsystems there is interconnectedness as according to Buddhist philosophy everything is connected to everything else. This relationship of systems is significant in describing the reciprocal relationships that exist between the heritage and other systems that tie these to tangible and intangible values, and the culture at the higher level.

In Buddhism the notion that everything is dependent and reliant on mutual assistance, support, cooperation, or interaction between everything is termed radical interdependence, for the purpose of the framework it is sufficient to simply refer to interdependence. Buddhist cosmology considers the entire cosmos as a cooperative, where everything lives together as a cooperative (Harvey 2003, Macy 1991a, Kalupahana 1976). A noble environment can only be built, or protected, when we realise that the world is a mutual, interdependent, cooperative enterprise. Thus we have the belief that everything in life is interdependent, there are interconnections, and there is interdependence. These qualities explore how one system or subsystem may be dependent on another. For example the Buddhist stupa or pagoda is dependent upon people worshipping around it for its very being for all time, it is this action that provides the meaning. If people did not worship around it or had not developed a belief in its sanctity then what would it represent or would it ever have existed. Clearly one is dependent upon the other for its significance or meaning. As discussed earlier, it is the next level of the relationship, the interdependence, of one system with another that a specific heritage system develops significance.

The mutual conditioning principle means that all conditioned things and events in the universe come into being only as a result of the interaction of various causes and conditions. This is significant because it precludes two possibilities; first that things can arise from nowhere, with no cause and conditions, and second, that things can arise on account of a transcendent designer or creator (Dalai Lama 2002 cited in Khisty 2006b). The all-encompassing range of mutual conditioning is best caught in the short, though deceptively simple formulation: "When this is, that is; this arising, that arises. When this is not, that is not; this ceasing, that ceases." (Smith and Novak 2003 cited in Khisty 2006b p 301). Initially, what was the context for the creation of the heritage? For some, cultural built heritage in the Asian region the circumstances that lay behind the origination underpin the character and qualities of the particular heritage. In Cambodia, Angkor Thom was erected as the heavenly palace of the ruler Jajavarman VII. This original conditioning led to the condition of the environmental system that led to the conditioning of the landscape system and the relationship between this and the building. In Agra, India, The Taj Mahal, the white marble monument created as an act to bury a much-loved Queen and then the Emperor who worshipped her, conditioned the monument as a mausoleum. The construction of this monument and its formal gardens conditioned the landscape on the banks of the Yammanu River, thus conditioning the greater environment with its form and silhouette against the horizon The conditioning analysis can be extended further and further. The conditioning dealing with the origination impacts with the other systems in which the heritage has relationships. While defining mutual conditioning, this discussion highlights the notions of holism and cyclical relationships implicit in systems theory.

Table 2: A framework for heritage conservation in south and Southeast Asia (Source: The Author).

Key relational qualities of heritage.	**Clarifying questions.**
Interconnectedness	• What are the interconnections with the cultural system? • What are the interconnections with the communal subsystem? • What are the interconnections with the tangible values subsystem? • What are the interconnections with the intangible values subsystem?
Interdependence	• Is the subsystem dependent upon other heritage subsystems? • Is the subsystem dependent upon tangible value subsystems? • Is the subsystem dependent upon intangible value subsystems? • Is the subsystem dependent on other cultural systems?
Mutual conditioning	• In what context was the heritage created? • In what context has the heritage existed? • In what context is the heritage perceived? • In what context is the heritage to be conserved/restored/rebuilt?

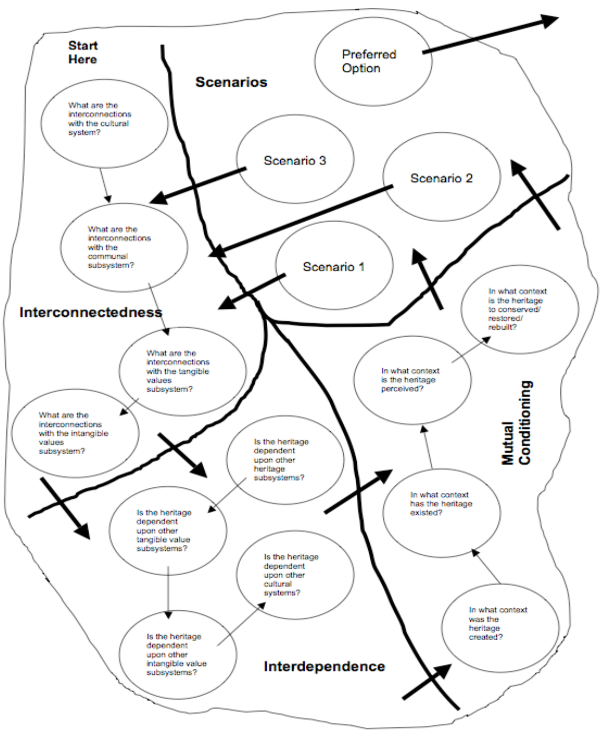

Figure 4: This diagram shows all the cycles in the complete process of applying the framework to the conservation of non-secular heritage in South and Southeast Asia (Source: The Author).

3.3 Discussion of the framework

The conceptual framework and supporting ideas presented here provide an alternative to the Western/Euro-centric approach for conservation strategies for the cultural built heritage in South and Southeast Asia. It is argued that systems theory provides a means of operationalising the alternative paradigm that, while based on describing the heritage and the culture with in which it exists as a series of systems and subsystems, has its theoretical argument very much founded within the philosophical and cultural experiences of the region. It is proposed that the systems theory framework is a means of exploring a heritage system whether it is tangible or intangible and determining how the heritage system exists within the larger cultural system in the context of developing a strategy for protection. The adoption of systems theory moves beyond the existing system of looking at the heritage in the terms of conditions of authenticity that are essentially a series of material terms with token gestures to traditions, feelings and spirit (Jokilehto 2006). The acceptance of the notions of intangible or immaterial values as described in the Nara Document on Authenticity (Larsen and Marstein 1995, ICOMOS 1994) or the Hoi An Protocols (UNESCO 2005) are the only presentations of possible exceptions to the accepted procedures and interpretations that are given in international charters and guidelines. They do not offer a viable alternative method for conserving heritage in South and Southeast Asia. In the same way as the current systems; they are only a product of the cultural and philosophical traditions of the west. It is argued that the framework presented here has substantially strengthened the premises of those documents by employing the essence of the cultural and philosophical experiences of the region.

In the tradition of systems theory the proposed conceptual framework would be made operational by the use of empirical research and data (Checkland 1999, 1994). The answers for the clarifying questions (refer Table 2 and Figure 4) would be provided by careful research into the heritage and its history, the values that underpin its existence, and all other data that provides a complete story about the heritage. This information would come from oral traditions and more tangible sources. The crucial issue is to understand the heritage subsystems and all its interconnections and relationships with the larger systems and other subsystems. This process is in marked contrast with Western heritage that is assessed to have authenticity resulting only from a number of supposedly universal material values (Taylor and Altenburg 2006, Seung-Jin 2005, 1998, Taylor 2004, Menon, 2003). The purpose of these clarifying questions, while exploring material values, is to underpin authenticity in the Asian context with those values that are significant to the heritage based on relational qualities of subsystems and systems.

As discussed above the proposed conceptual framework is supported by the process of generating scenarios that are then examined against the outcomes of providing answers to the clarifying questions. While scenarios have not been commonly used in the conservation decision-making process, these are common in planning decision-making (Lombardi & Brandon 2003, Lombardi 1999, Lichfield 1998, 1988, 1976). Scenarios are seen as simulating real world situations that can be tested under "laboratory" conditions to explore possible outcomes and use the result to make choices for courses or action. In this sense, the scenarios generated for the framework would be based on real-life solutions creating probable courses of action.

The reiterative process of testing these scenarios would then result in an appropriate course of action that accounts for the intangible values and sense of place that are critical to understanding the significance of Asian heritage. The scenarios can all be tested for their resilience in the face of known destructive forces, technological change, development pressures, and tourism.

4. Summary and Conclusions

This paper has presented an alternative paradigm and a structured framework for interpreting the cultural heritage of South and Southeast Asia for the purposes of developing conservation approaches. Based on established synergies between systems theory and Buddhism specifically (Chao and Midgley 2007a, 2007b, Midgley and Chao 2007, Khisty 2006a, 2006b, Macy 1991a, 1991b, 1976, Ellis and Ludwig 1962) and Asian cultures more broadly (du Plessis 2005, 2001, 2000, 1999, Churchman 1968), the framework has been constructed that takes into account, for example, the intangible values, sense of place, cultural traditions and philosophies that are elements of the specific cultural heritage of the region under study.

The philosophy of Buddhism is founded on three principles; interconnectedness, mutual conditioning and radical interdependence (Khisty 2006b, Macy 1991a, Kalupahana 1976). The notion that everything is related or connected to everything else, that an action cannot occur without a previous action is the key to these three principles. For these reasons Buddhism is seen as a holistic approach to the questions of life and matter. Providing the basis of a Buddhist hermeneutic and is seen to explain most of what occurs in Buddhism. As discussed in this paper, Buddhist ideologies and principles have been adopted as the key relational qualities of the framework that has been developed to provide an alternative approach to conserving cultural built heritage in South and Southeast Asia. Traditionally, problem solving in the scientific context has been reductionist in nature, breaking down the larger problem into smaller components. Conversely, systems theory focuses on looking at the problem and its context in terms of systems and looking at relationships between these systems. The other aspect of systems theory deals with the communication between systems and the feedback loops that exist that make the process cyclical and informative. The synergies that have been identified between Buddhism and systems theory are based on the nature of holism and the cyclical nature of communication and feedback loops. The cyclical qualities of the communication channels between systems allows for reiterative evaluation of the relationships while assessing the basis for protecting the cultural heritage.

Finally, from this discussion a conceptual framework was formulated that incorporated the philosophy of systems theory and principles of Buddhism. The framework has the key relational qualities, interconnectedness, interdependence and mutual conditioning that form the basis of the relationship between the heritage and the people who consume it. The interpretation of these key relational qualities is done with clarifying questions, which provide the opportunity to describe the key relationships that give the heritage its values and meanings, significant qualities in the context of how people view the heritage.

(email: malik@civil.mrt.ac.lk)

Abstract

The paper describes an on-going case study at Ma Oya river basin in Sri Lanka where the conflicting uses/issues of the natural resources in the river and its valley are identified through the consultation of key stakeholders. The study conducted in the entire down stream and immediate upstream of a proposed multi-purpose balancing reservoir at Yatimahana, included 145 Grama Niladhari divisions in 16 Divisional secretariats along both banks of the river. It assesses the natural resource uses; the present issues and future probable issues with regard to resource uses, stakeholder views and then discusses the probable social and environmental impacts of the proposed reservoir. The results obtained in the study are direct inputs for a five-step framework developed for educated trade-offs. The term 'educated trade-off' means that stakeholders are able to engage in technically, economically and environmentally (including socially) informed (educated) decision-making between the critical resource uses (trade-offs) in a river valley.

Keywords: educated trade-offs, stakeholder consultation, river basin development, natural resources

1. Introduction

Development activities in river valleys are usually planned and implemented independently by different user sectors. In most instances these decisions are based on purely sectoral interests (e.g. water for irrigation, mining of clay on riverbanks) and are planned primarily for economic or political benefits. The environmental and social impacts of such activities are generally not known and are often neglected at the design and planning stages [1]. Most of the negative long-term impacts of such activities/projects are realized only long after the projects have been implemented.

It is imperative to study the physical, biological, economical, socio-political and administrative impacts of a project, in order to find a viable solution for sustainable development of natural resources within a river basin, which are intricately woven with each other [2]. In addition, past research demonstrates that such resources planning without consultation of all the stakeholders in decision-making is highly ineffective [3]. In the recent times there is widespread recognition of the need for greater stakeholder consultation in water and other natural resources development projects. It is the premise of this study that in such involvements stakeholders should be able to engage in educated trade-offs between the values of the different resource uses/issues in a river valley or otherwise the consultations will be emotional. However, the main hindrance for educated decision-making by the stakeholders is lack of methods of educating the stakeholders on the technical, economical and environmental (including social) impacts of the decisions taken by one group of stakeholders on the choices of another group.

Thoradeniya and Ranasighe [4] proposed a framework on 'Educated Trade-offs' as a tool, which facilitates trade-offs between different resource uses by educating the stakeholders on the combined (economic and environmental) economic value of each resource use. The framework consists of five steps. The first step identifies the stakeholders and the conflicting uses/issues of the natural resources in the river and its valley, through the consultation of key stakeholders. The critical bounds of the technical requirements of the conflicting resource uses and issues identified (minimum required volume when the use is by extraction of water and maximum volume not to exceed the assimilative capacity of the river or river valley for other issues) are then estimated in step two. The economic value and the environmental value of the respective critical bound of the technical requirements are estimated in the third and the fourth steps. Combining the economic and the environmental value of critical bounds, 'educated tradeoffs' for stakeholder consultations are finally estimated [5]. The results of the analysis will be useful information for stakeholders to make rational decisions between different resource uses/issues in a river valley.

With regard to the resources uses of a river and its valley, the issues and stakeholders show a significant variation spatially and temporally. Therefore, it is expected that a more accurate scenario of the situation is possible through the bottom level (grass-root) stakeholder consultations. Further the literature survey did not reveal studies focused on basin wide grass-root stakeholder identification in planning and implementing development projects, which could have its impacts on a larger area beyond the project area itself.

The objective of this paper is to present as a case the results from an on-going study at Ma Oya river basin of Sri Lanka, where the proposed framework is being applied. A key stakeholder of the river basin, the National Water Supply and Drainage Board (NWSDB) has proposed a multi-purpose, balancing reservoir as a solution for the temporal water scarcities experienced at present. The economic justification of the project is through hydropower generation. However, the negative social and environmental impacts that could occur basin wide have not been adequately considered in the feasibility report. Therefore, the present study identifies the resource uses and stakeholders, assesses the stakeholder views, and then discusses the probable social and environmental impacts of the proposed reservoir and valuing such impacts. Thereby facilitating the stakeholders of Ma Oya river to engage in rational discussions leading to less-emotional decision-making between the different resource uses at times of resource scarcity.

The approach used in the study for consulting stakeholders, for identifying the resource use sectors and pertaining critical issues, proved to be efficient for a rapid assessment of spatial variation of a river basin situation. Estimates for prioritising the use sectors were possible with the data collected at the survey. Drinking water (dug wells), washing and bathing, and environment were the user sectors estimated as top priority in most of the locations.

2. Ma Oya river basin: uses and issues

2.1 Resource uses

Ma Oya river commences in the central hilly regions and flows to the Indian Ocean through north western Sri Lanka. The river drains a catchment area of 1528 km^2 along its total length of 130 km [6]. It flows through Kegalle district at upper reaches and acts as the boundary between Kurunegala and Kegalle Districts in its mid reach, thereafter as the boundary between Kurunegala and Gampaha Districts. The right bank of the final reach of the river forms the Southern Boundary of the Puttalam District and flows into sea at Kochchikade. (See Figure 1).

Annual average rainfall of the Ma Oya basin is 2219 mm [6]. The low rainfall values occur in the months of January, February, June, July and August. The basin covers five agro-ecological regions and the land use of the river basin is mainly characterized with paddy, rubber and coconut cultivations.

Figure 1: Ma Oya river basin and river network

The river flows are mainly used for supplying drinking water to 17 major population centers, two major industrial zones and also some private water supply schemes. The next major use of the river flow is as a pollutant carrier (absorber) from a number of cities as well as private poor dwellings located on the riverbanks and from a number of industries located in the river valley.

2.2 Issues of resource uses

Ma Oya river basin has been identified for its critical resource use issues. Highly stressed surface water resource situations are experienced during the 6-8 weeks of the dry season in spite of the fact that it is located within the wet zone of the country [6]. Thus during the low flow periods the two major uses (water supply and pollutant carrier) are conflicting with each other and results in critical water stressed situation both due to inadequate quantity and poor quality [7].

The other use sectors such as hydropower, tourism, sand and clay mining have also created localised adverse impacts to the environment and the local populations. The already documented environmental and social impacts due to the different use sectors, range from drying up of springs used for drinking and household needs of the villagers at upstream locations to dried up wells, abandoned paddy lands, pools of stagnant water creating breeding grounds for malaria and other types of mosquitoes in down stream locations [8]. The different use sectors are uncoordinated and the uses are uncontrolled.

The NWSDB, a key stakeholder of the river basin has proposed a multi-purpose balancing reservoir in the upper catchment at Yatimahana as the best option in an attempt to mitigate the expected severe water shortages in the near future due to the increasing demands, [9].

The objective of this reservoir project is to store the excess flows of the river during rainy seasons and then to release the required flows, under control, during the dry weather periods. The proposal acknowledges the importance of Integrated Water Resources Management (IWRM) and has considered irrigation, industry and hydropower sectors in addition to the water supply and sanitation sector. The irrigation sector water demand has been taken at present level with zero future growth while the demand by the industry sector is allowed a future growth. Hydropower is proposed mainly as a strategy for achieving the economic viability of the reservoir project [9].

3. Application of Educated trade-off framework

It is speculated that the implementation of the balancing reservoir may have adverse impacts on the other water use sectors. For example, the ground water table of the river valley could remain low for a longer period due to regulation of flow, leading to production losses in the agriculture sector. Also water quality could deteriorate with increased pollutant concentrations in the river again due to regulated low flows for longer periods. This situation could lead to limiting the growth of industries (requiring water as a raw material for production or seeking river as a pollutant dispenser) in the Ma Oya river valley.

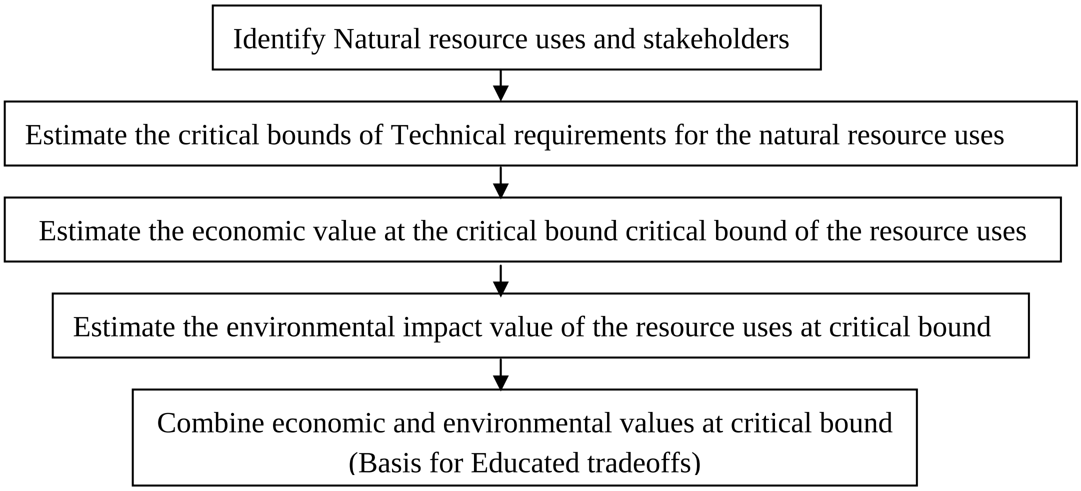

Figure 2: Five-step framework for Educated Trade-offs

Therefore, in resource scares situations the stakeholders require to make decisions on prioritizing the resource use sectors. The ‘Educated Trade-off Framework’ (See Figure 2) suggested in Ranasinghe [5] is applied for the proposed development work in the Ma Oya river basin.

4. Identification of the multiple stakeholders and the Natural Resource Uses/ Issues

4.1 Stakeholder involvement level and techniques

Identifying stakeholders and uses/issues (a situation analysis) is the first step of the ‘educated trade-off’ framework. The methodology used for this identification is to conduct sample surveys in the areas considered. Samples represented all sectors having a stake in the river including public administration, public and private institutions in the river resource use sectors, and representatives of social, political, religious, and ethnic groups of public at grass-root level.

Since the objective is to collect data for a situation analysis the stakeholder involvement level is low; ‘consultation’ as opposed to ‘participation’ [10]. The techniques used are a questionnaire survey and a structured interview. The feed back of the survey facilitates identification of the resource use patterns, critical issues, the environmental impacts already experienced and further possible social and environmental impacts in future.

4.2 Approach for grass-root stakeholder consultations

A six-step approach was designed to obtain necessary data from the grass-root stakeholders [11]. The first step is a desktop study where the Divisional Secretariat Division (DSD) was identified as the administrative unit to conduct the field studies, as the number of DSDs was small enough to handle within the scope of the study; rapid assessment of resource uses.

The second step is a combination of a reconnaissance survey and a visit to the selected administration units (DS office). The objectives of the reconnaissance survey are three-fold; to obtain the data required for planning the stakeholder meetings, such as maps showing Grama Niladhari Divisions (GND), stream network etc.; to create an awareness about the research at the DS level and to create an initial awareness among the concerned Grama Niladhari (GN); to obtain the necessary support of the government administration units for the study.

The data collected (DSD maps etc.) at the reconnaissance field visit are the base for the desktop study II at the third step. This step identifies the GNDs along both banks of the river. At the fourth step the GN's of the selected divisions are educated on the background, objective and the expected results of the research. This is achieved through written communication followed by telephone conversations where possible.

With the above insight, at step 5, the GN's are entrusted to select the appropriate sample representing the different resource use sectors. The final step involves a visit to each GND to administer the questionnaire survey and to interview each respondent.

4.3 Resource uses and Stakeholders

The representative sample constituted of 427 stakeholders from river estuary to Aranayake (a location upstream of the proposed reservoir). Table 1 gives the sample distribution according to the riverbank location and DSD. The number of GNDs in each DSD is also indicated.

The resource use sectors at each GN division could be identified through the stakeholder survey. The user sectors, which are critical at present, as well as sectors, which are expected to become critical in the future, were also identified. Table 2 gives the resource use sectors for six sample GNDs (1L – Kammalthara, 12 R –Thambakanda, 26 L – Nalla, 38 R – Koholana 51 L – Diyagama 75 R- Arama) selected at random. The use sectors, which are critical at present are marked '⊗' while those which are expected to become critical in future are marked '+'. The non-critical use sectors are marked 'X'.

The major use sectors of the natural resources of the river and its valley according to the number of GND are bathing/washing, sand mining, drinking water through dug-wells, agriculture through ground water, rearing animals and waste disposal sectors. The other use sectors, which are more localised in nature, are the water supply schemes, industries, clay mining, dinking water (direct), inland fishing and tourism.

Table 1: Stakeholder sample distribution

Left Bank			**Right Bank**		
DSD	**No. of GND**	**Sample size**	**DSD**	**No.of GND**	**Sample size**

	Dug - Wells		⊗ +	⊗ +	⊗ +	⊗ +	X
	Environment	⊗	⊗ +	⊗ +	X		⊗ +

⊗ - uses critical at present + - uses critical in future X - uses not critical at present /future

5. Technical requirements and economic value of project

Estimating the critical bounds of technical requirements of natural resource uses/issues is the second step of the framework. The engineering knowledge is utilized to develop the methodologies to estimate upper/lower bounds of the technical requirements for utilization of the different resource uses. Usually, when a project is proposed these bounds are already estimated. The estimates for lower bounds of the technical requirement of the river flow for four use sectors thus identified by the project report [9] on the proposed balancing reservoir are;

a) Water Supply and Sanitation Sector - Flow requirement at eight present extraction points down stream of the proposed reservoir is estimated as 170,000 m^3/day in 2015 and 237,500 m^3/day in 2025.

b) Industry sector - Flow requirement at the three present extraction points down stream of the proposed reservoir is estimated as 18,000 m^3/day in 2015 and 37,000 m^3/day in 2025.

c) Irrigation Sector - Flow requirement at the three existing schemes, which are non-functional at present, is 36 million m^3 per annum. This is considered a fixed value.

d) Environment Sector - The proposal has considered different flows varying from 3 m^3/s to zero for this sector.

Estimating the economic value of the technical requirements of the natural resource uses/issues at above stated critical bound is the third step of the 'educated trade-off' framework. This is again estimated in the feasibility report for the proposed balancing reservoir [9]. The report clearly indicates aspects considered for the calculation of economic parameters of the project.

The economic benefits of the project are due to power generation, water sales, crop production, land value increases, generations of new business activities. The economic costs of the project are due to capital costs, which includes construction costs of the dam and the powerhouse, refurbishment cost of electrical and mechanical components which has a life time less than the project life time and land acquisition costs (inclusive of resettlement, compensation costs) and recurrent costs, which include operation and maintenance costs, personnel and material costs.

The estimated economic internal rate of return (EIRR) for the base case is 15.2%. A sensitivity analysis has been carried out for five scenarios. 1) capital cost 10% higher 2) benefits 10% lower 3) benefits delayed by one year 4) combination of scenario one and two 5) combination of scenario one, two and three. The report [9] recommends the project as the EIRR stands over and above the cost of capital even under the worst economic scenario.

6. Environmental value at the critical bound of the technical requirements of natural resource uses

6.1 Estimates of social and environmental impacts

Estimating the environmental value of the critical bound of the technical requirements of natural resource uses is the fourth step of the framework. The net environmental value of the reservoir project will be the difference between the environmental (including social) benefits due to the reservoir and the social and environmental costs of the other uses due to the reservoir project. It must be noted that net social and environmental costs referred to here are those, which are either not quantified or underestimated, in the economic analysis. Then all of the environmental benefits and costs of impacts valued in constant value terms become line items in the economic analysis.

‘With project’ and ‘Without project’ scenarios are considered. ‘With project’ scenario prioritize reservoir releases to meet the minimum demand by the water supply and sanitation sector by acting as a regulating reservoir for water supply schemes of the NWSDB. In addition, depending on the flow availability, the reservoir will release a flow of 4 m^3/sec for hydropower generation. It is also proposed to release a flow of 1 - 3 m^3/sec as minimum environment flow requirement in the event that there is insufficient flow to meet the hydropower generation requirement [9].

The major factor that has been overlooked in this proposal is the livelihood and the resource use patterns of the grass-root stakeholders. As the present study shows 121(83%) of the GN divisions reported sand mining as a means of livelihood. The prevailing political system and the corruption of the regulatory and law enforcing officials encourage large scale sand mining resulting in a deeper riverbed. The regulated reservoir releases coupled with the lowered riverbed will result in longer periods of low water levels and could lead to a number of negative impacts as described by the stakeholder responses in the next section. A major positive impact that has been overlooked is the further reduction of flood damages, which has already diminished to a considerable extent with the widening, and deepening of the riverbed due to sand and clay mining.

6.2 Stakeholder Views

Views were elicited on conflict situations the stakeholders have faced with regard to present resource uses and also on such situations, which could arise in the future. 372 (87%) respondents agreed that their resource uses have faced conflict situation at present and 378 (88%) agreed that there could be such a situation in the future. 371 (87%) respondents believed that they know the reasons for such threats and conflict situation and 346 (81%) respondents of the total sample attributed the cause as the resource exploitation by other sectors.

Drinking water obtained through dug wells by the people living on the riverbanks is identified as the one of the two major user sectors at 129 (89%) GNDs, which is at a very critical situation at present at 114 (79%) GNDs. This is also the user sector expected to be in the most critical situation in future 116 (80%) as it is a basic requirement of human, which cannot be denied. Stakeholders responding to the survey claimed that the dry weather water level of the river has dropped up to 12 meters due to indiscriminate sand mining activities carried on the riverbed. As a result the water table in the vicinity of the river has also dropped resulting in deeper water levels in the dug wells. In most villages along the river the dug wells run dry within a short time after the rain has ceased.

Similarly bathing and washing is found to be the other major use sector, which is in a critical situation at present at 89 (61%) GND. Large numbers of people not only along the river but also from nearby GNDs depend on the river waters during dry spells, as this is their only source for bathing and washing. This sector is identified as threatened or critical due to a number of reasons; sudden deep pits created under water (*Wakkalam*) due to severe sand mining, at most of the earlier bathing spots (*Mankada*), which are very risky as the slightest error in a step could lead even to drowning. A number of deaths have been reported of whom most were outsiders coming for recreation. Deep sand mining has also resulted in surfacing the bedrock. Once the rock is surfaced it becomes slippery and could lead to accidents. Also, discharge of waste by different sectors such as factories, hotels, slaughterhouses etc. into the river specially during the dry spells has resulted in poor quality water unsuitable for bathing.

Another sector that is impacted presently, at 102 (70%) GN divisions out of the reported use at 125 (86%) GNDs, is agricultural lands on the riverbanks. On one hand, excessive land erosion is reported specially during floods incurring severe damages to the property. On the other hand during the dry spells these lands become very dry due to lowered ground water table resulting in reduced or no harvest.

Environment though is an indirect resource use sector, also receives priority attention due to the large number of people living in the riverbank areas, vegetation and the eco systems. The situation analysis also showed that out of 64 GN divisions who showed an interest on the environment, 49 (76%) declared that the sector is already threatened.

6.3 Gaps identified and next steps

The grass-root stakeholder consultations revealed that in most locations sand mining is continued at least as an illegal activity resulting in increasing depths of riverbed. Thus the three indirect water user sectors (dug-wells, non-irrigated agriculture and environment), which depend on ground water, are severely impacted. These impacts are directly related to the river water level but not to the flow. Therefore a gap is identified in the feasibility report as it focuses only on the river flow. The feasibility report had attempted to analyse all the water requirements by different user sectors either as a volume or as discharge.

Therefore, the next step would estimate the river water levels according to the proposed reservoir operations and to quantify the social and environmental impacts in space and time. Then the primary and secondary environmental valuation methods [12] will be utilized to estimate the economic values of the above environmental impacts, at the critical bound of the resource uses (reservoir operation) at resource scares situation.

Once the identified social and environmental impacts due to project is estimated, the final step of the framework ‘the net value of the critical bound of the technical requirements of natural resource uses/issues’ can be estimated by combining the economic and environmental values. The combined value of the critical bound of a technical use/issue would be in economic terms. The stakeholders of the river valley need to be educated with this newfound knowledge in order for them to be able to engage effectively in decision-making process. Knowing the technical requirements and the combined value of the critical bound of the technical requirement would help stakeholders to be educated with which uses need to be prioritized in a year that has less water.

7. Conclusions

This case study focused on identifying the different natural resource user sectors and the stakeholders, which varies spatially. The six-step approach adopted for this purpose proved to be efficient in achieving the set objectives. Particularly the approach to elicit views and information on the resource uses of the stakeholders through the respective GN's, was successful mainly due to two reasons. Firstly, the involvement of GNs as stakeholders were easy due to their educational level and secondly, in most of the occasions the participants chosen by the GNs proved to be from different user sectors with divergent views.

The research results clearly indicated the spatial variation of resource user sectors and the pertaining issues. Five resource use sectors, which were identified as threatened or as facing conflict situation at most number of GND locations are a) drinking water due to the drying up of dug wells, b) lands on the river banks due to severe erosion c) sand mining due to inefficient regulatory framework d) bathing and washing sector due to the high risk posed by deep pits beneath water level and pollution and e) environment.

The proposed 'educated trade-off framework' would be very useful in identifying the spatially varied stakeholders and the resource uses, the probable social and economic impacts and values of them and finally to obtain the combined value of the proposed reservoir development project.

FACILITIES MANAGEMENT

Briefing as a process of cultural knowledge exchange in a hospital partnering project from a Facilities Management perspective

Venny Chandra,
Faculty of the Built Environment, University of New South Wales
(email: venny.chandra@unsw.edu.au)

Abstract

Outsourced Facilities Management (FM) has been noted to be problematic in terms of understanding clients' needs, especially in the hospital sector. This paper argues that an understanding of hospital's needs inevitably requires an understanding of the hospital's organisational culture, where the 'value' for FM rests. Using a hospital partnering project as a case study, it investigates the *process* of learning about culture, an approach which has traditionally been treated as a black box. Nonaka's [1] theory on knowledge creation provides a framework for the study, with an emphasis on the socialisation process whereby individuals exchange their cultural knowledge through face-to-face experiences during briefing. Sackmann's [2] categorisation of knowledge proves useful in detecting such exchange. It was found that a lengthy, deep, and thorough discussion on specific topics triggered the sharing of cultural knowledge. "Creative chaos" in the form of problems, disagreements, and conflicts should be encouraged and managed as it facilitates the sharing of cultural knowledge. Finally, cultural knowledge exchange was found to be an extremely subjective process, whereby the briefing participants competed against one another to impose their version of knowledge.

Keywords: Cultural learning, Facilities Management, hospitals briefing, partnering, knowledge exchange.

1. Background: the need for cultural learning

Outsourced Facilities Management has been noted to be problematic in terms of understanding clients' needs [3, 4]. Cultural, systems, and operational differences between Facilities Management and hospital teams can mean that clients' needs are not effectively and accurately captured, causing a mismatch between the design and the intended use of the building [5]. In hospitals, the impacts of such mismatches can be enormous, including higher maintenance and operational costs, poor value for money, and even higher death rates [6, 7]. The challenge involved in understanding the hospital's needs and in designing appropriate facility strategies ultimately points to the importance of understanding the hospital's organisational culture. Organisational culture is often referred to as a social construct which is shared among members and represents the collection of agreed values, norms, beliefs, feelings and ideologies that makes up an organisation [2, 8]. Although organisational culture researchers have varied in their focus on either perspective, it is generally accepted that, in essence, organisational culture is represented by its members' mindsets, basic assumptions, or beliefs [8, 9]. Although culture is also recognised as being tacit, highly personal, hard to define, formalise and not easily observable but it is *learned* rather than derived from one's social environment rather than one's genes [10, 11]. It is a form of *learned knowledge* which is sustained by social processes and which defines the different kind of behaviours that are considered appropriate and acceptable. At a project level, the importance of understanding a client's organisational culture during the briefing process has been noted by various authors [12, 13].

However, previous research into the briefing process has almost exclusively ignored the need to *learn* the culture. Indeed, many still see the process of *cultural learning* as a separate variable rather than as necessarily embedded in the efforts to understand client's needs. This has meant that the processes needed to effectively capture cultural knowledge have remained undeveloped, as have the conceptual theoretical frameworks to understand it. This new perspective demands that the process of briefing is treated as an organic and cyclical process of *cultural learning*, where Facilities Managers and client representatives gradually converge upon a shared meaning of each other's cultures over time. It is one which is supportive of the strategic development in Facilities Management, but it is also one which challenges recent arguments on developing "value" for the profession [3]. The cultural learning perspective argues that 'value' for Facilities Management rests on developing capabilities to capture cultural knowledge through better cultural learning practices. It also advocates a higher level of awareness, receptivity and sensitivity towards cultural issues as a measure for higher competitive advantage.

This study also points to briefing as a context in which cultural learning can take place. As briefing process often occurs early in the building procurement process and is where clients' needs are captured, refined and balanced and then translated into a design brief [14], it can consequently be argued that the briefing process is a suitable context for cultural learning where learning about clients' requirements is most influential to the project outcomes. Green [15], and Barrett and Stanley [14] argue that 'briefing must be seen as a process not an event', where clients' requirements are progressively captured and translated into effect throughout the construction project in a process of social construction of the meaning of client requirements, rather than a one-way flow of information. In the hospital context, the New South Wales (NSW) Process of Facility Planning Guidelines refers to such a process as being part of the Project Implementation (PI) stage, which is when the outsourcing of Facilities Management occurs, and as such defines the briefing process for this study.

2. Framework: knowledge exchange through socialisation

The *process* of learning has largely been explored from a social constructivist perspective, which suggests that organisations continually strive to make sense of the world through conversations and the interactions between people as they negotiate meanings within their community [16]. It represents an important point of departure from the traditional view of learning as occurring only in individuals' heads, by shifting the focus of learning to the *social* arena in which it takes place. The rationale of adopting this perspective is that organisations now have the opportunity to purposefully manage their sociological environments in order to deliberately enable and support the learning processes. Such establishment of learning theories has also enabled the scrutiny of the *process* of learning to take place, rather than treating it as a black box, as has traditionally been the case [17], active and dynamic rather than passive and static. This view is valuable for understanding cultural learning in the hospital briefing context because it recognises the high level of complexity of hospital organisations and it also emphasises the importance for the Facilities Management team of managing the social environment during the briefing process. This is achieved by recognising that the interactions during the process can themselves be seen as contexts which present opportunities for both groups to learn about each other.

The knowledge creation theory developed by Nonaka [1] is best suited for conceptualising cultural learning because it is the *only* theory that acknowledges and emphasises the learning of tacit knowledge, which is particularly relevant to learning about culture as proposed in this study. A thorough review of this theory was presented in Chandra [18]. This knowledge creation process involves four stages of knowledge conversion, namely: socialisation, externalisation, combination, and internalisation. In particular, socialisation process which represents the first stage out of four stages is important in conceptualising learning though a social context. This socialisation stage will be explored in detail in this paper.

Socialisation is the process of the *sharing* of the tacit knowledge of organisational members, whereby they learn the norms and values of the organisation, share feelings, emotions and experiences in order to remove the barriers between self and others, so that they become part of that organisation [1, 19]. It is particularly relevant to, and useful for, studying cultural learning in the hospital briefing process, especially in the context of partnering projects, because socialisation allows briefing participants to get to know one another. It is not only that this is an opportunity for the Facilities Management group to understand the client's needs, but it is also an opportunity to align such needs with its facilities strategies and project constraints, and to prioritise them accordingly. In briefing, socialisation takes place when the Facilities Management group and the client group meet and share their cultural knowledge to better understand the hospital's facility requirements.

Socialisation takes place within "originating ba", which often takes the form of physical face-to-face experiences, in which language is central to the process [19]. Although Nonaka *et al.* [19] argue that non-verbal language can play an important role, it is also important to note that a non-verbal context for socialisation largely exists in an intra-organisational setting where members are familiar with one another. In hospital briefing such non-verbal context for socialisation may be difficult to attain because, in an inter-organisational, temporary and contract-bounded relationship between the Facilities Management and hospital groups there is often no common language in the first place. To this end, it is established that verbal language used during the briefing process signifies socialisation that occur between the Facilities Management group and the Hospital group whereby they exchange cultural knowledge.

3. Method: measuring cultural knowledge exchange

In measuring cultural knowledge exchange, it is first necessary to understand the range of briefing meetings involved. This study uses an Australian partnering project, where it involved a major redevelopment within an existing hospital precinct, and whereby the managing contractor was engaged prior to the design stage rather than later in the process as in the traditional method of contracting. The briefing meetings referred to in this study were called "user group" meetings and it was in such meetings that the Facilities Management group gained cultural knowledge that was important to the effectiveness of the design outcomes. During these user group meetings, the Facilities Management group and the various users of the planned facility had the opportunity to socialise and exchange tacit cultural knowledge, which became the basis for the data collection process.

Determining the sharing of tacit cultural knowledge – Culture is previously defined as a shared way of thinking, or a shared knowledge structure that people use to make sense of perceived situations. People in social settings exchange many different kinds of knowledge to define their own and others' culture [20]. The literature of organisational knowledge and knowledge management present various categorisations of knowledge (Table 1). It can be seen that the various categorisations of knowledge essentially refer to similar ways of differentiating knowledge. Sackmann's [2] categorisation of knowledge has been chosen to be the basis for discussion that provides a framework in which the transfer of cultural knowledge through briefing meetings can be detected. It was established that such knowledge is embedded in the contexts, which, in this study, took the form of explicit discussions on facility-related issues between the hospital and Facilities Management groups during briefing meetings.

Table 1: Summary of different levels of knowledge (Adapted from [18]: 28)

Authors	**Level of knowledge**			
Sackmann (1992)	Dictionary	Directory	Recipe	Axiomatic
Spek and Spikjervet (1997)	Data	Information	<u>Knowledge</u> Knowing what Knowing how Knowing why Knowing where Knowing when	
Pawlowsky (2001)	"What"	"How"	"What should be"	"Why-things-are-done-the-way-they-are

Dictionary knowledge refers to the labels used to describe or name things or events [2]. Other researchers refer to this type of knowledge as 'symbols', 'data', and in the context of communication, the 'what' questions. In the hospital briefing process such knowledge may refer to the exchange of information about facility requirements, such as the size of rooms the hospital needs and their preferred locations. **Directory** knowledge refers to commonly held practices, for example, knowledge about chains of events and about their cause-and-effect relationships [2]. This is also referred to by others as 'data which has been assigned a meaning', 'clustered data that is meaningful within a given context, or the 'how' question. In the hospital briefing process such knowledge may refer to the description of facility requirements, which may include "how" members of hospital groups arrive at the facility requirements, as stated within the brief documents. **Recipe** knowledge refers to knowledge in the form of prescription, repair, and improvement strategies, which includes recommendations of certain actions on how a particular problem should be solved [2]. van der Spek and Spijkervet [21] also suggest that knowledge at this level contains individuals' values and awareness. In the hospital briefing process, such knowledge can take the form of discussions on what the facility needs and what its requirements should be. **Axiomatic** knowledge refers to reasons for causation, and explanations of the final causes perceived as underlying a particular event, which is about the 'why things happen', why a particular problem has emerged [2] or 'why-things-are-done-the-way-they-are', and involving personal values. In the hospital briefing process this knowledge may take the form of reasons that explain facility requirements, such as explaining needs in the light of the hospital's facility problems, and their proposed culturally-bound practical uses. Bood [22] further observes that organisational culture is most equated with axiomatic knowledge, a type of knowledge involving fundamental beliefs or final causes that cannot be further reduced. More importantly, Sackmann [2] argues that these four types of knowledge do not exist in isolation, but that they form an integrative and interconnected *gestalt*, labelled the *cognitive culture map*.

Measuring the "focus" of interaction – The recorded briefing meetings needed to be transcribed so as to allow the researcher to reread and analyse repeatedly [23]. In measuring the focus of interaction, thematic content analysis was undertaken as it allows the analysis of the texts using categories, such as those of Sackmann's [2], and which was assisted by the qualitative research software NVivo. To achieve higher validity against the criteria and construct variables as well as inter-rater reliability, Krippendorff [23] suggests firstly the need for a coding procedure: A label (name), a definition of what the theme concerns (characteristic or issue constituting a theme), a description of how to know when the theme occurs (indicators) and any qualifications or exclusions to the identification of the theme, and finally providing examples to eliminate possible confusion when looking for the theme. Secondly, it must be ensured that themes be a repetition from various units, rather than a single occurrence.

4. Result and findings

It was necessary to separate the case study into two sub-cases, as they involved different sets of briefing meetings. There were a total of *nine* meetings for Case Study 1 and *six* meetings for Case Study 2. This difference was due to the differing nature of the facility planning process for each sub-case. In both case studies all meetings were attended by representatives of the following subgroups: clinicians, planners, contractors, and consultants.

4.1 Contexts of cultural knowledge sharing

Table 2 shows that in Case Study 1 the topic of space fit-outs seemed to dominate the briefing discussions, with the highest total number of occurrences (N=252), followed by discussions on space allocation (N=156) and layout (N=128). This was due to the nature of the department involved, as their operation relied on the equipment and technological advancement of the facility. In Case Study 2 the topic on space layout seemed to dominate the briefing meetings (N=300), perhaps also because of the nature of the department involved, for whom room relationships and placements were important for the effectiveness of their operations. Space allocation (N=67) and fit-out (N=36) seemed to be a secondary focus during the briefing process in this case because of the consultative rather than clinical (surgical) nature of the work of the clinical department involved in Case Study 2. In both cases, knowledge sharing occurred within the contexts of discussion on facilities requirements in terms of space allocation, space layouts and space fit-outs.

Table 2: Topics of cultural knowledge sharing [18]: 116

Case studies	Level of knowledge	Space Allocation	Space Layout	Space Fitout
Case study 1	Dictionary	49	30	54
	Directory	53	39	89
	Recipe	34	38	71
	Axiomatic	20	21	38
	Total	**156**	**128**	**252**
Case study 2	Dictionary	23	93	12
	Directory	22	128	17
	Recipe	13	60	4
	Axiomatic	9	19	3
	Total	**67**	**300**	**36**

4.2 Types of cultural knowledge shared

Figure 1 shows the different types of knowledge shared in the briefing meetings in both of the case studies. Directory knowledge, representing the "how" question, was most frequently shared during the entire series of briefing meetings, followed by dictionary knowledge, recipe, and axiomatic knowledge. An example of **directory knowledge** was "how" facility requirements were formulated, which triggered the sharing of background information regarding the project requirements. More specifically, much of the directory knowledge was shared in the context of explaining the communication process during the project and space fit-outs, such as regarding equipment fittings, doors, and windows and space layouts such as room details and relationships. For example, as the clinicians disagreed with the amount of space allocated for their offices, one planner explained "how" office spaces were to be allocated: *"{The CEO} is quite keen on more of a cheap way of looking at and managing office space, and if people can share, they will, and it is directly his will and within the space planning principles, and if your role is not a manager, then you share it"* (Planner 06, Case Study 1). This indicates that directory knowledge sharing occurred through a process of problem solving and was triggered by disagreements on facility-related issues.

Dictionary knowledge was less frequently shared than directory knowledge. Observations during meetings indicated that such knowledge was communicated with much reference to the briefs (eg Room Data Sheets / RDS) and hence was not fully verbalised. This meant that verbal interactions during briefing meetings did not focus much on the sharing of such knowledge, since such sharing could use texts as a medium for communication rather than verbal speech. For example, a contractor clarified the scope of the project by referring to the RDS: *"page 11, just to confirm, items not part of stage 1... Conferencing area is shared… office areas are not included in this part of stage 1 works"* (Contractor 07, Case 2). While this type of knowledge seemed to be basic and could be communicated through texts, it formed the basis for the sharing of other types of knowledge through uncertainties, disagreements, or conflicts.

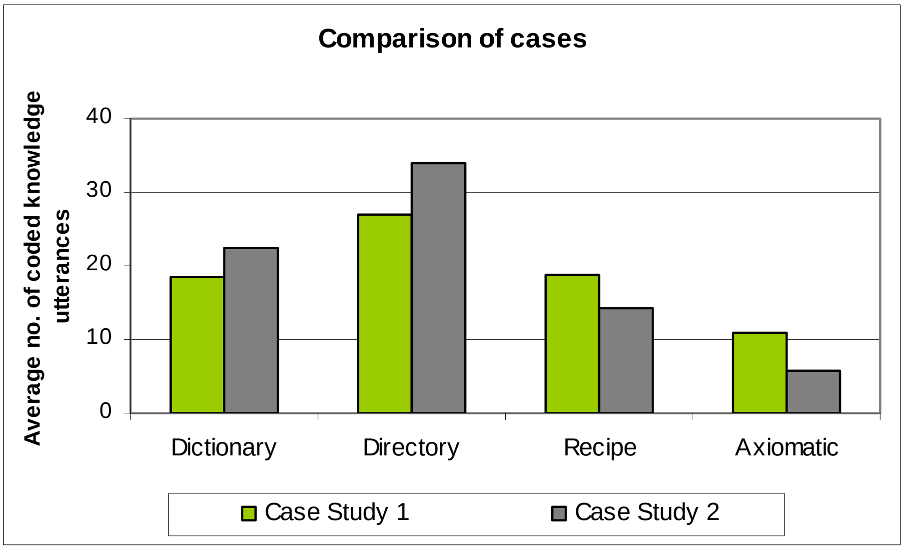

Figure 1: The types of knowledge shared on average during briefing meetings [18]: 117

Recipe knowledge was the next most frequently shared type of knowledge to directory, reflecting that the groups were learning about the project requirements and its problems, thus making recommendations in terms of recipe knowledge when problems remained unresolved and disagreements persisted. For example a consultant presented a recommendation on the door fit-out in Case Study 1, in which the clinicians insisted on have sliding doors in order to avoid encroachment into the rooms: *"If we are looking at a pair of door options, in terms of the impact on the room, we can have one leaf swinging 180 degree, so that it falls flat against the glass wall"* (Consultant 06, Case 1). The contexts in which these types of knowledge were shared were discussions about space allocation, layouts and fit-outs.

Axiomatic knowledge was the least shared among the subgroups, and seemed to emerge mostly during a lengthy and deep discussion on certain topics. For example the contractors asked the clinicians in Case Study 1 for justification of the size of glass windows, the placement of the glass windows, the types of glazing required for the glass windows, etc. A clinician responded by explaining the "why" of their requirement: *"The side window is meant so that a staff member from one room can see to the other one if there is nobody in there. The front window is so that people outside the room, at the nursing station, can see what is going on in the room"* (Clinician 03, Meeting 9) and another clinician added *"Because otherwise you have got to have a staff member looking after patients all the time, which means a long term recurrent cost, you must have twice the {number of} staff"* (Clinician 06, Case 1). The sharing of "why" knowledge is interconnected with the sharing of other types of knowledge (ie "what", "how", and "what should be"), which is consistent with Sackmann's [2] assertion that the different types of knowledge form an interconnected *gestalt*.

Still referring to Figure 1, it is important to note that the average sharing of recipe and axiomatic knowledge was consistently higher in Case Study 1 than in Case Study 2, which seemed to be influenced by the enthusiasm of the briefing participants in Case Study 1, which added to the dynamics of interactions during their briefing meetings. For example, one clinician in Case Study 1 acknowledged that they were *"most enthusiastic when it comes to this planning process"* (Clinician 03, Case 1). Another clinician explained their enthusiasm for aiming to alter the government's design guidelines by travelling extensively around the world to obtain supporting data: *"…we are so adamant on some of the design features we want to put in… we went around to look at the other {unit} on how the {space} allocation should be"*, and further explained that *"we have travelled extensively throughout the US, Canada, UK, Scandinavia, Europe, France, Germany, Adelaide, Melbourne and all the big cities looking at the design structure of the {unit}"* (Clinician 01, Case 1). The enthusiasm of the clinicians in Case Study 1 was acknowledged by clinicians in Case Study 2 who pointed out: *"what's ideal and best is what they {Clinicians in Case Study 1} want… Most of the time they will always want to stand for the best, because it is quite an ego-driven area within the hospital"* (Clinician 06, Case 2). This finding is consistent with Nonaka's [1] assertion that a group's enthusiasm, and thus cooperation and commitment, supports the sharing of knowledge.

4.3 Holders of knowledge

'Holders' in this section refers to individuals who participated in the briefing meetings and who uttered either knowledge about, *or* concern with, a topic. Knowledge, in this instance, refers to all categories of knowledge namely, dictionary, directory, recipe, and axiomatic. Figure 2 reveals a stark difference in knowledge held by the clinician subgroups between Case Study 1 and 2 (higher in Case Study 1 than Case Study 2). The clinician subgroup in Case Study 1 reflected the highest knowledge held among all subgroups, affirming an earlier finding that the level of cultural knowledge held was influenced by the enthusiasm and assertiveness shown by the group and that, at the same time, passiveness seemed to result in lower cultural knowledge being held. Furthermore, it is also interesting to note that the level of knowledge held by the contractors and the consultants was also higher in Case Study 1. As mentioned earlier, the dynamics of interaction initiated by the clinicians seems to have influenced not only the knowledge held by themselves, but also triggered the utterance of knowledge held by the contractors and the consultants. Figure 2 also shows that, during the briefing meetings, the clinicians held the most amount of knowledge compared to other subgroups. It is interesting to note that the contractors seemed to utter the least amount of cultural knowledge. The following section discusses the details of the holders of the different types of knowledge based on each case study.

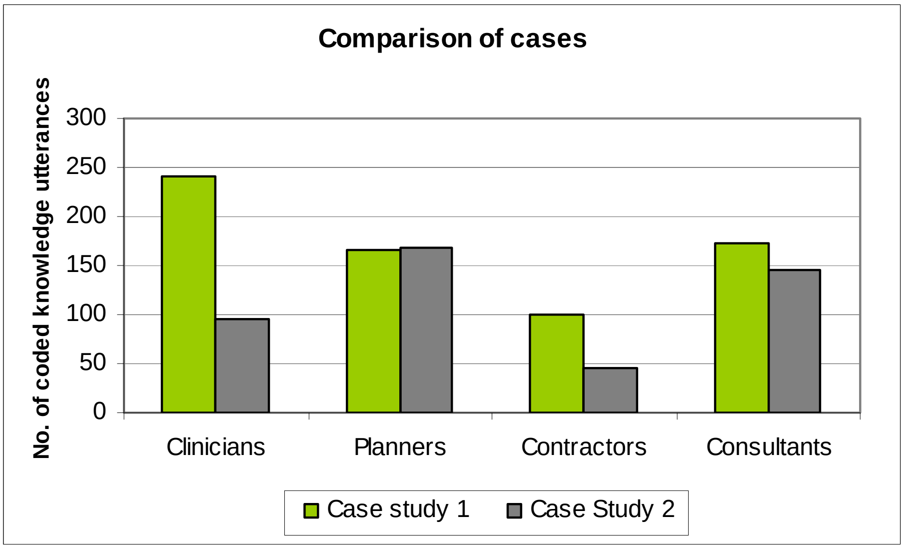

Figure 2: Holders of knowledge uttered during briefing meetings in Case Study 1 and 2 [18]: 120

4.3.1 In Case Study 1

Figure 3 shows that, except for dictionary knowledge, the clinicians uttered the highest amount of knowledge, compared to other subgroups. In particular, the difference seemed to be highest in terms of recipe and axiomatic knowledge, where clinicians made recommendations for developing facility strategies by stating their reasons for making such suggestions. This further reflects the enthusiasm and assertiveness of the clinicians during the briefing process. The planners mostly held directory and dictionary knowledge because they possessed much of the background knowledge of the project from the early feasibility studies undertaken prior to the briefing stage. The active involvement of the consultants was also shown, in that directory knowledge seemed to be mainly held by the consultants, perhaps due to their facility design experience relating to hospitals, detailed practical knowledge about the specific facility requirements of the project, and most importantly, as noted by Kelly *et al.* [24], their responsibility for translating the project requirements into design outcomes. This was also evident in the holders of recipe and axiomatic knowledge, where the consultants represent the second highest scoring group.

Analysis of Case Study 1 also suggests that knowledge exchange was enhanced through conflicts and disagreements among the clinicians themselves. For example, the clinicians had arguments about the room fit-out, in which the nurses were concerned about the complexity of operating of such fit-outs (ie operational issue), while the doctors focused on the medical outcomes (ie strategic issue). This is similar to the "creative chaos" referred to by Nonaka *et al.* [19] as being a factor that encourages knowledge exchange. From the cultural learning perspective used in this research, creative chaos is therefore desirable during briefing. This seems to contrast with the current briefing literature, which emphasises the importance of gaining consensus [25]. While consensus is eventually required, the findings of this study indicate that some chaos is first needed to encourage cultural learning. It also indicates that the briefing process was not a simple learning process between the Hospital and the FM group but, rather, reflected an unclear boundary between the learning participants (between the existence of subcultures and the existence of subjective/individual opinions) and between different levels of learning (individual learning to subgroup learning to group learning). For example the clinicians could come to disagreement among themselves, indicating the clients' inability to articulate their needs as pointed out by Barrett and Stanley [14], and Shen and Chung [25]. Nevertheless, this resulted in the exchange of cultural knowledge among the clinicians, as well as with the FM group, which presents as opportunities for clients to discuss, discover, and learn about their own requirements.

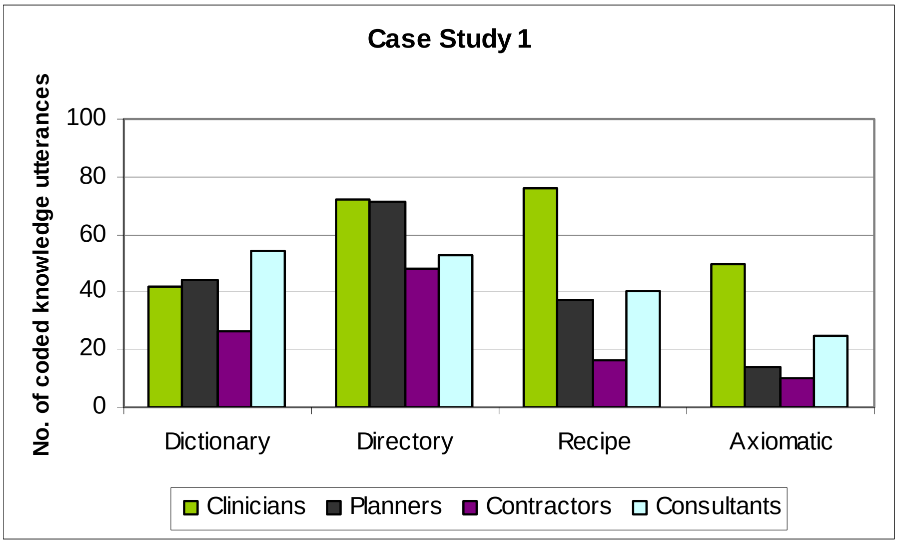

Figure 3: Holders of knowledge in Case Study 1 [18]: 121

4.3.2 In Case Study 2

As shown in Figure 4, the planners dominated the process of knowledge sharing throughout the briefing meetings, especially in relation to directory and recipe knowledge. Observations of the meetings indicated that this was because the planners initiated the majority of the conversations by providing background information about the progress of the design process. The consultants also actively provided responses by presenting draft drawings, explaining and aligning them with facility requirements, and prompting questions for further modifications. The clinicians, however, showed passivity in the process compared to the planners and consultants; for example, only a few of the members voiced their opinion when asked by the planners and/or consultants. This passivity was also reflected in the lower number of attendees in the meetings from this department, compared to those in Case Study 1.

It is interesting to note that, although the clinicians did not hold much knowledge overall, they uttered more axiomatic knowledge than the other subgroups. This indicates the negotiating nature of the briefing process, where clinicians, although relatively passive, persuaded others of their requirements by providing examples of evidence-based practices. For example, when given the total amount of storeroom area by the planners, the clinicians argued, by sharing knowledge about their daily routines, that *"if you look at our current storeroom, staff have to line up to get things because there is not enough space"* (Clinicians 11, Meeting 3). The basis for such negotiation tended to be disagreements on facility requirements, which surfaced as the groups addressed the "what", "how", and "what should be" questions of the facility requirements (ie dictionary, directory, and recipe knowledge). This confirms an earlier finding (in Case Study 1) that the exchange of axiomatic knowledge is encouraged by disagreements between and within the groups. Furthermore, such exchange was facilitated through discussions on other types of knowledge, rather than independently of them.

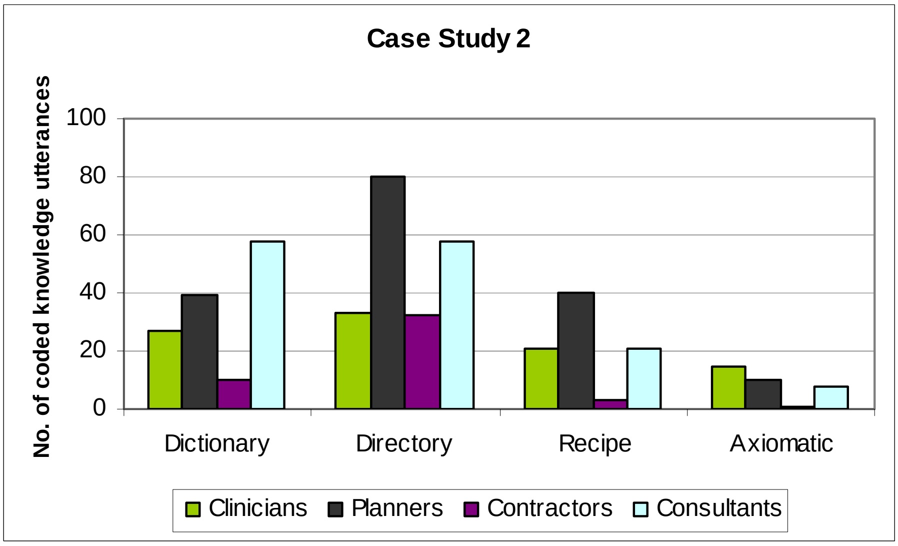

Figure 4: Holders of knowledge in Case Study 2 [18]: 123

5. Discussion and Conclusion

This paper has discussed the contexts for knowledge sharing, the types of knowledge shared during briefing meetings and the holders of knowledge within a hospital partnering project. The above analysis indicates that when the FM group and the Hospital group met the focus of their interactions was not on the sharing of axiomatic knowledge, as this type of knowledge seemed to emerge only during a lengthy and deep and thorough discussion on specific topics. Consistent with Nonaka's [1] assertion, axiomatic knowledge did not exist independently, but was embedded in discussions about facility requirements such as space allocation, layouts, and fit-outs. Furthermore, there appeared to be an unclear boundary between the groups and among members of the same group in the sharing of knowledge, when members learned about their own facility requirements. It was also found that in both case studies the sharing of axiomatic knowledge was largely initiated by the clinicians as they participated in the negotiation and bargaining process of facility requirements during the briefing meetings. This supports Green's [15] assertion that the briefing process involves a social construction of meaning, as facility requirements are defined during the briefing process. However, as opposed to Green's [15] view, the cultural learning perspective appeared to highlight that this process can be purposeful and extremely subjective, as briefing participants competed against one another to impose their version of knowledge through such sharing of axiomatic knowledge. For example, Case Study 1 participants shared much of their recipe and axiomatic knowledge in attempts to convince others of their viewpoints. With their enthusiasm and assertiveness the clinicians seemed to have influenced not only the knowledge exchange among themselves, but also among the contractors and the consultants in the negotiation process. Finally, the sharing of all types of knowledge also seems to be facilitated through problems, disagreements, and conflicts in facility-related issues (or "creative chaos" [19]).

Conversely, agreements seem to prevent the sharing of knowledge, for example, recipe knowledge. The implication for briefings is that "creative chaos" in the form of problems, disagreements, and conflicts should be encouraged and managed, so as to facilitate the sharing of axiomatic as well as other types of knowledge.

Abstract

Sanitary-plumbing system can waste energy and even become a source of fatal contamination unless designed, constructed or maintained properly. Human health and convenience are the two critical issues and it is important to identify, analyse and quantify the maintainability parameters of complex sanitary-plumbing systems to meet requirements of today's bigger and better buildings. This research was undertaken to investigate the common defects in sanitary plumbing system in high rise residential buildings and their causing factors which may be the critical maintainability parameters of sanitary-plumbing systems. From the detailed case studies of five residential buildings in Singapore, a total of 113 defects were identified for ten major components of sanitary-plumbing system. Out of them 56 were graded as significant by 33 experienced facility managers based on frequency of occurrence and their adverse effect on: economy, system performance, environment and health. Poor maintainability consideration in design stage was apparent from the comprehensive defect analysis. The defect commonly found in almost all the components was the "inaccessibility" for regular inspection and maintenance.

Keywords: Contamination, Defect analysis, Maintainability, Sanitary-plumbing, System performance.

1. Introduction

Apart from wasting precious energy and water, sanitary-plumbing system can become a source of fatal contamination unless it was designed, constructed and maintained properly. With time the concept of maintenance has changed from the action of "breakdown repair" to "preventive maintenance". Only clean water with quality hygienic standard is considered satisfactory.

Hence this system deserves a keen attention particularly in Singapore as abundant rainfall, high temperature and humidity, coupled with high population density can cause waterborne diseases to spread easily and quickly unless a high standard of public health is maintained [1]. In a recent survey conducted by Hassanain [2], design professionals of nine countries have proposed 41 design guidelines with an emphasis on occupant's health to a great extent.

Codes of practise, standards of design and operation handbooks have clear and well-defined guidelines for design and construction of sanitary–plumbing systems in general [1,3-5], along with detailed consideration for certain major issues such as piping [6], valves [7], pumps [8] and life cycle costing [9] etc. Yet major problems are reported frequently, all round the world such as leakage resulting in water scarcity [10], sewage contamination of potable water causing sickness [11] or recurrent cases of Legionella [12]. The root cause of many of these problems is derived from corrosion and wearing off of metallic parts which are common in pipelines, particularly in the consumer's plumbing fittings. Corrosion favours bacterial growth, developing high concentration of lead and copper components within the system and leading to dirty and contaminated water [13]. Researchers have drawn attention to various problems related to sanitary-plumbing system, such as lead contamination [14], biofilm formation [15] etc.

In most cases the solutions for a particular issue were seldom well communicated as a design, construction or maintenance guideline. Health and convenience are the two major critical issues, and it is not only important to identify and solve various defects, but it is equally essential to quantify and grade the maintainability parameters especially when qualitative decision making process is inadequate for complex sanitary-plumbing systems to meet the requirements of today's bigger and better buildings. To address the absence of such grading system, this research was undertaken to investigate the types of defects that are commonly occurring in sanitary plumbing system in high rise residential buildings and to identify the significant ones.

2. Research methodology

2.1 Data collection

In order to obtain a preliminary idea of common maintenance problems in sanitary–plumbing system, major components were examined in a systematic site investigation process. In the first phase of data collection, an in-depth field survey was conducted in five residential towers to identify the common defects occurring in each major component. Discussion with facility managers (FM) and maintenance personnel was followed by expert on-site inspection. Comprehensive photo of each component parts were taken to investigate elements such as the fixture and fittings in individual toilet units, water storage tanks and pumps etc. The defects were diagnosed with the help of information provided by FMs, maintenance records of the buildings and the knowledge gained through the literature review [16-23] were elicited.

From the defect analysis, it was observed that a defect can cause adverse effects on (1) economy, (2) system performance; (3) indoor environmental quality (IEQ); and (4) occupants' health and well-being. These factors contribute to the level of seriousness of a defect A frequent defect might not have significant effect, whereas a very serious defect may happen once in a lifetime. For example, a slow discharge rate of supply water is common but it may not have as much impact on the user when compared with the contamination of potable water from sewage which may cause serious illness. Therefore apart from the frequency of occurrence, the following four major impacts were also considered to be the significant factors caused by the sanitary-plumbing system defects. :

- Economic loss: accumulated financial loss in long term due to the result of the defect. For example, high consumption of electricity due to wrong design resulting in excessive pipe length and bending leading to energy loss of hot water before discharging through the taps.
- System performance loss: such loss occurs when the system performs significantly below normal operating efficiency. For example, slow or disrupted sewage pumping system choked by solid waste discharge.
- IEQ loss: This loss originated from the defect that causes deterioration of the built environment. For example, due to trap seal loss, foul air from the discharge pipes or stacks enters into the building.
- Human health loss: affects the health of the building occupants and maintenance personnel as a result of the defect. For example, illness caused by Legionella contaminations in water supply system.

The defect data related to major components and sub-components of sanitary-plumbing system was collated in a detailed survey questionnaire. In a face to face interview, 33 experienced FMs were asked to indicate the frequency of the defect in a five point Likert scale, where, 1 = ‘rare’, 2 = ‘sometimes’, 3 = ‘quite often’, 4 = ‘very often’ and 5 = ‘always’. In order to estimate the impact of each defect, the respondents were asked to indicate the significance of the defects in terms of four consequences also in a five point Likert scale, where, 1 = ‘negligible’, 2= ‘slight’, 3 = ‘moderate’, 4 = ‘serious’ and 5= ‘very serious / fatal’. Among ten major components, the questionnaire for sanitary piping is shown in Appendix A as an example.

2.2 Data analysis

Mean ratings for the level of seriousness of the defects were calculated from the feedback received. Mean rating for frequency was defined as $\overline{X}_{FR}$, while the same for four impacts, namely, economic loss, system performance loss, IEQ loss and health loss were denoted by $\overline{X}_{EC}$, $\overline{X}_{SP}$, $\overline{X}_{EN}$ and $\overline{X}_{HW}$ respectively. For each defect, the vales were calculated by a general formula (Equation 1). Using statistical tool SPSS 12, T-test was carried out to identify the significance of each mean. The midpoint test value of 3 (by definition) was assigned to measure whether the defects have a significantly large enough mean with p<0.005.

$$\text{Mean frequency of occurrence } \overline{X} = \sum_{l=1}^{5} i \times n_i \Big/ \sum_{l=1}^{5} n_i \qquad (1)$$

Where, i = frequency rating.

n_i = number of responses for i-th rating

3. Results and discussion

3.1 General observation

For water supply, in most of the condominiums or public housing in Singapore, a gravity supply system was observed whereas hot water is supplied mainly from heater of individual residential units. Tankless type instantaneous heater is commonly installed for shower unit where no hot water is provided for lavatory and kitchen sink. For sanitary works, ventilated stack is used for all buildings with a height more than six stories. The wastewater is collected and conveyed by combined sewers to sewage treatment works before final discharge into the sea. In general it was found that many defects occurred due to poor design consideration for maintenance. The access to various components or provision of work space for maintenance is inadequate. In concealed pipe work, it is difficult to determine the exact location and root cause of any fault. It was also observed that one defect may give rise to a chain of defects. For example, corrosion of piping may cause leakage, which in turn results in water ponding, backflow of dirty water from surrounding soil, as well as wastage of water.

3.2 Survey results

The summary of survey results is presented in Tables 1 - 6 for water supply, while Tables 7 -10 illustrate the prevalent defects in sanitary system. A total of 113 defects related to ten major components of sanitary-plumbing system were identified, out of which 56 were found serious and among those 13 were referred by FMs as frequent and 17 occurs in two or more categories. Economy, system performance, IEQ and health & well-being were affected by 40, 34, 9 and 20 defects respectively. All the significant defects for ten major components are graphically illustrated in the defect list (Tables 1-10). As an example, defects in sanitary piping are discussed in details in Section 3.3.

Table 1: A summary of the defects in supply main

Sub component	**Common defects (11 nos.)**	**Seriousness of significant defects (3 nos.)**
Piping	Overflow, contamination, slow discharge / backflow, hydraulic thrust, dirt accumulation at dead end, less supply, leakage, damage	Stop Valve	Unable to cut supply for repair	

Air valve	Air lock at high point (low pressure flow), Air gap at summit (normal flow)	

Table 2: A summary of the defects in service pipe

Sub component	Common defects (18 nos.)	Seriousness of significant defects (11 nos.)
Underground pipe	Settlement, damage due to settlement	Exposed pipe	Corrosion, other degradation	
Internal pipes	Leakage, contamination, air locks, slow discharge, noisy flow, dirt accumulation, supply-discharge interference, damage (thermal stress), poor accessibility, difficult to locate, difficult cleaning	
Valves	In-accessibility, supply suffers during repair	
Fittings	Corrosion	

Table 3: A summary of the defects in over-head / under-ground storage

Sub component	Common defects (14 nos.)	Seriousness of significant defects (11 nos.)
Tank body	Corrosion, leakage, poor / no ventilation, flooding around tank, clogged wash out pipe	
	hinders cleaning	
Intake	Overflow, interruption, back siphonage, stagnation / short circuiting	
Discharge	Contamination, level goes below pipe invert	
Controls	Faulty valve, alarm indicator etc	
Accessory	Corroded net or strainer etc, entry of dirt or insect	

Table 4: A summary of the defects in distribution pipe

Sub component	**Common defects (14 nos.)**	**Seriousness of significant defects (7 nos.)**
Underground piping	Settlement, damage due to settlement, mechanical damage, leakage	General	Contamination, degradation, low discharge rate, air locks, frictional loss, head loss at bend / joint, noisy flow, ugly arrangement	
Valves	In-accessibility, supply suffers during repair, corrosion of components	

Table 5: A summary of the defects in hot water supply

Sub component	**Common defects (8 nos.)**	**Seriousness of significant defects (5 nos.)**
Piping	Wastage of water, heat loss, short circuiting in the piping of the primary and secondary circuit, scaling, Legionella growth, corrosion	2 2.5 3 3.5 4 $\overline{X}_{FR}$ $\overline{X}_{EC}$ $\overline{X}_{SP}$ $\overline{X}_{EN}$ $\overline{X}_{HW}$

body	Corrosion	2 2.5 3 3.5 4 FR EC SP EN HW
Impellers	Corrosion, out of balance	
Valves	Damaged reflux and isolating valves	
Controls	Faulty control can't auto interchange duty and standby pumps after each cycle of operation.	
In general	Damaged pumps, choking, over heating, excessive vibration	

Table 7: A summary of the defects in sewage ejector or solid diverter tank

Sub component	**Common defects (8 nos.)**	**Seriousness of significant defect (4 nos.)**
Tank / pit	Poor accessibility for maintenance, poor working condition, inadequate ventilation,	2 2.5 3 3.5 4

	vandalism / break in, water penetration / ponding, corrosion	$\overline{X}_{FR}$ $\overline{X}_{EC}$ $\overline{X}_{SP}$ $\overline{X}_{EN}$ $\overline{X}_{HW}$
Air compressor	Incomplete sewage discharge	
Sump pump	Unable to dewater	

Table 8: A summary of the defects in sewage pumps

Sub component	Common defects (5 nos.)	Seriousness of significant defects (2 nos.)
Body	Corrosion	2 2.5 3 3.5 4 $\overline{X}_{FR}$ $\overline{X}_{EC}$ $\overline{X}_{SP}$ $\overline{X}_{EN}$ $\overline{X}_{HW}$
Impeller	Corrosion, out of balance	
Controls	Unable to auto interchange of duty and standby pumps after each cycle of operation.	
General	Long fibrous materials of raw sewage cannot be pumped (clogging), solids of diameter ≥ 64mm diameter cannot be pumped (choking)	

Table 9: A summary of the defects in sanitary piping

Sub component	Common defects (10 nos.)	Seriousness of significant defects (7 nos.)
General	Corrosion, leakages, slow discharge , no discharge, discharge of foul air into the building, poor accessibility for maintenance and repair, contamination , trap seal loss,	2 2.5 3 3.5 4 4.5 $\overline{X}_{FR}$ $\overline{X}_{EC}$ $\overline{X}_{SP}$ $\overline{X}_{EN}$ $\overline{X}_{HW}$

	mosquito breeding in open trap, noisy flow	

Table 10: A summary of the defects in sanitary fixture and fittings

Sub component	**Common defects (13 nos.)**	**Seriousness of significant defects (3 nos.)**
WC pan	Water ponding around pan, discharge pipe disconnected from pedestal type pan, collapsed / dislodged of support brackets of wall-hung WC	Flushing Cistern	Leakage of water and air at the connection of flush pipe and WC pan, damaged device no longer automatic	
Urinal	Clogged trap	
Bidet	Backflow or back siphonage	
Bath and shower unit	Leakages at the joints at the edge of wall and tray, poor maintenance of the waste pipe / trap under the bath	
Floor trap	Slow drainage	
Grating / cover for floor trap / waste	Corrosion, damaged gratings causes undesirable opening and penetration of garbage or other solid waste	
Accessory	Corrosion of installation screws	

3.3 Discussion

For three sub-components of sanitary piping, a total of ten common defects were identified from the first phase of data collection, among which none was frequent but seven were found to be significant for their impacts. Such piping seldom suffers from leakage, but it causes considerable amount of economic loss. This may be due to the corrosion of structural members initiated by water leaking through the joints of concealed pipes. Slow discharge is an example of system performance loss, but no discharge incurs huge cost as the trap or pipe that may require replacement. Though discharge of foul air into the building due to trap seal loss is a well discussed topic but it is considered insignificant from FMs' point of view. On the contrary, poor accessibility for inspection, cleaning and repair was reported as a major hurdle for maintaining proper IEQ. Contamination as caused by backflow and back-siphonage i.e. major defect of design or construction was considered expensive as replacement is the only remedy. Similarly mosquito breeding in open traps was found to have the highest emphasis for health and well being among all 113 defects as this may cause fatal Dengue fever to spread. For the same reason, this defect was considered to be a great expense on FM as failing to rectify this defect may incur huge penalty. Noisy flow as caused by interrupted discharge is an unpleasing example of system performance loss, often demanding costly cleaning or replacement.

From the present study, it was established that among many defects in sanitary-plumbing system, most of the defects can be prevented by considering four major maintainability criteria, namely, design, appropriate material selection, construction practices, and operation & maintenance (O&M) practices and few defects have more than one cause.. It is important to know at which stage what are the defects arise so that the appropriate preventive measures can be taken to improve the maintainability. It was found that among 56 significant defects, 38 are design related, 14 occurred due to poor material selection, 16 were due to bad construction quality and inadequate O&M practises were responsible for 19 defects. Especially poor accessibility for regular inspection, cleaning and routine maintenance was found to be one of the major and prevalent defects which can be addressed during the design stage.

4. Conclusions

The study had identified 56 persistent defects out of total 113 defects commonly occurring in ten major components of sanitary-plumbing system. The inaccessibility for regular inspection and maintenance was detected as the common defect for almost all the components. From the analysis based on feedback provided by 33 experienced FMs regarding: (1) frequency of occurrence of various defects and (2) seriousness of the defects in terms of their adverse effect on economy, system performance, indoor environmental quality and occupants' health & well-being, it was established that the most important contributing factors for maintainability is good design, next comes by O&M practices, followed by construction quality, and material selection. This comprehensive defect analysis was aimed to help the designers, contractors and facility managers to realize the long term effect of their decisions made and form the basis of an enhanced maintainability to promote good practices for efficient and safe functioning of highly maintainable sanitary-plumbing system. Further, this may provide a simple guideline for FMs to achieve and as well as owner to enjoy lower life cycle maintenance cost of building services. This generic research method can be applicable for any other building services.

Abstract

The idea of this paper is to understand the methods of managing performance in healthcare facilities management in the UK. Most of what is put forward in this paper is based on an already completed research study on 'the role of Facilities Management in the control of Healthcare Associated Infections (HAI)'. Therefore the findings presented in the paper are discussed with a specific focus on the control of Healthcare Associated Infections (HAI). The paper first reviews different definitions and concepts of performance management (PM). It then discusses some of the common performance management approaches used by facilities management (FM) services in hospitals in the UK. These discussions of the paper are based on the findings of a mixed methodology approach. The data sets obtained were subjected to rigorous qualitative and quantitative analyses. Based on the findings of the data analysis, the paper finally concludes that there is a need for a robust performance management approach in order to improve the quality of the National Health Service (NHS), UK.

Keywords: Domestic services, Healthcare Associated infections (HAI), Facilities management, Performance management

1. Introduction

This paper is based on research titled 'the role of Facilities Management services in the control of Healthcare Associated Infections' (Liyanage, 2006). Healthcare Associated Infection (HAI) by definition means "infection which was neither present nor incubating at the time of admission but has developed during the course of a stay in hospital or other healthcare facility" (Scottish Executive Health Department, 2002). Studies throughout the world document that Healthcare Associated Infections are major causes of morbidity and mortality. According to Ayliffe et al (1999) the acquired infection rate is approximately 5-10% in the UK and other developed countries. A review of literature suggests that errors in clinical practices dramatically contribute to the emergence of HAI (Bennet and Brachman, 1998). Nevertheless, some suggest that, if HAI is to be controlled effectively, it is also essential to focus on non-clinical areas such as Facilities Management (FM) as well (Meers et al, 1992; Horton and Parker, 2002).

FM in healthcare usually includes a myriad of services. These are mainly in two categories; hard FM and soft FM. Hard FM relates to management and maintenance of property and other physical assets, while soft FM includes the management of support services. The built environment, including infrastructure facilities such as estate and property, indoor air, structure and fabric, water supply, electricity and telecommunication systems come under the first category (hard FM); and catering, cleaning, waste management, security, and laundry describes the latter (soft FM).

The main aim of this paper is to present and discuss the methods of managing performance in FM services in hospitals from a control of HAI point of view. In doing so, specific attention is drawn only to the cleaning service, which for the purposes of this paper is classified as 'domestic services'.

2. Performance management

The concept of Performance Management (PM) has no generally agreed definition in or across the literature reviewed for this study. According to Martinez (2001), performance management is a term borrowed from the management literature that has only recently been adopted in the healthcare field. The term 'Performance Management (PM)' was first used in the 1970s, but it did not become a recognised process until the latter half of the 1980s (Armstrong and Baron, 1998). As Armstrong and Baron (1998) state, PM is mostly identified as a system which enhances individual performances to support or achieve organisational goals. Adair et al (2003) stress that the term PM cannot be defined in the absolute and that its meaning is contextual in terms of both individuals and activities. Many authors or researchers have different views on PM; some have taken a human resource focus to define performance management (Armstrong and Baron, 1998; Storey and Sisson, 1993), while others provide an organisational view of PM (Fletcher and Williams, 1992; Watkins, 2005). However, according to Donabedian (1980) it is not totally appropriate to consider PM in view of individual performance alone.

Performance Management (PM) can be seen as a significant area in the control of HAI in domestic services. However, it has seldom been recognised as a main component in the said area. As Bartely (2000) has recommended, PM is essential to assess the level of adoption of control of HAI standards in FM services. The Auditor General for Scotland (2000), also provides some of the benefits of PM as follows:

- Measure progress towards achieving corporate objectives and targets.
- Promote the accountability of service providers to the public and other stakeholders.
- Compare performance to identify opportunities for improvement. Performance indicators may be used to identify opportunities for improvement through comparison both within the organisation over time or between different units or organisations.
- Promote service improvement by publicising performance level.

PM can be used as an effective tool to detect pros and cons of the domestic service and it can also support strategic decision-making. It could be used as a point of reference to compare past performance levels with the present. Further, it could also be utilised to identify mistakes and assist with appropriate remedies to be taken.

3. Existing performance management approaches in FM services – case study findings

3.1 Details of the case studies

The existing performance management approaches used in FM services (specifically domestic services) for the control of HAI was identified using the findings of qualitative and quantitative methodologies. The qualitative methodology employed a case study approach involving 26 semi-structured interviews with key parties in the control of HAI in domestic services. For the purpose of this study, domestic services in hospitals were categorised as shown in figure 1.

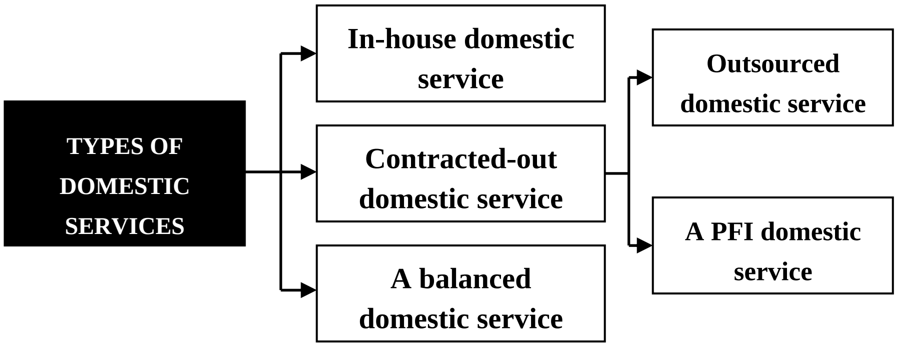

Figure 1: types of domestic services (Adapted from NHS Estates, 1998)

Using the above classifications two different types of domestic services were chosen for the case study approach.

The selected cases were: an in-house domestic service and a Private Finance Initiative (PFI) domestic service. Choosing an in-house and a PFI domestic service was strengthened by the increasing concern by the NHS for such types of services as well as their current level of use. For ease of reference the two case studies were coded as '*In-house case*' and '*PFI case*' in the study reported here. Both *In-house* case and *PFI case* are main hospitals in two of the largest Acute Trusts in the NHS in Scotland. In the In-house case, the domestic service was provided by an internal team that was under the control of the hospital management. The PFI scheme of this hospital was large; hence the private sector partner was a consortium (the special purpose vehicle, i.e. SPV) whose members included a construction company and a principal service provider. The client was the particular NHS trust. The construction company and the principal service provider were the main contractors. The principal service provider had sub-contractors to manage both clinical and support services (FM). The support service provider (i.e. the FM provider) managed all FM services including the domestic service.

3.2 Case study findings

Table 1 presents the PM approaches in-use for the control of HAI in the two case studies. Discussions related to all the above are presented in detail in subsequent paragraphs.

Table 1: PM approaches in-use in FM services

Both the *In-house case* and the *PFI case*, in the main, had two types of PM approaches, i.e. external audits and internal audits. The audits carried out by Audit Scotland were the main types of external audits in both cases. The Audit Scotland is responsible for investigating whether the domestic services achieve the best possible value for money and adhere to the highest standards of financial management. It provides a baseline review of hospital cleaning services and makes several recommendations. The recommendations are aimed at improving the quality and effectiveness of hospital cleaning. The review also incorporates a baseline assessment of compliance with standards for cleaning services issued by the Clinical Standards Board for Scotland - CSBS (2002). The Audit Scotland reviews are carried out together with the domestic managers in hospitals. Its reviews are conducted against a number of criteria relating to floors, fixtures and fittings, sanitary ware, walls, curtains and screens and waste bins. Each area is rated using a Likert scale of four, i.e. very good, acceptable, need for improvement or concern (i.e.

unsatisfactory). This basically provides a ‘snapshot’ of the levels of cleanliness in hospitals in Scotland. As one of the domestic managers from the *PFI case* noted:

“The Audit Scotland gives us an action plan to comply with for anything that they felt was unsatisfactory. We have to then respond within a given time frame.”

Audit Scotland completed its last audit in May 2002. However, it is supposed to carry out its audits in hospitals throughout Scotland, at least once every three years.

The *In-house case* had two other external audits, the environmental audits and the audits carried out for ISO 9001:2000 quality accreditation. The environmental audits are carried out quarterly, by the Health and Safety Executive (HSE) and Environmental Health. It is an independent review, which specifically audits the cleanliness of kitchen areas, ward areas and the conditions of hospitals. The ISO 9001:2000 audit, on the other hand, is a process level quality accreditation. It is carried out by an external organisation called SGS Yardsley. SGS Yardley conducts its audits twice a year across the NHS Trust of the *In-house case*. The audits not only include the domestic service but also areas such as maintenance, catering and portering. As the General Manager (Facilities) noted, this audit is similar to a rolling programme:

“Their (ISO 9001:2000) performance tool is a check list. They (the auditors) come with a list of areas to check. Each time they come, they check different areas, so, they make sure that they cover the whole service every year”

The ISO 9001:2000 audits provide a report on the performance of the *In-house case* at the end of each audit. It identifies any areas of shortfalls and provides a sufficient time period to rectify the problems. As the hotel services manager of the *In-house case* explained:

“It is a fairly robust system. They provide us with a corrective action form. If we have a number of corrective actions then they (the auditors) tell us that we have a poor performance level. Usually they benchmark our system against the number of corrective actions we have.”

The main types of internal audits carried out by both cases are known as self-audits. As the name implies, they are carried out by the domestic service itself. The domestic supervisors in the *In-house case* are mainly responsible for these self-audits. The supervisors go round the wards and physically check surfaces, walls, beds, and sanitary areas to ensure that the wards are free from dust. It is carried out weekly or at times, daily. If there are any under-performing areas then the supervisors have to bring this to the attention of the responsible domestics and the latter have to take necessary actions in order to rectify the problem. In the *PFI case*, the NHS Trust (client) and the PFI consortium carry out individual audits, simultaneously, to ensure performance of the contractor. The PFI contractor also carries out an audit similar to the *In-house case*. The PFI consortium and the NHS Trust adopt a point system when carrying out their audits. They allocate points to each and every area of the wards (depending on the level of risk involved in terms of control of HAI, e.g. very high, high, low, very low) and finally sum up the points to determine the total (out of 100 points). If the total is more than 90%, then the contractor's performance is very good.

The other types of internal audit in the *In-house case* are the ICT (Infection Control Team) audits. Some of the senior members of the infection control teams carry out these audits in order to check compliance of the domestic service with the requirements of the control of HAI. They check cleanliness in wards, cleanliness in sanitary areas, different waste segregations, staff compliance and hand washing procedures. The audits are carried out at least monthly.

Apart from the aforementioned audits, both the *In-house case* and *PFI case* have another PM approach in-use, i.e. the performance appraisal (PA). According to one of the domestic managers in the *In-house case,* performance appraisals and reviews have become a necessary part of the domestic service. However, due to time constraints, in both cases, it is limited to only appraisal and review of performance of domestic managers (including supervisors) not domestics. The domestic manager meets with their subordinates once a year and has a personal interview, approximately for one hour. The latter is asked about their job role, job satisfaction and any problems regarding their work. Apart from the performance appraisals, in the *PFI case*, personal development plans are also used as part of an on-going PM programme. This is also for domestic managers. As one of the domestic managers from the PFI contractor's side highlighted, it is a meaningful part of their career-planning process. It recognises domestic managers' contributions toward achieving organisational goals and identifies training and education needs. The *PFI case* also extends their use of PM by adopting programme evaluation techniques and benchmarking techniques in their service. The latter is mainly used to identify their current performance levels compared to previous performance levels whilst the former is used to review the performance of their programmes (e.g. effectiveness of training and education programmes for domestics).

4. Common approaches in managing performance in FM services - Questionnaire survey findings

4.1 Questionnaire survey details

Findings gleaned from the 26 interviews prompted the need to further investigate the most common PM approaches in-use in the control of HAI in facilities management services (specifically domestic services). A questionnaire survey was therefore carried out as the next step of the research study. All four different types of domestic services (refer to figure 1) were chosen for the questionnaire survey, i.e. in-house, outsourced, PFI and the balanced approach (a mix of in-house and contracted-out domestic service). The target population of the questionnaire survey was limited to only domestic managers and infection control team members across England and Scotland. A total of 412 completed questionnaires were received out of the 1304 sent out, giving an overall response rate of 31.60%. Frankfort-Nachmias and Nachmias (1996) state low response rate as one of the serious problems of a postal questionnaire survey. As they noted, the typical response rate for a personal interview is about 95%, whereas the response rate for a mail survey is between 20 – 40%. The response rate of this survey is therefore satisfactory.

The data collected from the survey was analysed using Statistical Package for Social Sciences (SPSS) version 12.0.

4.2 Questionnaire survey findings

As identified from the case study findings, much of the focus of performance management in the *In-house case* and the *PFI case* is on performance audits. However, it is understood from a thorough review of literature that number of other PM approaches which exist in organisations.

Undoubtedly, one of the most widely recognised PM approaches is the Balanced Scorecard (BSC). Developed by Kaplan and Norton, and popularised by the marketing efforts of major consulting companies, the phrase ‘balanced scorecard’ appears to have entered the management vernacular (Neely, 1999). Kaplan and Norton (1992) created the balanced scorecard to assist businesses in moving from ideas to action, to achieve long-term goals, and obtain feedback about strategy. The Balanced Scorecard identifies four fundamental perspectives: financial perspective; customer perspective; internal-business-process perspective; and learning and growth perspective. It expresses an organisation’s strategy as a set of measurable goals from the perspectives of owners/investors, other external stakeholders and the organisation itself.

The European Foundation Quality Management (EFQM) model is another popular model widely used in organisations. In the EFQM, the two main important criteria are the ‘enablers’ and the ‘people results’. The model consists of nine components, namely: leadership, people management, policy and strategy, resources, processes, people satisfaction, customer satisfaction, impact on society and business results. The assumption behind the model is that, excellent results with respect to performance, customers, people and society are achieved through leadership driving policy and strategy, people, partnership and resources, and processes (EFQM, 1999; as cited in Samuelsson and Nilsson, 2002). The model assists organisations to achieve business excellence through continuous improvement in the management and deployment of processes to engender wider use of best practice activities.

Likewise, there are several other approaches used by organisations in measuring and managing performance. Some of them are as follows:

- PQASSO (Practical Quality Assurance System for Small Organisations)
- the Big Picture (an organisational improvement framework and diagnostic tool for identifying strengths and weaknesses within an organisation or programmes of work)
- Investors in People (a national standard for improving organisational performance by training and developing people to achieve organisational goals).

All the above performance management approaches are a range of models and improvement tools that either provide a performance management framework for the whole organisation or support a particular aspect or area of performance.

A careful observation would suggest that some of these common approaches are used in healthcare organisations as well, e.g. BSC and EFQM. Besides, in the NHS, there is also a national Performance Assessment Framework (PAF) to assess performance in the NHS as a whole (NHS Estates, 1999), which is based on the BSC approach. The PAF highlights six areas of performance which, taken together, give a balanced view of the performance of the NHS: health improvement; fair access; effective delivery of appropriate healthcare; efficiency; patient/carer experience; and health outcomes of NHS care. The PAF is supported by a set of national headline NHS Performance Indicators (e.g. access, mental health, diabetes, cancer and coronary heart disease). Even so, currently, the PAF does not give much attention to infection control as part of their overall assessment in hospitals. In addition, it has also not given any particular attention to domestic services (and FM services as a whole).

Given the above discussions, a list of PM approaches (14) were put together, drawing on the literature and discussions with the participants of the case studies. These are given in Table 2 together with the overall mean scores and the rankings of the frequency of use of the PM approaches in the control of HAI in domestic services.

As table 2 results reveal, of the fourteen performance management approaches only the audits carried out by the domestic service is 'very frequently used' in domestic services (overall mean score is 1.62). It is further affirmed by its mode value being in the scale of 1. Four other approaches are also significant and fall in the category of 'frequently used' with mean scores in the range of 2.57 (audits by the Infection Control Teams) to 2.95 (patient satisfaction survey). Out of the nine remaining approaches, only three approaches are 'not frequently used', as they have mean values greater than 4. These approaches are the audits for ISO 9001:2000 quality accreditation, Balanced Scorecard and the EFQM Business Excellence model. Even though it was identified at the beginning of this section that the latter two are the most used approaches in organisations in-general (Neely, 1999), from a domestic service point of view, they can be identified as the least used approaches of PM as their mode values are 5 (i.e. not at all used).

Table 2: PM approaches in-use in the control of HAI in domestic services

Frequency	**PM approaches**	**Mode**	**Overall mean score**	**Rank**
Very Frequent	Audits by domestic service	1	1.62	1
Frequent	Audits by infection control teams (ICT)	2	2.57	2
Frequent	Environmental audits	3	2.58	3
Frequent	Audits by the National Audit Office	3	2.86	4
Frequent	Patient satisfaction survey	2	2.95	5

Frequently used PM

Fairly Frequent	PA for domestic managers	3	3.31	6
Fairly Frequent	Benchmarking techniques	3	3.37	7
Fairly Frequent	PA for domestics	3	3.44	8
Fairly Frequent	Personal Development Plans	3	3.48	9
Fairly Frequent	PAF by the NHS	3	3.74	10
Fairly Frequent	Programme evaluation techniques	5	3.87	11
Not Frequent	ISO 9001:2000	5	4.25	12
Not Frequent	BSC	5	4.41	13
Not Frequent	EFQM	5	4.72	14

Meaning of scale (frequency of use of the performance management approaches):

1 (Very frequent), **2** (Frequent), **3** (Fairly frequent), **4** (Not frequent), **5** (Not Applicable/not at all used)

5. Performance management in FM services – data synthesis

It is necessary for organisations to measure and manage their performance in order to know where they stand in terms of performance levels, to compare results with past performance levels or with others and to set goals for future improvements.

As mentioned in the earlier sections of the paper, the importance of domestic services (and facilities management as a whole) within the NHS should not be underestimated. Standards of cleanliness can vary enormously and have a direct influence on the quality of care received by the patients (NHS Estates, 2001). Therefore, PM should be an integral part of domestic service provision and best carried out with the full involvement of service providers. Robust approaches of PM should exist in domestic services across the NHS covering all aspects of cleaning and the control of HAI – from the activities of staff carrying out day-to-day cleaning tasks to the strategic responsibilities of managers engaged in the longer term planning of the service (Auditor General for Scotland, 2003).

From the case study findings, it was identified that several PM approaches, most of which are related to performance audits, are in place in the two cases (i.e. *In-house case* and *PFI case*). This may be due to the fact that audits have been the prime methodology for the assessment of service costs across departments and functions within Facilities for some years with national compulsory audit systems (Heavisides and Price, 2001). Even though, in this study, audits are taken as PM approaches, in reality it is only part of the PM cycle. The latter not only includes performance audits, but also performance measurement and performance control. According to Wikipedia (2006) 'audits' are independent review and examination of records and activities to assess the adequacy of system controls, to ensure compliance with established policies and operational procedures, and to recommend necessary changes in controls, policies, or procedures. It can be done internally (by employees of the organisation) or externally (by an outside firm). In the study reported in this paper, internal audits (carried out by the domestic services and infection control teams) appear to dominate the PM approaches. External audits such as environmental audits and audits by the National Audit Office also seem to be relatively common. These approaches, although essential for domestic services to ascertain snapshot reviews of the service and, at times, cost and output positions, are not geared towards measuring efficiency, efficacy and economy with respect to service provision. Further, it does not assist in continuous improvement. Thus, there is a need for domestic services to use rather more robust PM approaches that cover most aspects of PM. Balanced Scorecard (BSC) and EFQM are leading examples of robust approaches of PM. Although different, they share many common characteristics such as:

- They encourage whole-organisation thinking and management (Adair et al, 2003)
- They highlight the importance of effective stakeholder management, stakeholder integration, staff involvement and continuous improvement (Atkinson et al , 1997)
- They clarify the links between strategy, processes, and outcomes (Amaratunga et al , 2000); and, most importantly,
- They focus strongly on measuring and managing performance results

The Facilities Management 'Good Practice Guide' published by NHS Estates (2001), which has been designed to enable domestic services to assess their current performance in comparison with others, is integrated with the principles of EFQM. This is based on the premise that excellent results are achieved through the enablers of commitment, effective leadership, clear and realistic policies, good management of people and finance and the understanding and management of well-defined processes. Also the performance assessment framework developed by the NHS follows the principles of BSC. According to NHS Estates (1999), the use of the balanced scorecard allows organisations to get a more rounded view of performance by identifying different key elements of performance and understanding how changes in them may have implications for others. However, even though BSC and EFQM are thought to be the most used approaches in organisations in general, surprisingly, they are the two least used approaches in domestic services (refer to table 3).

The overall research findings suggest that the use of performance indicators and measures is very limited in domestic services. Financial performance is considered the prime performance indicator especially in the *PFI case*. This is mainly driven by the budget constraints occur in FM services in hospitals. Resources (including staff) are the other main indicator used by the domestic services in the control of HAI. An example of a performance measure used by the *In-house case* is also given as follows (see Table 3):

Table 3: An example of a performance measure

Description	Performance measure	Target	Signed by	Action plan
Beds are effectively cleaned and prepared for use with fresh clean linen	yes/no/not applicable	95%	ward sister/ auditor	(target and time scale)

The absence of a robust PM approach could be the main reason for the lack a comprehensive set of performance indicators and measures in domestic services. It was understood from the above discussions that most of the domestic services have only performance audits to gauge their performance. Even if they have other performance management approaches, most of them do not use its results to ‘manage performance’. For example, the domestic services do not feed back their performance results to the staff and managers, which can help to prevent repetition of mistakes. The domestic managers should not collect performance data simply because it is available, or because having large amount of data proves that they work. Instead, they should choose performance measures that can help describe the overall performance of their service, and directions towards the required goals and accomplishments. A robust performance management approach is therefore needed to enable the domestic managers to measure the effectiveness of all aspects of their working practices (both financial and non-financial). If these are not properly identified and measured, the domestic service, without a doubt, could be faced many challenges.

6. Summary and conclusions

Despite its importance, little has been researched or published in the areas of performance management in healthcare organisations, and even less so in the context of domestic services. There is evidence of a lack of common understanding of what is meant by performance, or how performance could be measured in practice, especially with regard to the control of HAI in domestic services. The main approach to performance management in domestic services is performance audit. The performance audits are either carried out by internal teams of the hospital (e.g. the domestic services or infection control teams) or external teams (e.g. the National Audit Office or environmental agencies). While the domestic managers, nationally, would agree that they are striving to improve their services in hospitals; the standards of performance remain extremely variable, mostly due to resource limitations such as budget constraints and staff shortages (because of high staff turnover and sickness absence) and tight time schedules. Besides, the lack of an overall yardstick (i.e. benchmark) to compare the variations in performance standards has exacerbated the problems in domestic services. A new mindset is, therefore, needed that moves away from the traditional one-sided ‘cost’ or ‘snapshot’ audits to a new multi-faceted approach of performance management.

A Reliability Based Approach for Management of Council Owned Buildings in Australia

Abdulkader Sharabah,
RMIT University Australia
(email: s3121930@student.rmit.edu.au)
Sujeeva Setunge,
RMIT University Australia
(email: Sujeeva.setunge@rmit.edu.au)

Abstract

With an aging stock of public buildings, development of innovative methods for management of risk of failure and optimizing of maintenance expenditure has become extremely important to Australian public work engineers. A major challenge in many sophisticated asset management systems is identifying the type and quantity of data required to establish a reliable predictive model for maintenance and renewal expenditure forecasts. With the high variability of condition data, a reliability based approach is more appropriate for predictive modeling. Another important observation made of traditional asset management systems is that the deterioration models are mainly a function of age. This has been observed to be unrealistic on many occasions.

The paper presents an innovative approach based on Markov process for deterioration modeling of buildings owned by local councils in Australia. The concept for the complete asset management model is presented with input data clearly identified. Using some preliminary data established from council records and consultation of experts, transition matrices for Markov process modelling have been established for major elements of council buildings. The complete process for deterioration prediction is demonstrated with a typical example.

Keywords: Markov process, Service life modeling, Infrastructure management, Risk management

1. Introduction

Management and sustainability of built infrastructure is an extremely important issue being addressed by many research organizations in the world. The research work funded by European communities lead the world in these areas as reported by Flourentzou et al [5], which are still continuing. There are several approaches reported in recent literature to address the issue.

These can be summarized as:

- Approximate methods where condition of different elements were rated A, B, C and D or 1, 2, 3, 4, 5 through condition inspections. Deterministic life cycle analysis is conducted assuming the time period of progression of deterioration to be fixed in one state (Hovde, [6]).

- Same as above with modifications for different exposure conditions and usage through fixed factors calibrated with data (ISO factorial approach Bamforth, [2], Tepley [13]).
- Reliability based methods using the discrete Markov chain for deterioration modelling.
- Reliability based methods using continuous Markov process (Maheswaran et al , [12]).
- Predicting life cycle of assets considering an integration of three drivers such as Market drivers, physical deterioration and functional obsolescence.

Out of the above, the most common approach used by the industry is a deterministic method based on condition data and fixed deterioration curves. However, these approximate methods lack the ability to account for uncertainties, which is essential to manage risk of maintaining assets to provide the required level of service delivery. Preliminary research at RMIT have indicated that to consider majority of the issues affecting management decision making for effective service delivery of councils a reliability-based approach incorporating some attributes of the ISO factorial approach and consideration of other drivers such as market and functional issues (Allehaux and Tessier, [1]) is essential. Use of Markov chain for deterioration modeling and decision-making is being explored at RMIT University in Australia to address this need.

Previous work on application of Markov process for deterioration modeling of structures have covered deterioration prediction of bridges due to chloride induced corrosion (Maheswaran et al, [11]), concrete structures (Lifecon, [11]) and separate elements of buildings (ISO1586, [9]). In no reported work, the application of Markov process has been attempted on a complex infrastructure systems comprising of a large number of elements. There have been some issues raised about the application of Markov process for predicting deterioration. The Markov curve has a shape which indicates flattening of the curve toward the end of the period whereas in real structures, opposite is observed. This is normally handled by predicting the last stage using a separate probability distribution (Lifecon, [10]).

2. Proposed methodology

2.1 Conceptual framework

In deterioration modelling the attributes of a model randomly change over time. A Markov chain is a probability model, which has a finite-state, for describing a certain type of stochastic process that moves in a sequence of phases through discrete points in time according to fixed probabilities. The process is stochastic because it changes over time in an uncertain manner. In this chain the future states are dependent only on the present state and independent from the any state before the present states. Markov chain consists of transition matrix and initial distribution. Transition matrix consist of a set of finite set of states S (1,1,3….n) and a propriety pi j to pass from state i to state j in one time step t. Time can be treated as either discrete (called Discrete-Time Markov Chain) or continuous (called Continuous-Time Markov Chain). In Markov chain the states are continuous and similarly the time could be either discrete (called Discrete-Time Markov Process) or continuous (called Continuous-Time Markov Process).

The first step for using Markov Chain modeling is evaluating the condition of building elements. This is to assess their physical, operational and maintenance conditions. For any building element a condition rating scheme constitutes of four ratings A, B, C and D where A represents new or nearly new element and do not required any maintenance action. D represents a condition which indicates that the element has to be replaced.

A	Excellent	The element is as new
B	Satisfactory	The element is sound, minor damage, minor maintenance required
C	Unsatisfactory	Major damage. Major maintenance required.
D	Failing	Serious damage. Element should be replaced

Although the deterioration processes evolve over continuous time, for simplicity, discrete time steps could represent these processes (such as the time of the building inspection). Hence in this paper Discrete Time Markov Chain will be considered as a model for predicting the life cycle for building element.

3.2 Discrete Time Markov Chain

Discrete Time Markov Chain is a finite-state stochastic process in which the defining random variables are observed at discrete points in time. This chain satisfies Markov property, which mean that given that the present state is known, the future probabilistic behaviour of the process depends only on the present state regardless of the past. If an element is in state "i", there is a fixed probability, Pij of it going into state j after the next time step. Pij is called a "transition probability". The matrix P whose ijth entry is Pij is called the transition matrix . Transition matrix consist of a set of finite set of state S (1,1,3….n) and a propriety pi j to pass from state i to state j in one time step t. In Markov chain pi j should satisfy two conditions

pij $\geq$ 0, and $\sum_{j} P_{ij} \leq 1$

This mean if an element is in state i, there is a (P_{ii}) probability that this element will stay in state i, and (1- P_{ii}) will move to next state j.

Present state at time t is i: $X_{t=i}$

Next state at time t + 1 is j: Xt+1 = j

Conditional Probability Statement of Markovian Property:

$$Pr\{Xt+1 = j \mid X0 = k0, X1 = k1,\ldots,Xt = i\} = Pr\{Xt+1 = j \mid Xt = i\} \text{ ---------(1)}$$

Discrete time means $t \in T = \{0, 1, 2, \ldots\}$

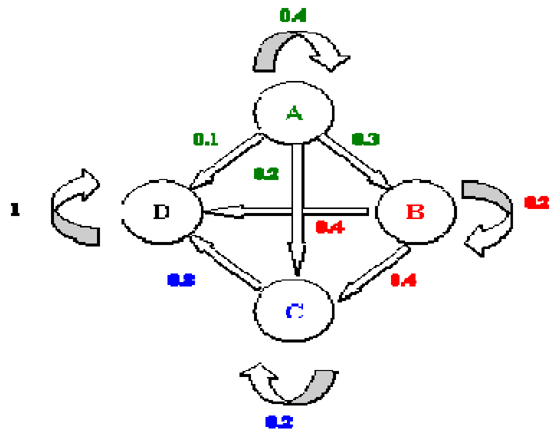

Figure 1: Transition from A to D

	State A	State B	State C	State D
State A	0.4	0.3	0.2	0.1
State B	0	0.2	0.4	0.4
State C	0	0	0.2	0.8
State D	0	0	0	1

Figure 2: Transition Matrix

Figures 1 and 2 show a typical transition matrix. The probability of an element being in a given state at a given point in time can then be depicted by the set of curves shown in figure 4.

An initial distribution 'v' is a single row matrix representing the number of elements in each state. In Markov chain after one time step the new distribution will be the result of multiplying initial distribution v by the transition matrix P

Distribution After 1 Step: vP

The distribution one step later, obtained by again multiplying by P, is given by $(vP)P = vP^{2}$.

Therefore distribution After 2 Steps = vP^2

Similarly, the distribution after n steps can be obtained by

vP^n

P2 is the two-step transition matrix for the system. Similarly, P3 is the three-step transition matrix, and Pn is the n-step transition matrix. This means that the ijth entry in Pn is the probability that the system will pass from state i to state j in n steps.

3.3 Prediction of the future cost

To predict the future cost for any element there are two kinds of costs: inspection cost, and element replacement cost or element repair cost, when the element makes a transition from one state to another.

Inspection cost is represented by the m-dimensional column vector

$$\mathbf{C}^{\mathrm{S}} = \left(c_1^{\mathrm{S}}, c_2^{\mathrm{S}}, \ldots, c_m^{\mathrm{S}}\right)^{\mathrm{T}} \qquad \text{---(2)}$$

Where each component is the cost associated with state i.

The cost of a transition is embodied in the m × m matrix

$$\mathbf{C}^{\mathrm{R}} = \left(c_{ij}^{\mathrm{R}}\right) \qquad \text{---(3)}$$

Where each component specifies the cost of going from state i to state j in a single step.

Expected cost of being in state i, (Jensen and Bard(2003)) is given by:

$$c_i = c_i^{\mathrm{S}} + \sum_{j=1}^{m} c_{ij}^{\mathrm{R}}\, p_{a\,ij} \qquad \text{---(4)}$$

Where, $p_{a\,ij}$ is the probability of maintenance action.

3.4 Absorbing states

An absorbing state is a state from which there is a zero probability of exiting. An absorbing state is a state j with pjj = 1. In other words, without any maintenance action, element which reached condition D will stay in that condition forever. Calculating the expected number of steps to absorption (elements pass from different states to end up in state D) can help to obtain an overall view about the estimated life cycle for that element.

To calculate the absorbing states

Let 0, 1, . . . , k be transient states and

k + 1, . . . , m – 1 be absorbing states.

Let qij = probability of being absorbed in state j given that we start in transient state i.

Then for each j we have the following relationship

$$qij = pij + \sum pirqrj , \ i = 0, 1, . . . , k$$

For fixed j (absorbing state) we have k + 1 linear equations in k + 1 unknowns, qrj , i = 0, 1, , k.

3.5 Long term behaviour of the Markov Chain

If there are recurrent actions taken to repair or replace the element in any state it leads to a steady state probability, which help to set a stable maintenance plan and expenditure.

Calculation of steady state probability can be given by,

Let $\pi = (\pi1, \pi2, . . . , \pi m)$ is the m-dimensional row vector of steady-state probabilities for the state space S = {1,…,m}. To find steady-state probabilities, solve linear system:

$$\pi = \pi P , \ Sj=1,m \ \pi j = 1, \ \pi j \geq 0, \ j = 1,\dots,m$$

3.5 Building Weights

In linking the Markov model to a decision making process, the building weighting method suggested by Zhang [14] is appropriate. He has divided building network(N) into each individual building (b) then divided the building into its constituting system (s) which is dependent on its components(c). Finally he divided the component to elements (e). He suggested that the overall performance of a building network is eventually dependent on the performance of all the buildings elements. For each element there is a composite measure (w) of key factors (distress, structural capacity, safety……… (Hudson et al [8]) Then he multiplied these weights by assigning value for these factors (v). The result will provide conditions index for this element.

$$CI_t^{bsce} = \sum W * V \text{ -(5)}$$

According to Zhang (14) there are four allowable management actions that could be taken for each element in any estate (a1=replacement, a2=major repairing, a3= minor repairing, a4 no action). These can be incorporated by substitution in to the same expression.

3.6 Application

A major challenge in application of the proposed concepts is the quality and quantity of the data needed. A probability distribution is needed for all major data categories for elements of an infrastructure system. With the support of the Brimbank City Council in Victoria, data are currently being collected for this purpose.

3. Demonstration of the method

Process is demonstrated with a division of a building into five key components:

- Building Structure (30% of building weight)
- Building Exterior (15% of building weight)
- Building Interior (25% of building weight)
- Building Services (20% of building weight)
- Building Site (10% of building weight)

(The weighting system has been developed in consultation with Brimbank City Council).

Figure 5 shows probability curves for the building external finishes with time. The time step considered is 1 year with external walls finishes reaching the condition ‘D” in 5 years. Transition matrix derived for the given probability curves are shown in figure 5.

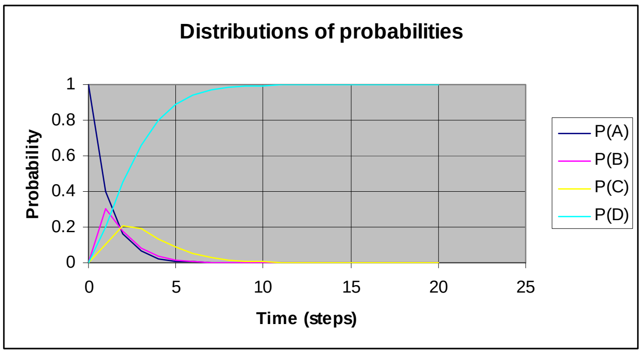

Figure 4: Cumulative Space

	State A	State B	State C	State D
State A	0.4	0.3	0.1	0.2
State B	0	0.2	0.4	0.4
State C	0	0	0.5	0.5
State D	0	0	0	1

Figure 5: Corresponding transition matrix

Once the transition matrix is developed for a given element type, the cost of maintenance can be calculated as a function of the deterioration curves.

The first step towards this is determining maintenance action matrix. Depending on the council asset management policy, different scenarios could be decided. In this paper a maintenance action has been assumed as per the following matrix

	State A	State B	State C	State D
State A	1	0	0	0
State B	0.7	0.3	0	0
State C	0.4	0.4	0.2	0
State D	0.5	0.3	0.2	0

Figure 6: Maintenance action Matrix

For example for elements in State C, 40% will be replaced to reach (State A), 40% will be repaired to State B, 20% will stay in State C

According to Zhang (14)

$sn=r*(M*P)^n$

Where

- sn – System performance
- M – maintenance policy matrix
- P – Transition matrix,
- r – Initial state vector.
- n – Time Step
- In external finish example (M*P):

	State A	State B	State C	State D
State A	0.4	0.3	0.1	0.2
State B	0.28	0.27	0.19	0.26
State C	0.16	0.2	0.3	0.34
State D	0.2	0.21	0.27	0.32

*Figure 7: (M*P)Matrix*

From this matrix future cost and status can be predicted as shown in figure 10 for ten time steps. Figure 8 shows the transient probability of the four conditions A, B, C, D against time step. In developing the figures, the cost is assumed to be in units with inspection cost assumed to be equal to one unit. Figure 9 shows the cost matrix for repair/maintenance.

Figure 8 also demonstrates reaching of steady state with a fixed maintenance regime. The asset manager can then identify the percentage of elements in each condition after reaching a steady state for a given maintenance regime. In this example, at the steady state, there will be 26.4% elements in condition A, 24.6% elements in condition B, 21.2% elements in condition C and , 27.8% of the elements in condition D. If this is not acceptable by the organisation, maintenance regime can be changed to reflect the strategic objectives of the asset manager.

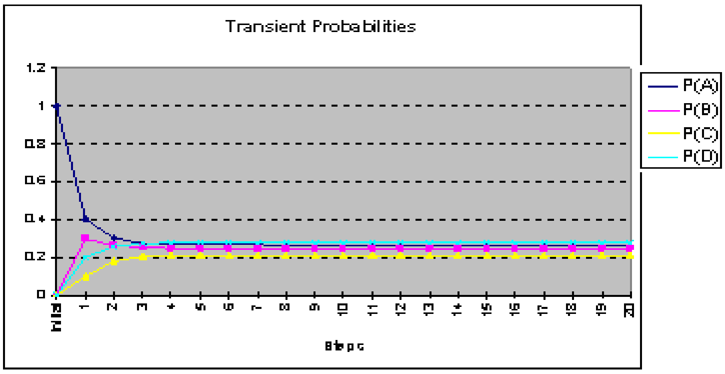

Figure 8: Future Prediction

	State A	State B	State C	State D
State A	1	0	0	0
State B	5	1	0	0
State C	7	4	1	0
State D	10	8	6	1

Figure 9: Repair/replace maintenance cost matrix

Time Step	State A	State B	State C	State D	Step Cost	Cum. Cost	NPW
Initial	1.000	0.000	0.000	0.000	2.400	2.400	2.400
1	0.400	0.300	0.100	0.200	5.507	7.907	7.406
2	0.300	0.263	0.181	0.256	5.783	13.690	12.185
3	0.274	0.251	0.203	0.272	5.852	19.542	16.582
4	0.267	0.248	0.209	0.276	5.871	25.413	20.592
5	0.265	0.247	0.211	0.277	5.876	31.289	24.241
6	0.264	0.247	0.212	0.278	5.877	37.166	27.558
7	0.264	0.246	0.212	0.278	5.878	43.043	30.574
8	0.264	0.246	0.212	0.278	5.878	48.921	33.316
9	0.264	0.246	0.212	0.278	5.878	54.799	35.809
10	0.264	0.246	0.212	0.278	5.878	60.677	38.075

Figure 10: Future prediction cost

To calculate the buildings weight all building elements should be inspected then overall building network weight formula could be applied. In this paper the effect of current physical condition of external wall finishes on the building weight will be calculated. Tables 1 and 2 present the assumed building element weighting for this example of external finishes.

Table 1: Weightings for Elements of Building Exterior

Building Exterior of the whole building weight	15.0%
External Walls	20.0%
Windows	13.0%
Doors	16.0%
Fire Escapes	16.0%
Roofs	16.0%
Steps/Ramps/Walkways	5.0%
Roofs	14.0%
Total Exterior weight	100.0%

Table 2: Weight factors for a given condition

State	Weight Factors
A	1
B	0.8
C	0.3
D	0.0

From the above tables, the discount weight for external walls finishes in state C can be calculated as = 0.3 * 20% * 15%= 0.9 %. However, according to figure 10, only 21.2% of elements will be in condition C. Therefore with the proposed maintenance action plan, we can say that the reduction of the building condition from 100%, due to deterioration of external finishes in condition C will only be 21.2% x 0.9% = 0.19%. The asset manager then can perform a similar evaluation for all the major components of the building to evaluate the reduction in building condition from 100%. This will allow him/her to establish a benchmark for the building condition.

4. Conclusions

The paper presented the concept of using Markov chain for deterioration modelling of buildings. Application of the methodology considering a fixed maintenance regime and an associated cost was presented. The methodology is quite powerful in establishing the relationship between an established maintenance regime and the future cost. This is then incorporated into the decision making through a building weighting method which can be used to enhance the outcomes of the Markov analysis process. Whilst the method requires a significant initial investment to establish :

- The deterioration matrix
- Maintenance regimes and associated costs
- Building weighting,

once the method is established, self calibration can be incorporated into the information system making the functioning of the system quite smooth. The concept is currently being implemented with a project funded by the CRC for Construction Innovation at RMIT University.

Abstract

The product-service paradigm requires a shift in focus for many engineering disciplines, forcing them to change from providing products to providing products and associated services. Such a shift is likely to present several challenges to the built environment due to its inherent organisational fragmentations and through-life discontinuities. This paper presents a preliminary conceptualisation of the product-service paradigm as seen from a built environment perspective. The proposed PPU model represents the meta-roles and the information flows, considered as key to sustaining the product-service concept within the built environment.

Keywords: product-service, PPU, knowledge management, through-life management, built environment, incentive flow-down, requirements flowdown, learning from use

1. Introduction

Engineering companies are perceived to be going through a paradigm shift, from providing products to total service business models. This paradigm shift, often referred to as product–service, requires the shift in focus from designing and selling physical products, to sell a system of products and services, which are jointly capable of fulfilling specific client demands. Complex engineering projects include large scale defence infrastructure (e.g. aircraft carriers), aircrafts, large scale construction infrastructure projects, software development etc. This does not, however, preclude the idea that product service paradigm is equally significant for engineering endeavours of a lesser scale (e.g. customised housing). Leiringer and Green [1] note that although in the construction sector, the development of the PFI (Private Finance Initiative) market has had a significant impact on how many companies win work, the extent to which construction operating companies have become more service-oriented is debatable.

This paper is an interim outcome of the ongoing EPSRC / ESRC funded 'Grand Challenge' project, Immortal Information and Through-Life Knowledge Management [(KIM) - http://www.kimproject.org]. KIM involves twelve UK universities, including eight EPSRC funded Innovative Manufacturing Research Centres and spans a number of industries including aerospace and construction. Its aim is to address a perceived shift among engineering and construction companies from product to a product-service paradigm, and to explore the implications of this for knowledge management.

This paper is aimed at presenting a preliminary conceptualisation of the product-service paradigm as seen from a built environment perspective. Firstly this paper will briefly introduce the concept of product-service paradigm. Secondly the specific research focus of the paper is presented. The procurer, provider and user (PPU) model is presented next as a preliminary conceptualisation of the product-service paradigm for the built environment. The conclusion and the way forward are presented as the final part of this paper.

2. Product-Service paradigm

Product service paradigm presents a different approach to the way engineering systems are considered. It puts the user at the heart of the system. This means that the satisfactory servicing of user requirements is a key priority, and in most cases dictates performance measurement. For example Maloney [2] states that there is no natural demand for the construction product; the demand for the constructed product is derived from the intended use of the facility. This entails that design, production, operation / use, maintenance / refurbishment, are no longer separate activities, but are part of a seamlessly integrated, multi-agent, multi-cyclical, long term supra system. Therefore the focus on whole life cycle of the product's ability to provide sustained services is an essential requisite. It requires new business, operational and information system models that extend many years into the future.

A shift from product to product service presents many challenges from several perspectives, as outlined in the following sub- topics.

2.1 Product development

Designing for product-service is extremely challenging. One of the main issues that needs addressing is 'how do we know what users of the facility need in several decades?'. As the user needs are strongly influenced by what happens in the broader external environment, predicting such future requirements become further challenging. Designing systems to co-evolve with the changing circumstances may be an avenue worth exploring in this regard. Need to support globally distributed design, production and use are also key considerations.

2.2 Information management

The through-life aspect of product service paradigm means that information will be continuously generated. McMahon [3] observes two issues that requires attention. Firstly, how to ensure that the information created and the knowledge gained during the design and subsequent operation of the product are recorded and organised in such a way that they are accessible through the whole life of the product, and of most value in product support and in further design work. This could mean that approaches to avoid information overload, and continued harnessing of the power of information technology developments, needs to be considered. Secondly, how to ensure that the organisations involved adopt the most appropriate strategies to maximise their performance in the new business approach.

2.3 Procurement

The success of through-life support depends heavily on the integration of a network of organisations such as specialised component suppliers, subcontractors and service providers. This network of organisations, the context and the environment within which it operate will change with time (e.g. staff turnover, technology changes such as hardware and software, user needs, market & social changes etc.). It is vital that procurement and contractual arrangements move towards providing integrated solutions rather than pursuing bounded interests.

Leiringer and Green [2] observe that the move from product delivery to also providing additional services can hardly be considered a paradigm shift. They contend that firms in a whole host of sectors would claim to have been operating in this way for a long time. However, they note that the trend for product manufacturers to add various forms of services to their offerings is clear. There are many reasons why a firm would want to undertake a transition towards this end. Such a change could be mobilised as a means of securing future business, or it could be initiated by a change in public procurement strategy.

3. Product-Service in the built environment

Blyth [4] notes that the relationship between organisations and buildings is dynamic and continuously changing. The predominant approach to building procurement has tended to assume that a building project is a self-contained event. The CRISP consultancy commission study [4] shows how buildings are part of a far bigger 'organisational project' and subject to rapid change;

- Adaptability and flexibility are not necessarily 'explicit' priorities during the briefing, design and construction of buildings, they often seem to be implicit;

- The definition of a 'flexible' building depends on the organisation using it, therefore it is difficult to brand buildings as flexible or inflexible;

- It is more important to test whether a building can respond to a variety of different demands rather than worry about trying to predict what those demands might be;

Blyth [4] states that the CRISP study did not reveal a particular pattern of change in the one building considered, but it did reveal how operational constraints can undermine flexibility strategies built into buildings;

- The operational constraints of an organisation need to be clearly articulated in the brief since they can easily conflict with physical building systems, therefore compromising the ‘flexible’ elements of a building;

- The study revealed that different stakeholders had different interests in adaptability and flexibility. It seems to matter most to those who manage buildings because they have to grapple with everyday management problems. Users probably notice it when things go wrong and designers only when they are asked to investigate a failure;

- Decisions affecting adaptability and flexibility are taken by different people during the briefing, design and construction process. Unless these are coordinated, the result may be a less adaptable and flexible building than anticipated;

- Maintenance of key client and design team personnel from when a building is designed and built to its adaptation several years later provides valuable continuity. For example, the cost of controlling infection in the environment may not be an explicit operational cost;

- Hidden building operating costs may distort perceived costs of running buildings;

- The procurement process is a vital link in achieving a coordinated strategy for matching user needs and building responses. Anecdotally, clients of PFI projects perceive that they are expected to pay a ‘high price’ or a ‘penalty’ to PFI contractors if they want to make changes. This suggests that clients are finding it difficult to transfer a major area of risk.

The CRISP study also reveals the importance of adaptability and flexibility, and noted that there is more work to be done to gain an understanding about how it impacts on organisations and buildings. It offered four specific further research directions;

- Longitudinal studies of buildings to reveal how the politics of decision-making in an organization affect decisions about buildings, and consequently how the building responds to changing organisational needs;

- Research into the cost and benefits of adaptability and flexibility by tracking how a range of buildings has responded over time and how the occupiers have changed;

- Comparative studies of a number of buildings into how they have responded to organizational change to identify common themes;

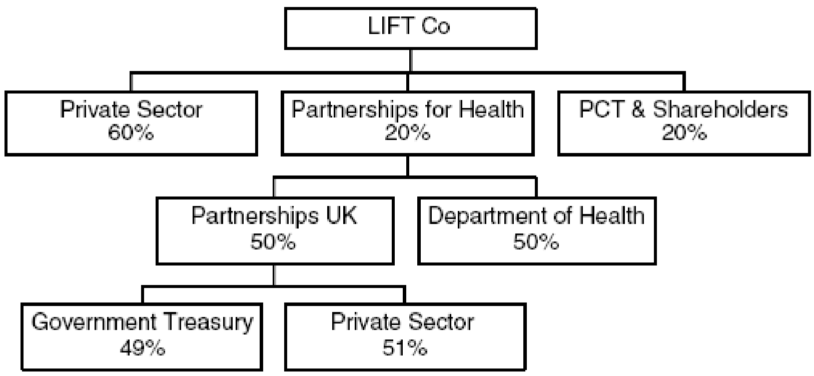
- A study of the speed of organisational change during the development of a building project from early briefing to handover to identify the effects on decision-making about the new building.

4. Stakeholders and through-life issues

Product – Service approach to the built environment (i.e. buildings, public and private infrastructure and other associated services) requires significant attention being paid to the involvement of stakeholders and their roles, over time. Since built products are expected to last for a comparatively longer life span, through-life issues related to how the buildings and the intended services evolve, bears a significant impact on the successful leverage of the product-service business models.

4.1 Stakeholders of the built environment

The presence of many stakeholders in the planning, design, construction and operation of the built environment is well documented. They range from national to local government agencies, designers, builders and facility managers to end users. Increasing focus on partnering and private financed initiatives for procuring public infrastructure such as healthcare, education and transport, has to a certain extent resulted in increased upfront mapping of the stakeholder engagement. Figure 1 below is such an abstract attempt to indicate one such high level stakeholder involvement in UK healthcare sector.



LIFT – Local Improvement Finance Trust

Figure 1: Ownership arrangement of LIFT companies [5]

Siriwardena [6] through a literature review demonstrated that although PPP/PFI context provides a case for product-service in the built environment, the origins and the diffusion has not followed with the same intention. Governments avoiding the use of public money to provide public services, and privatisation seems have been the driving forces for these schemes. The lack of emphasis on life cycle considerations, especially the maintenance / refurbishment aspects, and adaptability and flexibility within the PFI literature indicates the need for further research on the readiness of PPP/PFI schemes to act as the built environment's response to the product-service challenge.

4.2 Life cycle issues

Most buildings and infrastructure are built to last for a considerable period of time. Brand [7] quoting architect Chris Alexander notes "A building's foundation and frame should be capable of living 300 years. That's beyond the economic lifetime of any of the players." [7, p 194]. Koskela [8] highlighted several approaches namely life cycle assessment, product-service systems, product-life cycle management, systems engineering, integrated solutions, public-private partnerships, design studies and concurrent engineering, which claim to indicate life cycle considerations in engineering contexts. In a systematic comparison of the mentioned approaches, it was concluded that major focus tends to be directed towards the front-end of the life cycle, especially to redesign and design decisions, which conventionally are considered of crucial importance, especially from a life cycle view point, with relative less attention on the subsequent use, maintaining, refurbishment and disposal.

Multiple life cycles can be observed within built products over time. They include component life cycles, space and functional life cycles, physical life cycles and legacy life cycles. Table below provides an explanation these terms.

Table 1: Multiple life cycles of the built environment

Type of life cycle	**Description**	**Examples**
Component life cycle	Refers to the life span of various components in buildings	Lifts, electrical equipment, doors, windows
Space / functional life cycle	Refers to the life span of a particular space in a building. When the intended use of the buildings changes, these spaces will attain different names	Warehouse / storage spaces in buildings changing to office space over time
Physical life cycle	Refers to the safe technical life of the building	Buildings above this period are considered not safe and are generally demolished
Legacy life cycle	New buildings are built with many in existing sites, but carries the same names, and	Demolition and re-building of primary schools in UK Demolition and re-building of

	are its associated history	sports stadiums such as Wembley stadium in London

It could therefore be contented that conceptualising product-service for the built environment requires the consideration of changing roles of its stakeholders over time and the whole life cycle issues, tied together by information and incentive flows that facilitate continuous product and service delivery improvements.

5. Procurers, Providers and Users (PPU): towards a meta-role model

The main aim of the PPU model is to encapsulate the changing roles of the stakeholders over time, and the resulting shifts of the flows between them. It is important to note that over time, the roles (the type of vested interest) that stakeholders have is likely to change. Therefore, the terms procurers, providers and users are time dependent (meta) roles. The arrows in the diagram indicate the various types of flows that are considered as important for the sustaining effective product –service delivery in the built environment.

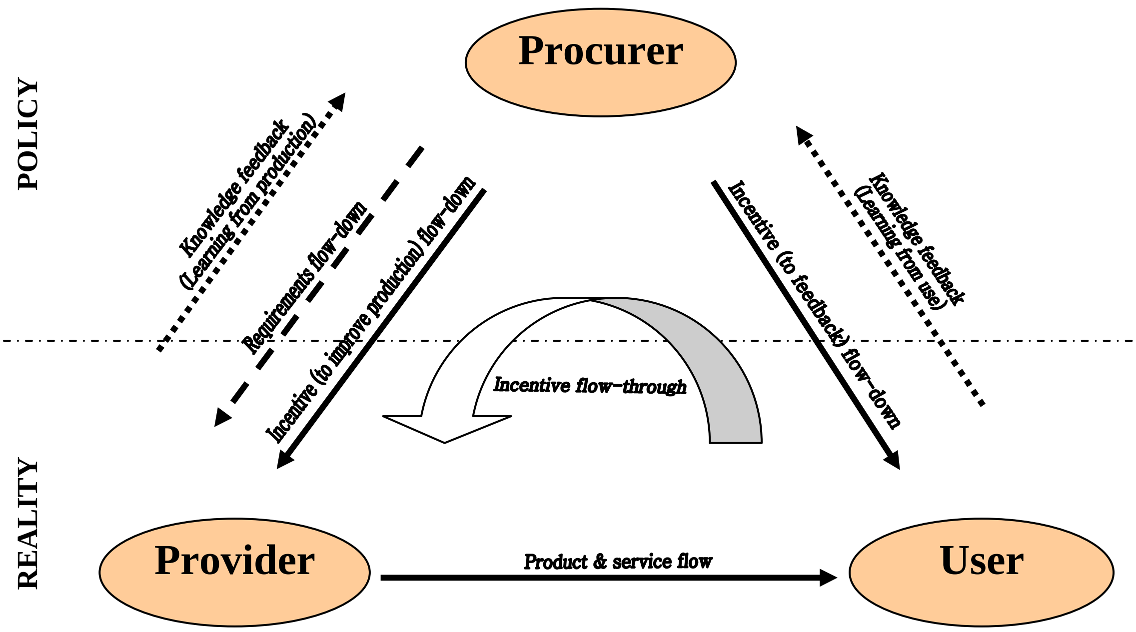


Figure 2: PPU model

The following table provides a brief explanation of the meta-roles indicated in the above diagram.

Table 2: Meta Roles of the PPU model

Meta Role	**Description**	**Examples**
Procurer	Procures the products and services needed to provide main public services	Central Govt., Local Govt. National Health Service
Provider	Provides design, production, maintenance and refurbishment services	Designers, Builders, Facility Managers, sub contractors
Users	Uses the built facility as part of its resource base to deliver the business objectives	

The following table illustrates one possible way in which the meta-roles are likely to change over time, in the primary education sector in UK.

Table 3: Changing stakeholder roles over time

	New build	Periodic service maintenance (5 years after)	Refurbishment (20 years after)	Demolition (60 years after)
Procurer	Central Govt & Local Govt.	Primary school	Local Govt.	Central Govt. & Local Govt.
Provider	Framework contractors	FM company	Contractors	Demolition contractors
User	Primary school	Staff and pupils of the school	Primary school	

6. Conclusions and way forward

The perceived shift from product to product-service is likely to present several challenges to the firms and stakeholders of the built environment. Aspects such as product development, information management and procurement need to take into account the changing roles of the stakeholders over time. Consideration of through-life issues also adds further complexity. The Procurer, Provider and User (PPU) model is suggested as a possible way to encapsulate the complex relationships and meta-roles, paving the way to guide future research of this project. The research team is currently engaged in field work studies in healthcare and education sectors, and hope to report the findings in forthcoming publications.

Asset Management Planning for Developing Countries

Peter Styles,
Independent Water Consultant
(email: peter_styles@msn.com)

Abstract

The built environment consists not only of buildings but also of the essential support infrastructure such as highways and utility services. These assets frequently fail because of inadequate maintenance and investment as they reach the end of their useful lives. Only with a system for the replacement of assets, when they become obsolete or beyond reasonable repair, can those responsible ensure the effectiveness and efficiency of their businesses. The methods employed in asset management have much in common with the accountants' approach to depreciation but differ significantly in that condition and performance are the prime drivers rather than age and fixed asset lives. The setting up of an asset management system is well within the capabilities of any organization and much time and effort can be saved if the tasks are dealt with in a structured manner. Thus the primary tasks can be organized into a sequence involving: inventory compilation, grading and costing. The resulting information can then be used to provide a valuation of tangible assets and forms the basis to drive the rehabilitation and replacement aspects of a capital investment program.

Keywords: asset management, inventory, grading, valuation, investment

1. The Context of Asset Management

1.1 The Meaning and Objective of Asset Management

Whilst the term 'asset management' may have different meanings to many people, its meaning in the context of the constructed environment is simple: "to ensure, through refurbishment or replacement, the continued delivery of intended outputs to the beneficiaries of those outputs". The receivers of the benefits are often referred to as 'customers' though in the case of a building they may be occupiers or tenants.

Asset management is not about the short term maintenance of assets which is a regular process concerned with keeping the asset in functioning condition for the operators. Nor is it concerned with the day-to-day management of the assets i.e. facilities management.

1.2 The External Context

Funding agencies, who bankroll much construction in developing countries, have recognized that, with finite resources, they cannot continue to pour unlimited funds into the premature replacement of neglected assets. This view is well founded and along with the concept of 'appropriate technology' coincides with the new morality of only providing that which can be sustainably managed thus avoiding problems for the next generation. There are many others who have a part to play in ensuring that constructions are sustainable. **Fig 1** shows the players in relationship to each other and the investment programme. It also introduces the asset inventory which forms the basis of asset management planning.

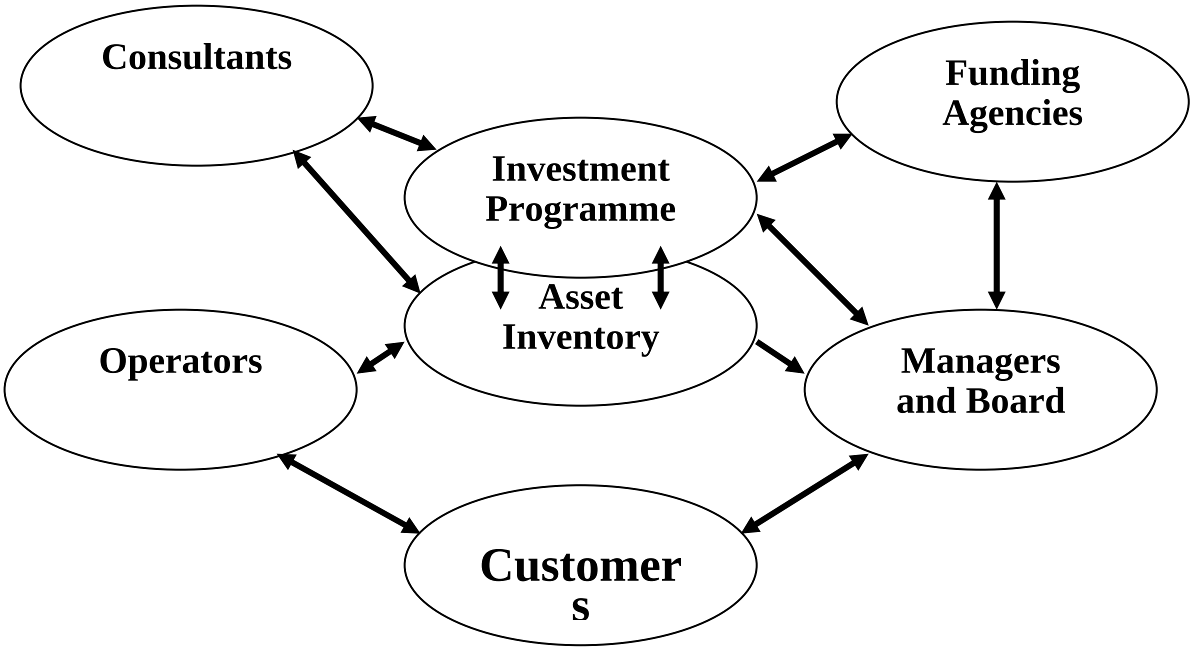

Figure 1- Stakeholders in the Built Environment

The term 'customers' is used to denote those who benefit from the output of, or use of, the constructed asset(s).

1.3 The Internal Context

An asset management plan needs to be administered and placed within a structure which is organized to deliver the planned benefits to the intended 'customers'. These 'capital' functions, which relate to the spending of funds, include:

- Strategic planning
- Asset management planning

- Project appraisal

- Investment programme management

Whilst some of the detailed tasks may be contracted out (e.g. to consultants), all of them must be present and effective for the outputs of a construction programme to be sustainable. The more advanced processes (especially design, tendering and construction) are normally outsourced.

The need for an asset management plan (AMP) is most evident in those areas where maintenance and rehabilitation have been neglected resulting in a lower level of service to customers. Where the care of buildings and operational plant is not properly managed, early renewal becomes the only option to abandonment. Thus heavy (re)investment is undertaken by funding agencies often on a (roughly) ten year cycle and little is done locally between interventions.

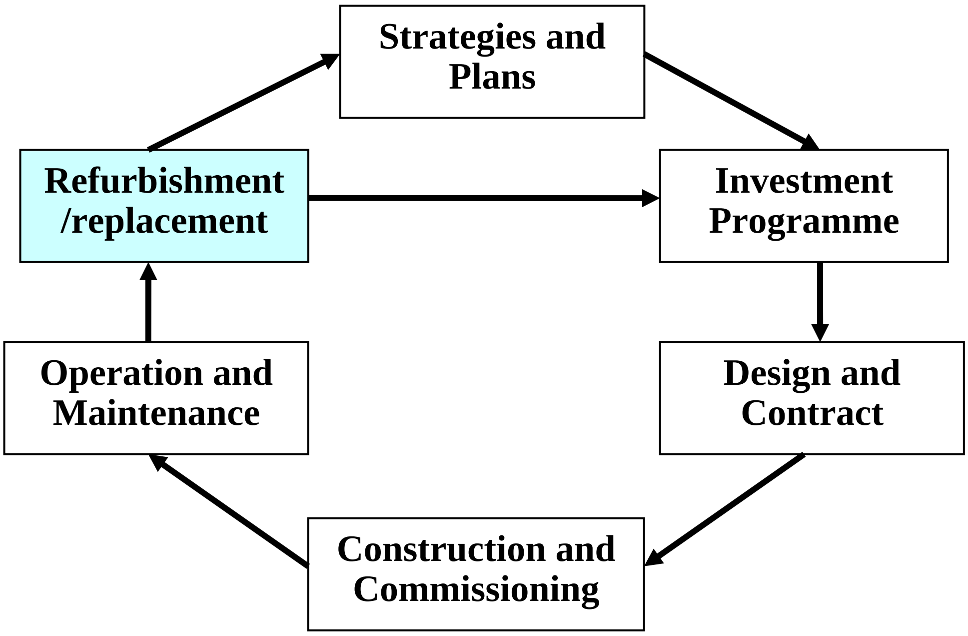

Figure 2- asset management covers replacement / refurbishment within the construction cycle
.

Asset management looks after the replacement and refurbishment of the assets by planning to keep them in operation before they wear out. Thus it can easily be seen to be an essential part of any sustainable system in the life of infrastructure - build only that which you can look after - and then look after it! [3].

1.4 Benefits

The benefits of an AMP can be listed:

- Provides a central inventory with unique references
- Provides consistent information on capacity, throughput, condition etc.
- Links investment with service levels through performance grades
- Provides a valuation of tangible assets
- Plans and prioritizes investment
- Can be used to measure and record improvement

Whilst these are not detailed here one can see immediate benefits such as the ability to feed consultants and project planners with up-to-date asset information.

2. Outline of the Methodology

An AMP consists mainly of an inventory of assets - usually contained in a database - and a computerized system that aids valuation and compiles output in such a way that the priorities for investment can easily be recognized and acted upon. **Fig 3** shows the typical layout of an AMP and the interaction of the components.

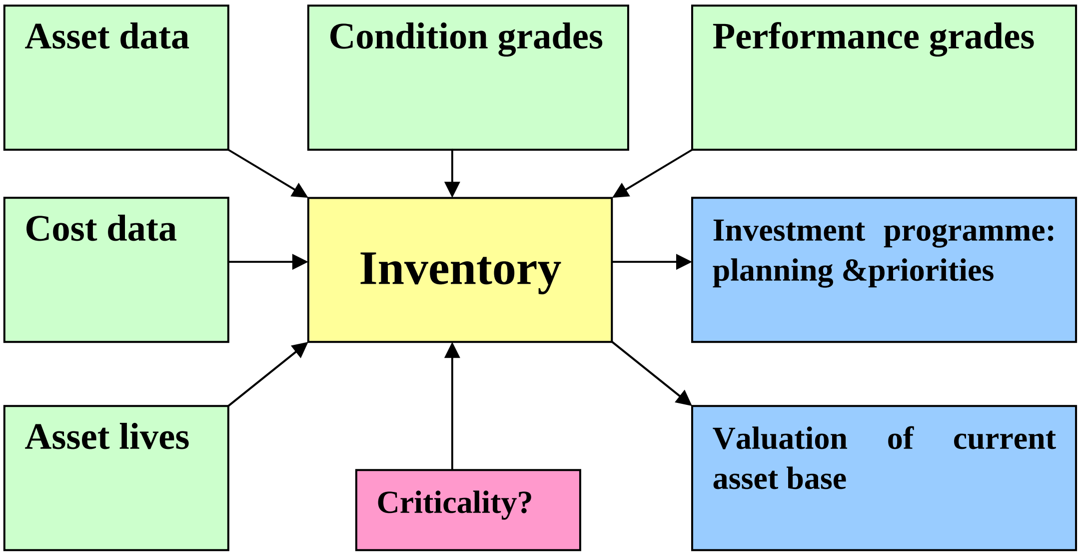

Figure 3- Typical AMP structure

The methodology involves firstly compiling a set of databases and spreadsheets - the inventory of all tangible assets. The most important assets will vary according to the nature of the business of the organization, thus for a water utility they would include dams, boreholes, treatment plants pump stations and pipelines but for a power company it would be generating plants, sub stations and power lines. A rail operator would wish to list lines, stations, goods yards and rolling stock etc.

After setting up a basic inventory the next stage involves assessing the condition of the assets, following this performance is assessed, and thirdly replacement costs are estimated. When these data are complete the condition and performance grades are compared with a look-up table and a percentage remaining asset life (RAL) is assigned. This, multiplied by the replacement cost gives the current asset value (CAV). The condition and performance grades, with the nominal asset life, can then be used to assign priority to the assets for replacement or refurbishment.

The remaining part of this paper is concerned with more detailed advice on setting up an asset management plan based on the author's TRAMP system developed for use by a water utility in the Caribbean [1].

2.1 Inventories

The organisation of the asset inventory is crucial to the success and efficiency of the planning process. Trying to put all of the data for an organisation (large or small) into a single inventory is fraught with difficulties. The data to be stored are so varied that a single table or set of related tables may soon become over complex and littered with empty fields. Whilst the data can be collected into a series of spreadsheets, there are considerable benefits in using a database which allows sorting and filtering to be done much more easily.

Data can be collected at three levels:

- plant or location level (one entry per site)
- process level (typically 10 entries per site)
- unit level (typically 100 entries per site)

Using a water utility as an example, the plant level would consist of a water treatment plant being considered as a single entry. The process level would take each part of the plant which performs a different process separately. At the unit level each pump, screen, channel etc. is included individually. The choice of the level to be used is crucial to data efficiency. The upper level is too crude and the lower level too detailed thus the middle level is normally recommended. Each component process is included in the inventory and separately graded.

As will be seen later in Section 3, it is also necessary to differentiate between structures and mechanical/electrical components as they have very different asset lives and often exhibit very different condition grades.

2.2 Organization

The development of a relational database may be beyond the means of many small organisations. There are therefore two approaches that can be taken:

- build up a single set of related tables in one inventory
- organize the data into separate types so that a series of 'flat file' tables are created

In the initial stages of development the latter option is by far the simplest to adopt and this is recommended. If, at a later stage, a relational database is required then it can be compiled relatively quickly as the problems concerned with the data collection and storage will, by then, have been resolved.

Any organisation will tend to have different types of asset. The typical division of data types, this time using an airport as an example, is given below:

- Land
- Runway
- Taxiways
- Terminals
- Traffic control
- Other buildings
- Fuelling facilities
- Mobile plant
- Miscellaneous e.g. vehicles, furniture, computers etc.
- Safety and security assets

2.3 Data collection

Data collection is a classic 'chicken and egg' conundrum. How do you know what to collect until you've tried? The resolution of this problem involves the development of the methodology first, then the use of test data to debug it. This will give a practical solution quickly but not the final structure; a database should be seen as a living entity and subject to further refinement.

The preferred process is to define an objective methodology and then collect data, at first subjectively and then objectively. In practice data collection tends to be undertaken before the methodology has been defined as this is the easiest thing to do and progress will be apparent even if the whole exercise has to be repeated. The use of a small sample of test data results in a robust system being reached quickly.

The primary entries can be set up from existing tables of assets, where they are available, and the principle exercises of correlation will be based on getting information from previous reports, system maps and from field operators.

Each of the organisation's functional areas will have existing data to be compiled as the basis of the inventory and there will be gaps, duplications and errors. The key to correcting these errors involves firstly cross-checking the data of the master sets against each other. Secondly a system of 'partial publication', to interested parties, is undertaken with selected areas highlighted for them to check. As each stage of data collection is completed the draft table is circulated to field operatives and corrections are requested. During this process most duplications and omissions are quickly picked up and the use of multiple names can be rationalised.

The procedure for compiling an AMP is listed below:

1. collect all existing data on systems and assets
2. structure database tables and headings
3. collect sample condition grade data
4. test database with sample data and design input formats (forms)
5. undertake condition grade assessments (site surveys) and compile database
6. develop levels of service (LoS) standards
7. undertake performance grading with operational staff and enter data
8. input asset lives
9. input cost data
10. design queries and output reports
11. run valuation and prioritization reports

2.4 Data Fields

A database requires that data fields be defined before storage can take place. The simplest guide to the likely field requirements is to look at the existing data sets or examples that have been produced elsewhere. It is simple to spot the recurring data requirements involving references, names, location, size, material, type, etc. These form the basic set up for the data tables and are revised once the initial system is compiled. At this stage the best way to debug the tables is to use a set of test data involving at least ten records.

2.5 Hardware and Software

The issue of hardware is now fairly simple as the preferred solution will always be to use the simplest system capable of doing the job. A single PC with printer is normally quite sufficient.

The wide availability of M/S Windows makes it a suitable platform and both XL and Access may be used in compiling the asset inventory.

There also exists, at this point, an obvious opportunity for a commercial or academic organization to build an on-line system which can be remotely accessed from anywhere in the world. Whilst the major benefit would ensue from providing clients with a ready made system, the greatest advantages could ensue from the parent organisation's ability to use the data for research.

Such a development could also be of great benefit to the funding agencies in being able to collect data in a standardised format.

3. Condition Grading

Condition Grades (CG's) are simply a consideration and recording of the soundness of an asset in terms of wear and tear. 'Condition' describes its structural integrity and safety, and is therefore that which can be seen. CG's do not take into account the performance of the item as performance grades are assigned separately. A sample grading structure is appended.

3.1 Survey

Condition grading is normally best undertaken by a team of two persons - one who is responsible for data collection and one who operates and maintains the assets on a daily basis. This ensures both local input and consistency. Simple forms are used to gather the information.

Condition grades for buried assets (e.g. cables and pipelines) are more difficult to assess initially and the first set of grades may be have to be subjectively applied. These are gradually improved as failure data, and survey information, linked to assets or areas, becomes available.

3.2 Grades

Each asset identified in the inventory must be given a condition grade. In the case of assets which consist of structural and mechanical/electrical (M&E) parts two grades are required. The basic grading system is simple and must be used consistently to aid comparisons with others:

Table 1- Basic grading system

Grade	Description
1	Excellent
2	Good
3	Adequate
4	Poor
5	Awful

Grades of 1 to 5 ranging from excellent (1) to awful (5) are assigned. To get a meaningful profile the grades must reflect the full range of assets. The appendix shows a more detailed description of typical generic condition grades.

4. Performance Grading

Performance grades (PGs) are a measure of how well an asset performs its allotted task and will reflect its reliability; it is not a measure of how new it is. Nor is it a measure against the specification but a grading against the required output **as perceived by the customer**. Assets can be in excellent condition but are not achieving the required output and vice versa. This is particularly true in the case of inappropriate technology (i.e. the wrong tool for the job).

In order to perform this task properly it is necessary, first, to define the 'levels of service' (LoS) that the customers receive or expect to receive. Thus grade 1 (excellent) represents the aspiration of the organization and grade 5 (awful) the lowest level of service that is supplied to a significant population.

A single PG will suffice for each asset/process, there being no need to differentiate between a structure and M&E components.

4.1 Levels of Service

The 'performance' must be assessed or graded against a set of defined criteria or 'levels of service'. These are set in relation to customer perceived performance rather than against abstract design criteria - in simple terms - i.e. does it do the job?

Thus, performance will reflect the loading, configuration and type of unit being employed and not its condition. A LoS scheme for a railway company could include:

- Punctuality
- Availability capacity
- Frequency of service
- Safety in transit

To allow a reasonable spread of occurrences within the grades the performance definitions should take account of the local situation.

4.2 Grades

Grades 1 to 5 are assigned within the same general approach - ranging from excellent (1) to awful (5) - as for condition. Again performance is assessed at the process level though a whole plant may be given a single grade at first and then refined as the information improves. Thus passenger delays at an airport could be graded 4 but on subsequent examination it is determined that the baggage handling system is to blame for the problem and the grade is then assigned to that process to reflect this.

Performance grading is undertaken between asset management staff and the managers responsible for the assets' operation. This ensures that consistency is maintained. An example of LoS for power supply is given below in Table 2:

Table 2- Sample level of service criteria

CS1	Continuous Supply
CS2	Supply for 100 hours per week
CS3	Supply for 50 hours per week
CS4	Supply for 25 hours per week
CS5	Supply less than 25 hours per week

5. Valuation

The valuation process is based on the replacement cost or ‘modern equivalent asset value’ (MEAV). This is reduced to a percentage of its full value according to the condition and performance of the asset to give the current asset value (CAV).

5.1 Asset Lives

The first step in the valuation process is to add the asset lives to the inventory. Typically structures will last 50-60 years and M&E plant about fifteen. A list of asset values, based on those used by the accountants, is developed for use in calculations within the database [2].

5.2 Modern Equivalent Asset Value (MEAV)

The inventory itself will not yet provide the valuation of the assets necessary for business purposes. In order to achieve this it will be necessary to add cost data for each type of asset. The replacement cost is used and it this can be based on size bands for the type of asset. The MEAV represents the cost of replacing the asset with an equivalent one that is capable of performing the required task and is thus based on throughput rather than capacity.

This same cost data can be used both in the valuation and, later in an investment programme as the first estimate for budget purposes. It is also useful in strategy development as the basis for appraisal of options. The values are based on cost curves or matrices as is most appropriate for each type of asset and are updated annually in a stable currency.

5.3 Remaining Asset Life

The remaining asset life (RAL) is calculated as a percentage from a look-up table contained within the database. A typical example is shown below:

Condition Grade

Table 3- % Remaining Asset Life (RAL)

Perf. Grade	**1**	**2**	**3**	**4**	**5**
1	**100**	**75**	**50**	**25**	**10**
2	**85**	**65**	**40**	**20**	**7**
3	**70**	**50**	**30**	**15**	**4**

4	**60**	**40**	**20**	**10**	**2**
5	**50**	**30**	**10**	**5**	**1**

5.4 Current Asset Value (CAV)

Calculating the current asset value is now simply a matter of multiplying the MEAV by the %RAL, e.g:

Say MEAV = $100,   Condition grade 4,   Performance grade 3

Refer to Condition / performance matrix for %RAL

Remaining Asset Life = 15%

Therefore CAV = 100 x 0.15 = $15

The database is configured to provide a report which summarises the replacement and current values thus giving a statement of the organisation's assets in operational terms for comparison with the book values contained in the accounts.

6. Rehabilitation and Renewal

The next step is to use the information gathered in order to be able to give priorities for renewal and refurbishment to all projects. Similar assets may be grouped into action plans for improvement or areas may be chosen for levels of service improvements. These should all be part of documented strategies - but that is another subject.

6.1 Priorities and Investment Program drivers

The prioritization of rehabilitation schemes can be set up, initially using the remaining asset lives:

- Calculate Remaining Asset Life (RAL) in years

  RAL(yrs) = AL(yrs) * %RAL /100

- Produce provisional priority listing based on RAL (in ascending order)

This can be further refined if assets have been assigned a 'criticality index', which represents the importance of the asset within the overall system, however, in most cases, it is valid to assume that the assets with the greatest throughput will be the most critical.

All that remains is to cross check which assets are already contained within projects, action plans or other initiatives:

- Annotate projects with project or strategy names

- Allocate remaining projects to the investment programme or to new action plans as part of overall strategy

7. Planning for the future

Long term planning may now be undertaken using the information from the database and associated strategies. Using the remaining asset lives, crude estimates of renewal rates can be produced as a basis (no more) for predicting annual expenditure on renewal and refurbishment. This, with prioritization of the investment programme, represents the next phase of development.

8. Conclusions

An asset management plan is essential for the long term sustainability of any group of constructed assets.

Whilst there is expensive proprietary software available, a simple system can be set up using a PC and a simple database. The methodology described can be adapted by any organisation or business for its own use.

It is not necessary to specify all of the requirements before commencing work; a gradual development involving the users of the data is preferred. Subjective judgements of grades may be made initially and later replaced with objective data based on measurement and observation.

To be effective, both condition and the performance of assets (based on levels of service) should be recorded.

The generic grades (1=excellent to 5=awful) are fundamental and must not be altered, however, the detailed grade descriptions should be amended to reflect the local environment and levels of service.

Research into the reasons for asset failure would be useful to determine the reasons why asset management is not universally understood and employed. With this understanding the sustainability of the constructed environment may, hopefully, be improved.

The time may now be opportune to create an easy-to-use, on-line asset management system within an academic or commercial organization concerned with the sustainability of the built environment.

9. Appendix

Sample condition grades for mechanical & electrical plant

CG	**Grade**	**Asset Description**
1	Excellent	• in 'as new' condition • electrically safe • requires only routine maintenance
2	Good	• shows only superficial signs of wear and tear, protective coatings still intact, no corrosion • electrically safe • infrequent minor failures
3	Adequate	• all components functioning well • significant signs of wear and tear, minor corrosion • electrically safe • regular minor failures but no major failures
4	Poor	• still functioning but requires substantial maintenance to be kept going • electrically safe but marginal • regular minor failures and occasional major failures
5	Awful	• frequent (monthly) breakdowns, not working or abandoned • electrically unsafe

(email: litay@bond.edu.au)

Abstract

Despite its rapid development in the last decade, infrastructure asset management today suffers from an identity crisis as the definition and scope of infrastructure asset management remains a contentious issue. The purpose of this paper is to trace the evolution of infrastructure asset management and evaluate the current practices. In the process, a framework defining the scope of infrastructure asset management is proposed. Notwithstanding the systematic approach that many organisations adopt to manage their infrastructure assets, this paper argues for the need to adopt a more integrated and strategic perspective in the light of the dynamic contemporary operating environment.

Keywords: Infrastructure, asset management, strategic, performance

1. Introduction

Infrastructure asset management (IAM) has emerged as a discipline to provide a more systematic approach to the management of infrastructure assets. The benefits of an improved asset management process envisaged by IPWEA [1] are enhanced customer satisfaction, governance and accountability, risk management, financial efficiency and sustainability. The purpose of this paper is to propose the need for an integrated and strategic approach to infrastructure asset management through examining the current practice of infrastructure asset management in the industry. The paper opens by discussing the development of IAM. The next section evaluates the current practices of IAM and puts forward a framework that encapsulates the scope of IAM. Finally, the paper reviews the current challenges to the management of infrastructure and concludes by arguing for the need of a more integrated and strategic approach to the effective management of infrastructure asset.

2. The development of Infrastructure Asset Management

The concept of IAM is not a new but an evolving idea that has been attracting the attention of many agencies operating and/or owning some kind of infrastructure assets. One of the first comprehensive adoptions of the term “asset management” was during the privatisation of water utilities in Great Britain in the 1980s [2]. In Australia, “asset management” made its way into the public works in 1993 when the Australian Accounting Standard Board issued the Australian Accounting Standard 27 – AAS27. Standard AAS27 required government agencies to capitalise and depreciate assets rather than expense them against earnings. This development has indirectly forced organisation managing infrastructure assets to consider the useful life and cost effectiveness of asset investments. The Australian State Treasuries and the Australian National Audit Office was the first organisation to formalise the concepts and principles of Asset Management in Australia in which they defined asset management as “ a systematic, structured process covering the whole life of an asset” [3]. This initiative led other Government bodies and industry sectors to develop, refine and apply the concept of asset management in the management of their respective infrastructure assets. Hence, it can be argued that the concept of IAM has emerged as a separate and recognised field of management during the late 1990s.

However, IAM is more than a new management buzz word. There are still many questions about what asset management really means today. In comparison to the other disciplines such as construction, facilities, maintenance, economics, finance, to name a few, infrastructure asset management is a relatively new discipline and is clearly a contemporary topic. The primary contributors to the literature in IAM are largely government organisations and industry practitioners [1, 3-8]. These contributions take the form of guidelines and reports on the best practice of asset management. Hence, the literature tends to lack well-grounded theories. To-date, while receiving relatively more interest and attention from empirical researchers [2, 9, 10], the advancement of this field, particularly in terms of the volume of academic and theoretical development is at best moderate. A plausible reason for the lack of advancement is that many researchers and practitioners are still unaware of, or unimpressed by, the contribution of IAM towards the overall performance of the asset. A more compelling argument against the progression of the concept of asset management is the general lack of an integrated framework that defines what IAM. This is expected as the discipline of infrastructure asset management continues to evolve.

Infrastructure investment and maintenance decisions in the past were made in accordance to tradition, intuition, personal experience, resource availability, and political considerations. There was no systematic application of objective analytical techniques in such decisions. To address this deficiency, many asset management systems with inherent investment analysis capabilities have been developed, in practice, and have been used for years. These asset management systems focus on databases, asset inventories, technical models and other analytical tools. Most of these systems are used to monitor conditions through which the organisations then plan and program their projects on a ‘worst off’ basis. Success was often measured in terms of controlling backlogs in the short term, not in optimising system performance or minimising user impacts [10]. In addition, many such asset management approach ignore a systematic wide focus that involves bringing a variety of assets under one single entity [11] [2]. The focus is more on individual assets rather than the long-term asset management needs of an organisation.

Due to the relatively long life-cycle of infrastructure asset, the consideration of a whole life cycle approach is becoming increasingly important in infrastructure investment decisions. This shift has forced the design, procurement and decision-making on infrastructure asset to be based on whole life value [12]. Life cycle cost is the total costs throughout its life including planning, design, acquisition, installation, operation, maintenance, refurbishment, and disposal costs attributable to owning or using the asset [13]. Thus, life cycle approach is becoming central to asset management by taking account of the total cost of an asset throughout its life [6, 7]. This strategic view is important as it takes a long term view of infrastructure performance and cost. Furthermore, IAM is driven by policy goals and objectives based on performance and sustainability. These strategies are analysed in terms of objective assessment of costs, benefits and level of service provided to ensure that the present needs are met without compromising the ability of future generations to meet their needs [7].

3. Current Practice and Scope of Infrastructure Asset Management

The preceding discussion suggests that the management of infrastructure assets has traditionally been approached from a *functional* perspective i.e., to ensure the optimum performance of the asset. However, there is evidence to suggest a broadening of this perspective to include infrastructure asset as an important business *resource* that is capable of contributing to the organisation's goals. In this context, the main goals of infrastructure asset management are to achieve maximum return on assets, optimise total cost of ownership and fulfil safety and environmental requirements. In other words, asset management can and should contribute to the broader corporate goals. Clash & Delaney [14] found that the organisational and business foundations as well as disciplined decision making are far more crucial to achieving the capabilities of effective asset management than that of a full-blown asset management system alone; thus alluding to the extended role of IAM. For asset management to become a true value-adding pursuit within a corporate framework, it must be primarily concerned with filling a strategic role, i.e. asset manager must be proactive not reactive in their approach [15]. They must be able to forecast the needs of their organisations and make forward plans that will support the aims of the organisation in the future.

In the age of competition, especially with more involvement of the private sector in the provision of infrastructure, there is an increased emphasis on the management of valuable assets. In the private sector, a performance-based asset management strategy is needed at the heart of all asset management approaches. Practitioners in private IAM want and need a better understanding of its meaning, impact, and value to their organisations. The goals of IAM must reflect business goals i.e. infrastructure asset must generate revenue and ensure that business needs are met without compromising the competitiveness of the business in future. As a result, innovative ways of managing assets are being practiced. The scope of IAM activities extends from the establishment of an asset management policy and the identification of service level targets which match stakeholder expectations and legal requirements, to the daily operation of facilities required to meet the defined level of service [1].

In this regard, it can be said that infrastructure asset management responsibilities are today numerous and complex. Consequently, many individual asset management processes and practices have evolved, each with its own focus. Due to the diverse guides issued by different organisations, infrastructure asset management as it stands currently can mean different things to different organisations. As a result, different organisations have adopted different aspects and principles of asset management in accordance to what asset management means to them, in practice. To this end, a framework that synthesises the current practice of infrastructure asset management is useful for forging a common platform upon which future discussion on infrastructure asset management can be based.

The scope of infrastructure asset management can be depicted through four quadrants (see Fig.1). The north and south axes represent a strategic vs operational perspective. The operational aspect of asset management involves the practical business of keeping the infrastructure in working conditions. The strategic perspective of infrastructure asset management considers the integration of the user needs, the environment and the business functions of the organisation in the longer term. The east and west axes are anchored on each end by distinguishing asset as a function versus asset as a resource to business. Asset as a function concentrates on what can be done to improve the performance of the asset, i.e., asset optimisation. Asset as a resource on the other hand, considers how asset can best used to enhance business goals.

	Strategic		
	• Strategic planning • Stakeholders relationships • Organisation structures **4**	• Risk Analysis • Asset Strategies • Market Analysis • LCC **2**	
Resource			**Function**
	3 • Return on Asset • Financial, Human • Asset quality • Performance Measure • IT Systems	**1** • Asset Database • Decision system • Condition monitoring • Life prediction	
	Operational		

Figure 1- Infrastructure Asset Management (IAM) Framework

Quadrant 1: Asset as a Function (Operational)

This group of IAM practices concentrate on improving the maintenance of infrastructure asset to prevent failure. They are concerned with providing an asset that is reliable and in optimum condition. The activities include the development of infrastructure asset databases, decision systems, condition monitoring, and life prediction system within an asset management decision support framework.

Quadrant 2: Asset as a Function (Strategic)

The asset management activities in this quadrant aim at improving the performance of infrastructure assets over a longer term. They are concerned with not only the provision of infrastructure assets for operation, but also how the asset can perform and provide value for money over a longer period of time. This includes issues concerning the individual asset procurement and management, overall asset portfolio and the maintenance of an asset strategy. The typical activities include life cycle costing, demand analysis, risk analysis (financial, technical and environmental), etc.

Quadrant 3: Asset as a Business Resource (Operational)

This quadrant considers asset management processes related to achieving organisational productivity and quality enhancements. This includes cost minimisation initiatives, compliance with local environmental goals, asset profitability and quality, internal organisation efficiency (e.g. IT, operations, human resources, finance etc.).

Quadrant 4: Asset as a Business Resource (Strategic)

This quadrant focuses on asset management responsibilities that supports and creates value to all stakeholders. It typically involves the development of an IAM strategy by undertaking market trend analysis, asset demand analysis and stakeholder consultation. Various infrastructure asset options are then weighed and considered for their ability to contribute towards the organisation's business goals.

4. The future of Infrastructure Asset Management

The discussion thus far has illustrated the development of IAM from a narrow functional perspective to a broadening role in enhancing business goals. The expansive scope of IAM was summarised through a proposed IAM model. It is cogent and timely to end this paper by considering the future challenges to IAM.

In recent years, the challenges that most industrialised economies face relates to those of building and managing infrastructure assets. On the one hand, infrastructure is vital for supporting economic growth, meeting basic needs, facilitating mobility and social interaction, on the other, environmental pressures in the form of changing climatic conditions, congestion and so on are likely to increase, turning the spotlight firmly on the inherent tensions between the imperative for further infrastructure development and the quest for sustainability [16].

Accountability has emerged as a requirement for any organisational structure, public or private. Those in charge of economic resources, such as infrastructure must give account of their stewardship, irrespective of whether the transactions and resources in question are those of a government or a private sector entity [17]. Van der Mandele et al [18] suggests that there are four main groups of stakeholders involved in the provision of infrastructure: users, service providers, government, and the general public. Each of this group has conflicting demands from one another. Users are constantly looking for better service level in terms of speed, capacity, security and reliability. Their main objective remains one of identifying the most cost efficient way of securing a high quality service [19]. Service providers are constantly looking at how they can cater to the demand of these users efficiently so as to maximise the return to their shareholders. They will always look at how operation cost can be minimised, and how to increase capacity and reliability of the infrastructure assets. Government is concerned with how to regulate the infrastructure asset so that it can support the economic development and yet is accessible to all population. [20, 21]. Accountability on the use of public fund to build, maintain and regulate the infrastructure assets is also a top priority. The nexus between use of infrastructure assets and the physical environment is the area of concern for the general public. This relates to noise, air pollution and a host of other environmental issues. With so many stakeholders involved, infrastructure asset provision becomes a matter of prioritising these demands, and deciding how these demands can best be met with the least compromise on organisational goals.

The existing literature has also provided other challenges of infrastructure management currently faced in the industry. These challenges are: The need to accommodate continuing growth to support the economic and social developments of the nation [16, 20]; Significant parts of infrastructure are ageing and nearing the end of their economically useful lives [22]; Current funding commitments are either inadequate or yet to be identified, to support the substantial costs of renewal and replacement [22]; Current planning and political processes do not provide the necessary long term focus [22]; Only limited infrastructure information is available in some key areas [22]; The increasing sense of vulnerability of society and its economic structure because of perceived rise of terrorism [16]; The continuing integration of economies and systems, for example through the increase globalisation and trade in goods, services and information [16].

Moreover, globalisation is intensifying economic and other linkages among countries making it increasingly necessary to plan, develop and finance infrastructures across national borders. The key players too change over time, as the roles and responsibilities of the public and private sectors shift and evolve. In this challenging environment, infrastructure owners/providers need to focus on stewardship to meet the expectations for quality including safety characteristics, operational efficiency and durability and accountability as guardian of infrastructure assets. Asset manager must be responsible, accountable, open, consistent and ethical in the management of asset concerning the level of investments in assets, the benefits and costs that arise from the investment and how well the assets are maintained and managed. Asset management decisions need to be based on a proper evaluation of options which take into account all costs and benefits over the life of asset, and incorporate an explicit analysis and determination of an acceptable level of risk [23]. This allows for more transparency in decision making and improves the process and accountability for capital and recurrent works. Hence asset managers must adopt a more holistic, integrated and structured process of maintaining, upgrading, and operating physical assets in a cost effective way [24, 25].

For this to happen, infrastructure asset management should be an interdisciplinary and comprehensive business strategy integrating finance, planning, engineering, construction, personnel, economics and information management. It should include all the dimensions proposed in this paper. In other words, IAM must not be approached only from a functional perspective but to also incorporate infrastructure asset as a important business resources from a more strategic perspective. It is a process for ensuring the requirements of organisations, users and other stakeholders are clearly understood and integrated into an asset management framework that optimises the outcomes achieved from policy and investment decisions [4].

5. Conclusion

The practice of infrastructure asset management has broadened in scope and complexity. Due to the lack of an integrated framework, it has led to an unsatisfactory state of confusion in practice and research. The contentious issue of defining IAM is a stumbling block to the advancement and accumulation of the IAM knowledge base. This paper has reviewed the development of IAM practices and formulated an IAM framework that categorised the practices into 4 quadrants. Most organisations have concentrated their IAM practice in one or two of these quadrants. However, with the increasingly challenging operating environment, such disparate practice of infrastructure asset management may not be sufficient to create maximum value and contribute to business success. Consequently, there is a need to adopt a more integrated approach to IAM through the incorporation of all the dimensions proposed in this paper. Only then, can infrastructure asset management be satisfactorily accountable to the different stakeholders.

Abstract

Management of solid waste has become as a major problem in Sri Lanka due to lack of proper separation, collection and disposal systems and insufficient legal framework. Among the sources of generating solid waste, residential developments are paramount importance. Over the past few years, considerable growth has taken place in the real estate sector particularly in terms of condominium developments due to high growth of population, urbanization and scarcity of lands in urban areas. The amount of waste that is being collected within these entities is higher than the individual residential houses and manner in which it is disposed and collected is different and complicated. Therefore it is important to manage and dispose solid waste in an effective way to reduce the environment burden as well as better hygiene living environment within condominiums.

The main purpose of this research was to review the existing garbage disposal systems, and improving functionality while enhancing the occupants' satisfaction. The survey was conducted by taking 130 occupants in private sector middle income apartments with response rate of 69%. The results revealed that certain drawbacks and inconveniences associated with the existing mode of garbage disposal. Further it was recognized the importance of design and operation guidelines which relates to the garbage disposal.

Key words: Customer Satisfaction**,** Garbage Disposal System, Condominiums, Demanded Quality, Quality Function Deployment

1. Background

1.1 Introduction

Solid waste management has emerged as one of the important areas of urban policy planning and management in all over the world with the population and urban migration. The United Nations conference on the environment and development held in Rio, in 1992, affirmed that environmentally sound waste management is one of the major issues that need to be tackled for maintaining the quality of the earth's environment and to achieve sustainable development. At present, the disposal of solid waste is becoming as severe logistic and cost consuming issue in many countries including Sri Lanka.

Due to high generation of solid waste in past two decades with the industrialization and urbanization, Sri Lanka is experiencing many environmental and health problems that aggravated by absence of proper management system and lack of forward anticipation and planning. And also no actions were taken to cater future demands [1],[2]. Further they have highlighted that the infrastructure and resources for waste collection are lacking in most part of the country, so uncontrolled scattering and dumping of garbage is wide spread.

Over the past few years, considerable growth has taken place in the real estate sector particularly in terms of condominium developments due to high population growth, urbanization and scarcity of lands in urban areas. Disposal of waste from these entities is arguably more complicated [3]. De Alwis [4] points out ,the per capita generation of solid waste has increased an average of 0.75 kg per person per day in 1986 to about 1kg person per day and the expected value in the year 2010 is 1.25 kg per person per day. Since there are hundreds of families have been living Colombo, sources of generating waste in high-rise apartments will become as a critical issue. Present situation is the most government formed condominiums and some of the private ones handled garbage inefficient and ineffective manner. According to Samarajeewa [5], there is a higher level of dissatisfaction with the method of garbage disposal in both public and private sector in Colombo Metropolitan Area (CMA).

1.2 Manipulating and Waste Handling in Condominiums

The domestic solid can be classified as garbage, rubbish/trash, ashes and bulky wastes [6]. Major difference between waste from high-rise buildings and single family units is the manner in which it is disposed and collected. In Hong Kong, conventional and automated refuse collection systems are commonly used in residential developments [7]. Though several modes of waste disposals are incorporated still operating improper systems and standards in place with regard to solid waste in most of the countries. There is no single approach has been accepted as the best method for waste management due to community and waste diversity. Most of solid waste professionals realise that ideal way to minimise the stress on disposal systems is to reduce the amount of waste that is produced. Thus reduction, reuse and recovery before disposal are vital to enhance the above concept. Reduction is using of fewer disposable goods. Reuse is using items again after initial consumption. Recovery is recapturing the material or energy value of the items at its highest point.

Handling, separation, storage and processing are critical steps of solid waste at the source before they are collected. This is applicable to condominiums as well. In high- rise buildings handling methods depend on the storage location and collection method. Basement storage, Outdoor storage/mechanized collection and specially designed vertical chutes are common garbage modes that can be identified in those entities. Both positive and negative impacts exist with the aforementioned systems.

1.3 Legal aspects behind Solid Waste Management

In order to execute and maintain any system in a disciplinary manner, there should be a well structured legal frame work. Under the Apartment Ownership Act (Amendment), no.39 [8], there are no strict provisions pertaining to the solid waste management within the apartment itself. But when applying for the registration of condominium plan, the common amenities should be in the satisfactory level. According to the guidelines provided by city planning division at Colombo Municipal Council, in order to get the building approval, applicant should submit the following documents with the design.

- In house collection methodology
- Waste minimization techniques
- Temporary storage methods
- Waste transfer system to the final transfer location
- Storage methodology

However to evaluate the aforesaid factors there are no certain parameters, procedures or standards than used merely as guidelines. The ‘Waste Management Zonal Concept’ is one of the strategies which was identified by the authority. Under this required rules, by-laws and guidelines have been formulated for waste segregation, collection, cleaning, transportation, and transferring, processing and final disposal of waste. However, theses rules, by-laws and guidelines are not being currently implemented and are only drafted rules for public comments.

Therefore, existing waste disposal methods which are being used in high-rise buildings, governing legal framework behind the solid waste management and its impact to the environment are key areas that need to pay more attention to design proper modes of garbage disposal.

1.4 Research Objective

The developers’ lack of understanding of user requirements and paying too much attention on profit maximization, usually results in a low quality product [9]. While developing the design, more consideration should go on basic amenities and maintenance to optimize the end user requirements. The research paper is planned to do opinion study on effective design and operational guidelines for the solid waste management system in the middle income apartments while satisfying the end user requirements.

2. Research Methodology

2.1 Data Collection

The survey was conducted by taking 130 occupants in private sector middle income apartments in CMA with response rate of 69%. The questionnaire consisted of nine (9) attributes of a garbage disposal system related to the functional and quality aspects, which were included based on the findings of pilot survey and literature. Same attributes were used to assess importance among the designers with response rate of 72%. Further interviews and participatory approached were used to support the questionnaire surveys.

2.2. Data Analysis

Based on a Likert scale of 5 to 1 [where 5= very important; 4=important; 3=somewhat important; 2=less important; 1=not important at all] the average degree of importance given by the respondents was calculated using Formula (1) [10];

$$\text{Degree of Importance} = \frac{\text{Sum of all the scales given by respondents}}{\text{No. of respondents}} \quad \ldots\ldots\ldots\ldots\ldots \quad (1)$$

Similar formula was used to calculate the average level of satisfaction. [where 5=extremely satisfied; 4=satisfied; 3=neutral; 2=dissatisfied; 1=extremely dissatisfied]

The standard deviation was determined to measure the dispersion of the data about the mean. Using the mean values and standard deviations computed from the data, a hypothesis test (t-test) was carried out to identify the factors which were significantly greater than 3. For this test, the null hypothesis was taken as H_0: $\mu \leq 3.00$, and the alternative hypothesis, as H_a: $\mu > 3.00$, where μ was the population mean of the corresponding factor. The t-test was performed at 5% significance level (alpha = 0.05) and the critical t – values for the sample were taken as 1.96 and 1.74 for occupants and designers respectively [11]. The results of the hypothesis test are given in Table 1.

Quality Function Deployment (QFD) methodology was evaluated in this research as a strategy to realize the importance of the customer in order to identify the demanded quality of solid waste management. House of Quality (HOQ) is the heart of the QFD (See Figure 1) and the name is obviously due to its shape [12]. Once the attributes of customers (voice of customers-VOC) matched with technical/design requirements (voice of designers-VOD), the design targets could be determined from the HOQ.

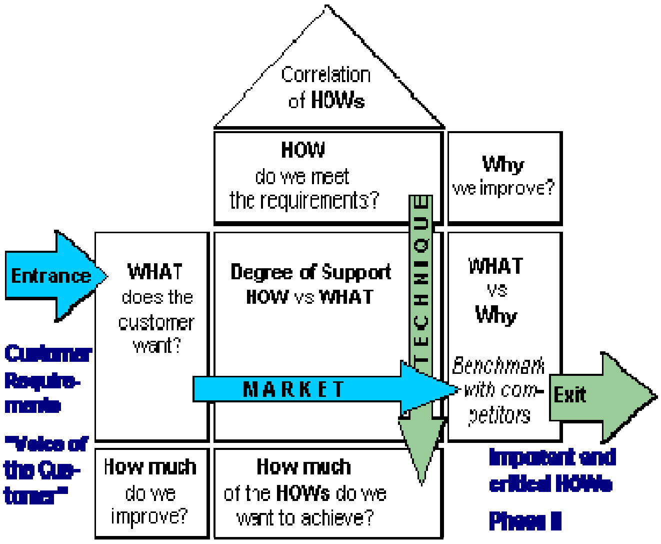

Figure 1: Basics of House of QualitySource: www.noweco.com

3. Results and Discussion

3.1 Degree of Importance and Level of Satisfaction

Basically, from occupants' point of view, satisfaction occurs when outcome meets or exceeds the users' expectations. Dissatisfaction occurs when a negative discrepancy is present between the users' anticipated outcome and the actual outcome. Data presented in Table 1 revealed that all the attributes are identified as critically important by both occupants and designers.

Table 1 – Attributes of garbage disposal system which are significantly not satisfied

Item	Attributes	Satisfaction (Occupants')		Importance (occupants')		Importance (Designers')	
		Mean	t-score	Mean	t-score	Mean	t-score
A	Sufficient space for service area	0.28	-27.80	4.27	16.88	4.61	24.04
B	Convenience of collection points at each floor	2.62	-4.35	4.43	24.34	4.44	18.92
C	Eliminate bad odours	2.41	-6.64	4.76	38.75	4.67	30.00
D	Effective collection and temporary storages at each floor level	0.28	-27.80	4.04	8.97	4.56	20.37
E	Ease of transfer to final storage within premises	1.92	-13.66	4.82	45.22	4.56	20.37
F	Effective final storage method	2.17	-10.16	4.59	29.32	4.61	24.04
G	Regular collecting and transferring solid waste to final storage	0.32	-23.29	4.51	28.68	3.94	12.05
H	Regularly collect by statutory authority	2.87	-1.76	4.62	31.74	3.89	9.49
I	Precautions to deal with accumulated solid waste due to failure of statutory authority	1.89	-11.40	4.62	28.02	4.50	22.05

There is no significance difference between the data derived from the occupants and the designers. However, occupants are highly dissatisfied with all the factors. It was revealed through unstructured interviews, the importance of indoor environment to users. This aspect is further justified by above statistics. Among the attributes given higher importance, C, F, H and I are closely related to the quality of the internal environment.

3.2 Expected Quality Vs Perceived Quality

Simply, the quality gap is determined the mean difference between degree of importance (expectation of service) and level of satisfaction (perception of service performance) of each attribute. The gap measure is managerially useful and provides a direct, clear sign of how to make the proper decision. The reaction of respondents in terms of their satisfaction regarding existing garbage disposal have been presented in Table 2.

Table 2- Attributes with Quality gap between expectation & satisfaction of occupants

Item	Attributes	Mean	Mean	Quality Gap
		Level of Satisfaction	Degree of Importance	
A	Sufficient space for service area	0.28	4.27	3.39
B	Convenience of collection points at each floor	2.62	4.43	1.81
C	Eliminate bad odours	2.41	4.76	2.35
D	Effective collection and temporary storages at each floor level	0.28	4.04	3.76
E	Ease of transfer to final storage within premises	1.92	4.82	2.90
F	Effective final storage method	2.17	4.59	2.42
G	Regular collecting and transferring solid waste to final storage	0.32	4.51	4.19
H	Regularly collect by statutory authority	2.87	4.62	1.75
I	Precautions to deal with accumulated solid waste due to failure of statutory authority	1.89	4.62	2.73

The larger gaps provide the attributes where designer/ developer needs to pay more attention as these indicate their failure to satisfy the attributes that are most important to the customers (occupants). The tabulate data illustrated the significant quality gaps in, regular collecting and transferring solid waste to final storage, effective collection and temporary storages at each floor level and sufficient space for service area. To improve the expected quality of the occupants these areas need to be prioritised. Interviews conducted with designers revealed that developers are not bothered about the quality aspects they are hurrying in completing the design and construction and prime intention is to maximize the profit. And also developers are come up with fixed budget and their goal is to increase the rentable area as much as possible.

However, in order to developers to survive in a competitive environment, it is important that firm should have standard data base that includes factors that influence customers' choice of housing and how people decide what will best satisfy their needs.

3.3 Integrating QFD and Survey results

The House of Quality (HOQ) matrix is the heart of the QFD. Demanded quality elements reflected the highly dissatisfying areas reported by occupants in apartments. Quality elements reflected design guidelines or activities rather than product attributes in this study. The application of HOQ matrix required input from two sources namely, the survey on residential apartments and expert opinion survey among construction specialists, such as architects, engineers and quantity surveyors specially involved in the design of high-rise buildings. Basic steps for development of HOQ matrix are presented in Table 3.

Table 3: Basic steps for development of HOQ matrix

Steps	Brief Description
1st Step	Identify the most important customer group – Occupants of apartment
2nd Step	Determine the customer demand (this is also known as 'demanded quality' and it represents the 'what' room in HOQ, Refer Figure 1)– Through Questioner Survey
3rd Step	Customer importance rating – degree of importance were taken using a scale from 1 to 5.where 5 for 'extremely important' and 1 for 'not important at all'
4th Step	Customer competitive evaluation (Illustrates customer perception observed in market survey)- this was not considered
5th Step	Determine the technical requirements (this is also known as 'quality element' and it represents the 'how' room in HOQ, Refer Figure 1)–Through Expert Opinion Survey
6th Step	Determine the relationship matrix between 'whats' and 'hows' – 1-3-9 scale was used where 9- strong, 3- moderate and 1-week relationship. Through Expert Opinion Survey
7th Step	The Correlation matrix (Inter relationships between technical requirements – 'hows vs hows') – this step was not considered
8th Step	Determine the target values : Absolute Importance (AI) and Relative Importance (RI) AI = ∑ (Degree of Information x Relationship Factor) $\text{RI (\%)} = \frac{\text{Absolute Importance}}{\sum(\text{Absolute Importance})} \times 100$ ***Eg: Effective Ventilation system*** *AI = [(4.76x9) + (4.26x9) + (4.04x9) + (4.59x3)] = 172.87* *RI = 172.87 / 1512.77 x 100 = 11.43 %*

After the relationship has been determined, the scoring was done. This shows target value or relative importance for each quality element. The larger target values have the great impact on the most important customer requirements and cater the great number of customer requirements.

Data presented in Figure 2 picturised the developed HOQ matrix. Based on the results of matrix, "sorting out of garbage", "effective building management", "selection of effective vertical transport mechanism", "effective design layout, well ventilated storage area", "efficiency of collecting by statutory authority and effective air locks/ ventilation system" were found to be most important quality elements in order to meet customer requirements. Therefore it was identified these quality elements have greater influence towards optimizing of quality of existing facility and end user requirements. Apart from above, the other elements like , "effective structural accessibility to disposal truck", "cleaning of garbage rooms after removing" are also have greater impact on satisfying the occupants' requirements.

Quality Element Strong - 9 Medium - 3 Weak - 1 Demanded Quality	Degree of Importance	A						B		
		Effective design layout	Effective air locks/ ventilation system	Well ventilated storage area	Sorting out of Garbage	Selection of effective vertical transport mechanism	Effective structural accessibility to disposal truck	Cleaning of garbage rooms after removing	Efficiency of collection by the statuary authority	Effective building management
Sufficient space for service area	4.27	9								
Convenience of collection points at each floor	4.43	9			3					
Eliminate bad odours	4.76	3	9	9	3	3	3	9	9	3
Effective collection and temporary storages at each floor level	4.04	9	3	3	9	9		9		9
Ease of transfer to final storage within the premises	4.82	1			3	9				
Effective final storage method	4.59	3	3	9	3	3				
Regular collecting and transferring collecting solid waste to final storage	4.51				3	9				9
Regularly collect by statutory authority	4.62				3		3		9	3
Precautions to deal with accumulated solid waste due to failure of statuary authority	4.62		9	9	9				9	9
Absolute Importance	**1089.82**	147.56	110.30	137.83	161.20	148.43	28.13	79.20	126.00	151.17
Relative Importance (%)	**100%**	13.54	10.12	12.65	14.79	13.62	2.58	7.27	11.56	13.87
Total average.	241	122.24						118.79		
	%	50.72						49.28		

Note : **A** : Design Aspects **B** : Operational Aspects

Figure 2: House of Quality Matrix

Further, based on the results obtained from the HOQ matrix, 50.72 % and 49.28% of relative importance are respectively covered the activities that are relevant to design and operational aspects. This shows both phase have same influence towards the successful of the project as a whole. Therefore, the appropriate way of exercising design activities can lead to better and quality product, to address this goal the QFD technique ought to be usable and useful.

4. Conclusion

It may be concluded from the above results that the attributes are considered as significantly important by both designers and occupants though all the attributes are dissatisfied by the occupants. Therefore comparatively higher quality gaps can be identified in all attributes. The difference is significant in the areas are, regular collecting and transferring solid waste to final storage, effective collection and temporary storages at each floor level, sufficient space for service area, ease of transfer to final storage within premises and precautions to deal with accumulated solid waste due to failure of statutory authority. Lack of recognition for user needs, absence of voice of the customer during the design phase, limited budget, greater profit margin and scarcity of lands on highly demanded areas can be identified as indirect reasons for this.

The areas having comparatively higher quality gaps are need to be given more priority when designing a garbage disposal system for high-rise buildings. And also in order to execute and maintain any system in a disciplinary manner there should be a well structured legal framework. Finally, the identified design and operational guidelines would be useful for both designers and developers in their future developments.

POST DISASTER RECONSTRUCTION

The Tragedy of Errors: Lessons for Local Government Reform in Pakistan's Earthquake Reconstruction Programme

Abstract

This paper reviews the rural housing reconstruction implemented by the government of Pakistan in the aftermath of the devastating earthquake that struck northern Pakistan on October 8, 2005. This government reconstruction programme, in the form of cash grants distributed in several tranches conditional upon the meeting of earthquake-resistant construction parameters, makes for an interesting case study on post-disaster reconstruction policy formation and implementation. Further, lessons learnt from the successes and failures of this programme may inform effective development and service delivery in developing economies of the region, such as Pakistan.

Keywords: Reconstruction, earthquake, local government, law, cash grants, grievances

1. Background

On October 8, 2005, an earthquake measuring 7.6 on the Richter scale hit the North West Frontier Province of Pakistan and the state of Azad Jammu and Kashmir, causing more than 70,000 deaths, incalculable injuries and wide-scale destruction of private houses and public infrastructure. Immediately after the earthquake, the government and non-governmental organizations (NGO) focused on relief to help victims survive the impending winter. As part of its relief scheme, the Government of Pakistan (GOP) provided a financial assistance grant to those who had suffered a death within their family, those injured in the earthquake and those who had suffered damage to their homes. Whereas the death and injury 'compensation' were a one-time payment, the housing grant was envisaged as the first tranche of a broader long-term private housing reconstruction scheme designed to help victims reconstruct earthquake-resistant homes. The financial assistance grant, including the first tranche of housing assistance, was initially administered by the Federal Relief Commission, a newly-created federal agency tasked with coordinating relief efforts undertaken by the Army, NGOs, international agencies and citizen volunteers. However, the task of designing and implementing the private housing reconstruction programme fell to another new centralized federal-level agency called the Earthquake Rehabilitation and Reconstruction Authority (ERRA).

Given its goals, the private housing reconstruction program can be viewed as a revolutionary government-sponsored service delivery and development program, *albeit* in this specific post-disaster environment. In the context of the Musharraf government's 2001 local government reforms and their heavy focus on local development and service delivery, the housing reconstruction performance offers interesting lessons for the reform of local governance in Pakistan. This case study is especially instructive because the historical causes of lag in development and service delivery failure – manipulation by the central government, absence of the political will, inadequate resources and lack of trained personnel, and apathy, indifference or a lack of demand by the citizens – are absent in this case.[1] In fact, not only has Pakistan received substantial international aid and technical assistance for reconstruction activities, there is also immense international and domestic political pressure to achieve the ends of the reconstruction plan. In that context, this paper evaluates the performance of the rural housing reconstruction process and identifies policy and administrative failures to highlight requirements for effective development and service delivery in Pakistan.

This paper will review the housing reconstruction process in some detail. It will also evaluate the policy and administrative failures in the implementation of the reconstruction plan and suggest avenues for the reform of local governance in Pakistan.

2. The Earthquake Reconstruction and Rehabilitation Program

The October 2005 devastated parts of the North West Frontier Province (NWFP) of Pakistan and the Pakistan-administered state of Azad Jammu and Kashmir (AJK). The district governments in NWFP are organized on the post-devolution model while AJK continues to retain the pre-devolution administrative structure.

One of the GOP's first priorities following the earthquake was to provide victims with temporary shelter to survive the impending winter. The central government created the Federal Relief Commission (FRC) to coordinate relief efforts and implement a 'National Action Plan.' Having struggled with its efforts to first distribute tents and later corrugated iron sheets, the government decided to facilitate the relief and rehabilitation process through a financial assistance scheme.[2] Initially, the government quickly distributed a cash grant to those whose houses had been damaged through the Federal Relief Commission (FRC). Once the relief phase was over, the Government of Pakistan began devising an ambitious plan to ensure the reconstruction of earthquake proof private housing and public infrastructure. Instead of leaving longer-term reconstruction to local or provincial/state governments, the GOP assigned the newly-created Earthquake Reconstruction and Rehabilitation Authority (ERRA) the task of designing and overseeing the process from the federal level. The rationale for centralization of reconstruction policy-making was stated to be the achievement of uniformity across the entire earthquake-affected area. This centralization also appears to reflect a belief on the part of the central government that the local and provincial governments lacked the capacity to design and implement such a program. Lastly, the donor organizations, most notably the World Bank, also demanded a significant supervisory role for themselves which could only be accommodated readily at the federal level. In addition to this centralization of policy-making, a range of new institutions and offices were created under ERRA to supervise the process at various tiers. Existing local government institutions, as well as the army, INGOs, national NGOs, and international institutions were involved in various aspects of the reconstruction program. We shall evaluate the institutional arrangement and implementation of reconstruction and derive lessons from it.

2.1 Phase I of the Housing Reconstruction Plan

In the first phase of the housing assistance program, FRC offered Rupees 25,000 (approximately USD $420) to anyone whose home had been damaged by the earthquake. Although this payment was envisaged as the first instalment of a multi-tier financial assistance program, there were no reconstruction-related conditions attached to this tranche, which actually served as a relief grant for most people. Neither were there any ownership requirements to determine eligibility for the grant; as a result, urban tenants, rural sharecroppers, illegal occupiers of government property, and landowners alike were held eligible for the grant. Indeed, the only restriction on disbursement of this tranche was the disbursement of one grant per roof, no matter how many families were residing under that roof. However, many families in these areas, particularly in AJK, occupy adjacent structures that serve as separate housing units but that are covered by one roof. Failure to recognize this living arrangement resulted in a policy that forced the government to choose one of several nuclear families living under one roof to receive the assistance funds, leading to resentment and bitterness.

Eligibility was determined by three member teams in AJK and NWFP, comprising of civil servants (mostly from the revenue department), army and local political representatives, who conducted surveys to verify damage. However, the process was cursory and the teams did not record the state of damage or other detailed information. Due in some measure to the scale of the disaster, the harshness of terrain, destruction of roads and transportation infrastructure and the urgency in completing this process, no effort was made to develop and announce a schedule for the inspections conducted by the assessment teams. This resulted, in a twofold problem. Many people, who had temporarily relocated out of the affected areas, had moved to relief camps or were away for work or some other reason, missed out on receiving the first tranche.[3] On the other hand, many sat waiting in their villages and towns for the assessment teams to appear, and became heavily dependent on relief goods. The failure to inform the public about the inspection schedules was telling of the inadequacy of the information management and distribution capacities of local, provincial/state and federal governments.

2.2 Phase II of the Housing Reconstruction Plan

Starting in January 2005, ERRA sprang into action and started formulating its housing reconstruction policy at the central level through input from donor agencies, international

NGOs, and consultants. On April 7, 2005, ERRA unveiled an elaborate cash assistance program for private housing reconstruction. The policy identified three categories of housing assistance recipients. Owners of completely destroyed houses (Category A) qualified for a total package of Rupees 175,000 (approximately USD $ 2,920), including the first tranche. Per this policy, an additional three tranches of Rupees 75,000 (approximately USD $ 1,250), 50,000 (approximately USD $ 830) and 25,000 (approximately USD $ 420) would be disbursed and qualification for each subsequent instalment would be subject to fulfilment of reconstruction conditions. The second tranche of Rupees 75,000 was primarily to enable people to clear the debris and build foundations according to approved earthquake-resistant design parameters. The third tranche of Rupees 50,000 was meant to be used on reconstructing walls according to the specified designs. A final tranche of Rupees 25,000 would be disbursed to construct a roof. This payment schedule was created in order to incentivize recipients to adhere to the designs for earthquake resistant housing and to facilitate inspections to ensure compliance. Ideally, this entire process was meant to be completed prior to November, 2006 so that victims did not have to spend another harsh winter without adequate shelter or in camps. The second category of housing assistance (Category B) recipients included those whose houses were damaged but reparable. These individuals were entitled only to a second and final tranche of Rs. 50,000 (approximately USD $ 830), for a total package of Rs. 75,000 (approximately USD $ 2,920) including the first tranche already disbursed. Finally, those who suffered minor damage (Category C) would not to receive any further assistance.

To accomplish its goal of distributing earthquake-resistant designs and training artisans and homeowners to construct in accordance with them, ERRA created a vertical structure. In recognition of the army's limited social mobilization capacity as indicated during the administration of the relief phase and the long-term nature of the process, ERRA sought willing local and international NGOs as partner organizations (POs) to help in this endeavour. However, since there weren't sufficient NGOs to cover the entire area, army personnel, particularly from the corps of engineers, were also recruited for this task. PO mobile teams, consisting of technical staff and social mobilizers, were tasked with distributing designs and informing and training locals. To train the mobile teams, ERRA created six Housing reconstruction Centers (HRCs) in NWFP and five in AJK, each headed by a Housing Reconstruction Coordinator. Although the HRCs are managed by an international NGO or UN agency, all HRCs within a particular district report to a district-level representative of ERRA called the District Housing Coordinator. The office of the District Housing Coordinator is situated in the District Reconstruction Unit (DRU) which oversees private housing and public infrastructure reconstruction. Another body, the District Reconstruction Advisory Committee (DRAC) has been set up, consisting of the District *Nazim* (in NWFP) or AJK government representative in (AJK), the DC (AJK) or the DCO (NWFP), Army representative, the District Housing Coordinator responsible for housing reconstruction and DRU Program Manager responsible for public infrastructure reconstruction to coordinate between the various civil, military and civil society organizations working at the district level. DRU in turn reports to the State Earthquake Rehabilitation and Reconstruction Authority (SERRA) in the state of AJK and the Provincial Earthquake Reconstruction and Rehabilitation Authority (PERRA) in NWFP.

SERRA and PERRA coordinate between the central office at ERRA, the DRUs, and the provincial and state governments in NWFP and AJK.

The following diagram shows the relationship between various institutions created or seconded by ERRA to undertake different aspects of the housing reconstruction process. As the figure indicates, this unduly complex multi-tier arrangement includes institutions with divergent command and reporting mechanisms, making coordination between them virtually impossible.

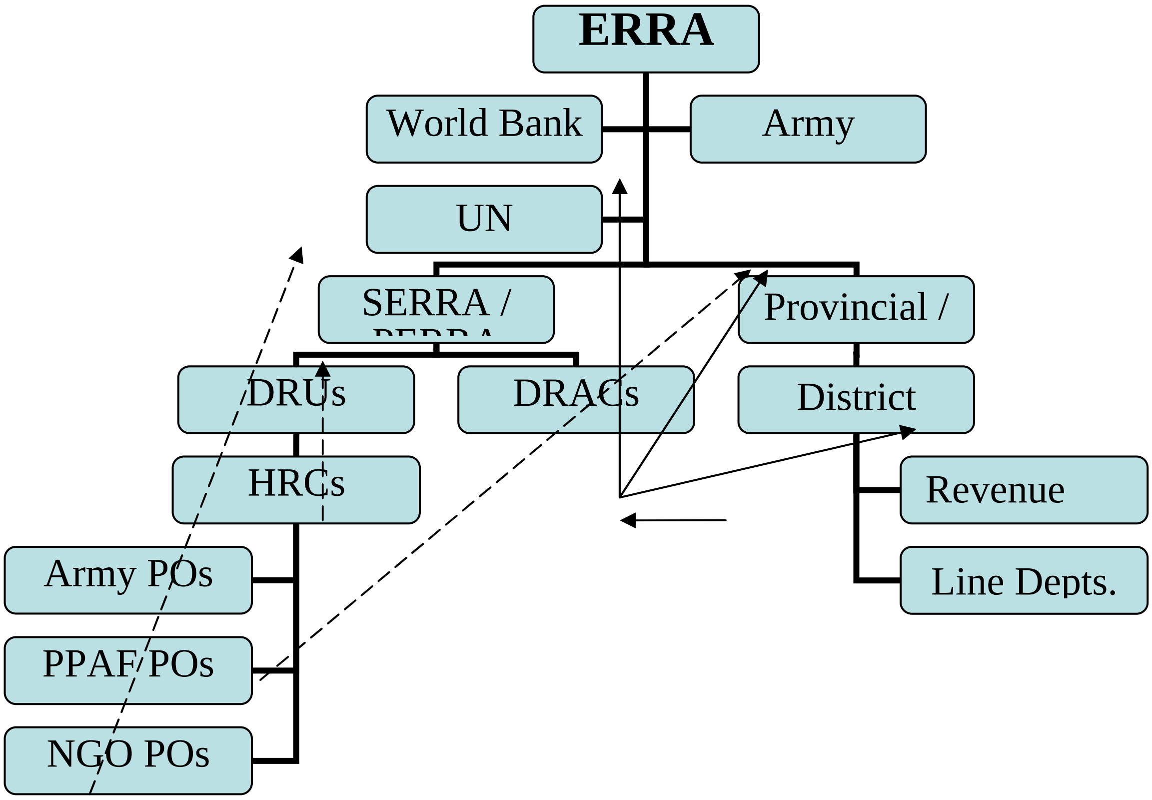

Figure 1- the relationship between various institutions created or seconded by ERRA to undertake different aspects of the housing reconstruction process

Given the time needed to establish this structure, ERRA began administering eligibility surveys for the second tranche even before the structure was completely set up. Eligibility determinations for this instalment were done by Assistance and Inspection (AI) teams in some areas and POs, particularly NGOs associated with the Pakistan Poverty Alleviation Fund (PPAF), in others. Per ERRA policy, the second tranche, in contrast to the first, was available only to legal owners of the property on which the damage or destroyed house stood. The rationale behind this policy was that while the first tranche was intended to provide people with a means to secure temporary shelter, the second payment is intended for reconstruction by the legal owner of the destroyed property. In theory, this is a reasonable policy. However, given local realities in many of the earthquake-affected areas, particularly in the NWFP where a significant percentage of the population live as tenants and sharecroppers, the legal ownership requirement was at odds with the purpose of enabling victims to rebuild their homes since it would leave so many sharecroppers without financial assistance.[4] Further, this created the possibility of hostility between landlords and sharecroppers resulting in widespread social unrest in some areas.

2.3 Grievances with the First and Second Tranches

Although the majority of victims appear to have received the first tranche, many rightful claimants did not receive assistance as pointed out earlier. While some have claimed corruption, political victimization or incorrect application of the policy (ie. asked for ownership status or NIC), most complainants missed out simply because they were away from their homes at the time of the survey.

Given the volume of complaints (estimated at more than 82,000 by June) and the lack of capacity to verify these complaints, neither ERRA nor the district administration took any effective action to address them. Further, there was an overwhelming sense that the majority (90 to 95 percent) of these grievances were not genuine. In fact, it was hoped that the second tranche survey would automatically resolve any genuine complaints arising from the first tranche. However, an analysis of the second tranche survey methodology suggests that this is unlikely to be the case. There are likely to be quite a few people in this category since once again inspection schedules were not announced.

In addition, the second survey itself has created a number of grievances. First, some have claimed that the AI teams or POs have classified them in a lower category of damage. Thus, individuals who believe they should be in category A or B might complain that they have been placed in B or C respectively. This is especially applicable to those who have cleared the debris or repaired their homes and thus cannot prove the level of damage they had suffered. A particularly explosive grievance, primarily in the NWFP, has been the second survey’s requirement for legal ownership. Since this requirement excluded several tenants and sharecroppers in NWFP’s overwhelmingly agrarian economy, it has created a great deal of resentment. Although ERRA has declared that any sharecropper that can provide a No Objection Certificate (NOC) from his landlord will receive compensation, the policy has created a number of problems and has been discussed in detail below. For now, it is sufficient to note that this policy has excluded a number of recipients who have missed out on the second instalment because they cannot establish ownership and has generated a new kind of grievance.

3. Other Issues with the Reconstruction Process: Designs, Timing, Inspections and Subsequent Tranches

3.1 Design Issues

In addition to grievances with the administration of the first and second tranches, there appear to be a number of problems with the remainder of the housing reconstruction policy. First, there have been several problems with preparing and distributing earthquake-resistant designs. ERRA took a lot of time in finalizing the designs, and the design parameters were changed on more than one occasion. The delay may be attributed partly to lack of capacity within ERRA to undertake the task itself as a result of which it had to involve other agencies such as NESPAK, ANCETT, etc. and had to reconcile the differences of opinions between these agencies' experts. As explained above, PO mobile teams were supposed to distribute the designs and educate people about meeting the parameters. However, delays in finalizing MoUs between ERRA and POs further hampered the process. Other means of distributing designs through mail, newspapers, or radio programs were not initially employed. While some of these avenues were employed later, inexcusable delay had already occurred. A lot of people began receiving cheques for the second tranche by mid July of 2006 but had neither received designs nor training. With no construction possible during the heavy Monsoon rains, the reconstruction of homes was barely begun prior to the onset of winter in November 2006. Further, in an effort to rebuild their houses prior to winter, many refused to wait for designs, which is a major failure of this program. This will result in either the construction of non-earthquake-resistant housing or changes will have to be made in order to receive further compensation causing hardships and additional expenses.

The content of the designs have also proved problematic. The designs contemplate a small steel concrete rural house consisting of two rooms and a kitchen. Locals oppose these designs for several reasons. First, steel and concrete are more expensive than mud, mortar, wood and other locally available materials. While the housing payments were never intended to cover the cost of an entire home, the money is proving even less useful given the expensive specified materials. Second, the transportation of these materials to remote areas, particularly where there are no metalled roads, is both costly and problematic.

3.2 Pre-Earthquake Landlessness

An issue that has arisen in some parts of NWFP is the landlord-sharecropper issue. As mentioned above, only legal owners were allowed to receive the second tranche of housing compensation. Following complaints by sharecroppers in the NWFP, ERRA announced that a sharecropper could receive the second tranche if he submitted a No Objection Certificate (NOC) from his landlord. The policy also prohibits landlords from evicting the sharecroppers for three years. In return, the sharecropper is obliged to spend the entire amount on reconstructing the house. Understandably, the legal ownership requirement was problematic for sharecroppers who constitute up to 20% of the potential claimants in some areas.[5] A landlord's refusal to sign an NOC may amount to de facto eviction if the sharecropper does not have other resources to build a new home. If the sharecropper makes a home without reconstruction assistance, it will likely not be earthquake proof leading to a failure of the reconstruction policy.

3.3 Post-Earthquake Landlessness

The earthquake has caused landslides in many areas, with the result that people in these high risk areas have been rendered landless. Therefore, even if these people are held eligible for cash assistance, they have no land to reconstruct on. Those affected have been residing in official or makeshift camp sites. The relief camps have caused numerous problems and social tensions related to lack of privacy (*purdah)*, sanitary facilities, insecurity and violence against women.

3.4 Delays in Urban Planning

While much of the earthquake destruction took place in the rural areas, two urban areas, Muzaffarabad in AJK and Balakot in NWFP, were severely affected. Since both towns are on a fault-line, there were discussions regarding whether these areas would be entirely relocated. While it has been decided that Balakot will be moved to a new site, Muzaffarabad is being re-planned but will remain at its original site. Unfortunately, however, both processes have been subject to much delay. Although the decision to relocate Balakot has been taken at higher levels, no formal policy has reached the locals. Consequently, people have started building on their other locations, which is sure to complicate any relocation plan ERRA eventually devises. In contrast, Muzaffarabad has a rehabilitation plan was created by JICA and ERRA. Given the complexity of relocating a city the size of Muzaffarabad, it was decided to keep Muzaffarabad at its original location to minimize conflicts and problems. The survey for the 2^{nd} tranche only began in urban areas in August 2006. Many people have complained at the delay and point out that the funds are not enough to construct a house in urban areas.

3.5 Ownership Disputes

ERRA's decision to predicate disbursement of the second tranche on proof of legal ownership has also subjected victims to several problems. Many legal owners died during the earthquake and their families did not immediately focus on changing ownership records and finalizing inheritance matters. When talks of the second tranche surveys began, ERRA announced that only legal owners would receive the second instalment. However, this information was not circulated to the earthquake victims in a widespread manner. As a result, many legal heirs did not have the appropriate documentation proving ownership when AI teams came to survey their homes for the second tranche and in fact only learned of the requirement during the assessments. The legal ownership requirement is having a number of repercussions for the financial assistance scheme. First, failure to inform people about the requirement has led to several victims missing out on the payment. Moreover, given the state of public infrastructure and revenue records, the decision to announce a policy based on finalization of ownership records has been difficult for both earthquake victims as well as an overburdened revenue office. As word spread, many people tried to finalize their records. Many, however, were unable to and those who missed out will likely take this issue to court. Indeed, this policy has significantly impeded the progress of the second phase of the financial assistance scheme and will contribute to the delay in reconstruction prior to this winter.

A study of property-related suits filed after the earthquake conducted by the authors may alert one to multifarious property disputes that may have arisen in the aftermath of the earthquake. A number of cases filed after the earthquake involve direct challenges to the denial of housing assistance or death compensation. Other cases hinge on other issues but betray access to housing assistance or death compensation as a primary motivation for litigation. Some cases involve challenges to the ownership rights of possessors. A few of the disputes relate to the urgent need to divide joint property (*mushtarka khata*). Since there has been a tendency not to formalize mutations of property for years, sometimes over generations, as a result the property becomes the joint property of all the heirs. After the earthquake, as many people are seeking alternate plots to build new homes, the division of joint property appears to have become a serious issue. Further, there are clear indications that disputes over boundary, water rights and passage rights are likely to increase due to the change in terrain, diversion or extinction of water resources and need for alternate land for reconstruction.

These findings have grave implications for the court systems in earthquake affected areas and access to justice. The courts in AJK are much better placed to deal with an increased case load due to recent reforms introduced by the Chief Justice of the AJK High Court. Further, since the revenue system has not been devolved, the district administrations possess the powers to dispose of such cases administratively. Nonetheless, the infrastructure and records of the civil court system and revenue administration have been badly affected and one may anticipate that any increase in the case loads will lead to delays and hardships. In NWFP, the backlog of cases in civil and revenue courts is much higher and even a small increase in caseload is likely to inundate the judicial system.

3.6 Vulnerable Groups

Vulnerable groups, including widows, orphans, and the disabled, have suffered disproportionately from many of the glitches associated with the financial assistance scheme. The lack of information regarding processes and procedures, the need to stand in line to receive cheques, open bank accounts, and register grievances, for example, has been especially difficult. Women, in particular, have suffered a great deal: given the social restrictions they face, travelling, standing in lines, having to go to male-dominated office environments, and their general lack of awareness about how government offices operate have resulted in many problems. Consequently, it may be expected that when faced with abuse, either from relatives or strangers, such as in cases of usurpation of their compensation, inheritance rights or property rights, they are likely to find it much harder to gain access to justice.

4. Analysis of the Causes of Policy and Administrative Failures

The above discussion of the problems afflicting the compensation process indicates that the rural housing reconstruction plan suffered from a number of policy and administrative failures. Many of these policy issues appear to be rooted in ERRA's failure to anticipate problems and appreciate local variations. The absence of local input resulted in a lack of ownership in the reconstruction process on the part of local government institutions and political representatives. The process suffered further from a failure to provide information regarding policies and their rationales. Other administrative failures stem from some of the structural problems that have plagued the reconstruction process. An analysis of these problems and their causes can offer important lessons for local government reform to achieve effective service delivery and development in Pakistan.

4.1 Centralization of Policymaking

As is evident from the above discussion, several of the housing reconstruction policies suffered from a failure to take into account local considerations. The process seems to have faltered on two levels. First, the policymaking was done at the federal level, mostly by ERRA, with very little input from local government and elected representatives. There was a deliberate attempt at achieving uniformity across the earthquake affected areas without realizing that one size may not necessarily fit all. This centralization was also premised on the belief that leaving the matter in the hands of provincial, state or district government institutions would lead to politicization, corruption, and maladministration of the program. Second, as and when the problems arose, ERRA took unnecessarily long to recognize the problems and identify solutions due to its faulty institutional structure plagued by mismanagement of information and ill-defined chain of command and control.

4.2 Absence of Institutional Memory and Feedback

The decision to create a new structure to administer the earthquake reconstruction process has brought with it a variety of problems. At the outset, the process has been challenging since ERRA has obviously not been involved in any such programs before and therefore has no institutional memory or experience to contribute to the current process. More significantly, the composition of ERRA leaves much to be desired in this regard. Despite the demands to appoint civil officers from the bureaucracy with significant local and provincial/state government experience that emanated from certain quarters in the early days of the relief and rehabilitation phases the military government chose to appoint serving army officers at the helm of FRC and ERRA central offices as well as ERRA field offices. Army officers typically have very limited understanding of the structure, rules of procedure and institutional ethos of civil institutions and scarce knowledge of local socio-political milieu that local government officials may be expected to possess. Other staff members of ERRA's central office, including those with non-military backgrounds, also appear to lack both disaster management experience and special knowledge of the local environments. Other institutions which were involved in the design of the reconstruction policy, namely the World Bank, UN and other international agencies, also lacked the ability to anticipate local issues and ramifications of the policy decisions framed in Islamabad. The views of district administrations, local politicians and the provincial/state governments were ignored to the notable ire of these institutional players. At a later stage, there was hope that ERRA would become more informed of the particular problems associated with the implementation of its policy choices. However, it appears that the communication has been one-way with ERRA issuing orders and expecting only good news in return. The communication failure may be attributed to the weak chain of command between ERRA institutions and the failure to clearly define their roles.

4.3 Delay in Establishing the Administrative Structures

The creation of ERRA and its subordinate institutions in the form of SERRA, PERRA, DRUs, HRCs, and others led to a need to create and staff a new organization and train new personnel. As a result, although ERRA was created in late October 2005, discussions related to housing reconstruction policies did not begin until January 2006, largely because ERRA was still establishing itself. Even after ERRA became functional at the central level, it took a long time to establish the vertical structure in the districts and below. In addition to delays in formalizing and creating ERRA’s structure, it took a great deal of time to provide resources to key personnel to do their jobs. Confusion in terms of roles and responsibilities has also hindered the process.

4.4 Weak Chain of Command

ERRA’s relationship with the district administration has been further complicated by the general dynamic between local governments and ERRA. Since ERRA has been created, there has been a distinct sense in the local governments that existing institutions were bypassed and resentment arose regarding the need to assign such a grave local matter to a centralized, parallel structure. The process of creating and staffing ERRA, training its personnel, and providing it with resources has raised questions about why the capacity of the existing local government institutions was not strengthened instead. District officials maintain that while ERRA will likely overstay its three-year limit, it will not be a permanent institution. Therefore, the expenditure on strengthening this temporary structure will dissipate vital resources in the long-run; resources which could instead have bolstered local government capacity and geared them towards an effective service delivery and development outlook. This criticism raises the obvious question about whether district administrations, particularly the devolved governments seemingly geared toward service delivery and development in the NWFP, would have been able to efficiently implement the reconstruction process. Judging from research trips watching the district administration handle the tasks assigned to it, there is an overwhelming sense that the district administrations would not have been able to handle the process on their own. District governments in both the NWFP and AJK suffered from a lack of capacity, technology, organization, and competent personnel even before the earthquake and these gaps were significantly widened due to the losses suffered in the earthquake. However, an approach that integrated the district administration in a way that would utilize their strengths and given them some responsibility and ownership would have gone a long way toward dispelling some of the current resentment that is being expressed.

The criticism that ERRA bypassed existing institutions is not confined to its approach toward the district administration. There were several institutions that ERRA could have used to facilitate the process: using the post office to mail cheques rather than requiring people to travel to central locations and wait in line; disbursing cash instead of cheques through the district government (as was initially done in AJK); printing lists of those held eligible in gazettes and distributing designs through post offices, banks or even local mosques; and publicizing information over the electronic and print media.

4.5 Information Management Failures

At a minimum, even if local input would not have made a difference on certain issues, ERRA's failure to publicize its policies, articulate the rationale behind them, and outline detailed procedures have left many people feeling victimized. For example, the majority of grievances in the first as well as second tranche resulted from a failure to publicize the schedule of inspection visits. Even people directly involved in the reconstruction process did not appear to have complete and up to date knowledge of various ERRA policies, especially since some of the policies kept changing, what to say of ordinary people. Most notably, the delay in finalizing and distributing designs is inexcusable, especially since easily available means were ignored. As a result, the general public remained generally ignorant of ERRA policies, the nature and roles assigned to various ERRA institutions and officials. The failure to consult and/or inform the public has led to the feeling that ERRA is insensitive or unconcerned about local problems.

5. Conclusions

The design of and the problems that have plagued the implementation of the housing reconstruction program of ERRA can teach us a lot about how to reform local government institutions in order to enable them to efficiently undertake service delivery and development functions. Many of the issues identified in this paper relate back to the debate over the efficacy of the devolution plan and the reform of local government in Pakistan. That the GOP did not entrust the reconstruction program wholesale to the local government may be attributed partly to the disorientation and capacity gaps caused by the earthquake in local government institutions. Nonetheless, the fact that when the local government was co-opted for aspects of the program even these were not fully entrusted to it, indicates the central government's lack of confidence in the competence and integrity of these institutions. For example, composition of the survey teams for both tranches was designed by ERRA in order to minimize politicization and corruption. Further, the scheme to involve POs for distributing design information and to undertake social mobilization, rather than the various local government departments, indicates an assessment on the part of ERRA and the central government that local government lacked the capacity for social mobilization and awareness creation. This is a stark admission of the continuing communication gap between local government institutions and the general public.

The analysis of the reconstruction program also indicates that it is important that policy-making should be done at, or at least informed by local level considerations. This can only be achieved if there is genuine public participation in policy-making. This shall be achieved not by nominally including politically elected representatives into the fray, but rather through giving elected local governments real voice and decision-making powers. In addition, there should be political accountability to the public in order to ensure that elected LG officials are swayed by local requirements rather than extraneous considerations. Therefore, it is not enough to make bureaucrats nominally responsible to elected officials; rather elected officials should be responsible for, and held responsible by the public for, the performance of local government. Finally, there should be means through which those especially aggrieved by LG decisions should be able to seek redress and hold LG officials legally accountable. Existing means, such as petition for judicial review (writ jurisdiction of High Courts) are not proving to be effective in establishing legal accountability of elected officials or bureaucrats. An effective system of administrative law at the local level is a pressing necessity.

The design of the housing reconstruction program and its failings has highlighted the acute need for developing additional capacity at the LG level. This capacity includes an appropriate administrative structure, the necessary infrastructure, adequate financial resources, and the development of social mobilization and information management capacities. Until this is done, and LG is provided the necessary tools to perform the tasks, it is unreasonable to expect any far reaching results.

An exploration of current planning, design and building issues in post-disaster housing reconstruction

Carolyn Hayles,
Planning, Architecture & Civil Engineering,
Queen's University Belfast
(email: c.hayles@qub.ac.uk)

Abstract

A number of housing projects funded by charities and NGO's in response to disasters, in developing countries are deemed to be inappropriate due to poor project management and limited resources which may comprise one or more of the following: limited knowledge of local climatic conditions; local materials; and the way people live and work within their communities; and often simply lack of experience. Habitually it is believed that there is neither the time nor resources to undertake detailed analysis to ensure what is being constructed is 'fit for purpose'. Large amounts of funding, often from charitable giving, are used to plan, design and build housing projects, projects unlikely to be sustainable due to ineffective and inefficient use of resources. Hasty decisions made without appropriate local consultation inevitably create inappropriate and unwanted results, such as housing which cannot be used by local communities; and housing that does not even meet local standards for safe building. The introduction of structured decision making to allow for the audit of the cognitive processes adopted, alongside access to appropriate tools and techniques to engender the adoption of local knowledge, will reduce the risk of unsustainable building projects. Research is currently being undertaken to capture tacit, implicit and explicit knowledge and map the project management practices of leading aid agencies (NGOs and charities working in disaster relief) to understand decision making practices that result in best practice amongst these organisations. This information will subsequently be used to develop best practice guidance to be disseminated widely amongst organisations providing housing during reconstruction following both man-made and natural disasters.

Keywords: disaster relief, decision making, housing, knowledge management, sustainability

1. Background

Housing recovery passes through four stages in the aftermath of a disaster: emergency shelter; temporary shelter; temporary housing; and permanent housing [1]; consequently reconstruction of housing stock after a disaster is not the same as providing shelter immediately following an event [2]. A number of what are intended to be permanent housing projects funded by charities and NGO's in response to disaster events are deemed to be inappropriate [3] [4] [5] due to poor project management and limited resources which may comprise one or more of the following: limited knowledge of local climatic conditions; local materials; and the way people live and work within their communities; and often simply lack of experience. Habitually it is believed that there is neither the time nor resources to undertake detailed analysis to ensure what is being constructed is 'fit for purpose'. Large amounts of funding, often from charitable giving, are used to plan, design and build permanent housing projects, projects unlikely to be sustainable due to ineffective and inefficient use of resources. Rushed decisions, made without appropriate consultation have resulted in inappropriate and unwanted housing provision, including housing which cannot be used by local communities [6].

Following the 2005 Tsunami the Royal Institute of British Architects (RIBA) made public statement in 'Building Design' that it had contacted BRE and Construction Industry Council to make sure the reconstruction effort's in Asia were sustainable and able to resist any future natural disaster. The RIBA also called from an education programme to ensure that rigorous construction methods would be used in countries vulnerable to future tsunamis [7]. It is uncertain whether this can be seen as a realistic goal or even attainable where there are innumerable relief and aid agencies working in isolation using different approaches and different solutions to meet people's needs.

Recent research undertaken by Levine *et al.* on disaster relief as it relates to housing provision and associated social concerns, has demonstrated that it is still deficient [8]. There is a perceived gap in the understanding of the longer-term impacts of post disaster reconstruction. It has been demonstrated that more research is needed on the effectiveness of longer-term development in communities where international aid and expertise have been provided. Implementing agencies rarely have the time and/or expertise to document properly what they have done or undertake comprehensive research on the value of their interventions. The aim of the wider research project is to capture tacit, implicit and explicit knowledge and map the project management practices of leading aid agencies (NGOs and charities working in disaster relief) to understand decision making practices in the final stage of housing recovery (permanent housing); decision making processes which have lead to best practice amongst these organisations. In this paper the major issues surrounding post disaster housing reconstruction are discussed.

2. Natural hazards and disaster events

There has been a significant rise in the number of disaster events over the past decade, as well as in the number of people affected by disasters associated with natural hazards; as documented since the beginning of reliable recording in the 1960s [9]. Far from being under control, evidence suggests that losses associated with the built environment due to these extreme natural hazards are increasing rapidly [10]. Indeed, there is a broad consensus that the number and cost of natural disasters is escalating worldwide[1] [2]. Traditional coping methods in both rich and poor societies are breaking down while evidence indicates that climate change is bringing new hazards as well as increasing risk from known hazards. In all this uncertainty, there is one undeniable fact; there is an unequal burden of disaster mortality [11] and climate change impacts on poorer countries.

[1] This increase is as a result of more frequent disasters; the growth of global populations located in increasingly vulnerable areas; and continued environmental degradation.

As a result disaster relief work has increased substantially in the past two decades [12]. However questions have arisen surrounding the appropriateness of the responses made to these disasters and how they are monitored in order to assess their effectiveness over the short, medium and long term [13].

Waiting for events to occur is no longer a viable option. The 'crisis survival' mindset needs to change to one of anticipation, intervention and prevention [14]. It is not enough to return hazard-hit communities to their frequently impoverished and vulnerable pre-disaster state [15], it is now necessary to 'future proof' design rather than adapting buildings for a changing climate once complete [16]. It makes economic sense to build in resilience and when there is adequate time and resources to make these sorts of design decisions. Rebuilding operations can be seen as an opportunity to create a more sustainable environment [17]; one which can withstand future hazards and builds in climate change considerations**;** making housing and communities safer, reducing the potential impact of any future disaster [18]. Consequently, **'**hazard risk reduction' and 'vulnerability planning' can and should be seen as a subset of sustainable development [13].

3. Climate change and increasing vulnerability

Since the beginning of this millennium, natural hazards have resulted in human disasters, which have in some instances reversed years of development work [11]. Climate change is expected to lead to changes in temperature and precipitation patterns over the next century that will, amongst other things, significantly affect human livelihoods. The predicted increase in extreme weather events disproportionately impacts the poor located in these at-risk areas [20]. Indeed some of the most significant impacts of climate changes are expected in tropical and sub-tropical regions, where most developing countries are situated [19]. In the context of past and present day failures to address poverty adequately, climate change is an additional obstacle to the achievement of sustainable development, the result of which is an increase in vulnerability of the poor[2] [8].

As climate change exacerbates vulnerability, measures to mitigate increased risk need to focus on reducing built environment vulnerability in the context of development efforts; particularly building adaptive capacity and technology transfer [21] [11]. Indeed the unpredictability generated by climate change places more emphasis on the need to identify and support generic adaptive capacity alongside hazard-specific response capacity [11].

The supply of appropriate housing is intrinsically capable of reducing vulnerability amongst the poor, not only against future disasters but in the shocks and crises that occur in routine life for the poor [22] living in the most vulnerable of geographical locations. Permanent housing must, above meeting basic accommodation needs [23][3] provide for peoples' psychological, social and

---

[2] Vulnerability is also increasing due to rising poverty, a growing global population, armed conflict and other underlying development issues. People can be exposed to physical and social vulnerability. The former includes old, poor or inadequate buildings. The latter considers the ability of an individual, household or the community to respond appropriately to threatening conditions and their aftermath [8].

[3] Article 21 of the UN universal declaration of human rights promotes the concept of housing as a right of all peoples [23].

economical expectations; in essence provide a starting point from where they will rebuild their lives [24].

4. Hazard risk and appropriate mitigation

4.1 Lessons learnt

As discussed above, the demographic distribution of hazard risk tends to be inequitable because geographical locations are frequently related to residents' demographic traits. This pattern is very common in developing countries where residents cannot afford homes in geographically safe areas [25].

As the incidents of natural disasters increase, it is imperative that NGO's and other agencies involved in disaster relief manage risk by learn as much as possible from each disaster recovery and reconstruction process they are involved with; both successes and failures [26]. NGO's play important roles in different stages of the 'disaster cycle' and different elements are attributed to its successful operation. For example, technical skills are important for rescue, whilst coordination is essential relief activities. These require different knowledge skills, competencies and attributes.

The disaster recovery period is a time with immense potential for confusion and conflict [27][4]. A successful NGO intervention should exhibit sustainability principles, working flexibly with local people and include multi-stakeholder cooperation [28]. Indeed, post disaster recovery processes can be used as a catalyst for sustainable development [18] [29]; upgrading livelihoods and living conditions leading to the potential revitalisation of local economies. However, post disaster rehabilitation projects have not always been effective [28], because they have not always taken a sustainable development approach.

Whilst structural/physical risk reduction initiatives, such as conventional and traditional engineering or planning which can easily create false security, are decreasingly seen as the solution, few alternative strategies are being developed to replace them [30]. Previous disasters must hold valuable lessons for those designing new buildings, and this tacit, implicit and explicit knowledge should be exploited. Detailed surveys of damage, particularly of smaller domestic buildings, can yield valuable information on areas where there is little research; for example how buildings perform compositely in a tsunami or earthquake, including the interaction between non-structural and structural elements [17]. Cross-disciplinary hazard risk-based management strategies to meet the challenges of climate change, together with design guidelines that account for both historical local climate conditions and scenarios for future changes, should be an important step forwards a more active and dynamic way of ensuring a high-quality construction process and sustainable development result [31].

[4] Research undertaken by Wu and Lindell [27] demonstrates that having a pre-impact recovery plan in regions of high risk appear to increase the speed of housing reconstruction following a disaster event.

4.2 Disaster risk management strategies

There is a clear role for disaster risk management as a response to future climate change, and there is no better time to implement it than when reconstructing post disaster. Any disaster risk management strategy must encompass political social, economic, cultural and engineering issues [17]. Where disaster risk reduction and climate change mitigation can be incorporated into development plans, sustainable development can be realised [11]. However, whilst risk reduction is becoming increasingly recognised as a key challenge for development, very little work has been undertaken to date to identify how this can be done [32], it has been suggested that "…the need to work on disaster risk has tended to 'fall between the cracks' of the grander framework of development cooperation and emergency relief." [33, pp186]. Indeed, there is evidence that risk reduction and planning are two marginalised activities within international aid organisations; hindering interest in a more integrated approach [30][5].

Consequently, there is a general consensus that disaster management should shift its focus from response and recovery to sustainable hazard mitigation [34] [35]. Hazard mitigation and planning should therefore be considered as more than an auxiliary issue and disaster risk reduction needs to be incorporated into the construction management process.

4.3 Construction project management and sustainability

The construction management decision-making process requires an in-depth integrated understanding of how to avoid and mitigate the effects of natural disasters. In order to be effective, resilience needs to be systematically 'built in' to the planning and design process and not simply added on as an afterthought [36]. It is therefore necessary to increase the participation of NGO's and the affected community within the construction process [37]. If mitigation strategies are to be successful, they must incorporate public participation at the local decision-making level. This will increase the likelihood that the solutions provided can be sustained [35].

The existing concepts of sustainability and sustainable development by definition have a focus on the medium to long term processes but need revision to include the implications of extreme events, regardless of whether these are natural or anthropological. In particular, those working on issues of preparing for climate change need to be informed by the body of established knowledge on natural hazards [13].

Mitigation of natural disaster within the context of sustainability requires changes and adjustments in the ways human settlements are planned, built and managed. Resources, technologies and organisational processes should be inextricably linked to the quality of the environment and to meeting people's needs. In this way, mitigation approaches can combat the real causes of

[5] Wamsler [30] undertook a study to determine the underlying reasons for the lack of integration of planning and risk reduction within international aid organisations. The study differentiates between people working within the field of development and those employed in the areas of disasters. It is suggested that these two groups lack the appropriate knowledge and adequate institutional structures required to effectively support their contribution to risk reduction and to co-ordinate their efforts.

vulnerability, and prevent and counteract the unnecessary creation of environmental and socio-environmental problems. Such an approach could have productive and lasting results, which would lead to continuity between mitigation and the sustainable development of human settlements [34]. This may only be achieved through appropriate housing design; activities that strengthen physical conditions, increasing self-reliance and community participation; and institutional reform at different levels to increase cooperation, awareness and effectiveness [34]. By supporting reconstruction programmes that promote community-based approaches to disaster mitigation, resources within the community and neighbouring areas could be exploited, which in turn would build capacity thus reducing vulnerability [38].

5. Sustainable Strategies

5.1 An appropriate response

Reconstruction programmes can experience challenges on unparalleled scales; examples include the aftermath of the Tsunami in Sri Lanka and the earthquake that devastated northern Pakistan (both in 2005), where a lack of strategic and professional expertise, coupled with a shortage of skilled labour and materials [39] [40], made it extremely difficult to supply permanent homes. There was widespread public criticism of the Sri Lankan government from the Western World and many organisations and individuals who had donated money; frustrated that one year on their money had not been spent and was not reaching the people. This criticism did not take into account the fact that an appropriate response and thus sustainable solution requires extensive and thorough knowledge transfer and management; and without appropriate and structured decision making processes in place, with pressured time constraints, significant mistakes can be made [39].

An appropriate response when reconstructing housing environments following a disaster is one that delivers solutions that optimise the design (its functionality and configuration) and manufacture (materials) of the build in terms of ecology, economy and social needs [37], for a sustainable solution is to be found. All too often reconstruction responses are driven by technology, limiting wider engagement with cultural and social issues [13]. These solutions must meet the basic needs of shelter and aliment. Adequate does not mean basic, as well as being long-lasting they need to be socially sustainable and meet the local peoples' cultural needs [12]. It is necessary to remember that **e**ver country, region even, may have its own cultural and socio-economic setting [29]. The housing must meet physical needs (functionality and configuration), but it also has to meet economic and technological (including practical building systems and building materials), as well as social and aesthetic needs (thus respecting the culture of the affected population) on a local scale [24]; if it is going to deliver sustainability. Local knowledge is essential to fulfilling these requirements and NGO's can play an important role as the interface between the people and government, by communicating people's needs and priorities to the government [28].

With this approach to decision making, end user satisfaction, environmental protection and disaster mitigation can be provided and achieved [41]. However this is not always the case as the decision making process is both complicated and fractious. Learning from the experiences of successful and not so successful projects could help with future project decision making processes, but very little is published that relates to the longer-term outcome of relief and reconstruction programmes; despite the sizeable amounts of (international aid) money involved [42].

5.2 End users and stakeholders

The design and implementation of any post-disaster housing reconstruction programme must find a balance between affordability, technical feasibility and quality of life. It must also recognise the end users as active stakeholders, aware and conscious of their own needs and wants, rather than as passive recipients, who need to be educated [43]. Freeman [2] and Schildermann [44] argue that governments and agencies need to actively engage end users, building on existing skills and capabilities within local communities, rather than rushing in to 'reconstruct' for them. Nowadays, the managers of most reconstruction projects claim that their projects are participatory, but the extent and nature of such participation is not always apparent [42]. Large, centrally planned and contractor-built housing is still the standard approach to post-disaster reconstruction [10] and whilst community participation may be widely encouraged by NGO's, policy makers, and scholars, very little knowledge exists about how this is applied at the project level and despite often good intentions, this level of participation is rarely obtained and the capabilities of the users are often significantly wasted [45].

Indeed, Davidson *et al.* [45] examined a number of post disaster reconstruction projects to analyse community participation. They determined that, in the majority of cases, community participation does not occur; demonstrating a significant gap between theory and practice. Where community participation is known to take place, up front involvement is more successful than when community participation is introduced to the later stages of reconstruction projects.

However Architects without Frontiers (AWF), a small organisation specialising in developing strategies which contribute effectively to the regeneration of communities and addressing underlying social or political issues, has demonstrates some success in this area. Critical to the process has been working closely with locals, educating and training them in the skills being provided, thus fostering self sufficiency [46].

5.3 Technological solutions

Despite the fact that a top-down, technology-driven, end-product approach is decreasingly seen as the solution [30], it remains dominant in post-disaster reconstruction, with the exception of a few isolated and relatively small-scale NGO projects [42] such as the work of AWF [46] and the Catholic Relief Services (CRS) [12].

Unfortunately, in a majority of incidences external technical consultants exercise considerable influence over technology choice. Indigenous building knowledge is often devalued by outsiders and indeed by local people themselves, who prize 'modern' building styles as symbols of development, and believe that they are more secure against natural hazards [42]. These beliefs are not unfounded as, for example, only steel and concrete technologies can actually withstand the forces involved in e.g. a tsunami, however these materials are not a sustainable options for the majority of people affected [47]. As a result post-disaster humanitarian assistance can increase vulnerability in the medium-long term [48] when what is built cannot be sustained.

For any reconstruction project to be sustainable, the building technologies need to be appropriate to local needs, resources and cultures. Indigenous technology, in its most advanced form, is the only technology that can sustainably rebuild devastated settlements [47]. Indigenous technology is particularly valuable for sustaining livelihoods because local skills and labour can be utilised during the reconstruction process. Indeed indigenous building technologies are well adapted to hazards. For example, certain timbers and bamboo structure resist earthquakes well because they are flexible. Despite the fact that traditional building technologies are capable of mitigating the effects of hazards if built appropriately, they have frequently been dismissed as inadequate and replaced with concrete based technologies, constructed by outsiders [22]. Marginalising local labour in this way can actually increase vulnerability to future hazards, as once the reconstruction project is over and the imported labour have left, the skills needed to extend, modify and repair houses using the new technologies are lacking, and in many instances the local people revert to traditional methods which can result in dangerous hybrid structures [42]. This is not to say solutions cannot and should not be adaptive or innovative; but these adaptations or innovations, which may originate elsewhere, must be guided by local knowledge and conditions. Also, when local people are involved in the reconstruction process, these approaches are more likely to be broadly accepted and to endure [26].

Indeed sustainability can only be achieved by using local resources (materials and labour) and cultivating skills and knowledge, thus creating micro-economies for those trying to get on with their lives post-disaster [47]. For example, following the earthquake of 2005 that devastated Northern Pakistan, CSR undertook to rebuild some of the most remote and neglected villages there. Reconstruction of permanent housing had been neglected because there was not sufficient expertise amongst those organising the relief effort [12] CRS found that the most effective way to rebuild housing that was safe, adequate and durable was to assist (through provision of materials and skills) local people to build permanent housing with materials they were familiar with. Indeed CRS's overriding aim is to train local people with the skills and knowledge necessary to do the job the next time [40].

When considering the additional burden of building for unpredictable changes in climate, it has been suggested that housing with a higher climatic safety level than considered necessary under the climate regime of today be adopted. However with limited funds this approach may not be considered cost effective, although weighing cost and benefit in this context is certainly not straightforward and introduces new challenges [31]. If there is a clear strategy for sustainable development post-disaster, climate change risk and adaptation must be considered and may in fact inform and contribute to an improvement of previous strategies.

5.4 Organisational and management issues

In regions where natural hazards are more frequent, it may not be possible to reconcile every risk [10], particularly risk associated with climate change. Ultimately, the success of any project hinges on co-ordination (organisational and managerial), both at local and regional levels, within and between organisations. Project leadership is also an important issue in any community-based activity and vital in post-disaster reconstruction [29]. Johnson *et al.* [49] undertook a study of post-disaster environments which demonstrated that the performance of housing reconstruction projects was directly related to the design and management of the project team itself; highlighting the importance of studying decision making in project teams and analysing organisational processes for best practice.

In the past concerns have been expressed that organisations with the necessary available expertise to provide assistance are not necessarily matched up with the expert bodies capable of delivering where help is needed and lack of co-ordination has been blamed [50]. The development of more integrated, interdisciplinary projects is restricted by competition for limited funding and by donors' separate budget lines for emergency relief and redevelopment. There are reports of tension between disaster specialists, development workers and urban planners, and the incompatibility that ensues impedes the establishment of more integrated projects, much needed if a sustainable solution is to be found [30].

6. In conclusion

There are large uncertainties associated with the future performance of the built environment due to changes in regional and local scale climatic conditions. Up until now major natural disasters have been regarded as individual, one-time, localised events, as opposed to regional and potentially frequent. Until the scale, complexity and potential size of these hazards are examined, adequate responses will not always be developed, much less implemented [8].

To secure a reduction in losses to natural disasters, the meeting of the UN's Millennium Development Goals [51], widen human development objectives, and implement successful responses to climate change, it is necessary to undertake a more integrated approach to disaster relief reconstruction [11]. To ensure that every house that is reconstructed following a disaster will work with or withstand future potential disasters, there needs to be an understanding and awareness of potential future risks (including climate change mitigation) alongside the development of strategies to survive or combat them. In order to develop these adaptation strategies, effective ways must be found to strengthen capacity [31] of all those involved. One way of doing this is through the study of current best practice. Meeting the challenge of creating sustainable and self-replicable approaches, approaches that enable large numbers of poor and vulnerable people who need safe, affordable housing to achieve this is the aim of organisation working towards sustainable development. Understanding best practice and how to replicate it, is the first step in achieving this goal.

7. Ongoing research

This study of the literature reveals that it is both prudent and necessary to establish to what extent local knowledge and technical and scientific information is exchanged between the different stakeholders (which includes the end users) and what is encouraging or constraining locally adapted solutions [31], particularly with respect to design, technology and materiality but also construction and building maintenance, in post-disaster housing reconstruction.

Research is currently being undertaken to capture tacit, implicit and explicit knowledge and map the practices of leading aid agencies (NGOs and charities) currently undertaking post-disaster housing reconstruction projects, to understand decision making practices that are working towards sustainable solutions and demonstrate best practice. The results of this research will be published at a later date.

Abstract

Disasters, both natural and man-made, have been occurring with increasing frequency and effect in recent decades in many countries around the world. Among them, Sri Lanka is yet to recover from the effects of December 2004 Tsunami. Among many other reasons it has been identified that lack of awareness of the mechanisms and systems for post disaster waste management is a critical issue of concern. None of the Sri Lankan academic institutions related to the field offer courses designed for the management of disaster waste within the country. Furthermore, none of these institutions conduct awareness programmes aimed at the public on new mechanisms and systems of management of disaster waste. To address these issues, this research aims to enhance capacities to develop new mechanisms and systems for sustainable post disaster waste management focusing on construction and demolition waste. To achieve the identified aim, the research will explore current status of disaster waste management in Sri Lanka and a framework will be proposed for enhancing capacities for sustainable disaster waste management in economical, social and technological aspects. The research methodology includes a comprehensive literature review, semi structured interviews and case study with selected personal views on management of disaster waste management. In this context, the objective of this paper is to present the current scenario of disaster waste management based on the results of a secondary survey.

Keywords: Capacity enhancement, Post disaster management, Waste management, Construction and demolition waste.

1. Introduction

1.1 Background

Disasters cause substantial damage around the world every year [1]. There has been an increase in natural disasters over the past few years and their impact in terms of human, structural and economic losses has also increased considerably. According to statistics issued by the Centre for Research on Epidemiology of Disasters (CRED) and United Nations International Strategy for Disaster Reduction (UNISDR) in 2006, natural disasters killed 91,963 people and destroyed US $ 159 billions worth of property and infrastructure in 2005. Apart from the tragic cost in lives it destroyed and damaged buildings and other infrastructure including building contents, even where buildings were not physically damaged it damaged vegetation at or near coastlines.

According to the European Commission - a key player in post disaster humanitarian assistance processes – the key issues that need to be addressed after emergency relief are: the creation of a foundation for sustainable and long term reconstruction and the commencement of governance structures and projects in critical areas of recovery, recreating communities and livelihoods, rehabilitation of the environment including waste management, rebuilding infrastructure and transport processes, and strengthening local governance [2].

Thus, it is evident that effective waste management strategies and strengthening local governance in related aspects following a disaster is emerging as an important area of consideration.

1.2 Research problem

Both natural disasters and conflicts often result in damage beyond economic repair of large quantities of building stock and infrastructure facilities requiring demolition with the subsequent removal of debris. The demolition of ruins and the reconstruction of buildings generate further construction waste.

According to official figures available on the Marmara Earthquake, Turkey, an estimated 13 million tons of total rubble quantity were generated as debris. Although a stationary recycling plant was implemented for processing this waste stream, due to practical difficulties the majority of construction and demolition waste were not processed. Ultimately, waste was disposed of at 17 dump sites, including some illegal dumping carried out at coastal lines during the emergency phase [3]. In the case of the Hansshin-Awaji earthquake in Kobe, Japan an estimated total quantity of over 15 million cubic metres of demolition waste were generated. Of this only a minor proportion of it was recycled with the majority being either disposed of or used for land reclamation [4].

Unplanned disposal causes numerous problems with an increasing population since it consumes a considerable proportion of already scarce landfill sites. According to statistics, in the USA, construction and demolition waste contributes approximately 29% to overall landfill volumes, in the UK it contributes more than 50% and in Australia it contributes 20–30% [5]. Hence, it is an increased necessity to reduce levels of waste generated in the post disaster scenario due to environmental and economic reasons.

The management of this debris, as well as waste generated during reconstruction works poses significant challenges to national and local capacities. If such waste is not properly managed, it may cause serious environmental and economic burdens on normal living conditions as well as on the reconstruction phase itself. This includes the negative effect that debris can have on general municipal waste collection and handling operations, which is one of the major challenges following disasters. These critical issues bear evidence to the fact that construction and demolition waste is becoming a global dilemma in post disaster scenarios.

1.3 Scope

In recent years, several major disasters have occurred in coastal areas worldwide. Among these the Asian Tsunami that hit the coast of Sri Lanka on 26th December 2004 was an unique experience which occurred within recent memory, where nearly one million people (234,000 families) were affected in 13 districts. Since the coastline of Sri Lanka is heavily populated, where most of industrial and commercial activities take place, the country's economy was seriously affected. In addition to loss of life, the tsunami destroyed and damaged buildings and other infrastructure facilities, damaged building contents, even if a building was not physically damaged it further destroyed or damaged vegetation at or near the coastline [6]. According to the Joint Report of Government of Sri Lanka and Development Partners (2005) [7], it destroyed US $ 900 million worth of assets and infrastructure in Sri Lanka. This is considered the highest ever recorded value of disaster/destruction damage caused by a single event, in the Sri Lankan context.

A specific proportional breakdown of the tsunami-generated waste is not available. A rapid inspection of waste generated at damaged areas, observed at unauthorized dumps and unplanned landfills, indicate that a large part of related waste consist of spoiled soil, damaged building material and vegetative matter, including branches, wood and domestic refuse. Smaller proportions of waste include plastic, metal (of various types and condition) and items of undetermined origin was also noted. No significant presence of hazardous chemicals or technological items (e.g., computers, televisions) was noted. Overall, an estimated 80% of waste consisted of either spoiled soil, building materials or vegetative matter.

According to the Progress Report of the European Commission Post Tsunami Rehabilitation and Reconstruction Programme (2006) [2], there are no such significant developments being made in respect of waste management in Sri Lanka, among the worst affected countries such as Indonesia and the Maldives. Local government authorities and volunteers worked diligently to remove debris and clean up neighbourhoods. Land owners also cleaned their own premises and disposed of waste off their lands by depositing it at outside locations for collection and removal. At present, collected waste is deposited at unplanned landfill sites in environmentally sensitive areas. (For some time now, dumping of waste on beaches or common lands has been made illegal. Some burning of waste still continues, but has been reduced by a general clean-up effort.) Limited, unorganised scavenging is taking place but it is focused on easy ways to collect high value items, principally usable sawn wood and metal. Owners of some waste, for instance a destroyed building, also retrieve bricks, wood and other reusable objects. These efforts, which shall be encouraged, reduce the waste stream, but probably not in significant proportions. Therefore, clearing, salvaging, rehabilitation and reconstruction work fully or partly require serious efforts of the government sector.

However, United Nations Development Programme Report (2005) highlights poor performance of post-tsunami rehabilitation operations affected by a lack of responsive capacities with local government institutions to address the needs of an event of such magnitude. This was mainly caused by the fact that the strategic and operational level capacities of institutions responsible for public and commercial facilities were not expected to cater for a devastation of this magnitude. As such it has been identified that capacities of relevant institutions in Sri Lanka need to be improved to launch successful post disaster recovery programmes and to face any future challenges similar to the Asian Tsunami (United Nations Educational Scientific and Cultural Organisation, 2005; Asian Disaster Reduction Centre, 2005). In particular, the Joint Report of Government of Sri Lanka and Development Partners (2005) [7] revealed that the construction industry in Sri Lanka did not possess the adequate number of contractors, equipment, skilled workforce, modern management practices or access to easy finance necessary to maintain the required speed of post tsunami reconstruction work. This is a critical issue that needs to be addressed for the purposes of effective post disaster rehabilitation. There are no readymade solutions and every programme must be appropriately designed for a given post disaster scenario. This concept is very effective for developing countries, since most of them lack resources and suffer from inefficient use of available resources.

Among many other issues, capacity building is becoming crucial to increase an organisation's access to information and technical know-how by improving internal management structures, processes and procedures as well as strengthening partnerships among various players in waste development process.

1.4 Aim, objectives

According to above discussions it is apparent that to implement effective post disaster waste management strategies, among many key issues, the capacity of a local area to cope with waste generated by a disaster emerges as a crucial issue. Therefore, the primary aim of this study is to identify capacities that need to be enhanced for a sustainable post disaster construction and demolition waste management process. The following are the objectives identified to achieve this aim:

- Understanding of key concepts of disaster management, waste management and capacity building
- Identification of relationships between construction and demolition waste within the context of post disaster scenario.

- Identification of adopted strategies in post disaster waste management at recent Asian Tsunami disaster.
- Identification of key factors hindering progress of construction and demolition waste management within the context of the recent Asian tsunami disaster.
- Identification of key enabling factors of capacity building in post disaster waste management process.
- Developing a framework to enhance capacities of post disaster construction and demolition waste management processes.

2. Research methodology

A comprehensive literature survey and review will be done on the concepts of post disaster management, waste management and capacity building by referring to official reports on rehabilitation and reconstruction efforts, text books, journals, articles, conference papers and electronic sources to familiarise and build up the research. The review will be extended to identify the relationship between construction and demolition waste within the context of the post disaster scenario.

The Tsunami, which hit Sri Lanka on the 26th December 2004, has been selected as the case study for this research since it was the major disaster which occurred recently in coastal areas of the Asian region, killing nearly 250,000 people around the Indian Ocean. A detailed documented survey will be carried out on post-tsunami waste management processes in order to identify the different waste management strategies adopted. Furthermore, both structured and unstructured interviews will be conducted with selected personnel in governmental and non-governmental organisations to collect information on post tsunami waste management strategies, their suitability, applicability and to identify key factors which hinder progress of disaster waste management. In addition, a questionnaire survey will be conducted among tsunami victims in order to identify issues relating to post tsunami waste management programmes already adopted.

An in depth analysis will be carried out to identify the key enabling factors of capacity building in post disaster waste management processes, based on the data collected through the local field survey.

A framework will then be developed by incorporating the above findings to enhance the capacities in terms of economical, social and technological aspects which contribute to sustainable post disaster waste management processes. The framework will be tested with real life scenarios and evaluated using domain experts.

3. Literature findings

Since the study is at initial stage, scope of this paper is mainly based on the secondary data that is collected through a detail literature review. The following section of this paper presents the literature findings on disaster management, waste management and capacity building in both a local and global context. In the later part a discussion will be provided on the current status of construction and demolition waste management in the Sri Lankan context referring to the case of the tsunami disaster.

3.1 Disaster Management

The world is facing a increased frequency and intensity of disasters – natural and man made with devastating impacts. Disaster Management Centre, Sri Lanka 2007 [8] defines “a hazard is a rare or extreme event in the natural or human-made environment that adversely affects human life, property or activity to the extent of causing a disaster”. International Strategy for Disaster Reduction – ISDR (2004) [9], has defined disaster as a “serious disruption, of the functioning of a society, causing widespread human, material or environmental losses, which exceed ability of an affected society to cope using its own resources”.

With reference to above definitions, key words and phrases in disaster are “sudden or unexpected, crisis situation, serious disruption of functioning of a society, causing widespread human, material, or environmental losses and overwhelms local capacity”. It should also be noted that in disasters there are no prior warnings and thus, people are not adequately prepared. This can result in disruption of an entire system. This study considers only one natural disaster, in the recent tsunami, which is categorised under Earthquake Hazards. A tsunami is a series of enormous waves created by an underwater disturbance such as an earthquake, landslide, volcanic eruption, or meteorite.

Disaster management is a “collective term encompassing all aspects of planning for and responding to disasters, including both pre- and post-disaster activities” [10]. It may refer to management of both risks and consequences of a disaster. Amarasinghe *et al* (2006) [11], defined disaster management as “an applied science, which seeks, by the systematic observation and analysis of disasters to improve measures to prevent, respond and recover from effects and consequences of a disaster”.

The disaster management cycle illustrates the ongoing process by which governments, businesses and civil society plan for and reduce the impact of disasters, react during and immediately following a disaster and take steps to recover after one has occurred [12].

According to Warfield at the Global Development Research Center [12], a disaster management cycle includes four phases: mitigation, preparedness, response, and recovery. According to his explanation, four disaster management phases illustrated here do not always, or even generally, occur in isolation or in this precise order. Often phases of the cycle overlap and the length of each phase greatly depends on the severity of the disaster. According to RICS (2006) [13], the disaster management cycle is visualised as a two-phase cycle. The main phases are pre-disaster risk reduction phase and post-disaster risk recovery phase as presented in figure 1.

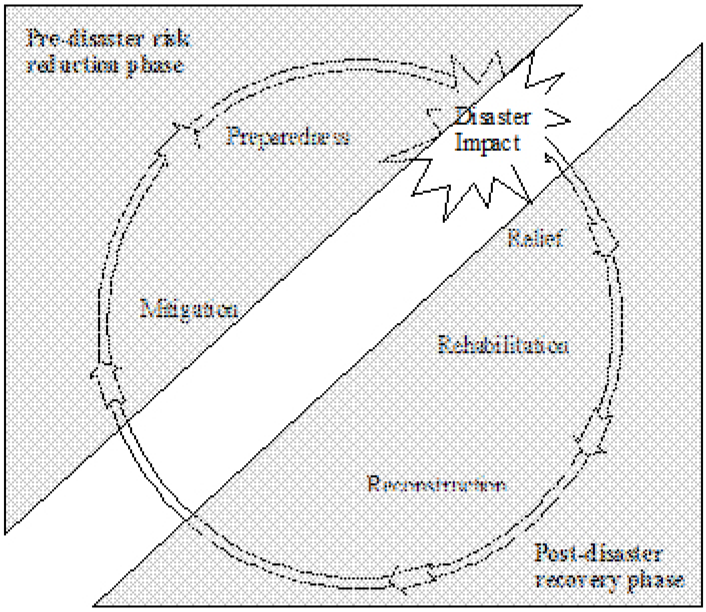

Figure 1: Disaster management cycle by RICS (2006)

This research mainly concentrates on the rehabilitation phase of the disaster management cycle. The rehabilitation phase is also known as the transitional phase. The main activities of this stage include removal of debris, assessment of housing needs and establishment of a baseline and eligibility criteria; plan and construct transitional shelters/repair lightly damaged property, provide job opportunities to survivors, public work programmes etc. To initiate other phases of the disaster management cycle it is important to apply appropriate strategies to expedite the rehabilitation phase and reduce future impacts of similar disasters.

3.2 Waste management: construction and demolition

There are scores of definitions introduced by many researchers on construction and demolition waste (C&D), which is posing to be a major environmental problem in many countries nowadays.

In general, waste is best defined as any material by-product of human or industrial activity that has no residual value [14]. But Pinto and Agopyan (1994, cited [5]) argue that construction industry waste has a residual value. Hong Kong Polytechnic (1993 cited [15]) defined construction waste as “the by-product generated and removed from construction, renovation and demolition work places or sites of building and civil engineering structures”.

All these definitions suggest that construction and demolition waste generated from construction, renovation or demolition of works, have a unique characteristic over other types of waste due to their residual value. Many researches proved that demolition waste contains higher proportion out of total solid waste generated in any country ([5, 16]).

As discussed at the beginning, the construction industry is the leading waste generator in the world. Many researches prove this fact ([5, 15]). Despite being a major generator of avoidable waste the industry has been slow to embrace environmentally friendly practices ([5]).Therefore, it is important to maximise environmentally sustainable values through minimising construction and demolition waste. Sustainability is a systematic concept, related to continuity of economic, social, institutional and environmental aspects of the human society [17]. Sustainable development or ecologically sustainable development is defined by the UN as “Development that meets the needs of the present without compromising the ability of future generations to meet their own needs” [17].

Therefore this study will propose a framework to enhance capacities to achieve sustainable post disaster waste management strategies.

3.3 Capacity building

The term “capacity building (CB)” and “capacity development (CD)” are highly elastic, in that they can be stretched to embrace different activities. Such activities include capacity building in various unrelated organisations, management schools, agricultural research and development, non-governmental etc. The term capacity building often implies activities which are carefully planned and executed in order to build the capacity. Capacity development can be defined as a process by which individuals, groups and organisations improve their ability to carry out their functions and achieve desired results over time (Peter, 1997 cited by [18]). This definition highlights two important points: that capacity building is largely an internal process of development and that capacity development efforts should be results oriented.

Capacity building is defined in multiple ways. With reference to United Nations Center for Economic Development (UNCED) (1992 cited [19]), capacity building encompasses a country’s human, scientific, technological and resource capabilities. A fundamental goal of capacity building is to enhance the ability to evaluate and address crucial questions related to policy choices and modes of implementation among development options, based on an understanding of environmental potential and limits perceived by people of a country concerned.

Capacity development is often needed to raise performance levels of a particular organisation. Organisational capacity refers to staff and resources, as well as its structure, management systems and linkages with other organisations. Organisational motivation refers to the culture and inducements which influence capacities of an organisation in pursuit of its goals. Finally, an organisation’s performance is reflected in its effectiveness, efficiency, and sustainability. The relationship between four dimensions is presented in figure 2.

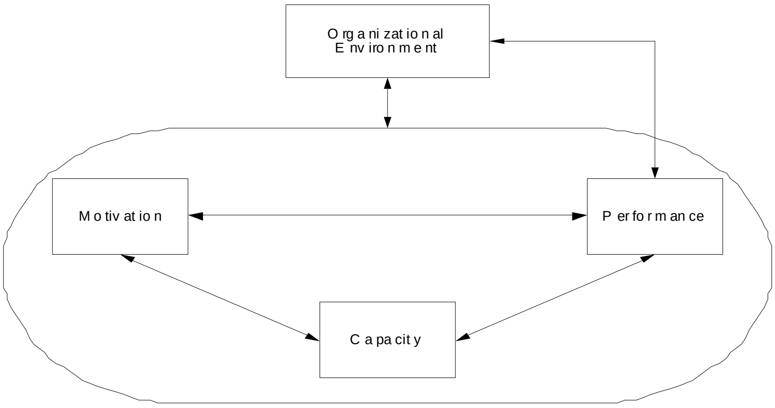

Figure 2: Relationship between organisational environment, performance, motivation and capacity.

Capacity development efforts may focus on different levels, ranging from micro level of the individual to the macro level of national and international organisations. According to Hortan, 2002 [18] capacity development efforts generally include one or more of the five approaches. They include information distribution, training, facilitation and monitoring, networking and feedback to promote learning from own experience.

Practically all capacity development efforts distribute information in one form or another. Training is another common tool used in developing participants' knowledge, skills, and attitudes. Facilitation by a change agent is generally more effective. However, facilitation tends to be labour intensive and considerably costly. Capacity development can also be promoted through exchange of information and experiences among people working on similar tasks in different settings, as well as through workshops, networks, and communities of practice. Learning within an organisation can also be promoted by internal evaluations that provide rapid feedback to individuals and groups (Leeuw and Sonnichsen 1994, cited by [20]).

Capacity development should not be viewed as a one-time event such as a training event or installation of a new accounting system. Capacity development is a process that needs to be managed over time. Research and development organisations need to continuously develop their capacities to deal with new opportunities and threats arising from changes in technology, markets, politics, and other factors. In this sense, there is no final, achievable goal for an organisation's capacity development.

4. Discussion

The following section provides a brief discussion on post disaster waste management strategies applied for the tsunami and its successfulness is based on information collected through secondary surveys.

The tsunami hit the coast of Sri Lanka on 26th December 2004. Nearly one million people (234,000 families) were affected in 13 districts namely, Puttalam, Gampaha, Colombo, Kalutara, Galle, Matara, Hambantota, Ampara, Batticaloa, Trincomalee, Mullaitivu, Kilinochchi and Jaffna. Since the coastline of Sri Lanka is heavily populated where most of the industrial and commercial activities take place, the economy of the country was seriously affected. In addition to loss of life, the tsunami destroyed and damaged buildings and other infrastructure, damaged building contents, even when a building was not physically damaged it damaged vegetation at or near the coastline. The destruction and damage has generated a large volume of solid waste.

Local government and volunteers are working diligently to remove debris and clean up neighbouring areas. Land owners are also cleaning their premises and depositing waste at locations for collection. At present, the waste collected is being deposited in unplanned landfills in environmentally sensitive sites. (Earlier dumping of waste on beaches or common lands was stopped. Some burning of waste continues, but has been reduced by the general clean-up effort.) Limited, unorganised scavenging is taking place but it is focused on easy ways to collect high value items, principally usable sawn wood and metal. Owners of some waste, for instance a destroyed building, are also retrieving bricks, wood and other reusable objects. These efforts, to be encouraged, will reduce the waste stream but probably not significantly.

The observed composition of waste suggests that a large portion of waste can be recycled. This would reduce the overall waste steam and the need for landfill space. Discussions with institutions indicate that a good part of recyclable waste (dirt, construction materials, and vegetative matter) can be used to rehabilitate near-shore areas degraded by mining for coral and later flooded by the tsunami, or as fill for areas damaged by erosion. Although initial discussions focused on shifting disposal from landfills to filling near-shore areas, agreement was reached that any rehabilitation work should be done with properly selected and prepared waste materials to avoid future environmental problems.

The collection and disposal of tsunami-generated waste should expand to include recycling of all appropriate materials. A large part of recycled material can be used to assist in the tsunami recovery process, including rehabilitation of affected land. Recycling will also reduce the volume of material which needs to be deposited into landfills, thus reducing overall negative impacts of cleaning and disposal processes.

In addition, responsible institutions need to fulfil the following requirements to effect a successful waste management process:

- Characterisation and quantification of waste
- Operations and logistics of recycling site set-up
- Disposal of items which cannot be easily recycled.
- Establishment of a permanent landfill

5. Conclusions

The generation of waste during a disaster is unavoidable and the only solution is waste minimisation. The primary area observed through this secondary review is the available opportunity to divert construction and demolition waste into reusable/recyclable building material. It can be mentioned that even though there are large number of opportunities in this regard in Sri Lanka this is still at the preliminary stage. Many constraints such as inconsistent nature of demolition debris, instability in the secondary material market, lack of interest, lack of government regulations, lack of interest for sorting, unavailability of required technology, improper and insufficient attention paid to quantification and identification of waste materials were identified as main reasons for being at the preliminary stage of waste management programmes. Finally, it can be concluded that the impact on the environment and economy from disaster waste can be minimised through proper benchmarking, being aware of consequences and trying to eliminate them.

Recently, the local industrial sector was changed to a certain extent, from its traditional fragmented processes towards a more client oriented business approach, which recognizes the importance of innovation, training and research. It was encouraged to modernise an organization by developing capacity and adopting collaborative and sustainable approaches within industrial sector of the country. This issue has still not significantly influenced the construction sector when compared to manufacturing and other industrial sectors. Therefore, this study will focus on enhancing capacities of post disaster waste management processes that will lead to sustainable waste management.

Abstract

Poor response capacity has been identified as a major inhibitor for successful post tsunami recovery attempts in Sri Lanka. Despite level of incentives aid and help which have been received from the international communities, both governmental and nongovernmental organisations, have evidently failed to deliver expected levels of performance in post tsunami recovery activities. It is of utmost importance to identify and overcome the related capacity gaps if Sri Lanka is ever to recover from the December 2004 devastation and any future disasters. Within the light of this, as the first step towards recovery, the country must fully understand the nature and scale of its capacity gaps related to the post disaster recovery.

Addressing this issue, the EURASIA (European and Asian Infrastructure Advantage) international collaborative research programme has conducted a series of interviews with key personnel in Sri Lanka to explore the nature and magnitude of this problem. The main objective of this paper is to present the outcome of these key expert interviews highlighting the priority attention areas and possible actions towards minimising the post tsunami recovery capacity gaps in Sri Lanka.

1. Background

1.1 Disasters and the developing world

During the past decade, the number of worldwide disasters has risen sharply. The Annual Disaster Statistical Review 2006 [1] highlights that the number of natural disasters that occurred in the period 1991 to 1999 varied between 200-250, while the figures have almost doubled during the period 2000 and 2006. Despite the continuous and rapid growth in the number of natural disasters, the number of actual victims affected by disasters has varied considerably along the timeline and across regions. During the last two decades, the average annual number of victims affected by natural disasters ranged between 100,000,000 to 300,000,000 [1]. Further, the Asian continent has experienced the greatest loss of life in absolute terms and in proportion to the population, due to natural disasters. As CRED [2] reports, the figures accounted for an average of 83.7% people killed in natural disasters in Asia, compared to Europe (10.55%), America (3.54%), Africa (2.16%) and Oceania (0.05%) during the period 2000-2005.

Within these fatality rates, a significantly higher number of death tolls is evident in developing countries compared to the developed countries [3, 4]. For an example, the earthquake which hit central California in 2003 with a magnitude of 6.5 on the Richter scale, took two lives and injured 40 people [5] whereas the earthquake which hit Iran four days later with a magnitude of 6.6 killed at least 26,000 people [5]. As one would suspect, this immense difference in the death toll is not uniquely related to factors such as population densities, as both events took place in areas with high-density populations. Not only do developing countries experience higher levels of mortality during a disaster, they generally require longer periods for post disaster recovery.

Within a typical disaster management scenario, 4 distinguishable stages exist [4]. Those are:

1. Pre-disaster planning
2. Immediate relief
3. Transitional phase
4. Medium/Long term recovery

Within the pre-disaster planning stage, the vulnerable counties prepare strategies and plans of actions to meet the demands of the future disasters. Just after the disaster itself, the immediate relief stage starts, within which the focus is on providing immediate relief to the victims. Often during this stage, the disaster receives the maximum attention from relief agencies and media exposing the affected communities to possible routes of obtaining required resources and help. After the immediate relief phase, the affected communities often go through a transitional period between the aftermaths of the disaster and their normal way of life. However, without a proper medium/long term plan for the recovery, the affected communities will experience a prolonged transitional period leading to an unsettled society.

As the “Mind the gap” report [4] highlights, even though the developing countries often receive financial and other humanitarian support from international communities, nongovernmental organisations and donor agencies as immediate relief aid, generally long-term recovery has primarily been identified as a national, sub-national and local government-led matter. As such, traditionally the donors and other organisations working towards humanitarian relief pay less attention to the long term recovery aspect of disaster management. Thus, not surprisingly, developing countries who witness disasters, often fail to launch successful long term disaster recovery programmes especially due to lack of resources and capacities, both in financial and intellectual terms. Consequently, this inability hinders the value of the resources dispersed and services rendered by the donor agencies within the immediate relief stage. For these reasons, there is a need to assess the long term disaster recovery issues in developing countries.

1.2 The case of post tsunami Sri Lanka

The case of post tsunami Sri Lanka exemplifies the issues related to the post disaster long term recovery in developing countries. Sri Lanka is a small island situated close to southern tip of India near the equator. It is a developing country with the total population just over 20 million. Before the Indian Ocean Tsunami, Sri Lanka was known to be a safe haven where outrages of nature scarcely occurred except for occasional floods and landslides. However, the Tsunami affected 75% of the coastline of Sri Lanka. It also resulted in the destruction of more than 100,000 houses [6] which in turn also resulted in the taking away of several livelihoods such as fishing, farming, tourism and handicrafts-related activities. In addition to commercial and non-commercial property damage, the number of deaths apportioned to the Indian Ocean Tsunami is estimated to be in excess of 130,000 with at least 31,000 of those in Sri Lanka [7]. The lack of awareness of the nature of a tsunami, among the Sri Lankan public, is quoted as one of the reasons for this mammoth death toll [8]. Indeed, the term “Tsunami” was heard by most of the ordinary Sri Lankans only after this devastation.

During the immediate relief stage, Sri Lanka received humanitarian relief aid from donors all over the world. This aid was in the form of financial assistance, equipment and materials and human resources for rescue/relief missions. While most of the aid was aimed at providing immediate relief to the victims, some of the funds were meant to be utilized for long term recovery attempts such as reconstruction of houses and infrastructure facilities.

Four years on, Sri Lanka is yet to recover fully from the devastation of the December 2004 tsunami. In fact, after a successful immediate relief phase [9], Sri Lanka is going through its transitional period between the short term relief and the medium/long term recovery. The Sri Lankan government started the long term recovery programmes with optimism and expectations for speedy recovery [9]. In fact the government expected the post tsunami recovery programmes to be completed within 3-5 years [10]. Further to this optimism, as Weerakoon et al [9] highlights there were pronouncements at political level about even speedier recovery intentions, such as meeting all permanent housing needs within one year of the devastation. However, this target has not been fully met even after three years [9].

With reference to the infrastructure, the pace of recovery of larger scale infrastructure projects, has reported been slow with an estimated 50% of construction projects yet to commence by end 2006 [11]. As GOSL [11] highlights, by end 2006, 134 of 182 damaged schools were estimated to be in various stages of construction. However, by the end of 2005, construction work had started only in 18 schools. Similarly, within the health sector only 55 of a total of 102 damaged buildings have been completed by June 2006 [9 cited 12].

1.3 Capacity building for post disaster recovery

From the above figures it is clear that the post tsunami recovery (long term) attempts in Sri Lanka were less than successful compared to the government's expectations and plans. One of the problems the governments of developing countries often face, with regards to post disaster recovery, is their response capacity. Generally, capacity at local government level to plan and implement post disaster recovery strategies is limited and incapacitated as a result of the disaster itself. In the light of this, strengthening local capacities for this process has been identified as a main priority [10, 13].

Strengthening national capacities of developing countries towards post disaster recovery predominantly demands financial incentives. Such incentives given by donors during a disaster are generally routed towards short term relief efforts rather than long term recovery programmes. As a result, the governments of affected countries (specifically developing countries) are financially incapable of launching successful long term recovery programmes [4]. As such, it has been identified within recent reports (e.g. [4, 10]), that the main focus of the donor organisations should be to achieve the appropriate balance of fund allocations between the immediate/short term relief and the medium/long term recovery. The donor organisations such as UN have recently recognised this aspect as a timely priority[10].

Lack of financial capability is a major contributing factor preventing a county from obtaining required physical resources such as equipment and infrastructure to launch successful long term post disaster recovery programmes. A lack of appropriate intellectual capacity can be recognised as another factor hindering the implementation of successful recovery plans. In this scenario, lack of intellectual capacity refers to lack of knowledge, expertise and training related to post disaster recovery within the relevant local authorities/institutions. Affected countries could be intellectually incapacitated for various reasons and at various levels. The Brain Drain, the lack of proper coordination between relevant authorities/institutions and immature organisational processes can also be highlighted as behind intellectually incapacitated countries. In some instances, mere lack of expectancy can also be a reason for a county to demonstrate intellectual incapacity in long term disaster recovery. For example, some of the Sri Lankan authorities [13] may have been incapacitated when responding to post tsunami (December 2004) recovery attempts due to the fact that Sri Lanka had not experienced a tsunami for centuries and there was no reasonably predicted reason for them to be prepared for devastation of that scale.

Highlighting the importance of improving local capacities in post disaster recovery, various reports (e.g. [11, 13, 14]) have highlighted the development of institutional mandates and capacities as a key focus area in achieving success in implementing its post tsunami long term recovery measures. These reports further acknowledge that identification of the capacity gaps in relevant institutions and authorities is a prerequisite placed above the task of developing institutional capacities and still very much to be completed along the country's journey to long term recovery from the December 2004 tsunami. In the light of this, this paper addresses the following research question:

“What priority capacity gaps exist within relevant authorities and institutions in Sri Lanka that need to be addressed to achieve successful long term recovery from the December 2004 tsunami?”

2. Methodology

The rest of this paper presents the outcome of an empirical investigation carried out by the authors with the intention of addressing this research question. This research work was carried out as part of an international collaborative research project, EURASIA. The **EUR**opean and **AS**ian **I**nfrastructure **A**dvantage (EURASIA) is a 3 year research collaboration between Europe and Asia funded through the ASIA-LINK programme of the European Union. The specific objective is to enhance the capacity of the partner institutions for training, teaching and research activities required for the creation and long-term management of public and commercial facilities and elements of infrastructure associated with post tsunami activities in Sri Lanka.

The overall approach to this research took the shape of a case study. This helped to meet the challenges of the research question being answered, specially to investigate the phenomena deeply and thoroughly, within the limited context of post tsunami Sri Lanka. The case study approach further supported the exploratory nature of the study where the concepts related to questions being answered gradually enriched throughout the investigation. Within this scenario, the boundary of the case study was defined as the post-tsunami recovery attempts in Sri Lanka. The unit of analysis was defined as the capacity gaps prevailing within the above boundary. The study was conducted as a single case study as the phenomena being investigated is unique, considering all the economical, cultural and geographical parameters related to the context.

The data collection approach was centred around a series of semi structured interviews conducted with 12 organisations involved in the post tsunami recovery programmes. These organisations were selected based on their level of involvement in the recovery actions in Sri Lanka. Main offices of all the organisations selected are based in Colombo, Sri Lanka, while the activities carried out by these organisations are geographically widespread to include all the Boxing Day tsunami affected areas, including the Eastern part of the island. All the interviews were conducted between 1st June 2007 and 30th June 2007, in English. Due to the high sensitivity of the issues being discussed, an agreement has been reached between the investigator and the organisations involved regarding maintaining the anonymity of the participants. For this reason, the true identity of the participating organisations or the interviewees has not been revealed within this paper. However, all the personnel interviewed within this study are either top level or medium level managers as the information intended to collect was of strategic level rather than operational level. During the interviews, information about the experiences of the interviewees regarding the successes and failures of the post-tsunami recovery attempts in Sri Lanka were collected. The interview guide prepared for the semi structured interview was structured in such a way that, as the interview progresses, it captures the issues related to the failures of recovery attempts and reasons behind success stories experienced by the interviewees. The preparation of the interview questions was informed by a literature review to note the capacity gaps already identified within the above context. This ensured that this research was not attempting to re invent the wheel.

All the interviews were transcribed and analysed to identify key capacity gaps that hinder the success of post-tsunami recovery in Sri Lanka. The data analysis strategy is based on the principles of content analysis where the concepts related to the phenomena are captured through analysing the contents of the interviews qualitatively. To ensure all the data captured during the data collection stage was treated with care and consistently, the authors used a qualitative data analysis tool namely, NVivo (version 7). This is a computer based qualitative data analysis tool to help organise and analyse qualitative data systematically and transparently.

The next section highlights the outcome of the analysis.

3. Analysis and results

3.1 The analysis process

The first step of the analysis was to identify “concepts” which emerged during the interviews. For this purpose, the interview transcripts were carefully reviewed by the researchers within NVivo while highlighting the main ideas presented by each interviewer for each question asked. These “concepts” were then recorded within NVivo as “free nodes”. Within NVivo a free node represents an idea that has emerged from a data source (in this instance from an interview transcript). Figure 1 below shows the list of free nodes identified within the transcripts analysed.

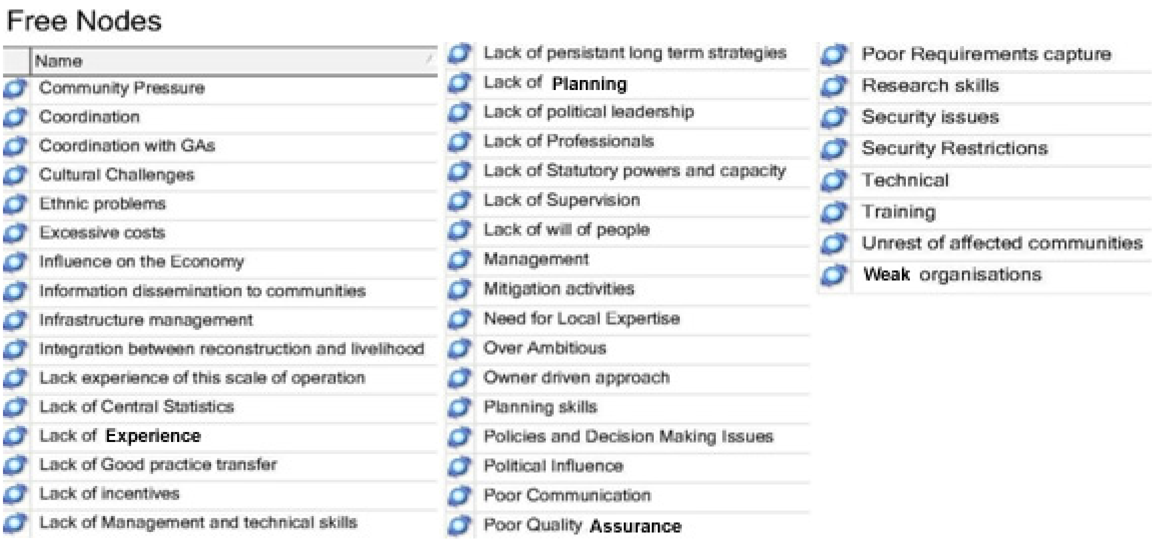

Figure 1- Concepts identified from the interviews as free nodes

Each of the free nodes identified above are based on comments made by the interviewees. While identifying these key concepts as free nodes, NVivo keeps a track of references about which interviewee(s) commented about the concept, and on how many occasions. There were instances where the same concept has been referred to by several interviewees more than one time. For example, lack of planning skills was identified as a capacity gap in 5 occasions by 2 interviewees during the interviews. During the first part of the analysis, these concepts were recorded in free nodes to ensure all collected data was considered in the analysis. The second stage of analysis focused on identifying how these initial concepts map together to answer the research question.

During the second stage of analysis, the initial concepts were mapped with the various aspects of the research question being answered. While the main aim of this research was to identify the main capacity gaps in post tsunami recovery Sri Lanka, the interview guidelines have been prepared to capture various elements of the main issue. For an example, the interviewees were motivated to talk about the capturing post tsunami recovery capacity gaps in Sri Lanka in four main areas. Those areas are:

1. Financing
2. Human resources
3. Institutional (both governmental and non governmental)
4. Skills References

Determination of these four areas is based on the outcome of a literature review, where the key elements of post disaster capacity gaps have been discussed based on previous work in the field. This discussion is considered to be outside of the purpose of this paper and is being prepared to be presented elsewhere.

Further, during the interview process the interviewees were guided towards revealing possible causes for capacity gaps and possible solutions to overcome them. For example, with the help of the focus of the interview guideline, the initial concepts identified in the first stage of the analysis could be converted into a grouped layout, which gives a clearer image about how those concepts map with the research question being answered. In NVivo this grouping of concepts can be presented as “tree nodes”. With the creation of these tree nodes, some key “themes” emerged about post tsunami recovery capacity gaps in Sri Lanka.

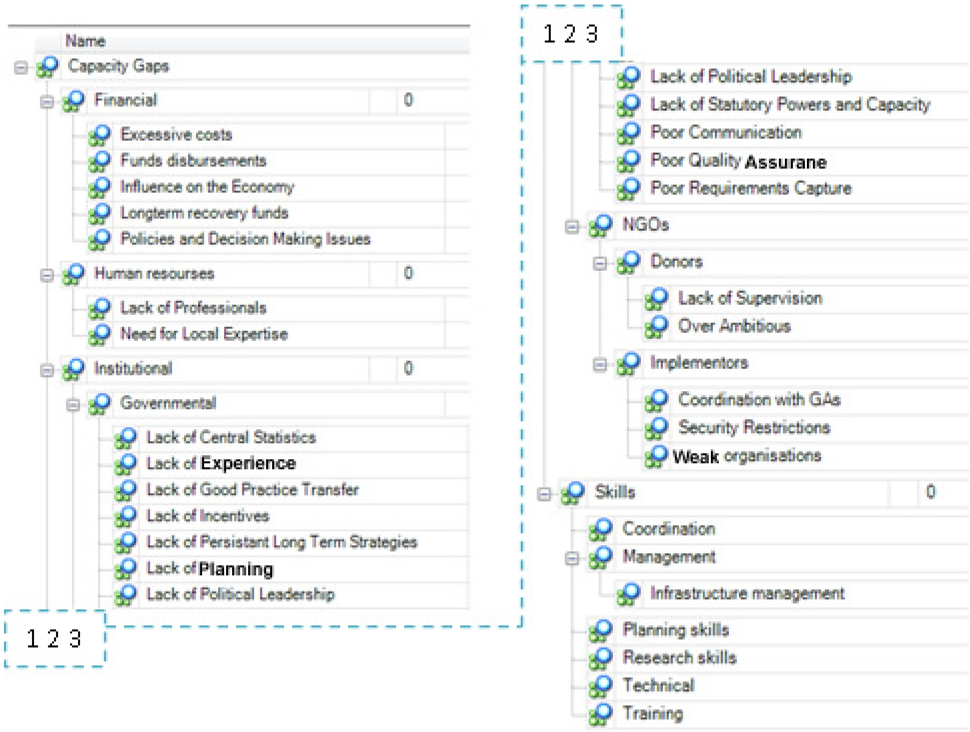

Figure 2 - Key themes organised as tree nodes

In addition to this "grouping", the researchers identified "relationships" within and between the concepts and themes. These relationships lead to present the identified capacity gaps with causal-effect explanations. The identified concepts, key themes and relationships were then modelled using NVivo to understand and represent the results more thoroughly. The next section discusses the results of the analysis in more detail with the help of the models.

3.2 Results

As discussed above, within this research, the capacity gaps in post tsunami Sri Lanka have been investigated in four main areas. The rest of the paper discusses the results of the empirical investigation with reference to these areas of capacity gaps. Further, under each area the results will be discussed with the aim of answering the research question "what are the main capacity gaps identifiable within Sri Lanka while attempting to recover from the devastation of the December 2004 tsunami?" Additionally, the causes and effects related to the identified capacity gaps will also be discussed, where appropriate, through the concepts and themes identified from the interviews.

3.2.1 Capacity gaps related to skills shortages and human resources

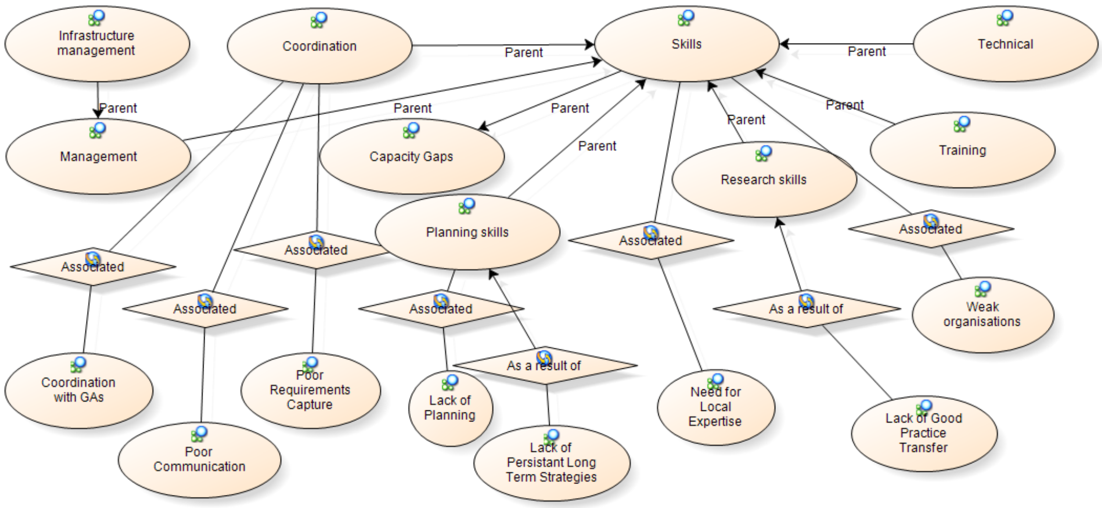

Figure 3 - Skills shortage as a capacity gap - links and relationships

During the interviews, skills shortage has emerged as a main capacity gap in post tsunami Sri Lanka. In fact 18 references were made by the interviewers in 9 occasions about various skills shortages as capacity gaps. As illustrated within the Figure 3 above, 6 main skills areas that require capacity enhancements have been identified from the research. These are:

1. Coordination skills
2. Management skills
3. Planning skills
4. Research skills
5. Technical skills
6. Training skills

Out of these capacity gaps in skills; coordination, management and planning have been identified as key areas of concern. Post disaster recovery attempts in general require a great deal of coordination between various parties, planning of appropriate actions and management of the work. Within the context of this research, the interviewees highlighted significant gaps in the above areas including the requirements capture actions to resettlements. For an example, during the interview, one interviewee pointed out that post tsunami housing reconstruction work in some areas do not appeal to the affected communities as the houses are constructed without giving much attention to the infrastructure availability within the area. In another interview, the same point was raised and highlighted the fact that some of the affected communities are not willing to be settled in the newly built areas as they were constructed without giving due consideration to the livelihoods of the affected communities (e.g. fishermen are reluctant to be relocated away from the coastal area). This highlights that the relevant authorities have not demonstrated required planning, coordination and management skills within the context of post tsunami recovery in Sri Lanka. Highlighting a planning issue, one interviewee commented that there is a visible lack of persistent long term strategy to implement the post tsunami recovery actions in Sri Lanka. For example, the interviewee pointed out that the government had to change its position on the costal buffer zone consistently to address the issues such as the community pressure. Had this strategy been reviewed thoroughly before the decision, the actions could have been implemented more successfully. These issues are not visible only in government authorities. In fact the interviewers have highlighted that fact that these issues exist in government authorities, donor agencies as well as in NGOs who are involved in post tsunami recovery actions. This issue will further be discussed under the section 3.2.2 below.

In addition to the skills gaps identified above, the capacity gaps in research and training have also been identified as shortcomings to implement successful post tsunami recovery actions. In terms of the capacity gaps in research, the interviewees felt that in general, the research activities are under-funded in Sri Lanka. Some interviewees specifically identified that disaster management research and training activities in Sri Lanka were not especially strong before the tsunami. Even though there is evidence to support improved research and training activities related to disaster management recently, interviewers raised their concerned about the current research and training capacities in Sri Lanka to deal with the demands of post tsunami recovery activities.

It has also been identified that some of the required technical skills for post disaster recovery in Sri Lanka are lacking. Interviewees commented especially about the shortage of construction technical skills in post tsunami Sri Lanka to cater for the massive demand created with the start of the post tsunami reconstruction work. As an example, two interviewees mentioned that labour rates in construction has risen sharply recently, demonstrating a shortage in skilled labour. Further, particular emphasis has been drawn to the fact that there are tsunami affected areas where the security problems exist due to the ethnic problem in Sri Lanka. Due to the reluctance of skilled construction workers to work in these areas, a prominent technical skills shortage exists.

As mentioned above, these skills shortages are not limited to one particular organisation, group or sector. Rather these have been identified in various authorities and institutions that perform main roles in post tsunami recovery activities in Sri Lanka. As such, the next section discusses the institutional skills gap identified within the post tsunami Sri Lanka.

3.2.2 Institutional and financial capacity gaps

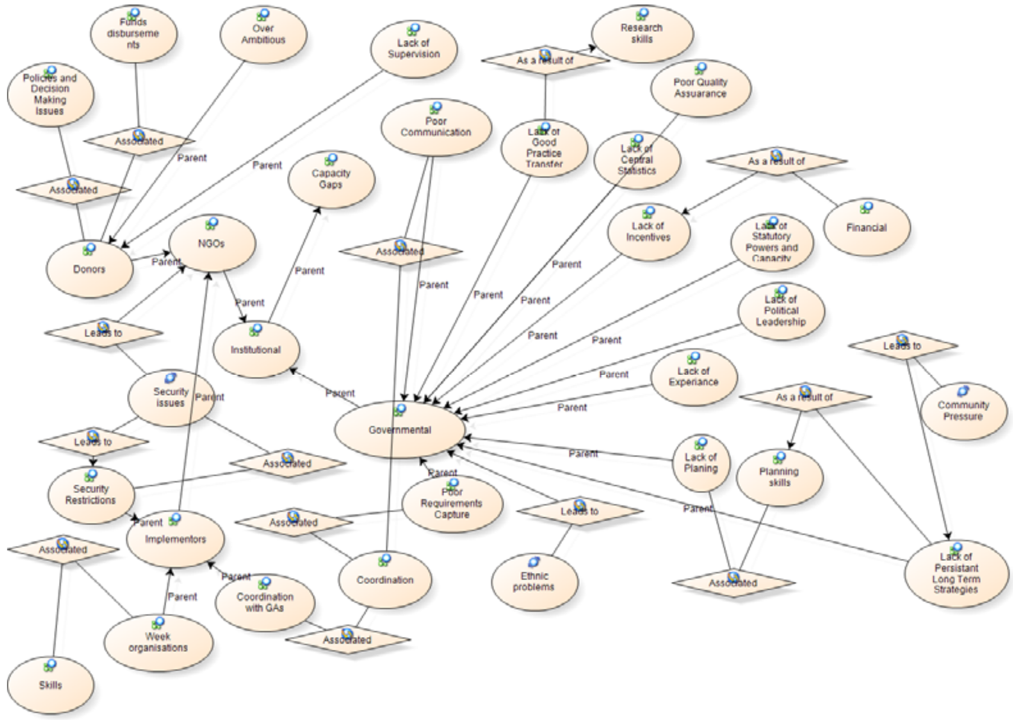

Figure 4 - Institutional capacity gaps identified within post tsunami Sri Lanka

Figure 4 above highlights the key institutional and financial capacity gaps and causal – effects relationships identified within the context of the research. Primarily, the institutional capacity gaps have been identified within two main groups of organisations involved within the post tsunami recovery context. These are:

1. Governmental organisations – These are the government owned organisations that carries the authority and responsibility for the overall post tsunami recovery strategies and actions.
2. Non-governmental organisations – These are the organisations that are involved within the post tsunami recovery process, outside the governmental direct control.

Out of these two groups, governmental organisations have been the most cited with relation to the areas of lack of institutional capacity in implementing post tsunami recovery actions. In fact, 8 areas of concerns have been cited by the interviewees in 16 instances, through 21 references. The areas of concern are:

- Lack of central statistics
- Lack of experience
- Lack of good practice transfer
- Lack of incentives
- Lack of planning
- Lack of communication

- Poor quality assurance
- Poor requirements capture

Out of these areas, lack of planning and poor communication has been cited frequently by the interviewees. This coincides with the discussion presented within the section 3.2.1 above, where these have been identified as the main capacity gaps related to the required skills. In addition poor quality assurance has been identified as an area where the government institutions show significant capacity gaps. For example, one interviewee highlighted that, despite the existing policies about construction quality, the houses constructed and allocated for effected communities varies significantly in terms of their quality, questioning the capacity of authorities to check and enforce the expected quality levels. During the investigation it was identified that the lack of experience to deal with the scale of the December 2004 tsunami was a main cause for the governmental organisations to demonstrate capacity gaps in various areas. For example, during the last 2 centuries Sri Lanka had not experienced a tsunami on any scale. This fact itself justifies, to a certain extent, why Sri Lankan governmental organisations were not able to handle a post disaster recovery attempt of this scale. Furthermore, this leads to the fact that the country is not ready with required central statistics to effectively handle the demands of this recovery attempt. One interviewee commented that the number of constructed houses in one of the relocation areas is greater than the affected communities in the surrounding. This highlights that the planning and requirement capture capacities of the relevant authorities were not optimal in this particular instance, and at the same time it highlights the issue of lack of central statistics about those affected.

From the non-governmental organisations' (NGOs) point of view, the institutional capacity gaps have been identified in two perspectives. The NGOs operate in post tsunami Sri Lanka under two capacities; as donors and implementers. From the donor's perspective, a number of interviewees have mentioned their rigid policies and decision making capacities on funds disbursement as a main capacity gap. As the interviewers pointed out, most of the time, the donors are less flexible with funds disbursement. Most donors prefer to fund short term relief actions and allow fewer funds for long term recovery actions. And often the donors were criticised for being over ambitious leading problems in implementing recovery actions. These gaps have been identified not only as the capacity gaps in donor organisations, but have been continuously discussed under the financial capacity gaps that post tsunami Sri Lanka is facing.

When an NGO operates as an implementer for post tsunami recovery actions, most of the capacities required are connected with reconstruction work. The main problem identified by the interviewees in this regard is their incapacity to carry out relevant reconstruction work in some areas due to security issues. Due to the ethnic problem prevailing in Sri Lanka, some of the worst tsunami affected areas cannot be reached by the organisations who are carrying out the reconstruction work. This hinders the effectiveness of such programmes. Moreover, some interviewees commented that some of these organisations demonstrate poor communication and coordination capacities especially when maintaining the link between the government authorities and themselves. Since the same is visible within governmental organisations, these organisations need to monitor the situation carefully to overcome this issue.

While essential, identifying the main capacity gaps which hinder the post tsunami recovery attempts in Sri Lanka is just a starting point. As discussed above, most of these capacity gaps have roots in problems which go beyond the scope of disaster management. It is therefore the role of the parties involved to analyse these factors and gaps in detail prior to embarking on post tsunami recovery actions.

4. Conclusions

Identifying capacity gaps is an essential task for Sri Lanka to overcome the problems they face with their post tsunami recovery attempts. It is evident that the government had ambitious plans and high expectations for speedy recovery but with less success rate. The capacity gaps existing in various scales under various organisations and circumstances have been identified as influential factors limiting the success of post tsunami recovery actions in Sri Lanka. Among other factors, various skills shortages such as coordination and planning skills have been identified as main capacity gaps which need immediate attention. Further, some of these capacity gaps in skills have led to the country to demonstrate capacity gaps in human resources such as lack of construction professionals and skilled construction workers.

In addition to the capacity gaps identified in general as above, institutions involved in the post tsunami reconstruction activities are also suffering from institutional capacity gaps. Among these, governmental institutions suffer from capacity gaps such as lack of central statistics and poor quality assurance. From the perspective of non-governmental organisations such as donor agencies and implementing organisations, a lack of coordination, security restrictions and policy issues have been identified as the main areas of concern. Dealing with donor organisations, unrealistic ambitions, rigid funding policies and lack of coordination with government organisations have been identified as issues which are needed to be addressed and at the same time as leading to financial capacity gaps that Sri Lanka is experiencing within the context of post tsunami recovery.

Abstract

Disasters are now considered as one of the biggest obstacles to sustainable development and social security of nations. Sri Lanka is prone to natural disasters such as floods, landslides and drought. In December 2004, Sri Lanka was hit by a Tsunami that affected severely. Recovery is a momentous challenge with less experience in large scale post disaster reconstruction. In this research paper, factors affecting for delays in housing reconstruction programme in Sri Lanka and related issues are addressed. Data were gathered through interviews from government organizations, NGOs and affected communities. The findings reveal various reasons that prolonged post Tsunami reconstruction and disturbances caused to smooth flow of reconstruction process by certain gaps. Inconsistencies of post Tsunami housing policy, land titles, government's lack of planning and recovery strategies, enforcement of buffer zone are the main factors affecting post Tsunami housing reconstruction programmes in Sri Lanka.

Keywords: Tsunami, Housing Reconstruction, factors , Disaster

1. Background

The world is immensely experiencing intensity of disasters – natural and man made - with devastating impacts. When a disaster strikes individuals and communities are affected, by seriously disrupting normal functions. The disasters cause widespread human, material and environmental losses. As reported by the Secretariat of International Strategy for Disaster Reduction [1], the last ten years saw 478,100 people killed, more than 2.5 billion people affected and about US $ 690 billion in economic losses caused by disasters. Disasters trigged by hydro-meteorological (weather related) hazards amounted for 97% of total people affected by disasters, and 60 % of total economic losses [2].

While the number of geophysical disasters - earthquakes, Tsunamis and volcanic eruptions - has remained steady, number of hydro-meteorological events – including droughts, windstorms and floods- has more than doubled since 1996. This could be linked to climatic change and scientists predict that global warming will result in more extreme weather patterns. [3]. Therefore, challenges of recovery from natural disasters will be with us for an unforeseeable future, with the need for effective post disaster response strategies.

On December 26, 2004 the deadliest Tsunami known in the history hit Sri Lanka, triggered by a massive earthquake of moment magnitude 9.0- largest earthquake recorded in 40 years. According to the Joint Report of the Government of Sri Lanka (GoSL) and Development Partners 35,322 people were killed, 1,000,000 people were displaced and over two thirds of the island’s coastline was affected by the Tsunami. [4]. Sri Lanka faced a big challenge in rebuilding the nation as a country that had not previously experienced such a disaster.

Relief, recovery, rehabilitation and reconstruction are the main activities in rebuilding an affected nation, where Government and Non Government Organizations are main stakeholders. However, as reconstruction and rehabilitation proceeded it is clear that moving from immediate relief effort to addressing the massive reconstruction tasks. Reconstruction involves different tasks and a set of large scale complex challenges. Donor-driven and owner driven are the main housing reconstruction programmes that are observed in current post Tsunami reconstruction process. Whether reconstruction of housing started at proper time, executed properly to achieve appropriate recovery of livelihoods as the planned output are some of the major factors affecting the success of the reconstruction process. Also, it is evident that the need for effective reconstruction and rehabilitation has reduced through time. A careful and in depth consideration is necessary to ascertain successfulness of the reconstruction process. Identification of challenges which delay reconstruction programmes will help in achieving better future for affected communities. As natural disasters are recurrent in Sri Lanka, in depth understanding of post-disaster reconstruction processes will help facing another disaster. This research paper addresses issues related to post Tsunami housing reconstruction in Sri Lanka.

2. Research Methodology

Interviews, semi-structured and unstructured, were conducted with governmental and non-governmental organizations and communities to collect data on post Tsunami housing reconstruction work to identify involvement of various stakeholders in reconstruction processes, their successfulness and factors which hindered progress such post Tsunami housing reconstruction work. Leading government and non government organizations, each numbering 5, were selected for the interviews. House owners from owner driven and donor driven housing reconstruction programmes were also interviewed.

3. Survey Findings: Factors affecting post Tsunami housing reconstruction

Several factors affecting related to post -Tsunami housing reconstruction programmes were identified through interviews, which are discussed below under several topics.

3.1 Inconsistencies in Tsunami housing policy

<u>Tsunami Housing Policy</u>

Tsunami housing policy consists of three phases as imposing of a buffer zone, relaxation of the buffer zone and the conversion programme.

a. Imposing of buffer zone or setback zone - Phase I

After the Tsunami, the government adopted a "no development" 100 meter buffer zone policy for districts of Kilinochchi, Mannar, Puttlam, Gampaha, Colombo, Kalutara, Galle, Matata and Hambantota; and a 200 meter buffer zone for districts of Jaffna, Mullaitivu, Trincomalee, Batticaloa and Ampara. The policy prohibited any new construction of buildings (permanent or temporary), reconstruction of completely or partially damaged buildings, and additions and alterations to existing undamaged buildings within the buffer zone. The introduction of buffer zone led to two types of housing programmes. They are:

Home Owner-driven housing reconstruction (In-Situ)
Donor-driven housing reconstruction (Relocation)

Home owner-driven housing reconstruction programme (in-situ)

Damaged (fully or partially) houses located within the buffer zone were repaired/reconstructed at the same premises. The GoSL provided grants provided by development banks and bilateral donors to affected homeowners to reconstruct their houses. The financial criteria included an assessment of damages on a point basis where a house deemed to be more than 40% damaged would qualify for a grant of Rs. 250,000 in four instalments, based on progress. A grant of Rs. 100,000 was made available to rebuild a house damaged less than 40%, in two instalments. However, as revealed by house owners, high costs of raw material and labour charges made it impossible to complete a house with such amounts at phase 1.

Donor-driven housing reconstruction programme (relocation)

Donors, of private, government and non government sectors, local and international, built or assisted in building houses at relocation sites for families who lived within the said buffer zone. The donors provided each new settlement with an internal common infrastructure while GoSL provided utility services up to the relocation site. The beneficiary remained the legal owner of his/her property within the buffer zone and received a full title to the property at the resettlement site, as well.

The buffer zone of 100m and 200m was revised in late 2005 and in April 2006, the RADA issued a revised housing policy. Enforcement of the buffer zone retarded commencement of reconstruction programmes by more than six months. Due to lack of reconstruction activities in Sri Lanka, some donors left with their unutilised grants to other Tsunami affected countries. Sri

Lanka missed a considerable amount of such intended grants while completion stages of reconstruction programmes are affected due insufficient funds.

As per the MoU signed by the government and some NGOs to carry out donor driven housing reconstruction programmes, GoSL was to provide lands to donors to construct houses and also to provide utility services up to such relocation sites. Delays in providing them caused further delays in providing necessary assistance by donors when constructing houses.

b. Relaxation of buffer zone - Phase II

In 2006, GoSL revised its post Tsunami housing policy by relaxing the buffer zone along with a "Revised Tsunami Housing Policy". Buffer zone relaxation changed numbers of housing units falling within one type of housing reconstruction programme to the other. Revision of buffer zone created immense confusion amongst beneficiaries. Only a few realised clearly about their housing entitlements at the beginning. With the switch from one scheme to the other, district/divisional secretariats had to revise lists of beneficiaries falling under each particular scheme. In addition, government had to arrange fresh funding sources and allocate funds for additional new beneficiaries.

c. Conversion programme – Phase III

Phase three of permanent housing reconstruction programme is the conversion programme. Major facts in the revised Tsunami housing policy are as follows.

<u>Revised Tsunami Housing policy</u>

* Government land + donor built house under a donor driven housing programme primarily for those who lived within the previous buffer zone.

* Government land + a government cash grant (Rs.250,000) to construct a new house + donor assistance to complete a house (not less than Rs. 250,000 depending on costs to meet a minimum standard) through a co-financing agreement.

* Government cash grant (Rs. 150,000 for 3 divisions in Ampara and Rs. 250,000 for Colombo) to purchase a land + government cash grant (Rs. 250,000) to construct a house + donor assistance to complete a house to a minimum standard) through a co-financing agreement.

* A housing reconstruction grant (Rs. 250,000for fully damaged and Rs. 100,000 for partially damaged houses) + donor assistance to complete only a fully damaged house to a minimum standard, through a co-financing agreement.

It allowed families to take government grants and build their houses at relocation sites. It included extended families, lessees and squatters. At phase III, house owners were granted a number of installments by co-finance agreements between GoSL and donors. Though the first instalments were released rapidly, subsequent instalments were subjected to thorough verification and approval processes. In some cases, monitoring visits and approval processes have taken much time which lead to small gaps in the reconstruction process.

d. Co-financing policy

According to the revised housing policy, NGOs and INGOs co-funded reconstruction of partially damaged units. The co-finance policy formulated by GoSL stipulated an equitable approach and recommended to address funding needs of most vulnerable families with regard to reconstruction of fully damaged houses. However, in practice this policy was not followed. Approaches implemented by co-financing agencies are built compensatory framework.

e. Rules on selecting contractors to reconstruction process

Government stated in the MoU that NGOs should select only contractors who have registered with the Institute for Construction Training and Development (ICTAD) to carry out housing reconstruction programmes. By that time, some donors have already started reconstruction programmes with the participation of affected communities themselves (community based system) in certain districts such as Galle. There was stoppage of work due to this rule which was later it was discontinued with.

Contractor selection for donor driven housing reconstruction programme was done by NGOs themselves. Thus, there was a tendency was to select the lowest cost rather than such other factors as quality. Hence, this necessitated some defected reconstructed houses to be demolished.

3.2 Conflicts on land titles

In the post Tsunami housing reconstruction process in Sri Lanka, donors were given lands to construct houses in donor driven housing programmes. For owner driven housing programmes, their own lands were used, while at phase III, house owners were allowed to buy lands from grants provided.

Scarcity of land

After imposing the buffer zone, GoSL was unable to provide sufficient lands for relocation housing projects because of scarcity of land. According to MoU signed by the donors and GoSL, it states that number of housing units agreed to be reconstructed by donors will also be determined by the availability of land. There are about 2880 damaged units that not relocated due to scarcity of land within Colombo.

Inappropriate conditions of provided land

Government provided marshy, futile lands to construct houses for some donors funded projects. It was necessary for donors to develop the land before constructing houses. However, donors did not accept to develop lands as according to the MoU, land and infrastructure development was to be carried out by the government. Due to insufficient funds, the government failed in that, and therefore, later the donors had to develop lands. A considerable time was taken to arrive at a decision through discussions. Besides, by engaging in additional works of land development, donors were unable to complete number of housing units they agreed to reconstruct. They spent more time on revising budgets several times as they had to spend more for constructing a house including land development. There is a special issue in the case of Homagama-Kahathuduwa housing reconstruction project, experienced by the Red- Cross Society. They were asked to construct 700 units as flats while the affected community preferred single storey houses. The land was sufficient for only about 350 single storey houses. Hence, none of the donors agreed to fund construction at that site. Even after more than 2 ½ years, still the construction has not started.

Land acquisition

Government provided both state owned and acquired private lands to donors to construct houses under donor driven housing programme. However, some land owners initiated legal actions against such acquisitions. Due to court orders some housing projects were discontinued with. It has taken a considerable time to solve these problems legally. Due to such, donors were unable to start reconstruction processes which ultimately has created gaps.

3.3 Ineffectiveness in monitoring funds

NGOs were allowed to manage funds themselves in the reconstruction programmes. Corruption has taken place in managing these funds which ultimately reduced the actual amounts made available for reconstruction. Actual amount of funds received by house owners also diminished in similar fashion due to absence of government monitoring. As emphasized by RADA, some house owners were over granted while others were inadequately granted. Total funding requirement for the owner driven programme is Rs. 10,690 million as they estimated in end of 2006.

3.4 Insufficient capacity of the construction industry

Capacity of the construction industry in the aftermath of Tsunami in terms of professionals, material, labour etc. was insufficient to carry execute construction smoothly due to high demand. Prices increased due to lack of material, labour etc. Due to high inflation rates also, house owners were unable to complete reconstruction of houses within limited grants in phase I of housing reconstruction programme. Specially for international NGOs, it was difficult to complete number of houses due to the complex situation of the construction industry in Sri Lanka. In addition, they had to hire technicians from foreign countries to carry out construction work.

3.5 Affected community’s crappy behaviour

As experienced by the National Housing Development Authority which assessed damages for compensation, conflicts have arisen when identifying houses as partially and fully damaged. In some cases, house owners have damaged their houses to obtain Rs. 250,000. Houses were built in different standards, sizes and costs by agencies and donors for a great variety of reasons. Some families received government grants as well as many other grants from agents while others received little or no grants at all. This resulted in inequity in districts, leading to social/communal tensions. As a result, beneficiaries were switching donors or waiting for the “best offer”, delaying the reconstruction process. Some house owners misspent their grants. It also delayed the process and raised complexity for NGOs in handling funds.

3.6 Government’s lack of planning and recovery strategies for post Tsunami reconstruction

Absence of a quality control system in donor driven housing reconstruction programmes has led to many issues. Due to inferior quality, some of the houses constructed by donors have been advised to be demolished and reconstructed, specially in the Galle district. It is stated that a policy is being drafted in respect of providing grants to people who live in inferior quality donor driven housing programmes to rectify damages, and enhance quality of constructions. Establishment of organizations such as TAFREN, TAFRER, RADA etc. to implement reconstruction programmes with less experience in housing has resulted in lowered effectiveness. Absence of the National Housing Development Authority in carrying out housing reconstruction programmes is a significant point of interest, as the NHDA is a well experienced mass scale national house builder.

Although it is stated in the MoU that donors shall enter into contracts with ICTAD registered contractors and that the work should confirm to ICTAD specifications, it is a questionable feature to note inferior quality in reconstructed houses.

3.7 Lack of communication and coordination among stakeholders

While some house owners eligible for to receive donor driven reconstructed houses continued to live in temporary housing, those who were ineligible have been granted with such reconstructed houses. It was also noted that while some affected families who are entitled to be relocated under donor driven housing programmes have been assisted with rebuilding, others who were eligible to rebuild with grants under the owner driven housing programmes have been relocated.

There were difficulties in coordination with more than 200 organisations involved in reconstruction programmes all over the island. Signing MoUs at both national and district level has led to several difficulties such as reconciling commitments and progress; NGOs were inconsistent in reporting progress and attending coordination meetings. Some information at national level is ambiguous and resulted in misinterpretations at district levels. Furthermore, frequent cancellations of coordination meetings have caused many gaps in a continuous programme. This is evident by oversupply of houses in the South with an approximately 6,000 housing units. NGOs emphasized that within a project team conflicts have arisen as different parties are involved with their own objectives, in the process. Specially, some foreign elements possessed private agendas over the post Tsunami reconstruction programme of Sri Lanka.

3.8 Existence of hostilities

Due to the conflict/ violence in the North and East provinces, gaps have occurred in both categories of reconstruction programmes. From distributing subsidies to completion of permanent shelters, gaps have occurred at certain phases of the reconstruction process. According to NGOs, difficulty in access, refusal to allow construction companies to function, inadequate facilities for NGO staff and labourers, restrictions on transportation of building materials are the main reasons. Both time and money has been wasted due to repetition of construction works from the damages occurred over the civil war. Worldvision, a NGO, emphasized that after building about 40 foundations for a relocation housing site in Sampoor, they were moved due to security reasons and restart the construction works. Both time and money has been wasted due to inaccessibility.

4. Conclusions

Successfulness of the post Tsunami recovery largely depends on successfulness of the housing reconstruction programmes. Family is the basic unit of the society and need to be recovered well in moving to develop a country. The findings by survey revealed that various reasons have prolonged post Tsunami housing reconstruction processes in Sri Lanka. Smooth flow of construction process is disturbed by certain gaps that occurred through out the reconstruction programme.

Relocation housing programmes are delayed mainly due to unavailability of appropriate lands to build large housing schemes, unavailability of clear beneficiary lists for consultation, unwillingness of beneficiaries to be relocated and inadequate provision of infrastructure by government and unavailability of good construction companies. Donors were unable to complete the number of units pledged due to challenges of the construction industry, complexity of work, high inflation, rates of row material and labour etc. After relaxation of buffer zone some families preferred to return to their own lands even though they were provided with houses built under donor driven housing programmes. Some donor driven houses are unoccupied, to date due to this. Absence of a technical quality control system in donor driven housing programmes is another major issue. It resulted in inferior quality houses funded by donors. Some of those houses were demolished and reconstructed, wasting both time and money.

Owner driven housing reconstruction programme is affected with gaps mainly due to insufficient grants. Specially in phase I, house owners were provided with a maximum grant of Rs. 250,000 to reconstruct houses. It was not sufficient due to high inflation and increasing prices of construction material, labours and professionals charges etc. To overcome this, the government changed the way of granting at phase III. However, there were lot of equity issues. Absence of government in handling regarding top up grants is the reason behind this. In some instances, the beneficiaries have misspent grants on alcohol etc.

In addition to that, all reconstruction programmes were affected by inadequate technical capability and unclear delegation of responsibilities among divisional, district and central government agencies and lack of coordination among community and various other parties such as affected/non-affected communities, INGO, NGOs, private sector, donors etc. Enforcement of the buffer zone delayed the housing reconstruction programme for about six months. Due to lack of construction activities, some donors left Sri Lanka and missed a considerable amount of grants which now delay the latter stage of the reconstruction programme. In the first phase, community based reconstruction is not allowed and some donors and communities who started the construction works face certain problems there. Declining security situation is the main reason for the slow progress of housing reconstruction in North and East provinces.

Absence of a government entity to control grants has caused equity issues all over the country. Government, as the leader role in reconstruction programme has to be more concerned regarding involvement in reconstruction programmes in depth. Due to absence of any programme regarding this, there are no records regarding top up grants and it is difficult to manage due to this. Furthermore, absence of clear records about how much the reconstruction programme cost to the country is a point where considerations have to be paid.

A huge amount of money from foreign countries/local donors as funds is misspent due to inefficiency of the government to handle a reconstruction programme. Hence, opportunity given by the Tsunami to develop the country has not been optimized. Number of completed houses can be used only to measure progress or successfulness of a post disaster housing reconstruction programme. Post disaster housing reconstruction programmes has to be more humanitarian than other developments. The ultimate goal of post disaster reconstruction processes shall be to attain a standard of living that is even better than what existed before the disaster. As a large scale disaster, the Tsunami is a completely new experience to Sri Lanka. Therefore, conducting a 100% successful housing reconstruction programme can not be expected. In the present context, shortcomings of post Tsunami housing reconstruction process have realized by government authorities and other responsible persons up to a certain extent. However each person who involve in post disaster reconstruction process have to be knowledgeable on their responsibilities, capacity to achieve the goal of reconstruction in moving to development goal of the country.

Abstract

Sri Lanka was found to be a disaster prone country in the recent past. The impact is more severe when developing countries are faced to various natural or man-made disasters. Impact appears in many forms; loss of lives and property, economic impact, social impact etc. As a developing country, Sri Lanka is much more concerned with the country's economic development. Therefore, it is wise to look into post-disaster activities in development perspectives and integrate disaster risk reduction concerns into economic development activities. This paper reveals the importance of post-disaster infrastructure reconstruction in economic development. A comprehensive literature review was carried out regarding the role of infrastructure in disaster management, economic development together with the key indicators of economic development.

Keywords: Tsunami 2004, Disaster management, Post-disaster infrastructure reconstruction, Economic development.

1. Background

The whole world is prone to natural disasters. Developing countries are faced with various natural risks leading to disasters, which cause immense loss of life and property [1]. The Tsunami of 2004 is enough to substantiate this argument. Disasters, man-made or natural, aggravate inequality and hinder progress towards the 'development goals'. Many researches have concluded that disasters damage the entire economy of the country including physical and human resources when disasters predominantly exist in the developing countries [2 and 3]. An average of 354 natural disasters occurred a year in the period 1991 to 1999. From 2000 to 2004, this rose to an average of 728 a year. The total number of people affected each year has doubled over the last decade. However, the most noticeable thing is, most of the victims are from developing countries [2 and 4]. Of the world's ten most severe natural disasters in 2004, five occurred in the Asia and Pacific Region, causing damage amounting to $55 billion, about 70 percent of the total damage, estimated at $80 billion [2].

Sri Lanka has experienced frequent natural hazards commonly caused by floods, cyclones, landslides, droughts and coastal erosion for generations with increasing losses to life and property in the past few decades [5]. Moreover, the tropical climate and heavy rainfalls, the climatically differentiated 'dry-zone', which subjects it to periods of drought while seasonal monsoons regularly bring about flash floods, river floods and storm surges in certain parts of low-lying river basins can also be seen. The Mahawansa' (Sri Lanka's ancient history chronicle dating from the Sixth Century) tells of a wall of water flooding the land 2,000 years ago. The undersea earthquake near the west coast of Northern Sumatra set off a series of other earthquakes, in December 2004, which led to a widespread disaster. The Tsunami in 2004, particularly in Sri Lanka, India, the Maldives, Indonesia and Thailand, also caused damage in Malaysia, Bangladesh, Somalia, the Seychelles and Kenya. The devastation caused by the tsunami in 2004, however, took Sri Lanka by surprise, warning that Sri Lanka is also vulnerable to low-frequency, high impact events causing extensive damage [5 and 6]. Sri Lanka faced one of the worst natural disasters with a large proportion of losses in housing and infrastructure. The destructive ocean waves killed more than 35,000 people and displaced nearly 2,500,000 people in Sri Lanka. The coastal infrastructure, namely roads, railways, power, telecommunications, water supplies and fishing ports were also significantly affected. The damage to its infrastructure is estimated to be over $1.7 billion [7]. As more infrastructure, is developed in rural areas, to combat poverty, and as the frequency and severity of natural disasters increase, the impact on the poor will become more critical [8].

2. Enormity of impact on infrastructure due to recent natural disasters

Natural catastrophes destroy essential rural infrastructure. According to Munich Re 1998, Asia, which accounts for half the number of the natural catastrophes in the world and 70% of all floods, the average annual costs of floods over the past decade is approximately 15 billion USD [8 and 2]. Much of the damage inflicted by floods is to the infrastructure [8 and 2]. By some estimates, infrastructure loss accounts for 65% of all flood loss [8 and 2]. For Asia, this would account for an average annual infrastructure loss of approximately 12 billion USD for the past decade [8].

If the size of the loss to infrastructure is compared to the worldwide lending activity of the World Bank, approximately 50% of the World Bank's total lending is equivalent to the total cost of damage to infrastructure due to natural disasters in the Asian context [8 and 2]. Over the past decade, the Bank has annually loaned approximately 25 billion USD [8]. The annual investment needed for post-disaster reconstruction of infrastructure and economic recovery in developing countries of the Asia and Pacific region would require an estimated $15 billion, for a total infrastructure-financing requirement estimated at $55 billion per year [2].

3. Disaster management and infrastructure reconstruction

3.1 What does infrastructure mean?

The term ‘infrastructure’ has different meanings in different fields. Infrastructure is generally structural elements that provide the framework supporting an entire structure. Infrastructure appears in many forms as economic infrastructure, social infrastructure, IT infrastructure etc. Economically infrastructure could be seen to be the structural elements of an economy, which allow for production of goods and services without themselves being part of the production process.

Economic infrastructure primarily consists of transportation (road, railways and bridges), energy and utilities (electricity, gas), water supply and sanitation services, telecommunication systems, health services and essential government services. The economic infrastructure system is composed of manifold elements. These are organised in hierarchical levels.

- Level of sectors (Ex: Energy, Information & Telecommunication, Transportation)
- Level of infrastructures (Ex: In Transportation: Road, Railway, Waterway, Postal)
- Level of components (Ex: In Railway Tracks, Stations, Control Centres, Vehicles)

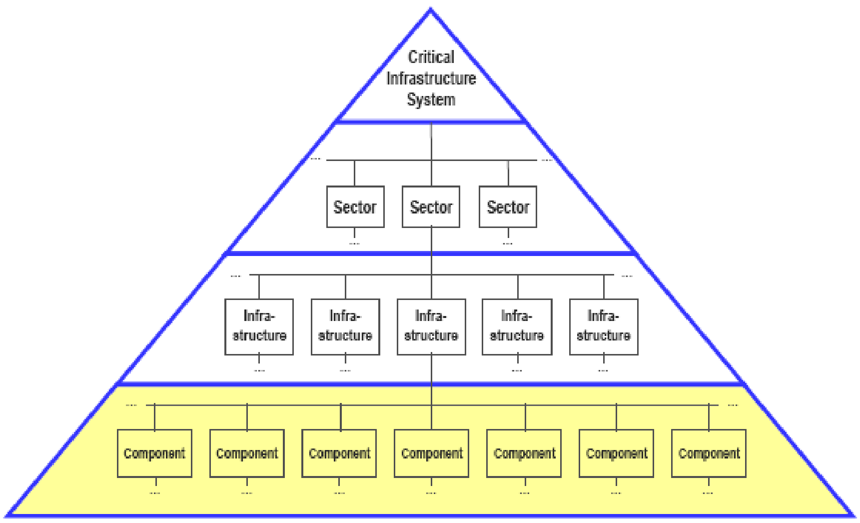

Figure 1: Critical Infrastructure System [Source: 9]

Social infrastructure consists of health, education, safety nets etc. However, in other applications, infrastructure may refer to information technology, informal and formal channels of communication, software development tools etc. The term “critical infrastructure” has been widely adopted to distinguish those infrastructure elements that, if significantly damaged or destroyed, would cause serious disruption to the dependent system or organisation. Natural disaster damage leading to the loss of certain transportation routes in a city (for example, bridges crossing a river), could make it impossible for people to evacuate and for emergency services to operate; these routes would be deemed critical infrastructure. Critical infrastructure is broadly defined to include the systems, facilities and networks, which support the health, safety and economic well-being of the population, during and after natural disasters [2].

This paper deals with the economic infrastructure, which comes to the society as an output of the 'construction industry'. The infrastructure of a country is part and parcel of the construction industry. Morton (2002) stated that on the whole, the built environment is designed, built and maintained by the construction industry, which includes civil engineering and infrastructure work such as roads, bridges and railways [10]. Construction is the one industry most likely to be beneficially impacted, at least in terms of increased activity, by an actual disaster [11]. Natural hazards potentially cause severe damage to buildings and infrastructure, resulting in considerable post-disaster construction. On the other hand some argue that in the longer term a major natural disaster can even generate a construction-led economic boom, for example Albala-Bertrand, 1993 [11].

3.2 What happens if infrastructure fails during disasters or if post-disaster infrastructure reconstruction process fails?

Infrastructure is critical to a safe and a resilient economy. Natural or even man made disasters have a profound impact on the quality of life through various means, such as the destruction of aspects of the built environment [2]. Therefore, a sudden disruption of infrastructure affects the whole humanity. Creation of significant negative consequences to infrastructure together with other built environment facilities due to disasters would lead to pathetic economic consequences and depauperated quality of life often for long periods of time [12]. There is a more limited sense of their broader macroeconomic significance or the problems they could pose for longer-term development [13]. This is partly because most assessments of the economic impacts of disasters have concentrated on the most easily measured direct losses and the practical difficulties of isolating and measuring the indirect and secondary impacts that result from the transmissions of a disaster shock through the economy [13]. Thus, when events such as natural disasters destroy infrastructure, their opportunity cost becomes painfully evident [2].

'Ignorance of infrastructure' affects the society in many ways. It exacerbates civil imperfections, demoralizes staff working in remote locations, mainly in vulnerable areas and thus further delays the process of state rebuilding, and undermines the effectiveness of the rebuilding process [14]. It also leads to poverty, hunger and infectious diseases [14]. Moreover, infrastructure failures can act on gender and other aspects of identity and exaggerate powerlessness, vulnerability and disability [14]. Admittedly, due to the strong dependency of society on goods and services provided by critical infrastructure, their failure may lead to disaster [9]. Poorly planned development can turn a phenomenon into a human and economic disaster. Infrastructure failures in the post-disaster period can become the fundamental reason for another series of devastating effects followed by other natural disasters. Whilst infrastructure can increase productivity, reduce the cost of production, increase trade and reduce poverty, it can create major disasters or can enhance the effects of one in a completely negative manner.

3.3 Role of the construction industry in managing disasters: Special emphasis on infrastructure

Ofori [3] has documented the importance of develop the construction industries of the poorer nations in order to equip them to manage disasters. Although the developed countries are considered to be well prepared to tackle disasters there are instances where even developed countries lacks the proactive measures to prevent them. For example, Bosher et al. [10] report that the construction industry in the UK does not appear to play a sufficiently integrated role in emergency management.

At the disaster reduction/mitigation phase, where the population returns to pre-disaster standards of living after the event, people recognise the need for certain measures, which may be needed to make the impact less severe during the next similar event. Investment in the infrastructure for disaster management is essential in this context as it can result in reduced loss of lives. The physical infrastructure can be developed to withstand disasters, reduce and even prevent damage from natural disasters [2]. For instance, drinking water systems can be very effective for flood management [2]. Infrastructure reconstruction programmes should however aim to change the vulnerable conditions for the development of the country. Reconstructing the infrastructure is often essential to sustain recovery after major disasters [14]. Moreover, critical infrastructure reduces the risk of failure and thus contributes to disaster reduction and prevention [9]. Investment in the infrastructure for disaster management is essential in this context. At the same time, it is necessary to explore the management of infrastructure systems and an association between natural disaster reduction/mitigation with infrastructure management and development.

As Asia and Pacific regional cooperation in developing the physical infrastructure for disaster management has so far been limited, the ‘United Nations Economic and Social Commission for Asia and the Pacific’ has recently declared their priority concerns on rebuilding infrastructure and investing in infrastructure for disaster prevention and preparedness [2]. The increased frequency of major disasters, such as the December 2004 tsunami and earthquakes in Gujarat, India; Bam, Islamic Republic of Iran has underlined the importance of technical cooperation in the region for developing better physical infrastructures [2].

It is claimed that the developing countries are less able to face the impacts of disasters and so it is imperative to develop the construction industries of the poorer nations in order to equip them to manage disasters [3]. The prevailing demand for development of infrastructure of the poorer nations is apparent as infrastructure can facilitate the day-to-day activities, reduce the losses resulting from disasters and facilitate post-disaster recovery [2]. Every nation must ensure that damage to the critical infrastructure is kept to a minimum during disasters through the necessary mitigatory measures. If mitigation activities before disasters aim, in particular, at protecting these critical infrastructures, it would result in effective and efficient relief and reconstruction activities in post-disaster phases [2]. As a nation, Sri Lanka should demonstrate a firm resolve in protecting infrastructures from further disasters, compared to what was significantly affected by the Tsunami 2004. The basic community infrastructure must be secured as much as possible and immediate approaches to such infrastructure and smooth recovery and reconstruction of them are very important in assisting humans on an emergency basis and immediate fulfilling of sanitation requirements of the community. Without doubt, major disasters require effective planning and programming for post disaster reconstruction, including rehabilitating physiologic, social and economic infrastructures, which are badly mutilated as a consequence of these disasters [1].

When the Tsunami struck the Sri Lankan coastal belt, there were no early warning systems to communicate the impending event to government or to coastal communities [15]. Physical infrastructures including early warning systems can make a major contribution both to preparedness for disasters and recovery from them [2]. Disaster planning and preparedness, is an important phase in the disaster management cycle. Construction and operation of signaling and communication systems like earthquake observation systems, meteorological observation systems and early warning systems, facilitation of additional water supplies and sanitation systems are a few activities coming under this phase. On the other hand, necessary preparedness measures are required to protect the infrastructure from coming disasters and also the infrastructure has a key role to play in saving people and other property at this phase.

After a disaster takes place, the most challengeable issue is to restore the society back to its original status or moreover restore it to a better state. Muzaffer and Faruk [1] have clearly identified one of the serious challenges confronting the developing countries is to provide sustainability of interventions undertaken as part of post disaster reconstruction. Sufficient examples have been identified to show that in many cases, reconstruction serves to reinforce and sometimes even increase the vulnerability of rural and urban areas [1], for example, in Turkey in the case of reconstruction following 1999 Marmara earthquake [1]. According to Anand [14], in post-conflict contexts, the infrastructure planners need to cope with the problem of the 'missing baseline'. This is basically applicable to natural post-disaster reconstruction process. The process needs to address not only the infrastructure that may have been damaged in the disaster but also the infrastructure that never existed or that has been damaged due to lack of maintenance over years. Within each phase of the disaster-management cycle, short-range goals can simultaneously contribute to long-range ones, such as strengthening people's capacity to withstand disasters. For example, the reconstruction of water supplies should merge naturally into on-going development activities (such as community mobilisation) to further improve the water-supply systems (or other agreed environmental health goals). During "normal" times, these health development activities should aim to reduce the vulnerability of people and infrastructure to future emergencies and disasters. Thus, the routine construction of water works should, for example, incorporate design features that protect them from known hazards.

4. What is economic development?

The major task of development economics is to explore the possibility of emancipation from poverty for developing countries [16]. From a policy perspective, 'economic development' can be defined as efforts that seek to improve the economic well being and quality of life of a community. It should be strongly focused on low-income developing countries where poverty is especially acute [16]. There are significant differences between ‘economic growth’ and ‘economic development’. The close link between these two is simultaneously a matter of importance as well as a source of considerable confusion [17]. ‘Economic growth’ has a connotation of quantitative expansions in economic variables, especially aggregate and per capita national incomes as measured by such statistics as GDP and GNI [16]. On the other hand, ‘economic development’ refers to not only quantitative expansions but also improvements in non-quantitative factors such as institutions, organisations and culture under which economies operate [16]. In linking infrastructure development with economic development, economic development encompasses policies and programmes to provide infrastructure and services.

A very wide variety of indicators can be used to measure the economic development differences between developed and developing countries. The key indicators among those are GDP per capita, life expectancy, literacy rates, quality of infrastructure, access to safe infrastructure, poverty reduction etc [16, 17 and 18].

5. Economic development through post-disaster infrastructure reconstruction

5.1 Overview

Calls have been made for a country like Sri Lanka to inform and design development efforts to reduce natural disaster related losses and contribute to truly sustainable social and economic development. Post-disaster infrastructure reconstruction can do a lot towards the achievement of this. Whilst the need for mitigation and reduction of natural disaster risks has been widely recognized all over the world, achieving this ambitious goal has proven difficult in Sri Lanka. The recent Tsunami in December 2004 is one of the best examples to demonstrate this. The tsunami in 2004 is distinctive among other natural disasters due to the massive economic impact it caused in a developing country like Sri Lanka. The tsunami struck at a time when the Sri Lankan macro economy was already under pressure on several fronts, reigniting fears of a slide into the kind of a crisis that was seen in 2001 when the economy contracted by 1.5% [19]. Overall damage to the Sri Lankan economy has been estimated at around US$ 1 billion (4.5% of GDP) except the assets losses in the informal sectors. However, the disasters have the ability to make an immense contribution to the particular economy where it took place and also to the surrounding economies. For example, the Kobe earthquake of 1995 killed over 6,000 persons, and destroyed more than 100,000 homes, still the economic recovery not only of Japan but also of the Kobe economy was rapid [20]. Lewis [21] has reported that the economic impact of disasters, especially on island states, has been for matter for concern and analysis (e.g. Lewis. 1991 b) and the impact upon development of disaster is frequently deplored (e.g ECLAC, 1978; 1988) – but what of the impact of development upon disasters?

The discipline of economics has very wide coverage, as it is underpinned by a matrix of political, religious, social, technological and environmental strands (Broadbent and Broadbent, 2006). It is therefore understandable why economics should play such a key role in both reconstruction and development initiatives, even though it can have a very frustrating impact when efforts set out to accelerate progress or achieve quick results [22]. Economics in disaster management is necessary to be looked in to several perspectives. According to Broadbent and Broadbent [22], a deeper comprehension of the role of economics in disaster management is required to improve the current way things done. It shows how economic analysis can be used to advise decision-makers about alternative policy options. Backhouse (2002) reports the role of economics in the shaping of history is very interesting and relevant to disaster management [22]. Economics applied objectively can lead to the selection of the best of all alternatives given a range of options [22].

5.2 Importance of post-disaster infrastructure reconstruction in it's contribution to economic development: Literature review

5.2.1 Role the economics perspectives play in post-disaster reconstruction phase

According to Jigyasu [23], the link between disasters and development is very critical. Lewis [19] reports that linkage between development and disasters has to be forged. Davis (2005) has claimed that looking at disasters as development opportunities is becoming one of the core principles of disaster and emergency management [24]. Disasters provide physical, social, political and environmental development windows of opportunities that can be used during the post disaster recovery and reconstruction not only to reconstruct the impacted areas, but also to improve the socio-economic and physical conditions of the impacted population in the long- run [24]. For developing countries or regions, it is a good opportunity to change its original economy development model and to push the urban and rural renewal forward [23]. Lewis [21] questions which way round should it be; disasters and development' or 'development and disasters'? Which comes first and which has the greater influence upon the other? However, disasters are not only consequences of existing 'development' processes, they can also serve to provide new opportunities for development through post-disaster rehabilitation [23]. The 'disaster continuum' approach positively attempts to align post-disaster assistance with development, recognising the intervening stages of recovery, rehabilitation and reconstruction as each stage should lead to the other in that sequence [21]. However, conventionally, reconstruction and development were perceived and represented linearly [21]. In reality however, they are simultaneous, each 'stage' overlapping with others and in responses to the same or different disasters [21].

Lewis [21] clearly admits that, in any case, development will have been taking place appropriately or inappropriately, planned or unplanned, successfully or not, for a long time. However, development does not have a universal frame of reference and it is determined by different 'world-views' and 'perceptions' on what development implies for a particular community or group of people [23]. It is argued, however, that there is a limited time frame of approximately two years for such opportunities to be utilized efficiently [24].

It is difficult to imagine a modern world without infrastructure and therefore the role of infrastructure in people's daily activities and economic growth of a country is apparent [2]. Along with supportive economic and financial policies, infrastructure has long been recognised as a key element of the enabling environment for economic growth [25]. The physical infrastructure is the nation's economic backbone as it constitutes the arteries for the facilitation of productive activity and the spreading of the benefits of growth by enabling goods and services to be distributed [3]. Construction represents most of every nation's savings [30]. Critical infrastructure provides society with essential goods and services on which the society strongly depends [9]. Infrastructure has strong supply and demand side economic linkages and caters directly to demand [2]. Infrastructure can contribute directly by providing and supporting the delivery of key services, such as those seeking to increase households' access to safe drinking water, basic sanitation, and secure tenure [25]. Similarly, the goals related to human development (education and health) rely on services that require supportive infrastructure—water and sanitation to prevent disease, electricity to serve schools and health clinics, and roads to access them [25]. Thus, it is evident that ultimately society strongly depends on critical infrastructure [9]. Improving trade efficiency can do much more to spur economic growth than tariff reform and improving infrastructure is a major factor in improving efficiency of trade [2]. It is found that availability of good quality physical infrastructure improves the climate for foreign direct investment (FDI) by reducing the "cost of total investment" incurred by foreign investors and thus raising the rate of return [2].

In the World Development Report 1994, The World Bank makes the direct link between infrastructure to poverty [8]. Freeman [8] has admitted that the clear link of natural disasters to poverty is through infrastructure. Accordingly, it is convinced that the linkages can be described in at least three components:

- access to infrastructure is often a measure of poverty,
- infrastructure is a key component of economic growth,
- loss of infrastructure may have significant indirect and secondary costs that directly affect the poor [8].

As stated by The World Bank, lack of access to infrastructure is a welfare issue. Further, access to infrastructure for the rural poor, primarily irrigation and transportation, increases income that enables the poor to manage risk [8]. The maintenance of infrastructure is essential to maintain economic growth, the primary linchpin in reducing poverty [8].

As many researchers have identified, Yaoxian [26] too has admitted that reconstruction following a natural disaster is a complicated problem concerning social, economical, cultural, environmental, psychological, and technological aspects. However, post-disaster reconstruction is relevant to development discourse. It is essential, not only to cope with the impacts but also to help ensure that the region sustains its economic growth [2].

Many international organisations work towards socio-economic development of developing countries. But among all such, The World Bank stands out as its mission is to 'reduce poverty and improve living standards through sustainable growth and investment in people'. In achievement of the above aim, The World Bank has a clear objective of promoting economic growth strategies based on expanded infrastructures, which are environmentally responsible and socially acceptable and bringing a sustainable future closer to today's reality. Virtually all World Bank activities have a bearing on poverty. Tackling natural or man-made disasters is an important part of this mission. Disasters represent a significant source of risk for the poor and providing assistance to prepare for and recover from natural and man-made disasters is an important activity of the Bank in achieving their above mission. The World Bank's 'Hazard Risk Management Team' aims to reduce human suffering and economic losses caused by natural and technological disasters by helping provide a more strategic and rapid response to disasters and promoting the integration of disaster prevention and mitigation efforts into the range of development activities. The Bank's operational policy on 'Rapid Response to Crises and Emergencies' deals with the issues related to emergency operations, but does not address long-term economic issues, including those triggered by economic shocks and requiring a policy response from the government that the Bank normally supports through development policy operations. The World Bank aims to contribute with sound economic foundations to infrastructure policy making. The 'infrastructure economic' approach emphasises the links between infrastructure service provision, economic growth, and poverty alleviation; while providing instruments of dialogue between different sector specialists, policy makers, and macroeconomics. The World Development Report 1994 [27], the seventeenth in the annual series, examines the link between the infrastructure and development and explores ways in which developing countries can improve both the provision and the quality of infrastructure services. In recent decades, developing countries have made substantial investments in the infrastructure, achieving dramatic gains for households and producers by expanding their access to services such as safe water, sanitation, electric power, telecommunications, and transport. In Sri Lanka, rehabilitation of the infrastructure focused initially on restoration of key transport and services, initiated speedily by the Government with donor support. Line ministries took the initiative on the repair of (or temporary provision for) broken portions of major roads, railway, electricity, telecommunication etc. on a priority basis. This raises the dilemma of what is to be prioritised, because the identification of priority infrastructure reconstruction issues is important to sustain the recovery.

5.2.2 Importance of post-disaster infrastructure reconstruction for millennium development goals

If we look at the role economic perspectives play in post-disaster reconstruction and the economic and development perspectives of natural disasters, it is worth further investigating the necessity of infrastructure in achieving Millennium Development Goals (MDG) of the United Nations and the World Bank because MDGs are set with a greater expectation of contributing to the economic development. More recently, the development community has emphasised that by promoting growth; reliable and affordable infrastructure can reduce poverty and contribute to the achievement of the Millennium Development Goals (MDGs) and there have been many recent attempts to quantify these linkages between infrastructure and growth, poverty reduction, and achieving related development goals [25].

Both the policy and the academic debates on the Millennium Development Goals of the United Nations have been a source of some frustration for infrastructure practitioners [28]. There is a sense that the goals fail to recognise the relevance of transport and to a lesser extent energy (since rural energy was recently added as a priority) in the fight against poverty [28] except for water and sanitation and to some extent telecommunications. This is partly because there is little knowledge about the basic relationship between infrastructure coverage and household income [28]. The frustration among practitioners has not been met by academics [28]. Indeed, while there has been a lot of talk about the MDGs in the development community and many publications on the health and education goals, there has been little academic work on the water and sanitation goals or the MDG gaps [28].

6. Sri Lanka's situation with regard to infrastructure reconstruction and development

An efficient network of economic and social infrastructure is a pre-requisite for achieving sustained high economic growth and development. Development, reconstruction, continuous improvement and maintenance of infrastructure network are vital to attain a sustained high level of economic development. Now, more than two years after the tsunami disaster, it is worth questioning whether these development opportunities have been used or lost? In Sri Lanka, although several initiatives were taken by the governments in the past to mitigate disaster damages they were mostly reactive emphasising relief and recovery rather than proactive with damage prevention or minimisation strategies [5]. In the aftermath of the tsunami, three task forces were set up; (1) Task Force for Rescue and Relief (TAFRER), (2) Task Force for Law and Order and Logistics (TAFLOL), (3) Task Force to Rebuild the Nation (TAFREN). Immediately after the tsunami 'The Centre for National Operation' (CNO) was set up in order to facilitate and coordinate emergency rescue and recovery needs. Later, in January 2005, the CNO was replaced when TAFRER and TAFLOL were merged to form TAFOR (Task Force for Relief), with a mandate for looking after the well being of affected groups. In November 2005 another institutional change took place - the TAFREN was replaced with the Reconstruction and Development Agency (RADA). However, the 2004 Tsunami made responsible parties act collectively for a comprehensive, long term and holistic disaster risk management framework (Jayawardane, 2006). In May 2005, the Sri Lanka Disaster Management Act No 13 of 2005 was enacted providing a solid legislative and institutional arrangement for Disaster Risk Management establishing a powerful National Council for Disaster Management under the President and the Disaster Management Centre (DMC) as the lead agency for disaster risk management. In November 2005, the Ministry of Disaster Management was established to provide undiluted leadership. The Ministry of Disaster Management declared its Road Map in December 2005 focusing on seven thematic components. 'Towards a Safer Sri Lanka - The Road Map for Disaster Risk Management – Volume II Project Proposal' [6] is a key Government policy document. The Road Map aims to provide an overall framework for disaster risk management in the country and is an effort, through the MoDM to unify efforts of different agencies [15]. The Road Map recognises that the tsunami has highlighted policy and institutional weaknesses in disaster risk management in the country [15]. It is expected that proper implementation of this Road Map will go a long way towards saving Sri Lanka from natural disasters. ‘Towards a Safer Sri Lanka - Road Map for Disaster Risk Management – Volume II Project Proposal’ [6] is not just about the tsunami. It is part of a need to fill the gaps, creating the social and political will to manage disaster risk and to coordinate activities [15].

‘The Road Map’ [6] has well documented that disaster events reported in the history have affected infrastructure facilities in varying degrees in Sri Lanka and resulted in people suffering for lack of basic facilities. This has lead to the responsible agencies struggling to get the facilities back to normal functioning conditions. This policy document is focused on seven thematic components, which are consistent with ongoing and past efforts in the field of disaster risk management and development planning, and as Hyogo Framework of Action 2005-2015. Critical infrastructure is deemed to be included under the theme called ‘Mitigation and Integration of Disaster Risk Reduction (DRR) into Development Planning’. ‘Providing safer critical infrastructure in hazard prone areas’ has been prioritised as one of the project proposals under the theme called ’Mitigation and Integration of DRR into Development Planning’. The above project proposal suggests that all critical infrastructure facilities must be designed to a given level of safety from disaster impact. Moreover, it suggests that such guidelines must be provided to designers and an adequate monitoring system be in place [6]. The activities identified in the proposal are;

- Formation of an Expert Group to cover different types of infrastructure
- Implementation of guidelines, codes for hazard resistant infrastructure construction
- Conduct a training programme for the infrastructure facility providing agencies and the engineers, planners and technical officers on the use of guideline
- Identify the critical infrastructure to be provided in hazard prone areas
- Develop guidelines for construction of critical infrastructure in hazard prone areas
- Review construction programmes to ensure adoption of hazard mitigation measures in all infrastructure development activities

(Source: [6])

The expected outcome of these actions is to increase the disaster resilience in critical infrastructure in hazard prone areas ensured through use of planning and construction guidelines.

On the other hand, the Ten-Year Horizon Development Framework (2006-2016) of the Government (The Ten-Year Vision) has recognised the importance of infrastructure to accelerate economic development [29]. For example, a series of large-scale infrastructure projects are to be implemented during 2006-2016 under the Ten-Year Vision. This includes power projects such as upper Kotmale hydropower plant, coal power plants at Norochcholai, Trincomalee and Hambantota, combined cycle power plant in Kerawalapitiya, transport development projects such as upgrading the Colombo – Matara railway line, new railway lines of Matara – Kataragama and Kurunegala – Habarana, light transit systems connecting Ratmalana - Battaramulla and Dematagoda - Battaramulla, [29]. At the same time small-scale infrastructure projects are also being developed under the Maga Neguma (road development) and Gama Neguma (village development) programmes [29].

Experience increasingly affirms that the post-disaster recovery phase provides a critical opportunity to introduce measures to reduce future disaster risk through new physical infrastructure. The study concludes that infrastructure can both reduce the losses resulting from natural disasters and facilitate easy post-disaster recovery and thus more investment in infrastructure reconstruction is needed while lessening the challenges confronted in the post-disaster reconstruction phase.

Sri Lanka has achieved an acceptable recovery in the southern part of the country but the northern region is lagging behind expectations, largely because of escalating conflict in the north and east of the country. What Sri Lanka was doing has not been working well enough in light of the enormous challenges faced by developing countries. The current infrastructure reconstruction process in the country is basically hindered due to the lack of institutional capacity and current security problems prevailing in the north and east region of the country. However, the main issue is whether these construction and reconstruction projects consider the economic development perspectives during the process**.** Moreover, whether they take into account the disaster reduction measures in the long-term construction?

While the infrastructure needs are increasingly well recognised, in many developing countries key infrastructure services are still in serious short supply and of poor quality. In particular, the coverage is typically much lower in rural areas where most poor people live in developing countries. But urban coverage is also under pressure, partly because of rapid rural-urban migration in many countries [25]. According to 'The Central Bank of Sri Lanka Annual Report–2005' [30], infrastructure facilities have been expanding in Sri Lanka but are not adequate or competitive yet, thereby constraining economic growth. Although these problems are most severe in low-income countries, they remain sizable in most middle-income countries too [25]. In Sri Lanka, the adequacy and quality of services provided by public enterprises in the areas of electricity generation, transmission and distribution, passenger transportation and water supply leave much to be desired while infrastructure facilities in the liberalised service sectors such as ports and telecommunications have demonstrated improved performance and an ability to face competition [30]. Also according to the report, the country has the potential to develop these service sectors and turn them around to be significant foreign exchange earners.

After the Tsunami 2004, the initial restoration work of infrastructure was completed within a relatively short period of time. Even though reconstruction and rehabilitation of the infrastructure is often essential to sustain recovery, there are some clearly identified key challenges in infrastructure sectors in post-disaster phases in Sri Lanka, particularly in Post-Tsunami 2004 [31]. The South Asian Disaster Report called, 'Tackling the Tides and Tremors' authored by Duryog Nivaran [15] has identified a key challenge with respect to the longer-term and larger task of developing the infrastructure and services along the devastated coastal belt and to new settlements; whether recovery is used to address disparities in quality and access of infrastructure and services to communities? Duryog Nivaran [15] questions, in particular, the extent to which infrastructure re-development extend towards and deals with issues related to poor people's infrastructure and service needs, reconcile environmental-development complexities and link development to future disaster risk management? [15].

7. The way forward

Within this context, it is worth studying how post-disaster infrastructure reconstruction projects address the above loopholes compared to general infrastructure construction projects. This leads to investigation of the speciality of post-disaster reconstruction projects compared to general infrastructure construction projects and whether the current post-disaster infrastructure reconstruction activities consider long-term sustainability and its contribution to economic development? In other words, how should reconstruction of infrastructure be carried out in a way that would contribute to the economic development of developing countries. Should there be any added or special strategies, features, objectives or concerns in post-disaster infrastructure reconstruction projects compared to general projects? If so, what are those? How can the above theoretical contribution of infrastructure on economic development be boosted? Identification of key indicators of economic development may be the first step towards this. Assessing the projects' special strategies, features, objectives or concerns against their impact on the indicators of economic development may lead to identification of necessary improvements in the post-disaster infrastructure sector, particularly sector wise impact of implementation of measures on mainstreaming of future disaster risk reduction on economic development.

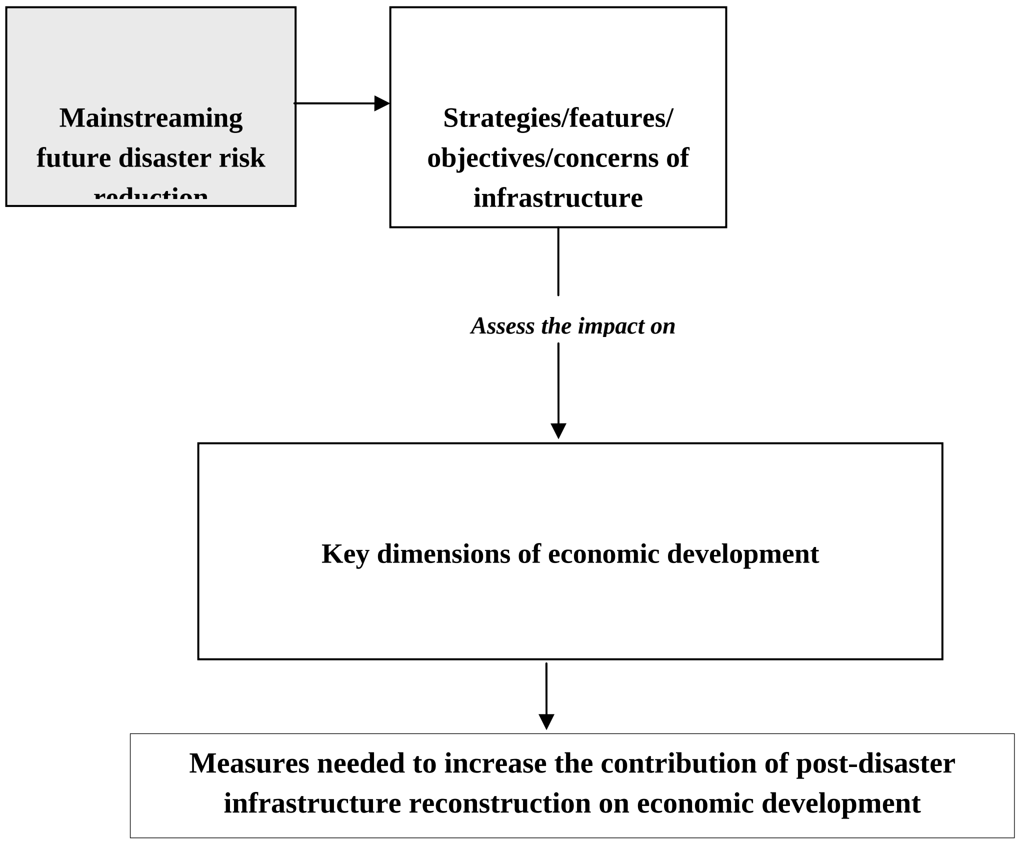

Figure 2: Research focus

8. Conclusion

Natural disasters destroy critical infrastructure. Through this research, an effort was made to identify the importance of post-disaster infrastructure reconstruction in economic development. Many researchers have affirmed that infrastructure has a strong link to economic development and then largely to the economic growth. Infrastructure development plays an essential role in reducing poverty in developing countries. Post-disaster reconstruction is found to be a good opportunity for focusing activities into development perspectives. In Sri Lanka, infrastructure facilities have been expanding but are not adequate or competitive yet, thereby constraining economic growth. In addition, the quality of some of the services remains insufficient. In the post-tsunami context, a key challenge with respect to the reconstruction of infrastructure is whether recovery is used to address disparities in quality and access of infrastructure and services to communities.

Abstract

Creating an organised common platform to capture, organise and share the knowledge on disaster management strategies is considered vital to enhance the effectiveness of future disaster management efforts. Hence, ensuring the availability and accessibility of accurate and reliable disaster risk information when required entails an efficient system for knowledge sharing. This paper highlights the importance of knowledge and good practice sharing in disaster management strategies, and discusses key lessons learned from 2004 Asian tsunami, particularly relating to the Sri Lankan context. Good practices and lessons learned are discussed on five different themes: social, technical, legal, operational and environmental. Further, the ISLAND website is introduced and developed as part of a research aimed at increasing the effectiveness of disaster management by facilitating the sharing of appropriate knowledge and good practices.

Keywords: Disaster management, Knowledge sharing, Lessons learned, Good practices.

1. Background

Disasters, both natural and man-made, have been occurring with increasing frequency and effect in recent decades in many countries around the world. According to the World Disaster Report 2005 [1], the number of reported disasters has increased steadily over the past century and risen sharply during the past decade. This reflects the high value of the infrastructure and assets at risk. Disasters bring about the loss of lives, property, employment and damage to the physical infrastructure and the environment. The Asia-Pacific region has experienced the greatest loss of life in absolute terms and in proportion to the population, due to earthquakes, tsunami, floods and tropical cyclones. The Asian tsunami that struck on the morning of December 26, 2004 is widely acknowledged as the largest, most devastating natural catastrophe in the Asian region. This left behind widespread destruction, killing over 250,000 people, damaging natural ecosystems and coastal infrastructure [2]. As such, there is a conscious effort for disaster management at national, provincial and sub-provincial level.

Effective lesson learning should reduce the risk of future disasters through well-informed mitigation and preparedness planning. Ensuring the availability and accessibility of accurate and reliable disaster risk information when required entails an efficient system for knowledge sharing. Despite its importance, knowledge appears fragmented, although there are undoubtedly many successful practices and lessons to be learned from 2004 Asian tsunami [3]. The UK Higher Education Disaster Relief Project Report 2007 [4] highlighted a lack of mechanisms at national level in the UK to link the expertise, skills and knowledge that resides in UK Higher Education with the practitioners in the humanitarian agencies. A lack of prior knowledge and proper point of reference have made most of the recovery plans guessing games, eventually failing without adding appropriate values to the recovery attempts [5]. In view of addressing the perceived need to share knowledge relating to disaster management strategies, the School of the Built Environment, at the University of Salford, undertook the research project '*ISLAND*' (Inspiring Sri-Lankan reNewal and Development), partly funded by the RICS Education Trust.

The paper aims to share good practices and lessons learned from 2004 Asian tsunami, while highlighting the importance of knowledge sharing in current disaster management strategies. It identifies appropriate good practices relating to several themes, based on case materials collated as part of ISLAND project. Accordingly, the paper is broadly divided into three sections. Initially, an overview on disaster management process and the need to share knowledge relating disaster management strategies are discussed. Secondly the paper introduces ISLAND project, where aims, objectives and methodology are presented. Finally, it provides an analysis on good practices and lessons learned from Asian tsunami disaster.

2. Disaster management process

Disaster management efforts aim to reduce, or avoid the potential losses from hazards, assure prompt and appropriate assistance to victims, and achieve a rapid and effective recovery [6]. As shown in Figure 1, the process of disaster management is commonly visualised as a two-phase cycle, with a post-disaster recovery informing pre-disaster risk reduction and vice versa. As Warfield [6] states, the disaster management cycle illustrates the ongoing process by which governments, businesses and civil society plan for and reduce the impact of disasters, react during and immediately following one and take steps to recover after it has occurred.

The significance of this concept is in its ability to promote the holistic approach to disaster management as well as to demonstrate the relationship of disasters and development. Recovery and reconstruction are commonly identified within the post-disaster phase, that is the period that immediately follows after the occurrence of the event. However, the terminology of disaster relief and recovery, rehabilitation and reconstruction is used without precise and commonly agreed definitions, although in practice, a distinction is drawn between the emergency relief phase and the subsequent non-emergency recovery [5]. Once a disaster has taken place, the first concern is effective 'recovery' – helping all those affected to recover from the immediate effects of the disaster. 'Reconstruction' involves helping to restore the basic infrastructure and services that the people need so that they can return to the pattern of life which they had before the disaster [7]. The importance of the 'transitional phase', linking immediate recovery and long-term reconstruction, is also stressed by a number of publications [2, 5]. With the recovery of social institutions, the economy and the main infrastructure, transition to the longer-term recovery and reconstruction process can be implemented.

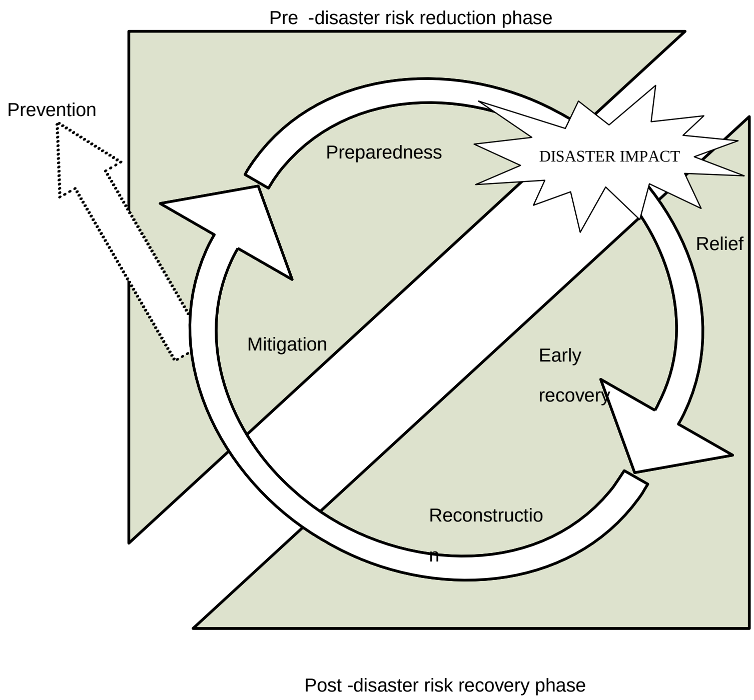

Figure 1: Disaster management cycle (adopted from RICS [5])

The pre-disaster phase of the disaster management cycle includes both mitigation and preparedness. As RICS [5] defines, disaster mitigation refers to any structural and non-structural measures undertaken to limit the adverse impacts of natural hazards, environmental degradation and technological hazards. 'Mitigation' measures may eliminate or reduce the probability of disaster occurrence, or reduce the effects of unavoidable disasters. As Warfield [6] describes, these measures can include building codes; vulnerability analyses updates; zoning and land use management; building use regulations and safety codes; preventive health care; and public education. In the ideal case, mitigation eliminates the risk of future disasters by effective sharing of lessons learned through 'preparedness' planning. Hence, the attention to disaster mitigation and risk reduction, which comprises the development portion, is equally important as disaster recovery and reconstruction, and rehabilitation. Greater attention to pre-disaster planning and preparedness, and sharing the lessons from previous disasters, could considerably reduce the risk associated with such events. Thereby, the mitigation phase, and indeed the whole disaster management cycle, includes the shaping of public policies and plans that either modify the causes or mitigate their effects on people, property, and infrastructure. Appropriate actions at all points in the cycle lead to greater preparedness, better warnings, reduced vulnerability or the prevention of disasters during the next iteration of the cycle [6].

Natural events however only become potential hazards when they threaten people or property [7]. As Warfield [6] states, natural hazards themselves do not necessarily lead to disasters. Natural hazards like earthquakes, however intense, inevitable or unpredictable, translate to disasters only to the extent that the population is unprepared to respond, unable to cope, and consequently, severely affected. An earthquake will cause little damage if it takes place in an empty desert. It may also cause little damage if it takes place where people can afford to be well protected. Hence, a natural event only causes serious damage when it affects an area where the people are at risk and poorly protected. Disasters occur when these two factors are brought together (as shown in Figure 2):

- People living in unsafe conditions
- A natural hazard such as a flood, tsunami, hurricane, earthquake.

Figure 2: Components of a disaster

Thereby, the threat from natural hazards can only be minimised through the elimination of unsafe conditions, as much as possible, in terms people, property and infrastructure. The role of the pre-disaster risk reduction phase, also referred as development portion, is considered to be vital in bringing unsafe conditions to a controlled safe environment, through mitigation and preparedness.

3. The need to share knowledge

There is a conscious effort for disaster management at national, provincial and sub-provincial level. Despite this, knowledge appears fragmented, although there are undoubtedly many successful practices and lessons to be learned [3]. Hence, there is a perceived gap in information coordination and sharing particularly relating to disaster mitigation. A lack of prior knowledge and proper point of reference have made most of the recovery plans guessing games, eventually failing without adding appropriate values to the recovery attempts [5]. The lack of effective information and knowledge sharing, and dissemination on disaster mitigation measures can thereby be identified as one of the reasons behind the unsatisfactory performance levels of current disaster management practices.

Knowledge can be differentiated between explicit, tacit and implicit forms of knowledge. Tacit knowledge represents knowledge based on the experience of individuals, expressed in human actions in the form of evaluation, attitudes, points of view, commitments and motivation [8]. Explicit knowledge, in contrast, is codifiable knowledge inherent in non-human storehouses including organisational manuals, documents and databases. In an organisational context, knowledge management is about applying the collective knowledge of the entire workforce to achieve specific organisational goals and facilitates the process, by which knowledge is created, shared and utilised [9]. However, within the disaster management context, knowledge management is about getting the right knowledge, in the right place, at the right time [3]. As a strategic approach to achieve disaster management objectives, knowledge management will play a valuable role in leveraging existing knowledge and converting new knowledge into action through the knowledge management cycle. In essence, knowledge organisation and human knowledge conversion processes can bring a comprehensive foundation to the common operating picture, interoperability, intelligence, training and acquisition [2]. In the light of this, it can be perceived that valuable knowledge on disaster management is present at three different levels: institutional, group and individual, in the forms of both tacit and explicit knowledge.

Thousands of organisations and institutions have been supporting the efforts on disaster management over last few decades. The linkages among all agencies working on disaster management need to be strengthened in order to derive the regional best practices and coping mechanisms [5]. In order to enhance the information sharing and management of the knowledge generated in institutions, it is essential to knit these organisations and institutions, and moreover groups and people working within them [2] more closely together. There are many gaps that could be bridged by the appropriate use of professional skills, but access to these by the local organisations on the front line of the recovery effort is highly constrained through lack of recognition of their existence. Therefore, recognition needs to be given for the institutions and organisations operating not only at international and national level, but also at the local level. In addition, this local knowledge can reside among the groups operating within different communities; hence, it can be extended to the existence of these formal and informal groups involved with the disaster management process.

The knowledge and experiences of disaster practitioners remain mainly in the individual domain. Due to its large geography, the experiences, approaches and adopted modalities for disaster management is not codified and remains with individuals as a tacit knowledge [3]. Acknowledging the need for a disaster knowledge-networking platform to facilitate interaction and have simultaneous dialogue with all related expertise dealing with disaster management, a knowledge management initiative was envisaged as a tool to store, retrieve, disseminate and manage information related to disaster management.

4. ISLAND project

ISLAND (Inspiring Sri-Lankan reNewal and Development) is aimed at increasing the effectiveness of the current disaster management strategies by sharing appropriate knowledge and good practices about post-tsunami programmes, particularly in the Sri Lankan context. To this effect, the research was built around following objectives:

- To create an infrastructure for developing, sharing and disseminating knowledge about disaster management for land, property and construction.
- To develop a knowledgebase on post-tsunami recovery efforts, including but not limited to, disaster mitigation strategies.
- To develop case materials on post-tsunami responses.

Although the initial research focused on tsunami mitigation strategies and Sri Lanka in particular, the infrastructure developed during the project is scalable to permit growth in the knowledgebase to address other aspects of disaster management.

4.1 Methodology

The research was carried out according to three Work Packages (WPs). Details of WP specific objectives and description are provided within the WP outline.

Work Package 1: Develop knowledgebase infrastructure

Aim: WP1 aimed to develop the infrastructure for capturing, sharing and disseminating knowledge about disaster management in land, property and construction. Going beyond the scope of mere information management, it integrated knowledge extraction and dissemination techniques within this WP. The objective of this initiative is to ease and speed-up the decision making process within disaster management exercises. Specifically, mechanisms were developed to extract and disseminate explicit knowledge from materials gathered in WP2. This provided the necessary scalability for the knowledge dissemination exercise within the proposed project, be it internal to an organisation or accessible worldwide, as the database can be hosted centrally. A dynamic web portal was created as the front end of this database, providing the search and update facilities, to ensure enhanced user friendliness and self expansion of the proposed knowledgebase.

Work Package 2: Populate knowledgebase

Aim: WP2 aimed to populate the knowledgebase with a range of land, property and construction information related to tsunami mitigation strategies. Accordingly case materials focusing on good practices and lessons learned from the 2004 Asian tsunami disaster, particularly Sri Lankan post-tsunami context, were collated and analysed. The portal user interface developed in WP1 provided the capability to upload case study information to the backend database. In addition, professional bodies and relevant research groups were identified and invited to contribute materials to the knowledgebase. This included: disaster recovery strategies, their effectiveness, drawbacks and current good practices; the level of community involvement; details on the allocation of funding to recovery and reconstruction programmes in the region;

details on short term relief and its benefits; plans for long term developments including the consultation process between the government and the local community, knowledge on planning and building settlements that respond to community needs while providing a more secure environment; and finally, information on reporting frameworks.

Work Package 3: Disseminate research and identify future research directions

Aim: WP3 aimed to disseminate the research outputs and identifying future research directions. The web portal forms the focal point for the research's dissemination strategy. However, the project will also use and integrate with other appropriate dissemination mechanisms. A range of academic publications and prestigious International Conferences on relevant themes were targeted as a means of promoting the portal and disseminating the case material to a wider audience.

5. ISLAND website

As part of WP 1, the ISLAND web portal and knowledgebase was developed to capture, process, and disseminate the lessons learned from the Indian Ocean tsunami in the form of policy advice and good practices to guide future post-disaster interventions. Hence, the web portal provides an organised common platform to capture, organise and share the knowledge on disaster management strategies and create a versatile interface among users from government, professional bodies, research groups, funding bodies and local communities.

Figure 3: ISLAND website - Home page

The knowledgebase was created to address several themes of disaster management based on published case materials collected on Asian tsunami disaster 2004, particularly cases from the

Sri Lankan context. Case materials are organised into types of disaster, phase, country, source, research methodology followed, level, scope and access to the study is stored in a MySQL database using a PHP-Database interface. With the usage of SQL query, simple and advance searchers are provided to retrieve and view data. Also a key word search function is provided in the same manner to search the relevant keywords in the description provided of the materials.

The web site provides an introduction to the ISLAND project and project output together with the publications of the project. The web portal acts as the public interface to share and disseminate the lessons learned and good practices in disaster management. Further, the portal provides tools to capture, acquire and organise knowledge, through which the knowledge database will be kept up to date and live with disaster management strategies.

6. Good practices and lessons learned

As part of WP2, an analysis of good practices and lessons learned from the Asian tsunami disaster was carried out based on case material collated, particularly from Sri Lanka. Good practices and lessons learned, relating to different phases of disaster management cycle, are summarised into several themes that emerged from case material: social, technical, operational, legal, and environmental.

6.1 Social Issues

The importance of community participation within reconstruction process, public awareness and education, and job creation programmes like Cash for Work (CFW) are emphasised in most of the case material collated. Within the last decade, growing recognition of the necessity of community participation for sustainable disaster reduction was translated into actions to realise community based disaster management. Major benefits of the community based risk assessment, mitigation planning and implementation processes underscored include [10]; building confidence, pride in being able to make a difference, and enhanced capabilities to pursue disaster preparedness, mitigation as well as bigger development responsibilities at the local level. Additionally, individual and community ownership, commitment and concerted actions in disaster mitigation, including resource mobilisation produce a wide range of appropriate and innovative mitigation solutions, which can be cost-effective and sustainable.

As Doocy et al. [11] state, job creation programmes have been used to provide aid to less well-off citizens and can be considered as antecedents to CFW, which are an increasingly common element of humanitarian assistance in food-insecure settings, disaster-affected areas and post-conflict environments. The tsunami of 26 December 2004 caused massive devastation and hundreds of thousands of people were no longer able to participate in their routine employment activities. Considering the benefits of harnessing idle labour in the immediate post-disaster period, cash for work programmes can be recognised as a logical response that provide a structured mechanism to engage people in low-skilled constructive activities while injecting cash into the economy and promoting decision-making at the community and individual level.

Experiences in implementing large-scale CFW programmes [10, 11] in the Asian post-tsunami phase have led to the following set of recommendations:

- Communities need to be informed of benefits and limitations of CFW.
- It is helpful to identify potential community coordinators as well as be aware of what other agencies are doing.
- Adequate attention should be paid early on to procurement, warehousing and the delivery of supplies and equipment in order to expedite CFW activities.
- Cash for planning is seen as a good way of working; aids participation in the planning process and promotes informed choice.
- CFW implementers either limit the need for technical expertise by providing simple project design or ensure the availability of skilled labour needed to complete CFW activities.
- Train local staff to lead these programmes and for community leadership
- Consider work groups with no more than 25 workers and a ratio of no more than four work groups to one supervisor (overall maximum ratio of 100 workers: 4 group leaders: 1 area supervisor) to ensure quality and efficient work.
- There is a need for synergy in communication/coordination between organisers and the community.

Public awareness and education are essential to protect people and property from disasters. A lack of awareness has been identified as a major reason behind the huge loss of lives and property from the 2004 Asian tsunami. Indeed, the term “Tsunami” was heard by most of the ordinary Sri Lankans only after this devastation. As Briceno [12] states, in Thailand more than 1,800 people were saved because a tribal chief recognised that there was something wrong and decided to evacuate his people up to the hills. A 10-year-old girl from England saved 100 tourists on a beach in Phuket, Thailand after alerting her mother of the imminent tidal wave and prompting a speedy evacuation to safety. The girl recognised the signs after learning about tsunamis in her geography class. Knowing what to do and when to do it is the key to saving lives. The media also have a social responsibility to promote prevention. Journalists need to be sensitised and maintain an ongoing focus on prevention aspects of disasters [12]. These disasters are happening on an almost daily basis around the world. Not to be overlooked is the media’s role essentially in early warning systems. The Asian tsunami disaster could be a trigger for the media to play a more active role in improving lines of regional and global awareness, and communication using new media technologies.

6.2 Technical know-how

The tsunami affected two-thirds of the coastline of Sri Lanka, and it also resulted in the destruction of nearly 100,000 houses and infrastructure such as roads, bridges etc [2]. Depending on the wave height, various types of structures were affected. Waves of up to 2m in height caused 1–2m high boundary walls to collapse. As wave heights increased, single-storey masonry structures were significantly damaged and were completely swept off their foundations at wave heights of around 4m. Buildings of two storeys and higher, especially those with concrete frames, had their infill masonry walls that were perpendicular to the waves knocked down by waves of up to 4m, but waves of even 5m did not cause the complete collapse of such buildings [13]. Partial collapse occurred, however, if foundations were undermined by waves of 3–5m in height.

According to Dias et al. [13], there are two common threads that run through the structural failures. The first is that structures have to be tied down in addition to being held up. The latter is obviously the focus of everyday attention, since gravity loads will assert themselves almost immediately otherwise. However, when natural disasters such as cyclones and tsunamis occur they have the effect of trying to lift up or push aside structures. Such actions can be resisted only by having a continuous chain of tying down from roof to foundation, and also by having sufficient gravity load to resist the overall upward or lateral forces. The second thread is that soil scouring has to be accounted for, or anticipated [13]. This can be done by improving the soil properties, especially soil that has been backfilled; deepening foundations, whether in buildings or bridges; and also by providing sufficient structural redundancy to prevent catastrophic collapse even if some foundations fail. The strategic use of natural features such as sand dunes and provision of vegetation barriers are also ways of mitigating potential tsunami damage [14]. In Sri Lanka, newly published national guidelines for reconstruction emphasise the importance of tying down structures against upward and lateral loads as well as the need to anticipate and reduce soil scour around foundations, especially of backfilled earth.

However, it was not only buildings that were destroyed due to the tsunami tidal waves, civil engineering structures like roads and bridges were also damaged. An investigation [15] on infrastructural damage in Sri Lanka due to the tsunami revealed the following:

- Damage to roads induced by the tsunami included erosion of embankments, erosion of abutment backfills and collapse of bridges following the loss of stability of the abutments.
- Erosion of embankments tended to have occurred at locations where the land was relatively low, presumably because the back flow of the tsunami concentrated on those parts of the land.
- No bridge girders were washed away by the direct impact force of the tsunami. However, it is too optimistic to conclude that bridges are always safe against the impact force of a tsunami.
- Existence of detour and quick restoration weakened the socio-economical impact of the damage.

6.3 Operational issues

Coordination is often a scarce resource in disasters, yet remains the key operational principle for effective response. It is important in order to avoid duplication of effort that resources are directed to those most severely affected by the disaster. Good coordination can also facilitate the learning of lessons. The importance of effective coordination of disaster management work at international, regional, national, organisational, group and individual level is overwhelmingly highlighted within the case material. Reducing risk depends on communication and information exchange between the scientific community and politicians. The Asian tsunami disaster showed that in the absence of an open dialogue, valuable information and research from technical sectors is redundant. As Senanayake [16] argued, there was a striking absence of expertise and professionals, from the region in the post tsunami operation in Sri Lanka, despite the stated aim to develop regional disaster response capacity in the Asia Pacific Region by a number of agencies. Hence, it is necessary to strengthen the link between scientific institutions and national and local authorities that need to react to avoid human, economic and social losses from disasters.

International, regional and national organisations should work better together and be better coordinated. Coordination is an essential element of disaster prevention, mitigation, preparedness and response for the entire UN system, governments and non-governmental organisations. Efforts need to be made to promote complementary services and avoid duplication [12]. A number of reports [2, 12, 16] emphasised the primary role of national authorities in coordinating and directing national and international assistance. Existing inter-agency coordination arrangements should be further strengthened, particularly concerning the sharing of information and knowledge in the early phases of the disaster response. Mechanisms should be devised to ensure the participation of smaller organisations and institutions with less international experience to the coordination process. Further, governments need to demonstrate their political will and commitment to disaster risk reduction through concrete measures e.g. reserve national budget line for disaster reduction, and strategic donor funds to support and build capacity for disaster risk management.

6.4 Legal concerns

Coastal zones and small islands are often densely populated areas that increase the risk to and vulnerability of people. Nearly 3 billion people, or almost half the world population live in coastal zones, which in many cases are prone to hazards including tropical cyclones, floods, storms and tsunamis [12]. Often coastal populations are dependent on the sea for their livelihoods (e.g. fishing villages) and do not have the choice to live elsewhere. Small island countries such as the Nicobar and Andaman islands are barely a few metres above sea level, which means that evacuation to higher land is almost impossible. Governments and local authorities need to take human habitats into consideration in long-term development planning, ensuring that risks are minimised.

Beyond preparing for evacuation and emergency response, communities can reduce their tsunami risk by modifying their land use planning and development approval practices. Although planning for tsunamis will not be a top priority for most coastal communities, relatively small efforts to plan for this hazard can significantly increase community safety. The US National Tsunami Hazard Mitigation Program’s publication ‘Designing for Tsunamis’ stresses the importance of understanding site planning. Through zoning, creation of open spaces and not allowing new development in potential tsunami areas, safer land use will be better able to protect people and buildings. Specific site planning strategies to reduce tsunami risk can include [14]:

- Avoiding inundation areas: site buildings or infrastructures away from hazard areas or locate on a high point.
- Slowing water: forests, ditches, slopes, or burns can slow down waves and filter out debris. The success of this method depends on correctly estimating the force of the tsunami.
- Steering: water can be steered to strategically placed angled walls, ditches and paved roads. Theoretically, porous dikes can reduce the impact of violent waves.
- Blocking: walls, hardened terraces, burns and parking structures can be built to block waves.

Several reports [12, 17, 18] emphasise the necessity for a national and institutional level legislative framework governing disaster management efforts. From the institutional point of view, the law should bring about a reform of the entire national institutional arrangement for disaster management, provide for the allocation of resources for preparedness and emergency response at all levels of governance, and create a permanent liaison mechanism with the international humanitarian community. Decentralisation of decision-making authority should feature prominently in the new set up. Administratively, such law should promote the development of detailed contingency plans at local level. Such plans should include [18]:

- Risk analysis, zoning and mapping,
- Comprehensive air, sea and road transportation arrangements (including stand-by agreements with the national air carrier and shipping companies),
- The pre-positioning of relief supplies and – notably - of fuel, and
- Backup emergency communications arrangements, notably assigning an institutional role to amateur radio communications.

Further, drafting of a National Disaster Management Bill is recommended, which should:

- Deal with the creation of policies/provisions/regulations at sectoral level to enable special conditions applicable for emergency response,
- Formulate operating policies for the mobilisation of military assets in disaster management and emergency response,
- Regulate the role of NGOs in the national setup for disaster response, and
- Specify provisions for the request and reception of international assistance.

6.5 Environmental concerns

The tsunami reduced some coastal communities to piles of bricks, tin and wood mixed with car and boat parts, construction materials, ocean mud and dead bodies. While the December 2004 tsunami killed more than 250,000 people in 12 countries and left millions of homes and businesses in ruin, officials were most worried about the killer wave's environmental aftermath. In many cases, the tsunami worsened pre-existing environmental management problems on the inhabited islands. The Joint United Nations Environment Programme (UNEP)/United Nations Office for the Coordination of Humanitarian Affairs (OCHA) Environment Unit (Joint Unit), integrated in the Emergency Services Branch of the OCHA, is the principal United Nations mechanism mandated to assist countries facing environmental emergencies.

As Casey et al. [19] argue, a common best practice approach to debris removal should be developed to minimise negative environmental impact. Related guidance material should be translated into local languages and effectively disseminated. Re-mapping affected areas before redevelopment begins can ensure the identification of hazardous areas created by tsunami-induced changes, such as mass graves and locations vulnerable to flooding. Remapping is therefore an important tool to help ensure that tsunami victims do not face new dangers when they resettle, and can also reassure affected populations of the safety of the locations where they rebuild. In this regard, local expertise and capacities in recycling, composting and environmental management can play a key part in clearing efforts. However, as Calvi-Parisetti and Pasche [20] argued, immediately following the tsunami, the inclusion of environmental issues into disaster management efforts at the national level was limited. Another revelation that has emerged from several studies is the fact that many operational agencies of the United Nations system have very little awareness of the potential environmental threats in the aftermath of disasters.

In Sri Lanka, the key environmental findings from the Rapid Environmental Assessment (REA) carried out on 2004 tsunami disaster included the following [19]:

- While there is damage to the natural and built environment in affected coastal areas, there are no major life-threatening environmental emergencies as a result of the tsunami.
- Specific coordination needs to enhance environmental risk mitigation efforts.
- Remapping needs to ensure effective reconstruction efforts.
- Areas of acute environmental concern requiring immediate attention include management of tsunami waste and debris, and sanitation and sewage issues in settlements.

Calvi-Parisetti and Pasche [20] prescribes the process to be followed when assessing environmental impacts after a tsunami disaster. Assessments carried out in the first 48-72 hours after a major disaster should aim at identifying major secondary risks through a relatively simple checklist that should become a standard feature of the overall emergency assessments. If such risks are identified, specialised expertise should be quickly mobilised for further assessments and quick response. The initial environmental assessment should also look at those issues that are not immediately life threatening but may become so at a later stage if not dealt with immediately. Once the most acute phase of the response is over, the environmental consequences of the disaster on the livelihood of the affected population should be assessed and programmes designed to address them. Finally, the environmental consequences of the disaster on ecosystems and habitats should be assessed in order that they may be addressed through programmes in the reconstruction/rehabilitation phase.

7. Conclusion

Information and knowledge play an extremely important role in effective disaster reduction and response. Good communication and exchange of critical disaster management information and knowledge could enhance coordination and integration of stakeholders' actions in disaster mitigation and response. This paper highlighted the importance of knowledge and good practice sharing in disaster management strategies, and discussed the principal lessons learned from the 2004 Asian tsunami disaster, particularly relating to the Sri Lankan context. Several good practices and lessons learned, from 2004 Asian tsunami disaster, are explored relating to five different themes: social, technical, legal, operational and environmental. The ISLAND website introduced an organised common platform to capture, organise and share knowledge on disaster management strategies. However, the UK Higher Education Disaster Relief Project Report [4] highlighted the lack of mechanisms at national level in the UK to link the expertise, skills and knowledge that resides in UK higher education with practitioners in the humanitarian agencies. Neither is there a comprehensive overview of the expertise which exists and who is willing to offer it. Therefore, ISLAND could be extended to create mini-hubs of academic (and non-academic) expertise in order to act as the mechanism by which needs for expertise in a range of areas could be identified by the humanitarian agencies. Further, case material relating to different phases and types of disasters could be collated and populated using the available infrastructure of the ISLAND website.

Abstract

Besides human casualties one of the most visible and striking effects of any major disaster is the destruction of houses. Construction of houses will be a major activity in the reconstruction phase of a disaster. The quickest and the most effective way to rebuild houses after a disaster is to employ what is know as the " Donor Driven" approach. In this approach the government or an external agency who is funding the project will lead the reconstruction process with the help of consultants and contractors procured for the project. The major limitation of this approach is that it may lead to housing that does not respond to the need of the victims. As an alternative, the so called "Owner Driven" approach has been used by some donor agencies as well as the government in many disaster situations. In this approach the disaster victims reconstruct their houses by themselves. The role of the external agencies is limited to the provision of financial and technical assistance.

Past research on the suitability of these two approaches to various disaster situations is limited to very few cases. The massive reconstruction programme implemented in Sri Lanka after the Indian Ocean Tsunami has used both these methods with varying degrees of success. Therefore, lessons learned in Sri Lanka would be a useful contribution to this growing body of literature on different approaches to post disaster housing reconstruction.

This paper aims to contribute to this discussion through a questionnaire survey conducted among beneficiaries of Tsunami housing programmes in the Matara District of Sri Lanka. The study found that Owner Driven approach has a number of advantages over Donor Driven approach. Nevertheless, Donor Driven approach cannot be totally dismissed as unsuitable because it has scored very high on some important parameters that are relevant for disaster situations.

Key Words: Disaster reconstruction, Housing, Sri Lanka

1. Background

Disasters cause a substantial amount of damage around the world every year [7]. In recent years several major disasters have occurred in coastal areas worldwide. On the 26th of December 2004, a major Tsunami occurred in the Asian region killing nearly 250,000 people around the

Indian Ocean. The Joint Report of the Government of Sri Lanka and Development Partners[3] issued in December 2005 highlights that the Tsunami on 26th December 2004 killed 35,322 people and destroyed US $ 900 million worth of assets and infrastructure in Sri Lanka.

One of the major challenges after a disaster is how the redevelopment activities should be undertaken. To rebuild the nation after a disaster, Governments adopt different reconstruction strategies. Different reconstruction strategies give different outcomes. Serious decisions must be made on how risks could be reduced to acceptable levels and these decisions have to be reflected in the reconstruction and recovery strategies that should be adopted. Identifying the most suited and applicable strategy for each situation is of utmost importance in order to provide better assistance to the victims and to avoid possible future vulnerabilities and environmental degradation.

Therefore, the aim of this research is to analyze the strategies used in post Tsunami reconstruction work in Sri Lanka. The main objective of the research is to identify the post Tsunami housing reconstruction strategies used in Sri Lanka, their applicability to Sri Lankan context and their successfulness.

2. Disaster Management & Reconstruction

2.1 Disaster management

Disasters are not totally discrete events. Their possibility of occurrence, time, place and severity of the strike can be reasonably and in some cases accurately predicted by technological and scientific advances. It has been established that there is a definite pattern in their occurrences and hence we can to some extent reduce the impact of damage though we cannot reduce the extent of damage itself. This demands the study of disaster management in methodical and orderly approach [5].

Disaster management has different emphasis in different disciplines. According to Central Emergency Relief Organization [2], disaster management is a collective term encompassing all aspects of planning for and responding to disasters, including both pre-disaster activities and post-disaster activities. It may refer to the management of both the risks and consequences of disaster.

Disaster management can be divided into four steps as: Emergency Response and Relief; Recovery and Reconstruction; Mitigation; and Preparedness [8].

2.2 Reconstruction Strategies

According to Kishore [6], any reconstruction programme has to meet a range of complex and often conflicting needs of affected people. i-Rec Coference held in 2004, has identified that reconstruction programmes often fail to take in to account the desires of disaster affected populations. If proper attention is not given to needs of affected people there is a possibility that the newly constructed facilities become obsolete from the day the construction is complete.

Therefore, reconstruction strategies should be implemented after studying the desires of the affected people.

According to Asian Disaster Reduction Center[2], post disaster reconstruction is a complex issue with several dimensions. Government, non-governmental and international organizations have their own stakes in disaster recovery programmes, and links must be established among them, as well as with the community. SMEC Group of Companies [8] mentioned that, reconstruction is one of the most demanding forms of activity after a disaster, because it operates in conditions of uncertainty, often in remote locations and within severe time constraints. Therefore, proper planning is of utmost importanance to reduce future vulnerabilities and to improve long-term sustainability. A good housing reconstruction strategy will take in to account the social need together with long-term disaster mitigation and sustainability. Barenstein [9] has studied these strategies following the earthquake that hit Gujarat in India on 26 January 2001. Barenstein [9] identified five approaches, namely; the owner-driven approach; the subsidiary housing approach; the participatory housing approach; the contractor-driven approach in situ; and the contractor-driven approach ex nihilo, that have been used during the reconstruction. The author has compared these five approaches and discussed the issues related to implementation of each of these methods.

Indian Ocean Tsunami provides an opportunity to study the different approaches used in housing reconstruction, their success, and related issues. According to Wegelin [10], Indonesia’s Reconstruction Master Plan for post Tsunami reconstruction set two core standards for tsunami victim household support. Each surviving household would be entitled to a grant of US$3,000 per house to rebuild the houses if it needed to be rebuilt from scratch and US$1,000 for damaged houses that could be renovated. Unlike in Gujarat, Sri Lanka used only two distinct approaches in housing reconstruction. They are, Donor Driven approach and Owner Driven approach [10].

Donor Driven reconstruction program is completely handled by the donor agencies as relocation of affected families within the buffer zone from the buffer zone became a necessity. All affected families were entitled to a house built by a donor agency in accordance with Sri Lankan government standards in a new location. In addition, the donor provides all common infrastructure for the new settlement, while Sri Lankan government provides the services up to the relocation site [10].

Houses got damaged partly or fully outside the buffer zone were included in the Owner Driven reconstruction program. The Sri Lankan government provided a cash grant to the affected homeowners for the reconstruction of their houses at the same site. The owner of a partly damaged house received a cash grant of Rs.100,000 and the owner of a fully damaged house received a cash grant of Rs.250,000 [10]. The Owner Driven approach enables the affected communities to undertake construction work by themselves with external financial support and technical assistance.

3. Methodology

First a comprehensive literature review has been carried out on disaster management and reconstruction strategies by referring books, reports, journals and research publications. The Tsunami, which hit Sri Lanka on the 26th of December 2004, has been selected as the case study for this research. A detailed documentary survey has been carried out on post-Tsunami reconstruction activities in order to identify the different housing reconstruction strategies adopted. Also 100 newly constructed or repaired houses have been inspected in the District of Matara in order to get a clear idea on issues such as buildability, sustainability, etc.

Both structured and unstructured interviews were conducted among officers of 11 Governmental and 6 non-Governmental Organizations, to collect information on post Tsunami housing reconstruction strategies, their suitability and applicability. A questionnaire survey has been administered among 531 Tsunami victims in the District of Matara, to identify the beneficiery satisfaction of the housing they obtained. The profile of the sample used in the questionnaire survey is given in Table 1.

Table 1: Profile of the sample

Category	No. of Dwellers	%
Donor Driven Housing Relocation Programme	261	49 %
Owner Driven Housing Resettlement Programme	255	47 %
Received only Temporary Housing	21	4 %
Total	537	100%

4. Results

With all findings from questionnaire survey, unstructured interviews conducted among Tsunami victims together with observations of the researcher and the views of officers of the relevant Governmental and Non Governmental Organizations, the successfulness of the housing reconstruction programme has been measured separately for Donor Built Programme and Owner Driven Programme using the parameters given below.

- Coverage
- Adequacy and sufficiency of the relief received
- Timeliness
- Overall satisfaction of the victims
- Other issues based on the observations of the researcher (Buildability, Sustainability, Extendibility)

4.1 Coverage

According to statistical details 74.30% of the housing units have been completed and 18.63% of the housing units are been progressing by September 2007 [11]. So the tsunami housing reconstruction progress in Sri Lanka is in fairly success stage when considering total planned duration of 3-5 years period. Beyond the above facts, the present housing coverage in Matara district has been concluded in following topics under two housing reconstruction strategies in order to identify the successfulness of the housing reconstruction programme.

In the case of donor driven housing programme in Matara district that total 62 numbers of sites assigned for relocation and out of that 48 numbers of sites have been completed. Although the 10 sites are currently in progress and 08 numbers of sites are not commenced yet. When concerning the total number of houses required for district of Matara has planned as 1678 units and already 1856 housing units have been completed. Also 371 housing units are in progress and 423 houses are not begun as it planned at the decision making stage. So as a conclusion it can be mentioned as more than 100% of total housing requirement has been achieved at the moment in donor driven housing programme in Matara district with an excess of 178 numbers of housing units [11].

Up to end of September 2007 that 96.70% of total number of housing unit in overall fully and partly damaged housing unit in owner driven housing programme has been completed in the district of Matara. So the remaining 2.7% is on progress and 0.6% of housing units are not begun yet. In the case of owner driven housing programme the housing progress in fully and partly damaged housing units are summarized in separately as following Table 2.

It can be seen in the 89% of completion in fully damaged houses and 99% of completion in partly damaged houses. So the money disbursements do not inevitably denote that the reconstruction of the housing units are completed from Rs. 250,000/= is given to fully damaged victims in 4 installments and Rs. 100,000/= is given to partly damaged victims in 2 installments. It has been observed when the dwellers have failed to show the progress of the work with in the stated requirements, and then the victims have been unable to collect the next installment according to disbursement schedule. So that they had to wait for further money arrangement from top up grants, loans and other assistances from third parties to complete their houses and that has affected a fairly less progress in owner driven housing programme especially in fully damaged houses.

Table2: Progress in Owner Driven Housing Programme

	Fully Damaged Houses		**Partially Damaged Houses**	
	Nr. Of Houses	**%**	**Nr. Of Houses**	**%**
Completed	1250	89%	4821	99%

In Progress	142	10%	25	0.50%
Not Started	11	1%	25	0.50%
Total	1403	100%	4871	100%

4.2 Timeline

To carrying out the research in several parameters that the scale has been used as “very satisfied”, “somewhat satisfied”, “somewhat dissatisfied”, and “very dissatisfied”. As shown in Table 3, the greater parts of the victims were at either categories of “somewhat dissatisfied” or “very dissatisfied” scales in both housing reconstruction programme. It is not an uncertainty issue due to that reconstruction has been designed to complete within 3-5 years of timeframe and still it has only taken nearly 3 years.

Furthermore, when concern about the views of the victims on the timeliness of the delivery of permanent houses that the Table 3 shows a fairly satisfied response to owner driven housing programme when compared to donor driven houses. In the case of owner driven programme has taken less time to arrange the financial assistance and other aspects but donor driven programme has get more time than owner driven due to acquire lands, design, contractual arrangement and construction in the whole procedure due to large scale of housing projects.

Table3: Satisfaction level regarding Completion Timeline

Reconstruction Strategy	Very Satisfied	Somewhat Satisfied	Somewhat Dissatisfied	Very Dissatisfied
Donor Driven	0%	7%	42%	51%
Owner Driven	5%	25%	43%	27%

4.3 Dwellers view on their permanent residence

One of the most visible and outstanding effects of any major disaster is the devastation of houses which destroys livelihoods, protection and privacy. So that, without framing to the timeline and cost of the reconstruction activities it is essential to evaluate the dwellers’ views to gain an overall satisfied output. Under this heading, the dwellers’ views were gained on their permanent residences while covering the nine salient factors and condition generally assemble with housing programmes in both donor driven and owner driven, which are mentioned at the beginning of this chapter. Although the scale used was the previous one used in the above that "very satisfied", "somewhat satisfied", "somewhat dissatisfied", and "very dissatisfied".

4.4 Quality / Strength / Durability

As shown in Table 5, in the case of donor driven programme, only 5% of the dwellers were very satisfied and 15% were somewhat satisfied while 47% were somewhat dissatisfied and 33% of the dwellers were very dissatisfied. Due to much more reasons are behind that and the dwellers were not satisfied with strength, arrangement of structure, quality of material used, improper land fillings and cuttings and dreadful manner of construction of the houses. Alos due to increament of intermediate dealers, in each transactions have end resulted to minimize the amount of money for single housing unit. Finally that has affected to carry out contractors' duty in less cost target, which reflected to select low cost and poor quality materials, offensive method statements, etc. By the way most observed projects are with small to sever defects and some houses are taken leave off. In most case the dwellers involvement to construction activities was less and that 5% of very satisfied has succeeded due to the dwellers participation.

Throughout the survey result 55% of the dwellers of the owner driven programmes were very satisfied and 34% were somewhat satisfied. Dwellers in owner driven houses argued that high level of quality standards can be achieved when the inception to completion is done with participation of the resident. Most often the owners have recognized that better design and structural stability with superior quality maintenance of their newly residences is well important to future vulnerability. Financial assistance gained from the state was reinforced by the top up grants provided by the private donors in most of owner driven programme and other than that further money recovered from loans, own money, relations and friends assistance, etc. So comparing the outcomes of the survey it should be noted that in the case of owner driven programme is in high position than donor driven programme in respect to quality, strengthen and durability of their permanent residences.

4.5 Functionality

In the case of functionality, according to Table 5 the majority of the donor driven programme (41%), was very satisfied and according to Table 6 majority of owner driven programme (52%), was somewhat dissatisfied. Most of deign in donor driven houses are done by the qualified architect by concerning the Sri Lankan culture with basic amenities. And some of international participant involvement caused to restrict that the local complimentary designs. It is a common intention when constructing a house by the owner that is tried to achieve better house in respect to present financial strength with basic amenities or less and remain part with further arrangements will be done in future after occupied. It is what that has been observed in most owner driven houses.

4.6 Space availability

According to the survey results, it has been recognized that equally fair distribution can see in according to Table 5 in donor driven progrmme in the case of space availability, which depend on several aspects such as members in a family, livelihood pattern, living standards, etc. And according to Table 6 the majority of the owner driven programme (59%), was very satisfied due to most of dwellers have identified their requirements and well established it concerning the number of family members. Although most fully damaged houses in owner driven programme have been observed as two storied houses by providing better space in vertical arrangement. Inadequate financial gainers have constructed their houses with less amenities and allocating insufficient spaces, which has resulted 15% of dwellers in somewhat dissatisfied category.

4.7 Aesthetics

As shown in Table 5, the majority, which is 52% of the dwellers of donor driven programme were somewhat satisfied and 22%, were very satisfied. In the case of owner driven programme 31% of dwellers were somewhat satisfied and 34% were very satisfied while amounts of 34% were somewhat dissatisfied in according to Table 6. In both cases, it has been observed that some of middle class people who were not satisfied as they lived in better appearance houses before the tsunami. In most of the cases, it has been identified that donors have got better appearance houses which were designed by the qualified architect. Also the most owners have designed their houses according to their concept with better appearance.

4.8 Flexibility to make any changes in the future

As shown in Table 6 & 5, the majority, which is 54% of the dwellers of the owner driven programmes, were somewhat satisfied and majority of donor driven programme which amounts to 56%, were somewhat dissatisfied with the case of flexibility to make any necessary changes in the future. It has been noted that most of the dwellers in donor driven programme do not have any intention to change it presently due to that the original deeds were still not handover to them and either allowable land area is not enough to do horizontal alignment or that the design is not concern the vertical alignment to further developments.

4.9 Agreeing to change the design as required

In the case of the agreeing to change the design as required too, in owner driven programmes 45% of the dwellers were somewhat satisfied and 33% were very satisfied, while donor driven programme 56% of majority were somewhat dissatisfied. Dissatisfaction of dwellers in the donor houses were high due to that involvement of victims in the design stage can not be seen throughout the survey, but only few of projects had been allowed to inspect their houses to victims in the construction stage that couldn’t support to change the design. So as a conclusion it has been noted that owner driven programme is in high satisfactory level compared in it to donor driven programme in respect to the support given to change the design.

4.10 Land size

In the case of land extent, the majority of donor driven programme (47%) was very dissatisfied and the majority in owner driven programme (52%) was very satisfied. It has been observed that major part of people who have moved to donor driven houses were not satisfied as they lived with adequate size of land area before the Tsunami. But now the most of donor's housing area is from 6 to 12 perches and it is nothing when it compare with pre tsunami owned land. Also there were no ground areas to most donor driven houses, which have been granted multi storied housing schemes but with some common area to social works. It is obvious to seen that most part of the owners were in satisfied level regarding their previous land extend, but only few cases have been identified as restricted areas to construction activities because of the buffer zone concept.

4.11 Location

According to Table 6 & 5, the majority, which is 66% of the dwellers of the owner driven programmes, were very satisfied and majority of donor driven programme which amounts to 41%, were very dissatisfied with the case of location. Most of the people in the Matara district who were affected to the tsunami are occupied in fishery industry. And most of other's livelihood activities are based with the sea. So majority of owner and donor dwellers have responded as it as major opportunity to located as near as the sea. But some of middle class peoples in both owner driven and donor driven programme have been observed that the relocation in inside villages is better than the previous coastal location, considering social and cultural issues.

4.12 Overall facilities provided

(Electricity, Water connection and Sanitary)

As per the result of the survey it has been identified that the overall facilities are available in donor driven programme and owner driven programme are in better position, which are shown in Table 4 categorizing in to three basic services that are electricity, water connection and sanitary facilities.

Table 4: Services in the house

Services	**Donor Driven**		**Owner Built**	
	Nr. Of Houses	**%**	**Nr. Of Houses**	**%**
Water	246	94.25	253	94.12
Electricity	231	88.51	234	91.76

Sanitary	210	80.46	210	82.35

If the above facilities are connected to both progammes in adequate manner, due to several reasons the dwellers satisfactions for those facilities are not parallel. According to Table 5 & 6, it shows the satisfactory level of two different housing programmes in the case of the overall facilities, which in owner driven programme 41% of the dwellers were very satisfied and 39% were somewhat satisfied, while donor driven programme 39% of majority were somewhat dissatisfied. It has been observed that at the beginning the facilities are connected to donor house, but it has been made grave malfunction outputs due to some issues, unexpected situations and conditions.

Furthermore Table 7 specifies the percentage of dwellers under each category on the two reconstruction programmes that the majority, which is 40% of the dwellers of donor driven programme were somewhat dissatisfied and 31% were very dissatisfied. In the case of owner driven programme 50% of dwellers were somewhat satisfied and 33% were very satisfied. So it is comprehensible that the dwellers, who were under donor driven programme were not happier with their permanent houses than the dwellers, who were under owner driven programme in the district of Matara.

Table 5: Satisfaction of the Dwellers – Donor Driven

Factors	Very Satisfied	Somewhat Satisfied	Somewhat Dissatisfied	Very Dissatisfied
Quality/ Durability	5%	15%	47%	33%
Aesthetics	22%	52%	23%	3%
Functionality	26%	41%	24%	8%
Space availability	20%	26%	29%	25%
Agreed to change the design as required	4%	18%	56%	22%
Flexibility to make any changes in the future	4%	23%	56%	17%
Location	16%	20%	23%	41%
Land size	6%	15%	32%	47%

Overall facilities provided	23%	28%	39%	10%

Table 6: Satisfaction of the Dwellers – Owner Driven

Factors	Very Satisfied	Somewhat Satisfied	Somewhat Dissatisfied	Very Dissatisfied
Quality/ Durability	55%	34%	11%	0%
Aesthetics	34%	31%	34%	1%
Functionality	13%	26%	52%	9%
Space availability	59%	24%	15%	2%
Agreed to change the design as required	33%	45%	20%	2%
Flexibility to make any changes in the future	22%	54%	19%	5%
Location	66%	19%	13%	2%
Land size	52%	26%	20%	2%
Overall facilities provided	41%	39%	20%	0%

Table 7: Dwellers' Total Satisfaction regarding their Permanent Resident

Reconstruction Strategy	Very Satisfied	Somewhat Satisfied	Somewhat Dissatisfied	Very Dissatisfied
Donor Driven	12%	17%	40%	31%
Owner Driven	33%	50%	15%	2%

5. Conclusions

The recent increases in frequency and magnitude of natural disasters have raised issues of increasing vulnerability of communities. The impact in terms of human, structural and economic losses has risen in recent years. The reconstruction process has very much depended on the administrative, political, social, economic and cultural context that coupled with many other unforeseen factors will affect the speed and coverage of the recovery programmes. In order to derive a better conclusion, the reasearch mainly focused in acutely on the successfulness of post tsunami housing reconstruction programme based on two strategies, namely, donor driven and owner driven.

Main outcome from this survey is that dwellers in owner driven housing programme is more satisfied than the dwellers in donor driven housing programme when concerning more parameters. In other word, it can be concluded as that owner driven housing programme is more successful than the donor driven programme concerning the dwellers' view. According to the research, it has been argued that the owner driven housing programme has been in prominent level in term of: Quality / Durability, Space availability,Flexibility to make any changes in the future, Agreeing to change the design as required, Land size, Location, Overall facilities provided (Electricity, Water connection and Sanitary). When looking at these parameters, which are superior in terms of owner driven, have proved that the dweller involvement throughout inceptions design to construction stage resulted better success in owner driven housing programme than those who were under the donor driven housing programme.

But contrast with the owner driven housing programme that the donor driven housing programme has been more superior in term of; Aesthetics and Functionality. Furthermore, it has identified those two main reasons behind that are, the donor houses have been designed by professional architects and most of the houses in the owner driven programme were half built and occupied with the intention of completing in the future.

Reconstruction process should be considered as development opportunities and should open the access of different types of innovative solutions. These innovations should lead to vulnerability reduction, and should enhance human and other activities security in long term. By providing buffer zone that the government has identified the vulnerable area in future disasters and it emphasized to categorized the post disaster housing reconstruction programme to the above discussed two strategies. By the way the donor relocation programme started later than owner resettlement programme, the progress at the district of Matara in the donor driven is fairly high compared to the owner driven. Comparing to other districts, the coverage in the both programmes in Matara district is high, but that dwellers' view on timeliness to delivery of permanent houses to the donor driven and compensation to owner driven house have been identified in less figure. And that is seriously shown in donor driven programme. Although, that have been found excess amount of donor driven houses at the present, still the victims are living in temporary houses. Also the assistance given to sub families' victims could be seen in erroneous manner and after 3 years back that most of the sub families still in the temporary house, when the excess amounts of donor houses are vacant.

It has also been observed that the dwellers' view on the State assistance throughout the housing reconstruction programme is fairly high in the owner driven houses, but view on the NGO assistance throughout the housing reconstruction programme have been fairly low compared to those donor driven ones.

By evaluating the overall information on the post tsunami housing reconstruction programme, the successfulness of the process as well as the victims' view of two different reconstruction strategies will be helpful to decision makers to get comprehensible idea regarding their applicability and drawbacks on both the programmes.

Abstract

Natural and man-made disasters are causing increasing losses to human lives and damages to property over the years.Srilanka is prone to natural disasters and there is growing recognition that there should be more concern on the area of Disaster. Housing sector is with the significant damages compare to other sectors. The need for managing disasters through construction industry is gaining importance in recent years. Construction industry has a much broader role to play in order to obtain the successful implementation of reconstruction. Capacity of the construction industry is therefore a critical issue. Capacity building and construction industry development are becoming inevitable in successfully managing disasters. The Srilankan construction industry did not posses required finance, human resource, management and etc for an accelerated tsunami reconstruction work. Purpose of this study is to explore the capacity of the construction industry in post disaster housing reconstruction.

This study was done through systematically reviewing the literature in capacity and the reconstruction principles. Data collection mode used for the study is questionnaire survey and documents survey. Data are collected from contracting organizations who are involved in post disaster housing reconstruction. Findings of the research reveal that, Contractors give importance to the human resource, finance and management capacities in the elements of the capacity building. Contractor's financing base changed about a considerable smaller proportion in response to reconstruction circumstances. Capacity in terms of contractor's organisational capacity was explored. Credit facility of the contractor's shows the increasing nature in the last three years. Main challenges they face in the successful implementation of the reconstruction are; non availability of labourers and materials. Significant Remedies to overcome such challenges are Planning of material requisition and pre-demand for construction workers.

Keywords: Capacity, Construction Industry, Housing, Post-disaster, Reconstruction

1. Background

Disasters, both natural and human-caused, have been occurring with increasing frequency and effect in recent decades in many countries around the world. They have had a disproportionately heavy toll on developing countries both in terms of loss of lives and damage to property [1]. More concerns have been given to the area of disaster and it is becoming main area of research, Due to its impact on the human lives and assets

According to Dilley et al [2], “Earthquakes, floods, drought, and other natural hazards continue to cause tens of thousands of deaths, hundreds of thousands of injuries, and billions of dollars in economic losses each year around the world”. EM-DAT, a global disaster database maintained by the Centre for Research on the Epidemiology of Disasters [3] in Brussels, records upwards of 600 disasters globally each year. It continues that Disaster frequency appears to be increasing. Disasters represent a major source of risk for the poor and wipe out development gains and accumulated wealth in developing countries.

Sri Lanka is prone to natural disasters commonly caused by floods, cyclones, landslides, droughts and coastal erosion for generations with increasing losses to life and property in the past few decades [4].He further indicates that the devastation caused by tsunami in 2004, however, took Sri Lanka by surprise warning that Sri Lanka is also vulnerable to low-frequency high impact events with extensive damage. The devastation according to Sisira et al [5] the earth quake that caused the tsunami on 26th December occurred at 6.58 am Sri Lanka time with the large wave hitting the east coast at 8.35 within a very short time over 36,000 people were dead, and several hundred thousand had been displaced. In addition, massive damage had been inflicted on thousands of houses and other buildings, railways, bridges, community networks and other infrastructure and capital assets. From this, it is very much clear about the magnitude and the significance of the impacts by the tsunami in 2004.

Considering the progress of the housing sector it is stated that in the IUCN 2005a [6] that the construction of semi-permanent and permanent homes began at government-designated resettlement sites located outside of the buffer zone. However, reconstruction was unevenly distributed and paced throughout the country.Even though several initiatives were taken by the governments in the past to reduce these damages they were mostly reactive actions rather than proactive actions to minimize the cause of the disasters.

It is further stated in the ADB’s Report 2005 [7] that the national construction industry does not have the necessary contractors, equipment, skilled workforce, modern management practices or access to finance required to speed tsunami reconstruction work. Inflation of construction material is a problem. Further challenges include procurement delays, environmental safeguards, security in uncleared areas, and capacity constraints. Capacity building is the critical element of the recovery and reconstruction process [7].

It is evident from above that the construction industry must be developed in terms of their capacity. It is necessary to provide the construction industry with the requisite capacity and capability [1].So that the srilankan construction industry can be able to carry out the required reconstruction, especially the in the housing sector, with the proper concerns on the capacity development.

Considering the factors which cause the delay in the successful housing reconstruction, capacity of the construction industry is one of them.Therfore Aim of this study is to explore the organizational capacity of the contractors in post disaster housing reconstruction and to investigate the remedies to face the challenges in successfully implementing the housing reconstruction. The objectives to achieve the aim are; to recognize the concept of capacity and capacity building, to identify the important elements of the capacity building in the housing reconstruction, to explore the demand created by the tsunami and the current status of the housing reconstruction, to explore the organisational capacity of the contracting organizations and to identify the challenges and remedies in successfully implementing the housing reconstruction.

2. Research Methodology

Research Methodology started with identifying research question which is from the literature survey. The literature review was done on the research subject area to understand the basic concepts on the capacity and the reconstruction. The collected literature was used to achieve some objectives and to identify the factors for capacity building elements, organisational capacity, challenges and remedies to the successful housing reconstruction .The literature shows that there is no academic work that examines the current situation of capacity of the Srilankan construction industry in relation to natural or man-made disaster reconstruction.

This study, for the purpose of data collection set its boundaries within the context of the contractors for construction industry. So that the ‘unit of analysis’ selected for this study is ‘Contracting organisations’ in the Srilankan construction industry. In this research 30 contractors who are involved in the housing reconstruction were contributed in the Colombo region to explore their capacity. Their ICTAD grading was ranging from M1-M6. The research design revealed the demand for primary as well as secondary data. For this Questionnaire and document survey was used. Data or information collection mainly dealt with the type of data, and the appropriate data collecting techniques that were employed for the study.

The purpose of analysis was to provide evidence of relationships and to aid the understanding of the objectives. The structured questionnaire was prepared from the literature synthesis and it comprised check list, and Likert scale rating. After data have been checked and entered, the next step was to display them for exploratory data analysis, by way of tables, bar charts, etc. The relative importance index (RII) and the Frequency analysis was used as analysis techniques. Contractor’s capacity was considered for the construction industry’s capacity and the housing was considered for the reconstruction process and contractors who contributed were only from Colombo region, are the limitations of this research.

3. Literature Synthesis

3.1 Housing Reconstruction In Post Disaster

The Center for Research on the Epidemiology of Disasters [8] in Brussels, Belgium, uses the following definition for disaster. “A disaster is a situation or event which overwhelms local capacity, necessitating a request to a national or international level for external assistance”. According to Songer [9] disasters are commonly categorized by their origin; natural or man-made. Most disasters investigated in the literature are natural disasters. He further follows as disasters may occur suddenly in time (a quick onset), or they may develop over a period of time (a slow onset). Most occur suddenly and perhaps unexpectedly. However, some events develop gradually, including some floods and famines related to drought. Factors that contribute to the vulnerability of communities and societies to the impacts of hazards are many. CERO [10] lists down the causes of disasters as poverty, population growth, rapid urbanization, lack of public awareness and information, changes in cultural practices, environmental degradation, war and civil strife.

Aftermath of the disaster should be given much consideration in terms of development. Shanmugaratnam [11] states a post-disaster situation can be seen as one of new opportunities for reconciliation, investment and growth, sustainable resource utilization, human capital formation, employment generation and human development.Therfore proper planning should be made in order to obtain maximum benefits. International and consequently national capacities for coordination, funding and implementation post-disaster are structured to offer support in independent sequential ‘relief ’, ‘recovery / rehabilitation’ and ‘reconstruction / development’ phases, regardless of whether the support is to water supply or shelter [12]. Further it continues to state that reconstruction is a high-cost and long-term commitment per capita, required after the Disaster.

Disaster management is a new and innovative method for preparing companies and organizations to address the substantial risk of disasters in the workplace [13]. Disaster management aims to reduce, or avoid the potential losses from hazards, assure prompt and appropriate assistance to victims of disaster, and achieve rapid and effective recovery [14]. According to Asian Disaster Reduction Center [15] the disaster risk management cycle, consists of four phases: Prevention/Mitigation and Preparedness in the pre-disaster stage, and Response and Rehabilitation/Reconstruction in post-disaster stage.

Jayawardane [4] in indicating the natural disasters and Srilanka, natural disasters in Sri Lanka are commonly caused by floods, cyclones, landslides, droughts and coastal erosion. The author further argues that the devastation caused by Indian Ocean tsunami in 2004, however, took Sri Lanka by surprise warning that Sri Lanka is also vulnerable to low-frequency high impact events with extensive damage.

According to ADB’s report in 2005 [7], it was estimated that Sri Lanka had 9.6 million building units of which 4.6 million or 48 percent were used as dwellings. 1.12 million Building units (around 12 percent of all building units in the country) are located in administrative divisions along the Srilankan coast which was affected by the tsunami. A damage overview and recovery need was produced by the ADB 2005 [7]; the tsunami surge completely destroyed around 99,480 homes and partially damaged about 44,290. The completely and partially damaged houses together comprise 13 percent of the housing stock in the administrative divisions along the coast. The net replacement cost for housing is estimated between LKR 46 to 51 billion ($437 million to $487 million).Since most of the affected housing stock was built over a long time period, its replacement value was depreciated by 30 percent to determine the damage estimate, which is in the order of LKR 32 to 36 billion ($306 million to $344 million) [7].

Demand for housing reconstruction was immensely created by the tsunami devastation. Following statistics shows the demand created by the tsunami and the current status of the housing reconstruction. From the RADA report [16], number of shelters after the tsunami struck as at 31.12.2005 was 57057 temporary shelters and in 31.12.2007 it was reduced to the percentage of 77.78% to 12682 temporary shelters. The original count after the tsunami struck was 98,525 and the revised count was 116135 .78.10% of the permanent houses have been completed up to the month of August 2007 and 22.08% of the houses are in progress according to the revised count. In the permanent houses completed 19.82 % are Donor driven and 77.79% are owner driven houses.28.14% of the houses were owner driven and 70.68% were donor driven in houses which are in progress.

In considering the housing reconstruction, Southern province has the completion percentage of 105.87% and western province is with 17.65%. In the North western province it has reached the 100% and in the Eastern and Northern provinces were respectively with the completion percentages of 80.02% and 36.71%.There are still some outstanding works to be carried out in the reconstruction of housing. The government of srilanka expects the outstanding works to be completed by the end of this year.

From the above data it is evident that the progress of the housing reconstruction is not within the stipulated time framework. Despite the many reasons which hinders the planned progress of housing reconstruction, the capacity of the construction industry is among them. Since the Srilankan construction industry lacks in capacity to fulfil the requirement due to a disaster, it is very important to make sure of the capacity of the contracting organizations to face any kind of challenges in relation to capacity for natural or man-made disasters. The need for understanding of the Construction industry’s capacity to carry out the reconstruction and to predict the performance on future disaster is becoming inevitable. Therefore the consideration must be given on the capacity of the construction industry in detail.

3.2 Capacity of The Construction Industry

In considering the Capacity of the construction industry, lots of attention has to given to the organisational capacity. Since the most of the stakeholders in the construction industry can be categorized into an organisation. In simple terms, organizations capacity is its potential to perform its ability to successfully apply its skills and resources to accomplish its goals and satisfy its stake holder’s expectations [17].The aim of the capacity development is to improve the potential performance of the organization as reflected in its resources and its management.

Therefore, to improve the capacity of any organisation there should be capacity building activities. The meaning of capacity building varies depending on the context where it is being used. According to the International Development Research Centre [18] in referring to the framework for organisational assessment, Organizational performance, Organizational capacity, external operating environment, internal environment are the main elements. Organizational performance refers to the ability of an organization to meet its goals and achieve its mission. Organizational capacity refers to the resources, knowledge, and processes employed by the organization. External operating environment refers to the external environment in which the organization carries out its activities. Internal environment refers to internal factors that influence the direction of the organization and the energy displayed in its activities.

Ofori [1] indicates that it is necessary to provide the construction industry with the requisite capacity and capability. The author further states that In particular, the construction industries in developing countries need to be equipped for these purposes, given the apparent differential frequency and severity of various types of disasters. This can only be achieved through deliberate, planned, strategic, systematic efforts. Further the author states that First, human resource development should equip construction professionals with the knowledge and skills required to undertake appropriate designs and construction .Second, a programme of materials development should be instituted in each region to find high-performing (disaster-resistant) materials which are suited to the local context and are of good quality, durability and affordability. Third, it is necessary to put measures in place in pursuit of the technological development of the industry to ensure that it has the capability to handle the various projects which will be required to provide protection against disasters, and those which the post disaster reconstruction process will involve.

Due to the high demand created by the tsunami, in order to cope with the planned progress, the contractors must increase their capacity. When they must increase their capacity in quantity and speed, more experienced and skilled resources are required to actually manage the projects. In addition to construction expertise, possibly large-scale, basic project management experience was also essential. For both of these skill-sets, smaller developing countries may not have people with this large-scale time-critical management experience, and ex-patriots with these skills frequently do not have the experience to understand the environment adequately.Rex 2006, as cited Haigh et al [19].

According to Haigh et al [19], there is growing recognition that the construction industry has a much broader role to anticipate, assess, prevent, prepare, respond and recover from disruptive challenges.

4. Key Findings

4.1 Important Elements of the Capacity Building In The Housing Reconstruction

The main identified capacity buildings elements of the Organisations from the literature review are Management system, Financial, Human Resource, Information System, and Marketing. Of which the respondents have indicated the importance of each element to their organisation in carrying out the housing reconstruction.

All the elements of capacity building were ranked using RII (Relative Important Index). According to RII calculated from the survey results, the Human resource took the first rank (RII - 75%). Therefore, it is evident that Human resource, especially the labour, is important as capacity building element in post disaster hosing reconstruction.

The Financial system was the second (RII – 73%) mostly needed element in the capacity building in post disaster housing reconstruction. The respondents believed that it is important because it decides on how much they can commit to any work in the post disaster reconstruction and the Donors and government agencies were looking into this because other factors such as experience would not be relevant in this case due to the fact that the housing construction in this big scale, very new to every one.

Further, the respondents believed that Management was important in order to carry out the disaster housing without any disruptions to the housing reconstructions. Which was one of the main backlogs in the housing reconstruction in Sri Lanka.This took place in the RII, third, with the percentage of 72%. The other elements of capacity building such as Information system, Marketing and other were concerned relatively low by the contractors who are in the housing reconstruction activity.

4.2 Exploration of The Current Capacity Of The Contracting Organizations

Explorations of the Current capacity of the contractors were focused through the Organisational capacity. Organisational capacity was considered in terms financial management system, financial stability, diverse and sustainable funding, management and staffing capacity, internal performance analysis, and customer service orientation. In addition to these, credit facility of the contractors was considered after the years of tsunami struck which is from years of 2005-2007.

Financial Management System

A well-functioning financial management system puts internal policies and practices in place for a contractor to monitor and maintain its financial health and to help ensure its long-term sustainability.90% of the contractors have stated that they conduct yearly or biannual audit. Conducting an audit represents good business practice for the contractors. It assesses whether the financial reports of the contractor are presented fairly and whether the contractor has complied with applicable laws and regulations. 76 % stated that they received the qualified opinion on its audit.70% indicated that they have no substantial concerns with the internal controls. Internal controls are an organization's accounting and other fiscal control policies and procedures that seek to minimize the likelihood that assets are misused or accounts are misstated. These must be due to good management practices among the contracting organisations to keep up their grades and to perform well to achieve their objectives.

Financial Stability

Financial stability refers to an organization's ability to manage the flow of funds into and out of the organization, and its ability to deal with a short-term cash shortfall. A contractor's total annual budget serves as an indicator of its general size, and perhaps the scope of its works and the size of its client base. About 65% of the contractor's total annual budget is over 20 million. 90% of the contractors indicated that they have reserve of funds or ready access to cash. Well-managed organizations maintain a line (or lines) of credit or at least some access to cash in case they experience a short-term shortfall or otherwise need access to cash quickly. 14% of the respondents have stated that they have delayed the payments.14% percentage of the respondents stated they have cancelled the contracts in particular circumstances. In considering the types of clients they treat ,since one contractor serve many types of clients, 54% are the Residential clients, 62 % are government clients, 46% are Industrial clients, 53% are Commercial Clients. It shows the client's base is on average and the contractor can expand in a reasonable manner to take advantages of opportunities for growth in the market, while not overextending itself.

Diverse and Sustainable Funding

97% of the contractors have indicated that they plan to grow the business in the future. Because all of the contractors are profit oriented in the stream of contracting business. However, growth that occurs too quickly or without forethought can actually hinder sustainability, if a contractor's revenues cannot keep up with its increase in staffing and other expenses.66% of the contractors finance base is changed 0-15% in response to reconstruction circumstances and 20% of the contractors funding base is changed above 20% in response to Reconstruction circumstances. Since all of the contractors are involving in the housing reconstruction and reconstruction works became their part of the business and it is a smaller proportion.

Credit Facility

Credit facility of the contractor was calculated by the adding the total credit facility of each contractor type in the years of 2005, 2006 and 2007.Then the Percentage change in the year from 2005-2006 and 2006-2007 was calculated. Weighted average was used get the final Credit facility changes in the sample size with the different number of contractors in each type. Final credit facility of the contractor graph shows the increase in the year for 2005-2006 and 2006-2007.The percentage of the increase in the year from 2005 to 2006 was higher than the year from 2006-2007.This may be due to the fact that the tsunami housing reconstruction activities were higher in the year of 2006 compare to the years of 2005 and 2007.

Management and Staffing Capacity

The leadership and staffing of any organization are critical to its ability to provide high quality and reliable construction to their clients .26% of the staff have 0-20% of the sufficient relevant education experience in relation to the construction industry and 46 % of the staff have 40-60% sufficient relevant education experience. It is resulted because most the local construction industry doesn’t employ well educated staff.53% of the staff has been well trained in the contractor’s general approach. This is because the most of the contractors doesn’t provide a standard training system or there are no proper rules and regulations governing the training for the staff. Capacity building is needed in these areas to the existing staffs.

Internal Performance Analysis

Any organization that is interested in maintaining and improving its organizational capacity should conduct regular and thorough analyses of its work and how it could improve its service delivery, as well as its overall outcomes.17% have stated they assess and review its own performance monthly, and 33 % stated they do quarterly, 40 % stated that they do annually and 10% stated that they neither assess nor review its performance. Most of the contractors review their performance in order to find whether they are in line with their objectives and for good organisation practices.83% have stated that they do solicit information from clients to determine their satisfaction. Majority of the contractors solicit information because it leads the contractor to review its performance and proper functioning of their business.

Customer Service Orientation

Contractors will be working closely with the staff, potentially over a long period of time, customer service is of particular importance 55% stated that they do provide adequate and appropriate customer service resources. It is on average level and most of the contractors do not offer client service orientation except the big contracting organisations. 52% have indicated that the resources are readily available to client and to client’s staff. Customer service orientation is on average and indicates the need for development to provide a satisfactory service orientation.

4.3 Challenges and Remedies In Successfully Implementing The Housing Reconstruction

Challenges in successfully implementing the housing reconstruction were identified in the literature synthesis and given to contractors in the form of questionnaire with the 5 scale Likert scale rating. The RII was calculated to each challenges and ranked. The same procedure was done to the remedies to overcome the challenges in the post disaster housing reconstruction.

It is very evident that the contractors have suffered in housing reconstruction by the non availability of labourers and the non availability of the materials. Availability of the labourers were the biggest challenge with the RII of 86%.The availability of materials was the second biggest issue with the RII of 83%.These two problems took forefront place compare to the other challenges they faced in the housing reconstruction. This is due to high demand of materials and labourers aftermath of tsunami. The devastation led the country to provide more than 100,000 houses in a moment. It caused a very high demand for materials and labourers. The effect indirectly affected the wages for labour.

Third issue they face mostly is the project management which was with the RII of 79%.The reasons due to the fact that the availability of the labourers and the availability of the materials caused the lagging effect on the project management. Other factors such as insurance processing, poor IT infrastructures were lowest in the contractor’s priority. This is because the srilankan construction industry is not that much developed compare to the other developed countries. So that the poor IT infrastructure, insurance processing were not considered much, since most of the contractors are small in size, by the contractors as the challenges for them.

In considering the remedies to the challenges, according to RII calculated from the survey results, the Planning of Material requisition took the first rank (RII - 81%). Therefore, the majority of the respondents stated that Planning of material requisition is important in post disaster hosing reconstruction to overcome the challenges. This was due to the challenges biggest issue of non availability of materials. The Pre-demand for construction workers was the second (RII – 75%) mostly needed in the overcoming of challenges in post disaster housing reconstruction. This was due to the reason that the higher demand situation existed for the labourers after the tsunami.

Further, the respondents believed that Proper co-ordination is important in order to carry out the disaster housing without any disruptions to the housing reconstructions. Which was one of the main backlogs in the housing reconstruction in Sri Lanka.This took place in the RII, third, with the percentage of 70%. The other factors such as better cost planning and control, earlier assessment of the impacts of the disaster elements and other factors were concerned relatively low in prioritizing the factors which could be used to overcome the challenges by the contractors who are in the housing reconstruction activity.

5. Conclusion

According to the results, it can be concluded that the most of the contractors have involved in Tsunami housing reconstruction work compared to other disaster. This may be due to the magnitude and significance of damage caused by the Tsunami devastation in srilanka.

Capacity of the construction industry was not in a position to cater the demand created by the tsunami. From the results of the document survey, the demand was not met by the existing capacity of the construction industry within the stipulated time to complete the all houses. The comprehensive literature review further reinforces this conclusion. The capacity building elements for an organisation is important for any organisation in considering the development. From the contractor's perspective, human resource, finance and management are considered as the most important elements in capacity building in the housing reconstruction.

Financial management system of the contractors is well above the average and shows the good capacity level and the financial stability of the contractors is also above average level. Diverse and sustainable finance of the contractors showed the above average level. This shows that the financing capacity is above average level. Management and staffing capacity is below the average level and shows the need for development of the capacity. Most of the contractors do review their internal performance and that is above the average level. Client satisfaction orientation is below the average level and shows the avenues for the improvement of the capacity in terms of organisational.

Credit facility of the contractor's shows the increasing nature according the years after the tsunami. This shows the contractors ability in the housing reconstruction after the tsunami in financial terms. Among the many challenges faced by contractors in successfully implementing the housing reconstruction, availability of labourers and availability of materials are the main factor which hinders the planned progress of the housing reconstruction. Planning of Material requisition, Pre-demand for construction workers were prioritized by the contractors to overcome the challenges in the housing reconstruction.

Abstract

A disaster is a serious disruption for the operation of a society, causing extensive lives and property losses. Since construction activities are highly knowledge-intensive, knowledge management (KM) practices will encourage continuous improvement, distribute best practices, quick respond to beneficiaries, share valuable tacit knowledge, reduce rework, improve competitiveness and innovations, and reduce complexities in post disaster housing reconstruction. Therefore, this research is to study and explore the degree to which the KM is involved in post disaster housing reconstruction and the effect that (KM) have on it (post disaster housing reconstruction) in the Sri Lankan context.

This study was done through systematically reviewing the literature in Knowledge (K), KM to highlight the basic principles. Data collection mode for the study was close end questionnaires and semi structured interviews. Data was collected from donor and consultancy organisations who are involved in post disaster housing reconstruction in Sri Lanka.

Findings of the study revealed that most of the donors and consultancy organisations carry out permanent disaster housing reconstruction for tsunami devastation. Further, the study reveals that organisations use competences and repositories as the main sources of knowledge internal and external to the organisation. Project reviews, task teams, face-to-face interactions, and electronic mail systems were used highly to support KM. Even though the performance of the work was improved through KM, lack of compiling and synthesizing the accumulated data, information and knowledge, storing and organizing would be the main challenge faced by these organisations. However, this study is limited to the donor and Sri Lankan construction consulting organisations, who are involved in the post disaster housing reconstruction in Sri Lanka due to natural disasters.

Keywords: KM sub process, KM, Knowledge, Natural disasters, Post disaster housing reconstruction

1. Background

1.1 An overview of disaster

A disaster is a serious disruption of the functioning of a society, causing widespread human, material, or environmental losses, which exceed the ability of affected society to copy using only its own resources [1]. Disasters can be classified as sudden or slow (according to onset speed), or natural or man-made (according to cause). Disasters are often named by the hazards that cause them [2]. A disaster occurs when the hazards impact badly upon a community, which is susceptible to that hazard. There are several hazards like floods, tsunami, tropical storms, landslides, drought, high wind, rock falling, etc. affect Sri Lanka from time to time.

Natural disasters attack the poor at three levels: they interrupt income, reduce personal assets, and destroy essential public infrastructure (World Bank, 2000a cited [3]). The World Bank estimates that losses due to natural disasters are 20 times greater (as a percentage of GDP) in developing countries than in the industrialized nations [4]. According to National Construction Association of Sri Lanka [5], a joint study by donors in January 2005, damaged over a US$ 1 billion worth of infrastructure (about 4.5 percent of GDP), but the replacement costs were estimated to be between US$ 1.5 billion to US$ 1.6 billion (7.5 percent of GDP). Further, Ofori [4] states that disasters have a greater impact on the built environment of developing countries than industrialized ones.

1.2 Post disaster housing reconstruction

Reconstruction means the action of constructing new buildings to replace buildings, which have suffered damage, or repair of damaged buildings (UN, 2006 cited [6]). Reconstruction stage develops after the rehabilitation stage and aims to provide proper permanent housing for the victims in a short period of time [7]. The stakeholders of post disaster projects are the government, donors, lending agencies, beneficiaries, contactor, and social, environment and religious groups.

Whilst relying on routine processes proved adequate in many ways for these small-scale disasters, a higher level of coordination and management would be needed for programmes of reconstruction following a larger disaster [8]. Further, Gunasekera [9] added that all the phases and activates of a project done under normal conditions have to be done when managing projects after a disaster and all phases and activities need to balance with the time factor. Most of the time, this is done at a cost, because there is a minimum quality level and scope requirement that each project has to achieve [9].

As per Barenstein and Pittet [10], one of the most visible consequences of many disasters is the widespread devastation of houses. Quarantelli (1995 cited [11]) proposed four stages of housing in the recovery process such as immediate relief (within hours), immediate shelter (within day or two), temporary housing (preferably within weeks), and permanent housing reconstruction (probably within few years).

Post disaster housing reconstruction is considered by many experts as one of the least successful sectors in terms of implementation [10]. Further, a lack of effective information and knowledge dissemination can be identified as one of the major reasons behind the unsatisfactory performance levels of current disaster management practices [12]. According to Banerjee (2005 cited [12]), a lack of prior knowledge and proper point of reference have made most of the recovery plans guessing games, eventually failing without adding appropriate values to the recovery attempts. Therefore, applicable external knowledge support based on actual recovery processes can play a crucial role in promoting post disaster recovery [13]. However, in case of the Sri Lankan construction industry, there has not yet been any appropriate research done in this area. Thus, little is known about how knowledge is managed in Sri Lankan post disaster reconstruction works.

2. Knowledge Hierarchy

2.1 Data, Information, Knowledge

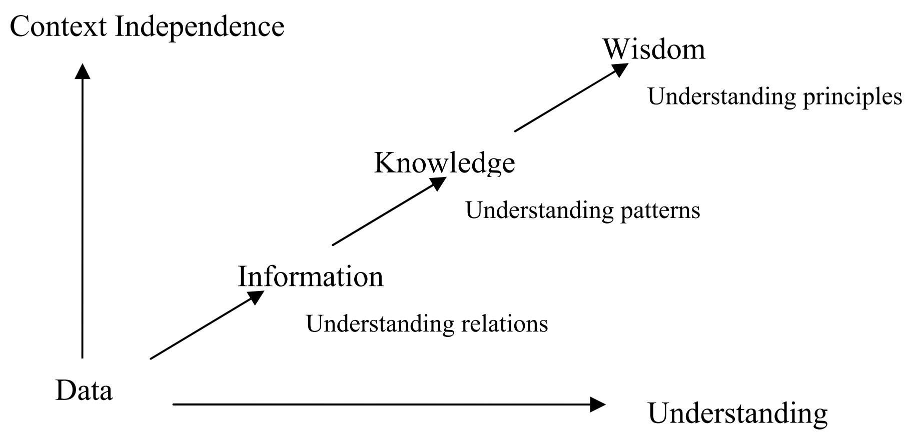

Figure 1: The relationship for data, information, knowledge and wisdom

Source: Gene Bellinger (cited [14])

A common theme in the KM literature is that data is combined to create information, and information is combined to create knowledge [15]. Information is data that has been interpreted, verbalized, translated, or transformed to reveal the underlying meaning and context [16]. For example, when a disaster occurs, different types of information might come from different sources, such as the disaster field, remote sensors, public information centres, and the World Wide Web [17]. Knowledge can be defined as a dynamic human process of justifying personal belief toward the "truth" (i.e. a justified true belief) (Nonaka and Takeuchi, 1995 cited [18]). According to Siemieniuch and Sinclair (1999 cited [18]), various classification of knowledge include: formal (explicit) and tacit (expertise) knowledge; foreground and background knowledge; classifications with respect to the role of knowledge for business relevance (e.g. knowledge of business environments), or with respect to the functional roles within an organisation (e.g. knowledge for control activities). One of the most practical distinctions is that between tacit and explicit knowledge (Nonaka and Takeuchi, 1995 cited [19]). As per King

[16], tacit knowledge is the personal knowledge resident within the mind, behaviour and perceptions of individual members of the organization. On the other hand, explicit Knowledge is the formal, recorded, or systematic K that can easily be accessed, transmitted, or stored in computer files or hard copy [16]. Knowledge sources, in this context, mean the ‘reservoirs of knowledge’, which a knowledge-worker has to fall back on in fulfilling his/her responsibilities [20]. As per Egbu, et al., [20] there are two main categories of knowledge sources, i.e. sources internal to the organisation (other individuals, team(s), routines, competences, and repositories) and sources external to the organisation (other individuals, communities of Practice, other networks, repositories, and knowledge gate-keepers).

2.2 Knowledge Management (KM)

Knowledge Management: the systematic strategy to collect; store; and retrieve knowledge, and then help distribute the information and knowledge to those who need it in a timely manner [16]. However, the KM has not only limited to human centered asset but also extended to intellectual assert. While some definitions specify the management of intellectual assets, it also spells out the benefits of KM. However, the parameters to be managed, has been fairly addressed by some academics like Huber (1991 cited [21]), King [16], and Robinson et al., [22].

Organizations who are successful in leveraging knowledge, normally witness increased efficiencies in operations, higher rates of successful innovations, increased levels of customer service, and an ability to have foresight on trends and patterns emerging in the marketplace [23]. The lack of common knowledge has been known to impede the flow of knowledge, resulting in failures to stimulate innovation and creativity in the organization (Simonin, 1999; Szulanski 1997 cited [23]).

2.3 Knowledge Management (KM) sub processes

The KM sub process has been identified as locating and accessing, capturing and storing, representing, sharing, and creating [20]. Knowledge acquisition is the process that involves imbibing information including making meaning of situations and other stimuli from the internal and external business environment [21]. Nonaka and Takeuchi (1995) defined knowledge production as a continuous, social process, which is a never-ending spiral of tacit and explicit knowledge through knowledge conversion, socialization, externalisation, combination and internalization [SECI] (Sverlinger, 2000 cited [20]). This is quite true when it comes to post disaster housing reconstruction, where the participants have to act according to the situation, which will have the above triggers and leads to knowledge production. According to Kululanga and McCaffer [21], knowledge sharing encompasses thinking, speaking and perceiving and is not merely ‘transferring’ knowledge and such a process is called ‘creative sharing’. National Disaster Management Division [24] suggests that in order to enhance the information sharing and management of the knowledge generated in these institutions, it is highly essential to closely knit the organizations and moreover people. Storage of knowledge involves the keeping of intellectual assets in a form that promotes its preservation, retrieval and-utilization (Walsh and Ungson, 1991; Miyashiro, 1996 cited [21]). Knowledge transfer can be defined as a sub – process of KM that occurs when two or more individuals exchange information, in order to move towards each other (or apart) in the meaning they ascribe to certain events [25].

2.4 Knowledge Management tools

Anumba et al., [26] distinguishes between KM tools, the terms ‘KM techniques’ and ‘KM technologies’ are used to represent ‘non- IT tools’ and ‘IT tools respectively (Table 1).

Table 1: A comparison between KM techniques and technologies

KM techniques	KM technologies
Require strategies for learning	Require IT infrastructure
More involvement of people	Require IT skills
Affordable to most organisations	Expensive to acquire/ maintain
Easy to implement and maintain	Sophisticated implementation / maintenance
More focus on tacit knowledge	More focus on explicit knowledge

Source: Anumba et al., [26]

2.5 Knowledge Management in Post Disaster Housing Reconstruction

KM initiative has been thoughtfully envisaged as a tool to store, retrieve, disseminate and manage information related to disaster management [24]. Furthermore, Johnson et al., [27] states that organisations, such as governments in continuously disaster prone countries needs the ability to act as learning organisations and channels of information as well; however they do not seem to take advantage of this opportunity. The value of KM is that it provides senior management with a rationale to support the creation and maintenance of repositories of project histories [28]. In order to improve housing reconstruction projects we need to look back at past experiences, which the processes that created them. The demand for efficient KM to help the agencies make post disaster housing widely recognized.

3. Research Methodology

Since the most of the objectives of this study was to identify and explore several parameters related to KM, ‘what’ type of question was more suitable for the study and therefore, the structured questionnaire survey was carried out. Seventy-five randomly selected sample of forty-five donors, and thirty consultancy firms were used for questionnaire survey. Semi-structured interviews were done to identify the KM sub processes involved in post disaster housing reconstruction. Twelve semi-structured interviews, six from donors and six from consultancy organisations were done to achieve the above objective. While the relative importance index (RII) was being used as an analysis technique for questionnaire survey, the semi-structured interviews were analysed using data matrix.

4. Research Findings

The total number of targeted respondents for the research was 75 organisations consisting of 45 donor organisations and 30 consultancy organisations. The total response rate was around 74.67%. The largest respondents were from donor organisation constituting 53.57% of the total respondents, whereas the other 46.43% of the respondents were from the consultancy organisations.

Post disaster housing reconstructions were done in Sri Lanka for several disasters such as draught, rock falls, tropical storms, fires, landslides, high wind, floods and tsunami. However, according to survey, it was found that in Sri Lanka, most of the post disaster housings were done for the tsunami (Figure 2) through donors and construction consultancy organisations. According to Figure 3, majority of the respondents (100%) stated that they were involved in permanent housing reconstruction. However, these figures were only relevant to the donor organisations and construction consultancy organisations, who were involved in post disaster housing reconstruction.

In this study, the sources of knowledge were categorised as internal to the organisation and external to the organisation. Table 2 indicates the list of sources of knowledge internal to the organisation in descending order of 'usefulness' as perceived by the respondents.

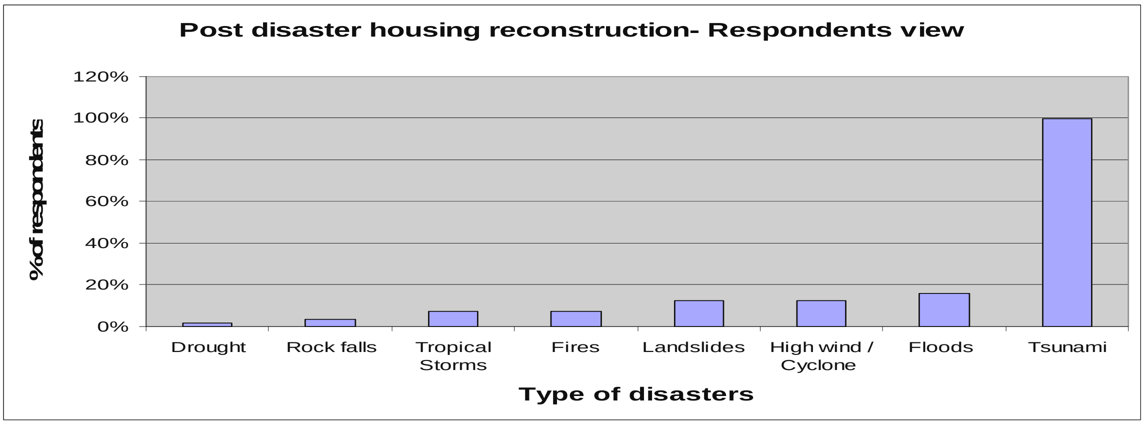

Figure 2: Post disaster-housing reconstruction

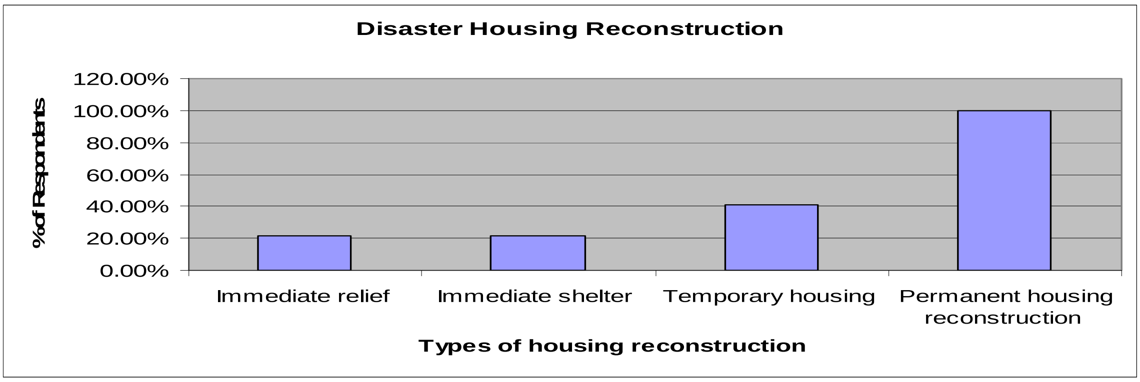

Figure 3: Types of post disaster-housing reconstruction

Further, Figure 4 illustrates the repositories used internal to the organisation. Majority of the respondents responded that they have used project-monitoring documents (87.50%) more often than other repositories. Reports (82.14%) were the second mostly used repositories.

Further, Table 3 suggests that the most significant external source of knowledge related to post disaster housing reconstruction in Sri Lanka was repositories. Moreover, the knowledge gatekeepers were the least significant external knowledge source.

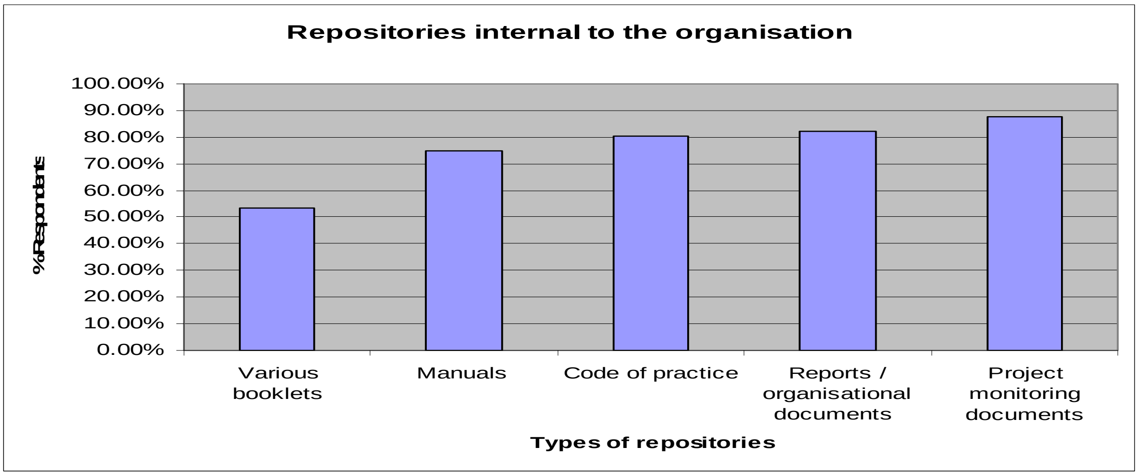

Figure 4: Repositories – internal to the organisation

Table 2: knowledge sources – Internal to the organisation in descending order of use

Competences
Lessons learned
Repositories
Team(s)
Other individuals
Routines

Table 3: knowledge sources – External to the organisation in descending order of use

Repositories
Communities of Practice
Other individuals
Other networks
Knowledge gate-keepers

Table 4 stipulates that the e-mail system was the high-useful KM technology used in post disaster housing reconstruction by donors and consultants. Next significant tool was the costing and cost management system. According to Table 5, the face-to-face interactions, task teams, and project reviews were the most significant non - IT based tools in post disaster housing reconstruction.

Table 4: KM Technologies

IT Based Tools in descending order of usage	
1. E-mail system	**9. Skills Yellow Page**
2. Costing and cost management system	**10. Groupware**
3. Document management system	**11. Technical call centre**
4. The central project file	**12. Web based application**
5. Intranet	**13. Taxonomy / Ontology**
6. Knowledge bases	**14. Extranet**
7. On-line project management	**15. On-line procurement system**
8. Data and text mining	**16. On-line KM system**

Table 5: KM Techniques

Non - IT Based Tools in descending order of usage	
1. Project reviews	**9. Seminars**
2. Task teams	**10. Training**
3. Face-to-face interactions	**11. Communities of practice**
4. Formal meetings	**12. Focused group sessions**
5. Brainstorming	**13. Knowledge gatekeepers**
6. Site liaison initiative	**14. Apprenticeship**
7. Quality circle	**15. Share fair**
8. Recruitment	

While lack of compiling and synthesizing the accumulated data, information and knowledge, storing and organizing was the most significant challenge, conflicting priorities between KM and other business functions was the least significant challenge to KM in post disaster housing reconstruction (Table 6).

Improved performance was the key benefit that the respondents got through KM and the other benefits like effective monitoring of initiatives, efficiently and effectively use available resources were some of the highly rated benefits among respondents (Table 7).

Table 6: Challenges to KM

Challenges to KM in descending order	
1. Lack of compiling and synthesizing the accumulated data, information and knowledge, storing and organizing	**10. Organisational culture**
2. Lack of systematic collection of standardized data	**11. The difficulties associated with communicating the benefits of KM**
3. Lack of documentation of knowledge and application of lessons learned and best practices for decision-making	**12. Poor IT infrastructure**
4. No validation mechanism	**13. Bureaucracy associated with KM**
5. Lack of measure to value the performance of knowledge assets	**14. People’s fears**
6. Unstructured KM approach	**15. Conflicting priorities between KM and other business functions**
7. Overload of information in the form of reporting	**16. Change management**
8. Changing people’s behaviour	**17. Employee resistance**
9. What knowledge should be managed	**18. Lack of top management support**

Table 7: Benefits of KM

Benefits of KM in descending order	
1. Improved performance	**11. Innovation**
2. Effective monitoring of initiatives	**12. Organisation can retain tacit knowledge**
3. Efficiently and effectively use available resources	**13. Dissemination of best practice**
4. Improved decision-making	**14. Increased intellectual capital**
5. Improved reconstruction project delivery	**15. Risk minimization**
6. Improve effective acquisition, sharing and usage of information within organisations	**16. Lower cost in managing the projects**
7. Reliable, useful, up-to-date and timely knowledge can be created and shared	**17. Promoting fair practices among the disaster management community**
8. Can avoid repeating past mistakes	**18. Creates competitive advantage**
9. Better valuation of Resources and services	**19. Increase profit, market share, market size and reduce cost**
10. Respond very quickly to client’s needs and external factors	

Most of the KM sub processes were practiced by the donors and consultancy organisations, but in an informal way. The respondents believed that the knowledge capturing is important to function effectively, work quicker, plan better, reduce cost, give good out put to beneficiaries, get more resources (attract new donors), carry out future disaster reconstruction, give good solution, learn from, and have a win-win situation. Further, the importance of knowledge creation or production was to improve performance, motivate staff, increase organisational asset, etc. While knowledge sharing was vital in order to grow knowledge; get best decisions; avoid duplication; save time and energy; share correct and timely knowledge; improve relationships, the knowledge storing was essential to get accurate information future; reduce cost; justify and accountable to donors and communities; and to show transparency. Moreover, the significance of knowledge transferring was to learn more, increase effectiveness and efficiency of the work force, reduce cost, change the quality of construction, capacity building for local technical people, get timely advice, and disseminate knowledge.

5. Conclusions

This research has investigated the concept of KM in the post disaster housing reconstruction in Sri Lanka. Mostly, the construction industry is relied on expertise of key members of staff. KM can be used as a tool to store, retrieve, disseminate, and manage information related to post disaster-housing reconstruction. It can be concluded that the most of the donors and consultancy firms, who do housing reconstruction, have got involved in tsunami housing reconstruction work compared to other disasters. Further, the respondents were mostly determined on permanent housing reconstruction rather than other types of disaster housings. While competence was the most significant internal knowledge source to the organisation, repositories were the most significant external knowledge source to the organisation. Analysis of the sample revealed that project-monitoring document was the highly used repository internal to the organisation.

While the e-mail system was used predominantly as IT based tool for KM, the project reviews; task teams; and face-to-face interactions were the most significant non – IT based tool for KM. This was further supported by the semi-structured interviews. The findings suggest that lack of compiling and synthesizing the accumulated data, information and knowledge, storing and organizing was the major challenge in managing the knowledge faced by the donors and consultants who do post disaster housing. This may be due to the sense of urgency shown by the parties. The improved performance was viewed as the key benefit of KM in post disaster housing reconstruction.

The KM sub processes are important in order to avoid duplication of knowledge creation, store knowledge on local technical people, carry out future disaster reconstruction, change the quality of construction, disseminate knowledge, grow knowledge, get best decisions, get more resources (e.g. attract new donors), give good output to beneficiaries, improve performance, improve relationships, increase organisation asset, plan better, reduce cost by avoiding repetitive tasks, save time and energy etc.

Even though the study presents most of the elements of KM, most of the organisations have not implemented KM formally into post disaster housing reconstruction. Although, it can be concluded that the awareness of KM is there in the industry to implement KM in post disaster housing reconstruction to improve the performance. During the course of research, the researcher came across some interesting research opportunities. They are, study the same research question with additional unit of analysis, i.e. with donor, owner, consulting, and contracting organisations, study the each KM sub processes individually to deeper scope with regard to disaster reconstruction, study the role of KM in disaster management, and studying the procurement arrangement in post disaster housing reconstruction.

Abstract

In the past few decades many nations have experienced quite a large number of natural disasters. Although they are developing new systems to avoid or reduce the devastation caused by disasters still many countries are struggling to recover. The literature on disaster management has begun to recognise the activities carried out during post disaster as an opportunity for nation and communities to develop. Post disaster reconstruction is a significant period in disaster management where it becomes a window of opportunity for communities and nations. Since women are one of most vulnerable groups in disasters and, as there is a need to recognise this human resource for their own development and for community's benefit, this research looks into the experiences of women in post disaster reconstruction. The study aims to present their experiences in post disaster reconstruction by considering their roles and challenges in this process in order to analyse the importance of post disaster reconstruction towards their development. This research has been based on theoretical and practical knowledge obtained through comprehensive literature review.

Keywords: Disaster management cycle**,** Empowerment, Post disaster reconstruction, Women

1. Introduction

The occurrence of natural and human-caused disasters has increased over the recent decades in many countries around the world. Disasters are generally large intractable problems that test the ability of communities and nations to effectively protect their population and infrastructure and, its capacity to recover rapidly [1]. During disaster management, post disaster reconstruction stage is confronted with many barriers in making the disaster an opportunity for development due to its ineffectiveness and inefficiency. Reconstruction is a rebuilding measure which involves not only constructing physical structures but also building the confidence, self-respect, self-esteem, self-dependency, mutual support and mutual trust and, the rebuilding of communities. This long-term process focuses on human and material resource development, coordinated effort towards independence, sustainability and empowerment. The United Nations [2] defines disaster as a serious disruption of the functioning of a community or a society causing widespread human, material, economic or environmental loss that exceeds the ability of the affected community or society to cope using its own resources. The disasters can be in the form of a battery of floods, droughts, cyclones, land slides, earthquakes, communal riots, armed conflicts, fires, volcanic eruptions, epidemics and industrial disasters.

This study focuses on naturally occurring disasters and their effects. However though these disasters are naturally occurring phenomenon, the intense impact of a disaster is exacerbated by human actions including incomplete development practices. Although there have been improvements in the emergency response to natural disasters, permanent reconstruction is often inefficiently managed, improperly coordinated and slow to get off the ground [3]. However post disaster reconstruction (PDR) is an important stage in disaster management where it becomes a window of opportunity for the community's development.

Present literature on disaster management emphasises the importance of gender sensitivity in PDR [4]. It argues that gender consideration will help for better targeting of resources to reach people in greatest need; for more accurate service provision to meet actual needs; to decrease vulnerability to future disasters and to prevent or mitigate negative impacts to second generation [4]. In addition earlier studies found that the gender composition of the population tends to change following a disaster where the percentage of female-headed households typically increases [1]. Furthermore it states that, during the post disaster phase the roles and responsibilities of women can change dramatically. In addition, the level of risk experienced by women to disaster is more than men and women are also more vulnerable in post disaster stages [5]. Therefore it is important to study women's experiences in PDR in order to improve their development.

Although the roles of women have changed noticeably in the past decades still they find it difficult to improve their status within the community. This research aims to present a review of literature related to women's experiences in PDR in order to analyse the effects of post disaster reconstruction towards their development. The study identifies their experiences with regard to their participation and confronts challenges related to women's development during PDR in the disaster cycle. In addition this study discusses whether PDR fosters or hinders women's development. This research has been based on theoretical and practical knowledge obtained through a comprehensive literature review.

2. Natural disaster management cycle

Natural disasters can occur as slow-onset natural disasters such as droughts or as rapid-onset disasters. The magnitude of disasters is documented by reference to the degree of vulnerability of the affected population [5]. A population's level of risk to disaster is determined by the type of hazard and the calculation of the level of vulnerability which is determined by social, physical and attitudinal variables [5]. Although in disasters it is difficult to differentiate between different stages, for management purposes there is a standard disaster cycle and each phase merits special considerations. The cycle includes disaster mitigation and prevention, preparedness, emergency, rehabilitation and reconstruction [1]. Each phase in the cycle requires particular types of interventions and programming. According to Ariyabandu and Wickramasinghe [5], disaster management is a collective term encompassing all aspects of planning for and responding to disasters which includes both pre and post disaster activities. Further they state that the disaster management cycle includes the shaping of public policies and plans that either modify the causes of disasters or mitigate their effects on people, property and infrastructure. Disaster management should not be seen in isolation but it should be considered at various phases of management in addressing the issue.

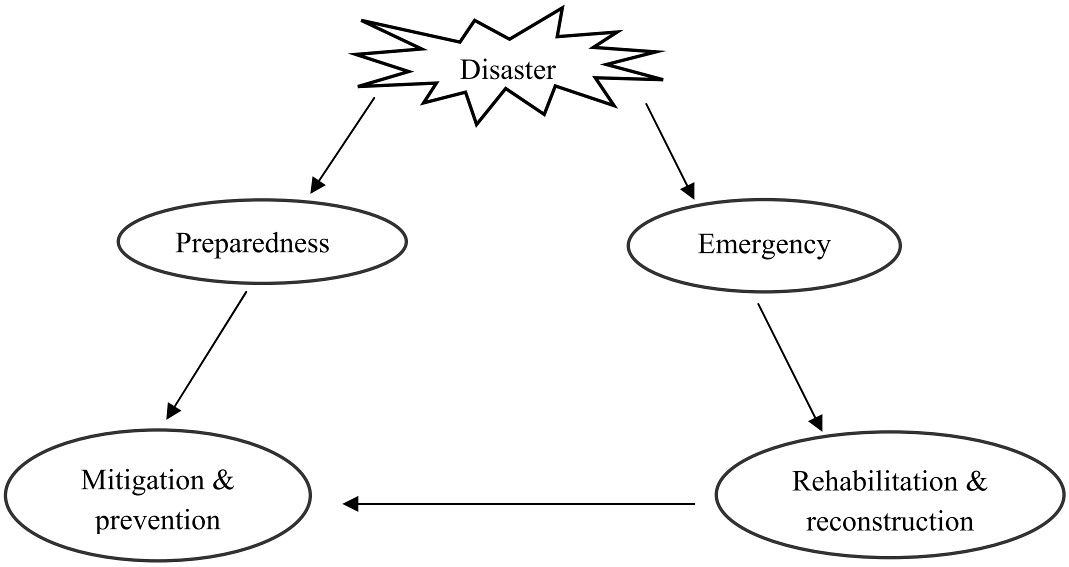

Figure 1: Natural disaster cycle (*Source: [1])*

2.1 Disaster mitigation and prevention

In the natural disaster cycle, the pre-disaster phase includes mitigation and prevention and, preparedness. During mitigation stage activities are related to elimination or reduction of the probability of the occurrence or reduction of the effects from unavoidable disasters. The mitigation process includes building codes; vulnerability analysis; zoning and land use management; building safety codes; preventive health care and public education. The success of mitigation measures depends on the integration of appropriate measures in national and regional development planning. Its effectiveness will also depend on the availability of information on hazards, emergency risks and the counter measures to be taken.

2.2 Disaster preparedness

During the disaster preparedness phase, measures are undertaken to control the impact of the event through ensuring a structured response and establishing mechanisms for effecting a quick and orderly reaction to it [6]. These are not aimed at preventing the occurrence of a disaster. Further this stage includes the development of awareness among people on the general aspects of disaster and how they need to behave in future by educating them about the disaster signs, methods of successful evacuation and first aid measures. In addition formation and training of local committees, building of communication systems, meteorological observation systems, facilitation of basic utility systems such as water supply system and sanitation are some of the activities undertaken during this phase.

2.3 Emergency phase

The emergency response aims to provide immediate assistance to maintain life, improve health and support the morale of the affected population. The emergency phase involves immediate post recovery which can last for days, weeks or months depending on the nature of the disaster and local conditions [3]. During the emergency phase, relief agencies or groups focus on preventing additional loss of life through actions such as search and rescue, emergency food and water, temporary shelter, and temporary transport. The focus of this phase is on meeting the basic needs of people until more permanent and sustainable solutions can be provided. Humanitarian organisations are often strongly present during this phase in the disaster management cycle.

2.4 Rehabilitation and reconstruction phase

The recovery activities, which include both short and long term, continue until all systems return to normal or improved status. The rehabilitation phase includes medium term interventions such as construction of transitional housing, provision of basic food to the affected population, provision of social services, road clearing, income generation, water system rehabilitation [1]. As the emergency is brought under control the affected community is capable of undertaking a growing number of activities aimed at restoring their lives and the infrastructure that supports them. There is no distinct point at which immediate relief changes in to rehabilitation and then into long-term reconstruction development.

The reconstruction period includes the long-term and often substantial investment in rebuilding the physical and social infrastructure of affected regions. PDR is a process that is the interaction of complex social, technological and economic factors and actions [7]. There will be many opportunities during the reconstruction period to enhance prevention and increase preparedness, thus reducing vulnerability. However though many organisations are involved in relief and rehabilitation most often they focus on the emergency and reconstruction remains neglected [8]. Therefore it is necessary for organisations which are concerned about disasters to utilise the opportunities and develop the community’s capabilities.

3. Women’s experiences in post disaster reconstruction

3.1 Women's participation

Generally the role of women in the post disaster stages are categorised under three main areas: reproductive roles; community roles and productive roles [5]. Reproductive roles include roles within household and the family: inclusive of bearing, nurturing and rearing children; cooking; cleaning the house and yard; marketing; caring for sick and elderly, etc. These roles may be expanded to include agricultural work in the home stock within household, long-term work of rebuilding family and community spirit, etc. which do not give economic values. Women's community roles include: maintaining kinship relations; religious activities; social interactions and ceremonies; communal sharing and caring activities; communal survival activities, etc [5]. These are generally done voluntarily and do not provide economic returns. Although these are usually related to reproductive function, there are instances where it includes work related to relief and reconstruction including the physical reconstruction of their homes [9]. Finally, productive roles give economic remuneration for manual labour, professional labour and subsistence activities. Although generally women's roles are classified under above three categories, Fordham [10] states that there is no simple distinction between private and public labour of women which usefully frames neither women's disaster responses nor can women's work be neatly confined to discrete categories.

The degree of vulnerability among women and their participation during post disaster differ considerably. Disabled, elderly, pregnant and lactating women and widows often require assistance on a longer term or sustained basis, whereas other women can be supported up to the point where they achieve food and economic self-sufficiency. These distinctions are important in determining the types and levels of support to be provided to them. Therefore more local knowledge and wisdom needs to be incorporated into post-disaster recovery and development planning, particularly as they relate to women. According to the International Labour Organisation [13], it is now widely accepted that women are not only responsible for attending to the basic needs of their children and families, but also account significantly for productive and income-generating activities. In addition, in a disaster situation women have demonstrated their capacity as income-earners, producers and managers of food production, providers of fuel and water, participants in cultural, religious and political activities.

The reconstruction phase is a significant period in disaster management as the results of the process are directly open to evaluation and criticism. The literature on disaster management [11] suggests that women's work around the household, on the job and in their neighbourhood contributes significantly to the social construction of daily life under extreme and routine conditions [12]. However the recognition of the importance of their work and their development is sill remains a question.

During the reconstruction phase and especially in temporary shelters, women take on a triple duty of reproductive work, community organisation and productive work in the informal economy, while men tend to return to their traditional role of waged work outside home. The tremendous impact of the disaster on children and elderly are largely shouldered by women. Generally in post disaster situations the officials in charge for reconstruction activities finds it difficult to obtain timely and accurate information. This is partly because of decision making which does not follow its usual procedure due to the urgency and the pressures and flow of information to lower ranks does not work in its routine way. In certain cases the implementation does not happen effectively. Thus, the contribution of women to this will be of great help.

Recent literature on PDR emphasises the dominance of men in development processes. Further, women remain marginal to the process and the study recognises the importance of offering diversified packages to women in post disaster stages as not all women are from educated backgrounds.

3.2 Women's challenges

According to the International Labour Organisation report [13], there are four general impacts that disasters have on the work of women. Firstly, women's economic insecurity increases. Since their productive assets are destroyed they often become sole earners, their household entitlements may decline, their small-businesses are hard-hit and they lose their work. In developing countries, after natural disasters, women lacking in land titles or farming small plots may be forced off their land [13]. Moreover, since land and employment arrangements are often negotiated through men, women may lose access to both without a man to represent them. Most importantly the gender stereotypes limit women's work opportunities especially in the post disaster reconstruction stage. In addition, due to economic downturns after natural disasters women lose their jobs more quickly and in greater numbers than men [13].

Women's workload increases significantly following a disaster and their working conditions in the household and paid workplace deteriorate e.g. through lack of child care and increased work and family conflicts [13]. The increase workload stems from damaged infrastructure, housing and workplaces; the need to compensate for declining family income and social services and the responsibility to care for orphaned children, the elderly and the disabled. This in turn limits women's mobility and time for income generating work. Furthermore this leads to women recovering more slowly than men from major economic losses, as they are less mobile than male workers, are likely to return to paid work later and often fail to receive equitable financial recovery assistance from the government or external donors [13]. In certain communities since women often take on more waged or other forms of income generating work and engage in a number of new forms of disaster work, they have also expanded their responsibilities.

While women are severely affected by natural disasters this often provides women with a unique opportunity to challenge and change their gendered status in society. □Women have proven themselves indispensable when it comes to responding to disasters [4]. Following Hurricane Mitch in 1998, women in Guatemala and Honduras were seen building houses, digging wells and ditches, hauling water and building shelters [4]. Although often against men's wishes, women have been willing and able to take an active role in tasks that were traditionally considered as male tasks. This can have an effect of changing society's perceptions of women's capabilities. Women are most effective at mobilising the community to respond to disasters. They form groups and networks of social actors who work to meet the most pressing needs of the community.

According to a study on past disaster experiences, a pre-existing pervasive culture of acceptance or denial concerning violence against women including no existing criminal legislation on domestic violence, presents compounded problems for organisations attempting to support women in the wake of the tsunami. The denial or trivialising of violence against women by authorities only adds to the problem [14]. In certain developing countries the prominent finding of male dominance and its negative implications is what underscores the importance of the longer-term vision for structural change to address gender inequality [14].

4. Discussion

The reconstruction is a rebuilding measure that involves building the confidence, self-respect, self-esteem, self-dependency, mutual support and trust and the rebuilding of communities. In order to have a successful completion of disaster reconstruction it is important to include the participation of social actors of the community. During PDR, in addition to men, women are also engines of recovery who possess qualities vital for disaster response and who can help to keep the fabric of society in tact. Since crises present an opportunity to break-down gender barriers and as coping prompts men and women to step out of their traditional places, unequal pre-disaster gender roles can be changed. During recovery periods women have been able to carry out community mobilisation for recovery programmes in developing countries with critical support and planning [16]. In many instances, after gaining economic independence through income generating projects, women have been largely instrumental in promoting youth projects. Thus, their mobilisation capacity can be increased through their economic independence.

Reconstruction is a long-term process and it focuses more on human and material resource development, coordinated effort towards independence and sustainability. In order to achieve the above objectives the concept of empowerment can be used as a tool. In reconstruction the most vulnerable and marginalised sections like women, children, the poorest section of society, etc. are the primary stakeholders who need to be considered as partners in the empowering process [8]. In disaster circumstances, empowerment would enable women to increase their human and economic developmental goals. Through women's participation in planning, design, implementation, monitoring and evaluation, the processes of recovery and reconstruction can go beyond the provision of basic needs. Their participation may engender a level of community cohesiveness and security, with greater potential for realising development goals. However it is advisable to organise and implement community measures that do not violate the stability of the family structure. Working in traditionally male fields like construction; launching small businesses; contributing to discussions on reconstruction; and pursuing education, even while displaced, can empower them. In addition, if men are absent, gender roles are obviously open to change. These circumstances can increase women's economic independence, their ability to provide for their families, their decision making skills and social prominence. However such positive changes need support.

According to report by UN-HABITAT [15], when women are empowered they have the capacity and the inner will to improve their situation and gain control over their own lives. Further it states that, this can lead to an equal share in economic and political decision-making, and control of economic resources. The report by Department of Economic and Social Affairs [16] states that, in addition to poverty, environmental degradation and differing needs of men and women, the marginalised role of women within many organisations and their absence from decision-making structures contribute to their vulnerability in post disaster situations. Kumar-Range (1999 cited [16]) points out that though women tend to be active in communities and households they are marginalised by agencies and organisations responding to the disasters.

In a study by Bradshaw [17], in post Hurricane Mitch, participation rates of women in community based projects and programmes have increased from under a quarter to over half the women interviewed in the four communities considered for the study. The lowest levels of participation are recorded amongst young female partners or wives in male-headed households and the highest levels are amongst female heads of household. This is perhaps not surprising since women heads are assumed to take on dual responsibilities of male heads and female partners when they head their own households. This was supported by the fact that female heads appear to have been actively targeted in reconstruction. While over half of the number of women interviewed think women are participating in reconstruction only a quarter state that it is women who benefit the most from reconstruction and the majority see benefit as being for family. This shows that mere targeting of women as better deliverers of services and resources may indirectly reinforce traditional gender roles and relations rather than transform them [17].

Although an understanding of the factors that affect vulnerability is crucial, the focus on women's empowerment draws attention to the importance of understanding both women's and men's capacities and potentials as well. This understanding is only possible through the consistent use of participatory methods and a focus on understanding and strengthening women's forms of organisation. Women should be involved in disaster reconstruction processes as having an active role in planning, needs assessment in the construction.

Generally, disaster creates a socially acceptable and legitimate reason for women to get into the public arena. In a way it creates a kind of recognition for women’s mobilisation to advocate for their needs and also their initiatives. This coincides with the present concern about the willingness to recognise and responsibility to act. Thus, women’s priorities like the provision of community services, collective businesses and access to credit, housing cooperatives, safe housing, etc., become concrete issues of engendering local governance. However, this is always at stake, and the critical issue for women here is building a critical mass to continue to advocate for them. Most importantly women need to become aware of their potential and this opportunity during their experiences.

Training for women must respond to the full range of their aspirations and potential. Interventions also must include those working informally or in the home. Women often know local conditions better than anyone. Therefore they bring crucial knowledge to the planning and implementation of reconstruction projects and decision-making structures [6]. Their participation in turn helps to develop an economic, social, and legal environment propitious for women’s success. Long-term recovery strategies should capitalise on positive changes and avoid reverting to pre-disaster patterns. With PDR activities both women and men can find new opportunities for decent work to aid the recovery of their families and communities.

5. Conclusions and the way forward

Disaster response needs a partnership between all the actors in society including the marginalised groups and individuals at all levels, most importantly at community level, where women normally operate. When disasters strike, associations for women and youths can be mobilised and play key roles in relief and recovery. During the PDR phase some activities can be resuscitated. It is wise to search for the hidden resilience displayed by communities affected by disasters and then to build upon it. This would entail a conscious strengthening of local knowledge and wisdom, applying appropriate solutions to crises. One goal should be to increase economic possibilities that promote political, social and economic empowerment of communities wherever possible, without introducing externally generated institutions.

One of the main sustainable means for disaster victims to overcome their marginal condition is through an adjustment process of empowerment, allowing them to fulfil their basic human development needs. When designing protection and assistance programmes for women during and following emergencies it is essential for planners to broaden the concept of women's status from the narrow conceptualisation as daughter or mother or wife. The capacity of women to mobilise people and manage change should not be underestimated. Instead of feeling that their voices cannot be safely heard, opportunities for women to engage in management and decision making related to all levels of disaster response and reconstruction should be offered. This can enable disasters to provide physical, social, political and environmental development opportunities that can be used during the PDR. This would lead to not only reconstruct the affected areas, but also to improve the socio-economic and physical conditions of the impacted population in the long run. This study has been undertaken as part of a research study which focuses on the empowerment of women in post disaster reconstruction.

Abstract

In order to accommodate the growing complexity of construction process, various management systems and methods have been developed through academic research and applied in industry practices. Among those, supply chain management (SCM), as a significant component in construction material procurement, becomes increasingly popular, especially within the context of broader cooperation, vertical disintegration and the viewpoint of a networked supply chain in the construction industry.

Following the Boxing Day Tsunami in 2004, the procurement and supply of sustainable and legitimate construction material for the massive reconstruction became the first priority of almost every organisation involved in this process in Indonesia. As a result, the competition for limited resources and the lack of effective coordination between reconstruction agencies has nearly tripled the cost of a standard house and leaving thousands of people in transit living conditions two years after the disaster. Based on the reconstruction experience in the worst affected area, Banda Aceh, this paper will examine the modern literature on supply chain management (SCM) and analyse this process in practice associated with construction material procurement, review the problems inherited in the Indonesian context and analyse the proposed procedures of local and international procurement of construction materials to streamline the supply. Conclusions will then be made based on above-mentioned analysis for future development and adoption of an integrated SCM concept in post disaster reconstruction.

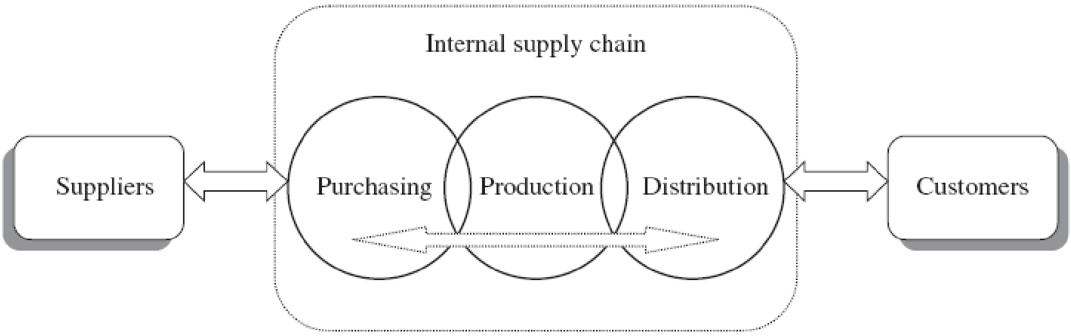
Keywords: Supply Chain Management, procurement, disaster reconstruction, Tsunami, Aceh

1. Literature review

1.1 SCM Literature Overview

In order to accommodate the growing complexity of construction process, various management systems and methods have been developed in academic researches and well applied in industry practices. Among those, supply chain management (SCM) becomes increasingly popular; this especially within the context of broader cooperation, vertical disintegration and the viewpoint of a networked supply chain in construction industry. Its popularity has been stimulated by a range of sources including the quality revolution (Dale et al. 1994), notions of materials management and integrated logistics (Carter and Price 1993), a growing interest in industrial markets and networks (Ford 1990, Jarillo 1993), and influential industry-specific studies (Womack et al. 1991, Lamming 1993). ‘Supply chains’, ‘demand pipelines’, ‘value streams’, ‘support chains’ are some examples of the terms used to describe this process.

A typical supply chain is illustrated in the following model developed by Chen and Paulraj (2004) as “simply a network of materials, information and services processing links with the characteristics of supply, transformation and demand”. The term SCM was originally introduced by consultants in the early 1980s (Oliver and Webber 1992) mainly focused on the lines of physical distribution and transport and has subsequently gained tremendous attention (La Londe 1998). Besides its initial interests gathered to explain the logistics activities and the control of materials and information flows, researchers have also explored into other areas such as strategic, inter-organizational issues (Cox 1997, Harland et al. 1999), to discuss an alternative organizational form to vertical integration (Hakansson and Snehota 1995), to identify and describe the relationship a company develops with its suppliers (Narus and Anderson 1995), and to address the purchasing and supply perspective (Farmer



1997).

Figure 1: A typical supply chain model (Chen and Paulraj, 2004)

The main body of SCM literature has been explosively enlarged during the latter half of last century due to its various contributing knowledge fields such as purchasing and supply, logistics and transportation, marketing, organisational behaviour, network, strategic management, information systems management and operations management. However, only some critical elements of SCM and its performance measurement, which are relevant to the current process of post-disaster reconstruction in Aceh, will be covered in this literature review.

1.2 Supply Management Overview & Communication Needs

A predominant approach to SCM research is the so-called ‘supply management’, which emphasizes primarily the buyer-supplier relationship (Leenders et al. 2002) within the process. Since suppliers have a profound and direct impact on cost, quality, time and responsiveness of the buying firms, the management of relationships with other members of the supply chain (i.e. buyer–suppler relationship) is increasingly being referred to as SCM (Chen and Paulraj, 2004). The literature on SCM has constantly emphasized the importance of effective two-way communication to the above relationship. Hahn et al. 1990, Galt and Dale 1991, Krause 1999, Carr and Pearson 1999 argue that in order to jointly find solutions to material problems and design issues, buyers and suppliers must commit a greater amount of information and be willing to share sensitive design information. However, this is often achieved through engineer-to-engineer communication on design issues keeping in mind to improve process capability, manufacturability and performance without affecting profit margins (Bhote 1987, Dobler et al. 1990, Turnbull et al. 1992). Poor communication was often a fundamental weakness in the interface between a buying firm and its supplier, which undermined the buying firm's efforts to achieve increased levels of supplier performance (Lascelles and Dale 1989). This is a major problem experienced by various agencies involved in the Aceh reconstruction and embodied in competition for resources and increased difficulty in materials procurement.

1.3 Supplier Base Reduction and Long-term Relationships

Traditional practices of supply chain management tend to contract with multiple suppliers even for the same material or component. This is partially due to the consideration of risk reduction with multiple options and avoidance of becoming source dependent. However, reduction of the supplier base is a unique characteristic of contemporary buyer–supplier relationships (Newman 1988, Helper 1991), because the administrative or transaction costs associated with managing a large number of vendors often outweigh the benefits (Dyer 2000). This is especially the case in the Aceh reconstruction given the limited availability of construction materials and often inadequate administrative abilities of reconstruction agencies. Many firms are reducing the number of primary suppliers and allocating a majority of the purchased material requirements to a single source (Pilling and Zhang 1992, Kekre et al. 1995). The benefits attributed to this practice often exceed those achieved through traditional bidding from multiple sources, which often emphasizes low price at the expense of performance (Mohr and Spekman 1994). Moreover, supply base consolidation sets the stage for future development of the chosen suppliers (Handfield 1993).

Long-term relationships between supplier and buyer have become a crucial characteristic of modern supply chain relationship (Shin et al. 2000). Through close relationships, supply chain partners are willing to share risks and reward and maintain the relationship over a longer period of time (Cooper and Ellram 1993, Stuart 1993). Hahn et al. (1983) compared the potential costs associated with different sourcing strategies and suggested that companies would gain benefits by placing a larger volume of order with fewer suppliers using long-term contracts. Moreover, through a long-term relationship, the supplier will become part of a well-managed chain and will have a lasting effect on the competitiveness of the entire supply chain (Choi and Hartley 1996, Kotabe et al. 2003). A well-coordinated joint order of similar construction materials by several NGOs would be a good example of sustainable management of such practice.

Selecting suppliers for specific goods and services is a critical decision for most organizations, since supply performance can have a direct financial and operational impact on the business (Bailey et al. 1994, Ittner et al. 1999). A quality focus in supply management is supported by many conceptual studies. Choi and Hartley (1996) found that companies place more importance on consistency (quality and delivery) and the least importance on price. On the whole, quality, on-time delivery, and uninterrupted supply become critical selection criteria because supplier failures on these dimensions have more serious adverse effects on the buyer's operations (Ellram 1990). Trustworthiness, integrity, commitment, and characteristics that imply 'fair dealing' are also considered with importance in selecting the supplier (Anderson and Narus 1990, Lewis 1995). Specifically, suppliers who are unwilling to share information on cost, quality and production can be screened out, because willingness to share information is viewed as a signal of the trustworthiness of the supplier (Dyer 1997).

A recent trend of supplier certification provides a potential solution to the procurement problems related to selection of tenders. It involves the thorough examination of all aspects of a vendor's performance and is expected to enhance buyer–supplier trust and communication, to improve supplier product quality, to reduce communication errors, and to reduce inspection and inventory costs for the buyer (Schneider et al. 1995, Larson and Kulchitsky 1998, Ittner et al. 1999). Recently, supplier certification has been extended to include the logistics function. American Quality Foundation and Ernst and Young (1998), in their international quality study of over 500 organizations, reported that formal programs for certifying suppliers showed an across-the-board beneficial impact on performance, especially in quality and productivity.

1.4 Supplier and Logistics Integration

Integration is another key word in SCM involving the new building construction process. The involvement may range from giving minor design suggestions to being responsible for the complete development, design and construction of a specific part of the building (Wynstra and Pierick 2000). According to reports by Naumann and Burton in 1980's, suppliers accounted for approximately 30% of the quality problems and 80% of product lead-time problems. Studies by Mabert et al. (1992) found supplier involvement to be an important part of the strategy in five out of the six firms they examined who were attempting to collapse new product development time. Furthermore, research has concluded that the effective integration of suppliers into new product development can yield such benefits as reduced cost and improved quality of purchased materials, reduced product development time, and improved access to and application of technology (Ragatz et al. 1997, 2002, Primo and Amundson 2002).

Besides the supplier integration, other internal and external integration issues in supply chain logistics are recognized and attracting more and more interest from researchers. Logistics has traditionally been defined as the process of planning, implementing and controlling the efficient flow and storage of goods, services and related information as they travel from the point of origin to the point of consumption (Chen and Paulraj, 2004). Some major activities included in the logistics domain include transportation, warehousing, purchasing and distribution. The traditional approach of logistics integration across functional boundaries within a firm is termed 'internal integration' (Bowersox and Daugherty 1987), whereas a more recent approach of logistics integration across firm boundaries is termed 'external integration' (McGinnis and Kohn 1990, Stock et al. 1998). External integration has been the subject of a good deal of research in logistics management, the name underlines the needs for mutual completion of procurement, production planning and distribution in order to carry out a unitary process (La Londe et al. 1970, Busch 1988, La Londe and Powers 1993). Enterprise logistics integration is the extent to which a firm implements both internal and external integration. It can be characterized by integration of logistics activities across functional departments within the firm, as well as integration of the firm's logistics activities with the logistics activities of other supply chain members (Stock et al. 1998).

2. Methodology

The methodology used in this research includes firstly a comprehensive review through the modern literature of SCM, focusing on several aspects closely related to the post disaster procurement process in Banda Aceh, namely, communication needs, supplier base reduction, long-term relationship, and supplier and logistics integration. Those topics would later be addressed and referred to in case experiences discussions. Two authors of this paper spent a monthly fieldtrip in Banda Aceh 2 years after the Tsunami with the Indonesian branch of an international humanitarian aid organisation involved in the houses reconstruction project for local refugees. During the fieldtrip, extensive interviews were carried out with construction managers, procurement managers from different NGO's and UN agencies; representatives from local authorities overseeing the reconstruction process in Aceh; and local staff in those NGO's, members from local Village Development Committee and affected communities. Major obstacles associated with construction materials procurement were identified during interviews. Two typical methods representing local and international supply chains for timber procurement were selected out for detailed analysis. Data collected and ideas generated from this series of interviews and pilot case studies were incorporated and expressed in the discussions within the following sections. Several recommendations were made in the conclusion to tackle the problems encountered in post-disaster procurement and to streamline the supply chain for reconstruction.

3. Supply chain and material procurement experiences in the Aceh Tsunami reconstruction

During the 2004 Boxing Day Tsunami, some 130,000 people were killed in Aceh alone and 37,000 remain missing. 3 months later, another big earthquake on March 28 2005 added 1,300 to the death toll in Nias, Simeulue and southern coastline of Aceh. These consequent tragedies caused immense economic, social and environmental devastation to Aceh and surrounding areas that were already under the poverty line. It is estimated in an official report (BRR April, 2006) that approximate 123,000 new houses are needed for re-establishment, relocation and resettlement of Acehese tsunami victims, let alone the accompanying tremendous reconstruction of infrastructure.

There are approximately 290 NGOs and donor organizations operating in Aceh and Nias in 2006 managing as many as 828 projects. In order to generally coordinate and manage the reconstruction effort in an overall prospective, the Agency of the Rehabilitation and Reconstruction for Aceh and Nias (BRR) was established by Indonesian Government Regulation No. 2/2005 on 28 April 2005, 4 months after the Tsunami. It is estimated that at least US$5.8 billion will be needed in the recovery phase for Aceh and Nias. The situation now is that US$4.4 billion1 has already been allocated to different projects, and the people of Aceh and Nias may have a chance to better build back their

[1] US$4.4 billion: The Government of Indonesia has allocated 1.1, NGOs 1.5 and official donors 1.8 billion in US dollars.

livelihood with total pledges of US$9 billion (3 billion more than least budget required). The major issue is becoming how to spend this money wisely and in the most needed areas.

A major problem faced by almost every organization involved in the Aceh reconstruction is the supply and procurement of legal and sustainable construction materials, especially the massive needs of timber. As mentioned in a NGO's report on supply chain management, "whilst timber has been previously procured, it has not been without delays and the quality in some cases has been questionable." A review and general introduction of timber supply problems inherited in the Indonesian context will first be made, followed with the analysis of the possibility and proposed procedure of procuring local and international timber.

3.1 Timber supply problems

Although seriously damaged during 2004 Tsunami in coastal areas, 70% of mainland Aceh is still covered by natural tropical forests, the best remaining tropical forests in Indonesia and rich in biodiversity. One can easily visualize the beautiful green land under the plane when flying over the Sumatra Island. It is the natural gift inherited by generations of Indonesian people but now forced "open for exploitation" (Indonesia-Relief News). In spite of a moratorium on logging in Aceh implemented pre-Tsunami, extensive illegal logging is currently taking place in Aceh forests, this is usually referred as related to a so-called "Timber Mafia" situation, this term is used to describe a consortium of government officials, army, police, businessmen, etc who allegedly conspire together to gain large profits from the illegal logging of the forest estate. Problems in getting legal and sustainable timber supply for reconstruction are frustratingly experienced by almost every agency over the past year and this situation could continue for longer.

The Government of Aceh (represented by BRR regarding reconstruction) is reviewing its timber policy in light of the Tsunami and the need for timber for recovery. The acting Governor is in favour of a "Green Aceh" with no logging and supporting WWF and other conservation NGOs' programmes promoting the use of imported timber from sustainably managed forests for reconstruction. This is also supported by the Ministry of the Environment. On the other hand, Government of Aceh realized the tremendous needs for legal timber supply within the area. At the end of 2005, Indonesian Ministry of Forestry decided to restore forest concession (HPH) to 11 companies in Aceh to enable them to supply timber needed for the Aceh reconstruction and agreed to increase timber quota for Aceh to 400,000 cubic meters for 2006. This decision had to be made since timber suppliers from other provinces, such as Riau and Kalimantan, are reluctant to cater for the needs in Aceh due to high cost of transportation and the complicated process of applying for legal documents (i.e. SKSHH) to facilitate the transportation.

It is estimated in a recent survey (BRR and The World Bank 2006) conducted by BRR and The World Bank that bribes and illegal payments that truck drivers pay on the Banda Aceh - Medan road to corrupt police, military, state officials and preman (criminal) groups at various security posts and weigh stations are Rp. 340,000 on average (single trip on either direction). This not only constitutes a major cost for timber transportation but also has negative influences to potential timber dealers from outside provinces. However, the number of illegal payments experienced a significant decline in last 3 months associated with the pull-out of troops and police from Aceh province mandated by the Helsinki peace agreement.

There are other specific problems in timber procurement in Aceh, such as the legitimacies of importing timber and associated timber treatment methods. It is partially due to confused and sometimes conflicting information from different government sources, which could only be explained as internal uncertainty and inconsistency with Indonesian timber policies or failure in execution of established standard regulations. A list of 25 local timber supplier companies approved by BRR was given to representatives from various NGO's during a BRR's timber policy meeting in July 2006, which several days later was reduced to a list of 5 and handed out to local project managers during another local staff meeting. These were only recommended as reliable and not guaranteed as legal. The responsibility of ensuring legality of procurement with those companies remains on NGOs' shoulders. It is almost impossible for any organisation to take on such a big risk (even one piece of illegal timber will result in the whole package being confiscated) and continue operating.

3.2 Timber procurement procedures

In spite of these difficulties, timber for Aceh reconstruction is still procured legally and sustainably, or at least non-illegally and non-unsustainably, from some sources to some organisations. All of them can be categorized either as locally supplied or internationally imported/donated. The procedure followed in each will be introduced and generally reviewed:

3.2.1 International timber procurement

A flow chart of international timber procurement procedure has been developed as below based on an introductory paper of suggested purchase flow prepared by Ralph Douglass from British Red Cross (Douglass July, 2006).

1. prepare house design and detailed Bill of Quantities	2. prepare purchase documents: a. Request for Quotation, b. Technical specification schedule, c. Proforma Invoice	3.send above documents to potential suppliers and invite to bid
		4. submission of bids and tenders evaluation
7. the Irrevocable Letter of Credit (ILC)[2] prepared by purchaser's bank accepted and confirmed by supplier's bank using the information in Proforma Invoice (2c)	6.successful tenderer accepts the offer and submits a Proforma Invoice (2c), thus a contract relationship is formed	5. notify successful tenderer and confirm intent by issuing a purchase order
8.production initiated		
9. shipping schedule organised and notified to the purchaser by the supplier	10. shipping documents[3] sent to the purchaser by the supplier on port of departure	11. purchaser applies to the BRR for tax free gift status on the basis of being a registered tsunami reconstruction programme in Aceh
		12. ILC payment and documents exchanges occur
	14.following logistics from ship at arrival port (Belawan, Medan) to final destination	13. purchaser or its shipping agent arranges customs pre-clearance, phytosanitary etc. using the shipping documents and support letter from BRR

Table 1: Flow chart of international timber procurement procedure for Aceh reconstruction

[2] the basis and payment terms of international timber trade, almost no suppliers will start purchasing logs or initiating production without a satisfactory ILC confirmed by their bank first.

[3] including documents of clearance of goods through customs and quarantine requires: a. Invoice b. Packing list c. Phytosanitary certificate from port of loading d. Air Bill or Bill of Lading (B/L) as a substitute for other documents but only possible for a temporary period

Imported timber from New Zealand or Canada using the above procedures has usually been treated as a Hazard Class H3.1 standard for an above ground application. The specific treatment method is LOSP (Light Organic Solvent Preservative) rather than CCB and CCF used in Indonesia. The prices range from USD$420-590/m3 CIF (Cartage, Insurance and Freight) at Medan depending on required grade, treatment and processing options, while local timber prices are usually within USD$350 – 550/m3 from legal sources. Although the price is understandably higher than the local one, there are several advantages of importing timber for the Aceh reconstruction.

The first advantage is the longer and guaranteed durability and protection from weather changes and insects and fungi attack under Indonesian conditions. It has an internationally recognized guarantee of sustainable management and production of timber with other internationally recognized 3rd party certification and audit of treatment standards, certificate of origin and chain of custody. Another advantage is the large amount available (30,000 – 40,000 m3/month if long term orders are placed) while uncommitted local supply is limited to approximate 1/10 of that from international sources. The supply chain is simplified and bureaucratic process of applying SKSHH[4] and other legal documents from the Government of Aceh could be avoided. Most importantly, for every log sourced internationally for use in Aceh, one tree from local tropical forests could been saved.

However, some disadvantages are obvious and make this option less attractive when decisions are made at an individual organisational level. Besides the higher prices, longer delivery schedules (at least 4-6 weeks, but generally believed as 10 weeks) often excludes it as an option. The required amount of timber is limited at each time of procurement thus the large availability of international sources is no longer an advantage. This is partially due to the lack of overall supply chain management and communications between procurement and project teams. A large order of timber, could be streamlined and procured at a lower price, then subdivided into small packages with only several hundreds cubic meters each and procured once in a while creates a longer and complicated timeline. Storage of a large amount of international timber is another problem because of the associated demurrage charges that are extremely expensive if the shipment has to be left at the port. Timber is a natural product that must be kept dry and out of direct sunshine if possible. Thus the warehousing facilities are essential in the logistics of transporting timber from port to construction site, while local timber could be delivered to the site at vendor’s expenses as required each time. The uncertainty of legitimacies within the Indonesian context related to imported timber, together with issues related to donation and standard treatments required, further contribute to the unpopularity of international timber procurement in Aceh.

[4] a legal document for cross-provinces timber transportation in Indonesia, only valid per truck per travel

3.2.2 Local timber procurement

Similarly, in order to understand the local timber procurement procedure, a flowchart developed and handed out as a suggested guideline by BRR is attached below:

Procedure for obtaining recommendation of timber transportation
Program Rehabilitation and Reconstruction NAD-NIAS

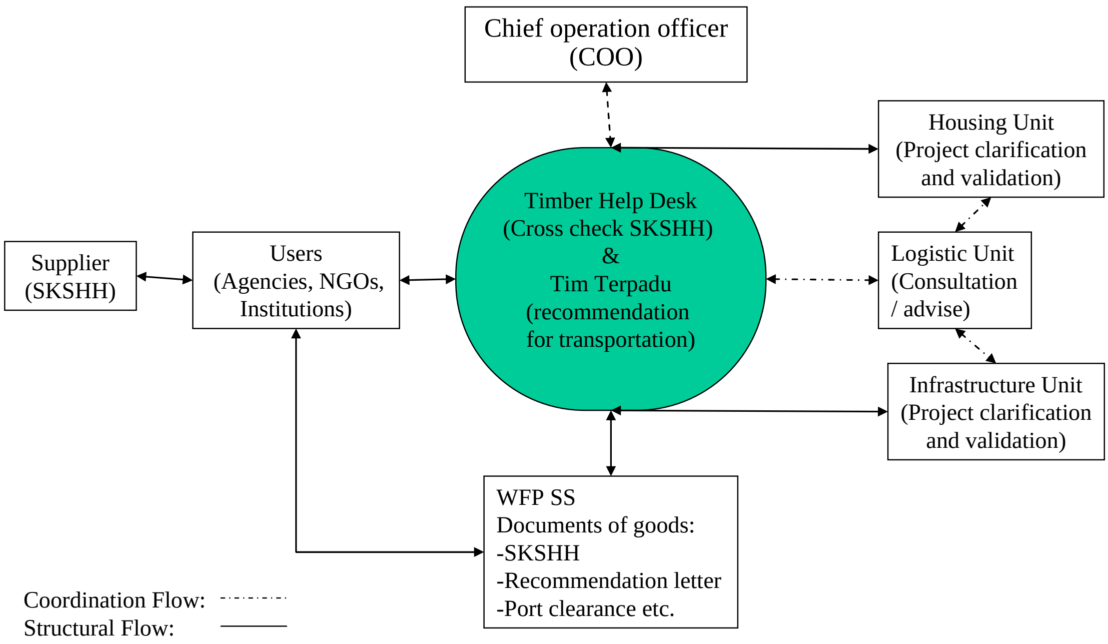


Table 2: Local Timber Procurement Suggested Procedure from BRR

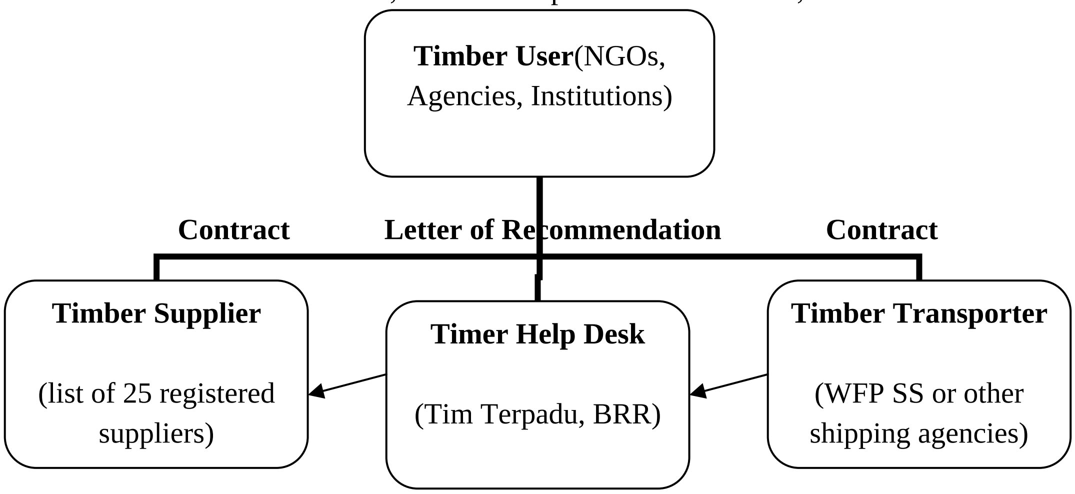
Although aiming at providing recommendations for timber transportation, this flowchart could also be used as a guideline for local timber procurement and associated logistics. There are some terms used only in Indonesian timber industry that are worth explaining. The big circle in the flowchart represents Timber Helpdesk and Tim Terpadu in BRR headquarter, the most important interface to users, suppliers, shipping agencies and other departments in Government of Aceh. Timber Helpdesk was designed by BRR in order to address timber issues for reconstruction and rehabilitation in Aceh and Nias. It has a dual role to facilitate the demand and supply of timber and to monitor the timber used for reconstruction within this region. SKSHH appears many times within the flowchart, as explained in footnotes before, it is a set of documents used to define the legality of timber and it is required when the log is transported from the concession companies to the industry or when semi-wood products are ready to be marketed and transported to their final destination. It is worth noting that SKSHH is not required for imported and donated timber.

A typical procedure for local timber procurement could be categorized into 3 steps with different relationships between timber user/ purchaser and other involved parties, demonstrated below:

Table 3- Typical Procurement Procedure for local timber supply

As can be seen from above table, in order to procure local timber, the user has to contact a



potential supplier based on the names registered with BRR in step 1. Then the classical tendering process needs to be completed within this step and an agreement or formal contract needs to be entered into with the preferred supplier. After this, the user moves to step 2 and submits a request to Timer Help Desk or directly to Tim Terpadu in BRR for a Letter of Recommendation to purchase timber. In order to process this request, Tim Terpadu has to check with its Housing Unit and/ or Infrastructure Unit for the project clarification and validation to make sure that the user is permitted to order timber and that the amount and type of timber requested is in accordance with their needs (see flowchart in Table 3). Photocopies of the user's Project Concept Note5 and the Contract in previous step are required in order to issue the recommendation letter. Then in step 3, the user has to provide photocopies of documents gained from step 1 and 2 (Contract and Letter of Recommendation) together with an order request to the timber transporter and enter into another contract for transportation. The transporter recommended by BRR to reconstruction agencies in Banda Aceh is the shipping services provided by WFP (World Food Programme).

Overall, it is important that timber users understand the definition of legal timber and the assurance measures in obtaining only legal timber. Legal timber as defined in a BRR guideline (BRR July, 2006), means that the timber is harvested from legal concessions in accordance with national regulations. Legal concession is a legal timber company that holds a permit for forest utilization from the Ministry of Forestry. The user can purchase timber or timber products directly from merchants, but the responsibility for obtaining legal timber remains that of the user. It is recommended that all the timber bidders for the Aceh reconstruction are required to provide valid forestry permits as well as SKSHH as a pre-qualification for tender.

[5] Project Concept Note should be approved beforehand by BAPEL BRR, the executing agency.

3.3 Review of other options

Alternatives to limited timber supply and other options for sourcing materials for construction are explored and reviewed by organisations involved in the Aceh reconstruction. Those alternative methods and suggestions include using steel trusses (or steel high-pitch roof), windows, doors and ventilation frames or coconut trees as structural component as replacements to timber products.

The high prices associated with using steel trusses as replacements to timber are the main obstacle. Several factors may contribute to the problem. It is understandable that steel is more expensive than timber, but this shortfall could be reduced if less steel is needed for a roof than the amount of timber needed for a timber truss. Actually, a steel high-pitch roof requires much less steel in volume than a traditional timber truss roof. The high price is partially because the steel roof systems commercially available now are in mass production, mainly cater for the needs as factory storage and heavy industry buildings. The pricing of steel roofs for Tsunami relief houses could be significantly reduced if all the reconstruction agencies with the same intention in Aceh organize their individual requests into a bulk order and choose both local and international companies with reliable reputations for a competitive tender for mass production. However, this is moe easily said than done. The current coordinating agency BRR has growing power and may be able to do this for its prefabricated houses in the future. Another concern about the use of steel trusses is the acceptance by the community. People are more conservative in remote areas and it is still unclear whether they are willing to move into a “light and shining” steel roof house. This will require a significant amount of on-site community participation and socialization beforehand.

Coconut trees as another source for timber as “palmwood” is a relatively new process but has huge potential to ease the pressure on the world’s rainforests, especially in Banda Aceh coastal area, as an ecological substitute to endangered and limited hardwoods. They usually come from farmed plantations of old coconut trees and really are an enormous source of timber that until now have been a wasted by-product from the fruit and food industry. In recent years people have recognized and explored the potential use of this vast, alternative supply of timber and found that it performs as well as or even better than traditional hardwoods.

Usually, the outer, harder part of coconut trees is used in structural materials for building construction, flooring/decking and furniture design, while its relatively soft inner core is suitable for cladding, screening and homewares. These could be used as profitable by-products for the milling workshop owners if mass production of coconut timber for construction is feasible in Aceh in the near future. Another advantage is that the coconut palm is branchless; palmwood is free from knots, which makes it an ideal timber. The issues related to the level of acceptance by the affected community and forestry authority remain. The mass production of coconut timber in Aceh remains a good theory. However, since more and more research results and real life experiences in favour of this option become available internationally, it is a good opportunity to explore this idea further in Aceh using a government or community-based initiative to cater the massive needs for timber.

4. Conclusions and recommendations

The needs for improved communication between reconstruction agencies and their material suppliers are well recognized, but hardly addressed. As mentioned earlier in the SCM literature review, buyers and suppliers must commit a greater amount of information and be willing to share sensitive information to achieve increased levels of supplier performance. Good communication is the basis for building a long-term relationship with reliable suppliers. This should be encouraged in order to reduce the supplier base and minimise the administrative or transaction costs associated with managing a large number of vendors. Certain certificates or well-designed criteria for pre-qualification will contribute to the supplier selection process and supplier base consolidation (e.g. require timber bidders for Aceh reconstruction to provide valid forestry permits as well as SKSHH before further consideration of their tenders). Integration, another key principle in contemporary SCM, is suggested in the Aceh reconstruction practices at both supplier and logistics levels.

In relating to timber procurement process, the procedures of international and local timber supply for reconstruction in Aceh are reviewed in the paper followed by discussions on alternative ways of using steel trusses or coconut timber as solutions to the current problem. It is suggested that reconstruction agencies should seek every possible way of using local timber sources with policy clarifications and transportation suggestions from local reconstruction authority BRR, while exploring the legal, economic and logistic feasibility of imported timber. In order to facilitate the process, it would be better to have an overall procurement plan for the whole project rather than the range of small ones before starting any negotiation with potential vendors. This should streamline the supply in later stages and result in a better supply arrangement. More studies are required into the use of coconut timber. It remains an attractive potential for rural areas and isolated islands when policy barriers have been removed. The possibility of milling and use of seized timber or timber from other sources should also be investigated.

The use of familiar and locally available materials for reconstruction should be encouraged. The sustainability dilemma with the use of timber is the balance between the preservation of the environment and the provision of housing. The supply of timber offshore might provided great relieves at initial response, but in long term, it means that the important economical "kick start" provided by aid in country (and specifically in Aceh) is lost and the aftermath are housed people in a context of greater poverty. This leads into the need for alternatives such as the use of coconut timber and possible substitutions for the major uses of timber in house reconstruction.

Recycling certain construction materials from damaged houses remains another possibility since most steel doors and window frames from the disaster were not seriously damaged and are in large demands. Substitutions could be the use of light gauge steel sections, roofing that can span without the need for timber trusses, and different door and window frames. Furthermore, there is also the option to use shorter life span materials for doors and windows with the idea that they would need to be replaced earlier than usual (lowering quality). Although more expensive than timber, steel trusses could be a back up option given the short time and high demand. With a more integrated supply chain, the price could be lowered with mass production. This could be made possible with joint efforts of other reconstruction agencies.

SECTION XI

DEVELOPING THE LAW CURRICULUM IN BUILT ENVIRONMENT EDUCATION

The Teaching of Law to Non Lawyers

Carrie de Silva Ll.B (Hons) MA

Rural Practice Advisor, College of Estate Management
cdcowap@harper-adams.ac.uk

Abstract

Teaching law to non law students can raise concerns of perceived relevance, accessibility, engagement, purpose and pedagogic issues surrounding delivery. This paper considers these matters against the background of law teaching on the RICS (Royal Institution of Chartered Surveyors) accredited rural practice estate management programme at Harper Adams University College. Various teaching methods engaged by the authors are explored, with particular concentration on the introduction of case studies / scenarios at an early stage of studies to ensure the relevance and practicality of the course, in the context of future careers, is better understood by all students.

Key Words : law, teaching, non-law students, estate management.

1. Background

This paper is based largely on the experience of teaching law to students of rural land management at Harper Adams University College.[1] Harper Adams was, until 1995, known as an Agricultural College and was founded in 1901 on the monies left for the purpose by Thomas Harper Adams upon his death in 1892. The College occupies a rural site in north Shropshire and has a working farm of 500 acres together with 175 acres of woodland. The agricultural roots of the college are evidenced by signs outside each classroom urging students to remove their wellies before entering! The designation University denotes degree awarding status and the word College indicates a limited range of subject matter. In 2007 we became the only land-based HEI to have research degree awarding powers.

Agriculture is still a major area of operation with other key subjects being agricultural and off-road vehicle engineering, countryside and environmental management, agri-food business and marketing, rural leisure and tourism, veterinary nursing and, the course with which the authors are most closely involved, land management, an RICS accredited course aimed predominantly at prospective rural practice chartered surveyors.

[1] For a useful comparative discussion of the legal content of construction and surveying courses across seven institutions, see Hutchinson (2005).

Law modules, or modules with a substantial legal element, delivered to students of land management at Harper Adams include :

- Law for Estate Managers (first year introductory module)
- Planning and Environmental Law and Practice (second year)
- Agricultural Tenancy Law (final year)
- Business, Residential Tenancies and Land Law (final year)
- Revenue Law and Statutory Valuation (final year)

Other modules, such as Taxation and Rural Professional Practice, also have a substantial legal aspect and use the materials and techniques of the law.

The subject matter and learning outcomes have evolved with reference to various sources. Several members of staff are practicing chartered surveyors, examiners for the RICS professional qualification, members of the RICS Rural Faculty Board and members / examiners of other relevant bodies such as the CAAV (Central Association of Agricultural Valuers) and the ICF (Institute of Chartered Foresters) and are thus well placed to know what students require in their future working lives, as is vital on vocational courses. A recent questionnaire to rural practice surveyors seeking course evaluation highlighted law (notably land law and taxation) as being of major importance. This echoes studies into the teaching of law on other non law degree courses (see Monseau, 2002 based on Finance students at Rider University, New Jersey, USA), and indeed within built environment education itself (Morris 2007). The appropriateness of questioning of practitioners on the content of academic courses has been doubted (Brack, 1997) but the focussed nature of a professional accredited degree would seem to validate this approach, indeed QAA (Quality Assurance Agency) codes of practice urge employer liaison (QAA 2000).

The RICS qualification requires students, in their two years pre-qualification work experience (the Assessment of Professional Competence - equivalent to a solicitor's training contract), to gain experience in many 'competencies' (RICS, July 2006, i) and, of these, many are law based or have a substantial legal element, including :

- Access and rights over land
- Building control - legal / regulatory compliance
- Capital allowances
- Capital taxation
- Compulsory acquisition and compensation
- Contract practice
- Housing management and policy
- Landlord and tenant (includes rent reviews and lease renewals)
- Planning
- Procurement and tendering
- Purchase and sale

In addition to substantive competencies, the overall objectives of the APC is that students demonstrate awareness of the 'professional and commercial implications' of their work and they have an 'up-to-date and developing knowledge of legal and technical matters' relevant to work and the law of the region or country in which they practice (RICS July 2006, ii).

The relevance of law on any business degree needs no underlining (Byles and Soetendorp, 2002) and the above gives an introduction to the very specific context and relevance of teaching law to prospective chartered surveyors. . In addition to the substantive content of a law module, in considering the QAA objectives for honours degree students in a number of disciplines, the study of law clearly develops a range of transferable skills. In course accreditation, the land management degree at Harper Adams makes reference to the QAA subject benchmark statements for Agriculture, Forestry, Agricultural Sciences, Food Sciences and Consumer Sciences (QAA, 2003) and General Business and Management (QAA, 2007).

Intellectual skills raised in the QAA subject benchmark statements include :

- The ability to define and solve problems
- The ability to analyse, synthesise, summarise and critically evaluate information
- The ability to integrate lines of evidence from a range of sources to support findings and hypotheses
- The ability to appraise academic literature and other sources of information

Practical skills include :

- The ability to apply a range of methods to solve problems
- The ability to present research findings in a number of forms

Communication skills include :

- The ability to seek out, recognise and use a range of information sources
- The ability to communicate effectively in written, graphical and verbal forms

ICT skills include :

- The ability to use the internet critically for communication and information retrieval

Law is also highlighted as relevant subject matter in the Building and Surveying benchmark statements, notably : '… *law relating to land tenure, use and development of land which could include building control, statutory planning, health and safety, project procurement, dispute resolution, employment legislation, equal opportunities* …'. In the understanding and skills section the statement also stresses legal principles and the legal context (QAA, 2002). Although in designing the law modules at Harper Adams the subject discipline benchmarks have been referred to, others may conclude that they also need to refer to the Law benchmark (Byles and Soetendorp, 2002).

This paper concentrates on teaching law in the context of the requirements of a professional body (the RICS), and many other non lawyers undertaking legal studies would have a similar remit (e.g. accountancy students). However, law is taught across disciplines where other rationale are at play, such as the concept of citizenship (Byles, Linda and Soetendorp, Ruth, 2002) or business (Skwarok, 1995) and the problems and approaches relevant to our land management students may well be relevant in other environments where law is a vital element of vocational preparation but is not central, either for work or in students' perceived hierarchy of importance (Lampe, 2006).

Having established that law needs to be taught for substantive content, to comply with professional, educational and business needs and to develop transferable skills beyond the acquisition of core knowledge - what problems have been encountered in attempting to impart the law syllabus to these non law students?

2. Academic Range

Some issues have been raised due to the wide academic range on arrival, of students accessing the course, a result of the very specific professional focus of the course and the limited range of institutions offering a rural practice specialism.[2] We have students ranging from those with three, or even four, A grade A2s to students together with entrants holding a National Diploma in Agriculture, access course transfers, HND transfers and GNVQs. This level of academic diversity - means that teaching methods, particularly in the first year, need careful consideration (Davis, 2003).

As a College, we have a higher than average number of students with dyslexia,[3] perhaps due to the practical / vocational nature of many of our courses. As well as the obvious problems with written English, dyslexia also compromises attention span, the ability to take notes and a myriad of other skills which can no longer be taken for granted in higher education (Association of Dyslexic Students in Higher Education, 2007).

3. 'Law is Irrelevant'

Some students clearly understand the relevance of their legal subjects, particularly so after their work placement year (all Harper Adams BSc degrees are four year sandwich courses). However, although, as lawyers we might live and breathe Lord Wright's : '*Law in its own way covers the whole range of human activity - there is no side of life which it does not touch …*' (in Gower, 1950) others, who have not really addressed the practicalities of what their chosen profession actually involves, wonder what law has to do with surveying and valuation (Allen, 2006)! Any hope of effective teaching requires, as a point of commonsense, underpinned by academic study, that the raising of student awareness of relevance and of student engagement is constantly to be strived for and monitored (Ramsden, 1992 and Corbin, 2002). Morris (2007) suggests that the goal in teaching law to built environment students is twofold: to be able to work intelligently with lawyers, and to keep themselves out of trouble through the practise of 'preventive law *and its counterparts, preventive leadership, preventive networking and so on*'.

4. 'Law is Hard'

A broad range of areas are covered although, particularly in the introductory first year module, they are not covered in any great depth. Nevertheless, the wide range of material to which students are introduced and the unfamiliar terminology makes the subject forbidding for some. This is not the place to explore changes and any perceived 'dumbing down' of

[2] The Universities of Cambridge, Reading and Aberdeen offer closely related courses but only the Royal Agricultural College has a direct equivalent.

[3] In 2005/06, 16% of HAUC (Harper Adams University College) students declared a disability (HAUC Registry 2006), compared with a national average of 7.9% (Houghton and Wray, 2007). Dyslexia was the disability of 85% of that 16% (i.e 13.6%).

secondary education - we are where we are (Datta and McDonald-Ross, 2002), but it is clear that the written language of law can be unfamiliar (Douglas, 2004), inaccessible (Christudason, 2004) and generally overwhelming (Allen, 2006).

The perceived demands of Law modules are often exacerbated by comparison with other modules. There has been a consensus, following discussions in Course and Examination Boards, that the level of the more testing subjects (Taxation and Agricultural Tenancy Law have been particularly singled out) is appropriate and that all modules on a course need not be of precisely equal demands, if such an exact science were possible.

5. Law Lecturers

A final issue that can arise in the teaching of law to non lawyers, which should not be overlooked, is the background of the lecturer. Those who read law a considerable number of years ago may be heavily immersed in 'black letter' content, unimaginative delivery styles and the traditional domination of the study of sources of law (Soetendorp and Byles, 2000) probably through the medium of lectures, tutorials with a heavy pre-reading load and assessment through essays. There has been, then, the temptation to develop learning through the instrument of primary sources of law (Carrington, Schlegel, La Piana and Kalman, 1995) with a somewhat narrow pedagogic range (Carter and Unkerlesbay, 1989).

That a blinkered concentration on cases and statutes, with no reference to context and the wider world, is limiting was recognised over 100 years ago by commentators such as the estimable Oliver Wendell Holmes : '*For the rational study of law the black-letter man may be the man of the present, but the man of the future is the man of statistics and the master of economics.*' (Holmes, 1897). It is, then, clearly apparent that the black letter approach is not appropriate to courses where, in particular, (a) the students will not / cannot engage in the volume of reading and (b) where many subjects have to be covered in less detail. In an era of widening participation and the atypical student, limited reading may be due to a myriad of reasons such as work and family commitments or health issues and must not simply be seen as a reflection of academic skills on arrival to higher education. A defence or denial of black letter teaching for *law* students is left for others to consider.

We are, then for reasons of practicality and accessibility, into the realms of 'translating' the law rather than having students make extensive use of primary sources. The materials are reduced to a core. Although there are dangers in this (Ward and Slater, 1990) there is a considerable need (regardless of an academic ideal), in many of the legal subject areas, to get across a level of 'prophylactic law' - a minimum level of knowledge to avoid dangerous or expensive mistakes (Soetendorp, 1996) in professional life. To recognise legal issues, to avoid causing problems, and knowing when to refer to a lawyer is what is needed. Side arguments about the purposes of higher education, the development of abstract thought and learning for its own sake are important and diverting questions for another forum but it is taken as a given for the purposes of this paper, that the law teaching is directly related to the education of future surveyors, rather than an isolated academic frolic. An emphasis on skills (Cox, 1992) and context (Saunders and Clarke, 1997 and Tyler, 1995) rather than purely 'knowledge' (Harris, 1992) has become a feature of the law, as well as non law, curriculum, as encouraged by the Marre Report (Committee on the Future of the Legal Profession, 1988). This enables a greater interaction between law and non law pedagogic literature and lecturers with an inter-disciplinary relevance that was, perhaps, not previously the case.

The need for context is ideally embedded in course objectives (Woodcock, 1989) - how will the law affect the working life envisaged by the students (Endeshaw, 2002, and see the quotation from Morris 2007 above)?

These, then, are some of the problems which the teacher of law on a non law course needs to work through. There needs to be a consideration, *regardless* of practical problems, of what the students actually need to get out of their law modules. Subject benchmarking statements, professional guidance (both from the RICS Practice Guidance and anecdotal evidence from practitioners) and the experience of colleagues has been drawn on to determine the mix of factual, substantive knowledge and the transferable (Committee of Inquiry into Higher Education, 1997) research and evaluation skills needed on the law modules which also seek to support ' … *diversity, flexibility and learner autonomy*' (Hinett, 2002). Over all of this is a sense that, although not teaching future lawyers, there are key features to be transferred across the disciplines, which might encompass :

- where the law is to be found
- that the law is constantly changing (Soetendorp, 1999)
- the ability to identify legal issues (Cownie, 2004)
- the ability to go beyond the surface learning of facts, through to a deeper understanding (Marton and Säljö, 1976 and Meyer and Land, 2005)

This latter ambition for our non-law students has often been ignored by vocational law modules which have resorted to a diluted delivery of facts, without the contextual framework offered to law students (Broadbent, 2005).

We would argue that the context of another profession adds a further requirement, the ability to solve multi-faceted problems which contain a strong legal dimension. In this context law is only one of several competing frameworks, none of which will 'win' but all of which must be reconciled for an optimum technical or client-orientated 'solution'. This is normally at its most evident in practice, and the final assessment of the RICS APC can be interpreted in these terms. Within the academic component of professional development, the multi-faceted complexity of professional problem-solving can be seen to develop from year to year. Therefore first year students might solve problems within a single dimension, while final year students will have to incorporate several competing academic and professional paradigms. Although Morris (2007) has argued that : '*Both students and practitioners alike need to see that various subjects and disciplines are like islands of the sea, all seemingly standing apart and discreet; but the law is the sea itself, and under the covering water, all the islands are actually connected in one*', this is perhaps to overstate the centrality of the law in comparison with the other disciplines. A similar analogy may be drawn for economics or management studies for example; nevertheless the general idea has considerable utility.

The remainder of this paper relates to the attempts to improve the engagement of students and the effectiveness of module delivery as measured by attendance, tutorial engagement, exam performance and the quality of written work.

6. Lectures

Given the oft quoted ineffectiveness of the lecture (Gibbs and Habeshaw, 1996), why is the average module still based around this ‘traditional’ (Le Brun and Johnstone, 1994) medium? The lecture is almost inevitable due to the size of groups involved which, at Harper Adams are not large by many standards but are too large for other methods of teaching for at least part of the course (up to 90 students). Other methods can and are being explored, such as the delivery of materials by internet / intranet and having fewer, small classes, e.g. meeting once every fortnight with a far greater emphasis on student centred learning (di Napoli, 2004) which is, of course, in line with Dearing (Committee of Inquiry into Higher Education, 1997) and other reports (Department for Education and Employment, 1998). However, the lecture it is, for now at least.

Much has been written on ways to improve lectures (e.g. Jenkins, 1992; Gibbs, Habehsaw and Habeshaw, 1997; Fry, Ketteridge and Marshall, 2003 and, particularly enjoyably, Blight, 1998) and over-emphasis on black letter content can do little to ameliorate the problems noted above. Although keen to develop effective ways of engaging and educating non-law students, the dissemination, or at least introduction, of a base of information is still most effectively done through the lecture and although primary sources do not hold a central position (Carrington, 1995) for the education of non-lawyers, an explanation of the existence and mechanisms of primary sources of law still usefully forms the firm foundation onto which a more free-ranging case study methodology can be constructed.

7. Notes

To avoid the problems of incomplete notes and to aid private study, the notes for the entire first year law module have been bound into book form which includes :

- lecturer prepared study notes of the ‘translation’ order mentioned above, i.e. abbreviated key points of law
- a small number of law reports in full and extracts from statutes
- gapped quizzes and questionnaires, either for revision or to take the student through the self study of a discrete subject area
- a few oddments for added excitement, e.g. the Carbolic Smoke Ball advertisement (*Carlill v Carbolic Smoke Ball Co.* [1893])

Although the notes do not obviate the requirement that students refer to text books (given the nature of the course, there is a limited requirement for them to refer to primary sources of law), it has been found that many text books, even when specifically for non-lawyers (the module reader is *Estate Management Law*, Card, Murdoch and Murdoch, 2003) are not easily accessed by our students. Putting law into standard English (Asprey, 2003 and Balmford, 2001) and explaining terms which it does not always occur *need* explaining (Allen, 2006) aids teaching effectiveness and the retention of interest considerably (see Cruikshank, 2002). A regular vocabulary test carried out in week 1 of the first year including words such as 'dissenting' and 'rebuttable' gave rise to concerns as to how much of a lecture or demanding text was being followed, with a greater need for 'translation' materials.

8. Scenarios

In addition to the notes, the idea of a greater emphasis on problem based learning was developed through the introduction of a rather contrived 'Law Story', written as a starting point to underline the relevance of legal studies to the students' personal and professional lives. Each chapter takes no more than a side of A4 - a lot less in most cases - and on the back of each page a list of the legal issues is given, together with the relevant cases or statutory references. Having used Law Story in various ways, it has been found that giving it out towards the end of the semester is more beneficial when students (hopefully) have a chance of spotting some of the issues rather than being overwhelmed. Short periods of time at the end of tutorials are set aside to look at a given chapter with students working individually for five minutes and then coming together in small groups to see how many points can be identified.

9. Case Studies

The most fundamental development in teaching practice which has evolved to address the problems encountered in teaching law to non-law students has been the introduction of the case study as a *starting point* to learning. (That is 'case study' meaning problem / scenario, not in depth study of a legal case.) The aim is to lead the student to clearly see the relevance of their legal studies, to direct the lecturer away from too dry and formulaic an approach, and help make materials more accessible in giving purpose and focus to private study. Morris (2007) found that the majority of students wanted '*more detailed illustrations*' and case studies, '.. *perhaps for the vivid exemplary or story content of case reports, which are more accessible to new learners than 'black-letter law*.'

Case studies have traditionally been used after a body of legal rules and information have been imparted by lecture, addressing none of the problem issues raised above and resulting in students lacking engagement before they ever get to assimilate the information and attempt to reach the higher level educational objectives of analysis, synthesis and evaluation (Bloom, 1956 and Anderson and Krathwohl, 2001) to apply their knowledge. In an expansion of the 'Law Story' exercise, larger problem cases / scenarios have been given early in the module with learning centred around information needed to deal with the situation, i.e. self-study is focussed on the problem in hand.

An example of such a scenario, in the area of professional negligence with the added complication of contractual relationships, is as follows :

> Henry Harper-Smythe, FRICS FAAV, a chartered surveyor and an employee of Edwin Harper-Smythe & Co., carried out a full structural survey on a small Victorian cottage which Mr and Mrs Adams were thinking of purchasing for their daughter to live in whilst she was at university, for approximately £90,000.
>
> Mr Harper-Smythe was employed by the building society who were loaning Mr and Mrs Adams 50% of the asking price.
>
> There was considerable evidence of alteration in the house in the form of wall and fireplace removal. As a result of his examination of the property the surveyor submitted a report which valued the property at the asking price with no recommendation for any further work or investigation.
>
> Six months later the bedroom ceiling collapsed as, it was discovered, the support system had been compromised by the removal of a wall without the necessary reinforcement.
>
> There was extensive damage to the property and Miss Adams was badly bruised and severely distressed.
>
> **Advise Henry Harper-Smythe and Edwin Harper-Smythe & Co. as to their potential liabilities.**

Rather than starting with the rules of negligence and discussions of decomposing snails in Scottish cafés nearly 80 years ago (*Donaghue v Stevenson* [1932]), students can see immediately that the issues relate to work they may well be undertaking, or be closely involved with.

The evidence of the effectiveness of this approach is currently anecdotal but another year through the module will see the introduction of formal evaluation in terms of :

- attendance
- student evaluation a month into the module
- student evaluation at the end of the module
- a comparison with both examination results and qualify of question answers

Interim results, from student module evaluation and discussion groups, indicate a greater understanding of context and a slightly greater engagement with self-study, although this has had to be very carefully directed. Clearly, some of the problems which this approach sought to address would indicate that, once a student discovered or was told that a problem involves negligence, they are unlikely to engage in wide background reading around the subject!

There also needs to be a confidence on the part of the lecturer that there may be gaps in the imparting of what might be considered standard basic cases and statute law in a given area in exchange for a greater engagement and understanding of the legal implications raised in a practical situation.

A second example of a case study is drawn from a final (honours) year module in the same programme called Revenue Law and Statutory Valuation. This module addresses the relationship between the legal frameworks in which many valuations are undertaken, and the implications of this for valuation methodology and practice. There is also a wider practical dimension in that the work of the valuer in practice does not just stop at the preparation of formal valuation reports, but is also concerned with the negotiation of optimum outcomes for a client in practical land management and development terms. *Arthur's Yard* is a case study designed to tease out some of these relationships for students.

COMPULSORY PURCHASE - COMPENSATION FOR LAND TAKEN

1. Study the plans to see the location and proposals for Arthur's Yard.

2. Arthur's yard itself started life many years ago as a roadside petrol station, garage and cafe. Externally it has degenerated over the years to become a 'greasy spoon' paradise for bikers. In recent years he has built up quite a scrapyard to the rear of the premises with an unparallelled collection of British bikes, past and present, in it. This development just happened as time went along, without the formality of planning permission etc.

3. The area to the rear of Arthur's has been designated for housing development in the local development plan. The only access to this area is down the side of Arthur's, opposite Greenacre (a rather plush bungalow which obtained planning permission many years ago, but which in fact has never been built). However, this area is too narrow for access and Arthur has let it be known that he would be willing to make available a strip down the side of his premises (of which he has little need) to widen the accessway to acceptable standards. The problem with this is the burden of the restrictive covenant enjoyed by the owners of the Greenacre site preventing Arthur from building on this part of his property. It was made many years ago, before the nearby row of houses was built.

4. The outline proposal for a nearby new road has been known in the area for many years. To Arthur's astonishment, the detailed proposals for the new road show his entire premises to be required for the construction of a new roundabout. This has prompted a number of angry, but rather random, thoughts on Arthur's part :

   He had ambitions of a roadside restaurant or similar development on the new junction if it became difficult to continue the parts business with the new housing at the back;

   He should be compensated for the loss of the 'ransom' he was going to extract for access to the rear land, but now they have put in an access off the new roundabout!

   There is no way he is going without payments well above the odds for all the aggravation this has caused him!

They'll have to pay him to set up a new business just the same somewhere else; in fact they will have to provide the site and new replacements for some of the specialist bike-repairing machinery he has put together over the years (that will be some consolation as most of it is worn out anyway).

There aren't many specialist bike scrap yards around, and so that should be worth extra payments on the compensation as well.

etc. etc. etc

Now to the rather dry bit :

Arthur has appointed you as his expert advisor on these matters (good luck!). Identify and evaluate the issues raised as far as compensation for land taken is concerned.

As well as material on statutory compensation, you may also find it useful to refresh your knowledge of planning from earlier modules, and to consult a land law textbook on the circumstances in which restrictive covenants can be removed or discharged.

Students find this a challenging exercise as it integrates a knowledge of statutory valuation principles, the development planning system in the UK under which policies for the direction of new development are determined, valuation methods, and general land law concerning the circumstances in which restrictive covenants can be discharged or modified (including the criteria under which the Lands Tribunal will discharge a restrictive covenant). Finally the students can see how these various facets must be combined to generate a strategy for dealing with Arthur's requirements as a client - this includes the management of the client himself through the process. Fifty-four students studied the module in 2006/07, of whom 48 responded to an evaluation questionnaire. Of these students 46 students rated the module 'excellent' (21 students) or 'good' (25 students). Amongst the written comments offered by students of relevance to the use of case studies were:

> ".. makes compulsory purchase lively and interesting - quite a hard task."
>
> "Very practical examples when teaching"
>
> "Good up to date subjects and case studies"

10. Conclusion

The two case studies show how the complexity of professional problem-solving can be developed from a first year module with its emphasis on two complementary legal strands (contractual and tortious liabilities), to the final year module which seeks to integrate a number of disciplines which make up the modern estate management syllabus. Both case studies are grounded in an appreciation of the professional context in which students and practitioners must apply and interpret the law, while the latter study also provides an opportunity to explore some of the specialised legal decision-making machinery which covers landed interests (the role of the Lands Tribunal).

In conclusion, the teaching of law to a diverse range of students whose primary interests might lie well outside the content of the law modules requires careful thought, planning, a willingness to try a range of teaching and assessment ideas and the grace to alter and abandon 'pet' theories which fail to engage or prove effective.

It is hoped that the combination of course materials and delivery vehicles has, at least in part, addressed some of the problems in the law modules at Harper Adams and may provide some ideas for others.

Landlord and Tenant Law for Surveyors – A Problematized Case Study

Brodie McAdam,
Research Institute for the Built and Human Environment, University of Salford
(email: w.b.mcadam@salford.ac.uk)

Abstract

A lawyer new to higher education reflects on the initial delivery of a Landlord and Tenant Law module to Level 2 full time surveyors. The paper identifies specific challenges to learning that this delivery posed. These include the relative inexperience of the lecturer; the amount of syllabus to be covered; the tension created by the twin characteristics of the module, being at the same time both obligatory and, arguably, peripheral to the main degree; the aptitude and inclination of the students; and the teaching and assessment methods implemented. These challenges are contextualised against the assessment performance of the students. Having problematized the delivery, the paper assesses it in the context of current thinking regarding pedagogical 'best practice' for facilitating deep legal learning in non-cognate cohorts and proposes some areas for development..

Keywords: Law, Pedagogy, Non-Law Students, Teaching and Learning

1. Context and Methodology

1.1 Overview

This paper is a reflection on the delivery of a series of lectures on the topic of Landlord & Tenant law to level 2 undergraduates enrolled on non-law programmes by a novice lecturer. These reflections on practice were prompted primarily by the stark mismatch between the lecturer's expectations of student achievement and actual achievement as demonstrated by the end of course exam. The aim of this paper is to draw out ideas for the future development and improvement of this, and similar, courses.

1.2 Context of Lecturer

When I stepped into a classroom in February 2007 to deliver the first lecture in a series relating to landlord and tenant law, I was not within my comfort zone. Though, at 36, hardly in the first flush of youth, I was a novice lecturer.

Pickering [1] argues that the novice lecturer experiences to a heightened degree the feelings of isolation, uncertainty, multiple role conflict, dependency on management, expanding administrative loads and juggling work and home responsibilities, which have been identified as characteristics of the academic role by Knight and Trowler [2]. In the relatively short time I have been in academia since that 'inaugural' lecture, I have experienced all of those feelings, but on the day itself I was, if anything, bemused. Unlike Pickering's subjects who, though novice lecturers were expert in their field, I was a novice lecturer who, prior to preparing the lecture series, had only distant memories of learning (a small part of) the subject some 12 years earlier, while studying to become a solicitor.

As well as being new to the subject, my formal pedagogic knowledge was also minimal, being limited to an acquaintance with (an old edition of) McKeachie's Teaching Tips [3]. My informal pedagogic knowledge was a collection of largely unarticulated feelings regarding the 'right' way to teach, drawn from my own experience as a learner. Cownie [4] makes a persuasive case that legal academics who teach should be fully conversant with educational theory, failing which their rationale for their chosen pedagogic approach is 'a mere assertion of belief' [4:232]. Bailey [5] draws on Freire's concept of *praxis* - the union of reflection and practice – to argue that 'theory without action is a form of mental game playing and that action without theory is simply flying by the seat of your pants' [5:308]. Adopting Bailey's imagery, Cownie argues that the majority of academics are 'flying by the seat of their pants', because they are engaged in the action of teaching, without any knowledge of the relevant theories.

That aptly describes my situation as I commenced my lecture series.

1.3 Context of Learners

The course was delivered to a mix of Building Surveying students and Property Management and Investment ('PMI) students. Both these degree programmes are designed to conform to the QAA benchmark statement on Building and Surveying [6]. The programmes also benefit from accreditation from the Royal Institution of Chartered Surveyors [7] and the Chartered Institute of Building [8]. All of these sources of curriculum guidance afford some place to the learning of law, though, understandably, law is not accorded a leading role. The QAA guidance, for example, includes the study of what may loosely be described as built environment law (e.g. law relating to land tenure, building control, planning, dispute resolution, procurement, health and safety) as one of 6 themes which 'curricula may include as appropriate' [6:2]. Likewise there is a legal component to 2 of the 6 groups of 'knowledge and understanding which graduates are expected to acquire'[6:3].

These requirements are reflected in the proportion of law specific modules which the two streams of students must study at the University of Salford. Four out of the eighteen modules which comprise the Building Surveying curriculum (six modules per level, at 20 Credits each) are devoted to legal subjects. The PMI course has three law modules.

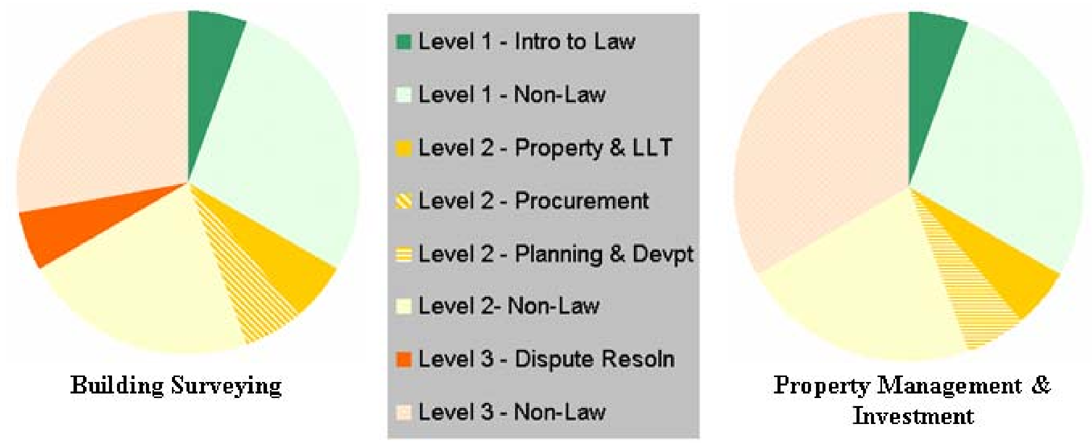

Fig 1. Comparative Breakdown of Legal Aspects of 2 Undergraduate Programmes

The course I delivered was the second half of the Level 2 module in Property and Landlord and Tenant Law. For efficiency the first half of the module is delivered to 4 cohorts of students, but only two of these go on to study Landlord and Tenant law.

1.4 Context of course

38 students were registered to the course, 24 in Building Surveying and 14 in PMI. Average attendance ran at around 24, and 3 students (1 BS and 2 PMI) attended no sessions at all; simply submitting coursework and attending the exam. Eleven face to face sessions were allocated to the course, each time-tabled for two hours.

Baderin [9] contends that the conventional learning and teaching method for undergraduate *law* courses is a combination of large-group lecture sessions and small-group discussion sessions,, these smaller sessions being designed to 'encourage student understanding of the subject area and to motivate and energize them to think creatively about relevant and appropriate issues' [10:335]. Similarly Tribe and Tribe, describing the situation some 15 years earlier, indicated that the prevailing norm was two hours of lectures per subject per week, consolidated by small group work [11].

The two hour slot earmarked for the course under consideration was allocated by the timetabling department on the basis of a one hour lecture and one hour tutorial. However, as only a single hour was provided either in teaching space or work-load allocation for the entire cohort's tutorial, the reality was that I had two hours per week with all the students together.

2. Approach to delivery

Absent any significant level of educational theory I approached the initial delivery with a positive, but inelaborate desire to get the students interested in the subject and so incline them towards learning.

2.1 Relevance of subject

One aspect of my conception was to encourage the students to engage with legal principles and primary legal sources in a way which replicated practice. It seemed intuitively right that highlighting links between the subject and the 'real world', particularly possible future career activities, would be more engaging for students and more likely to be remembered. Subsequent consideration of theory reveals that my 'assertion of belief' (à la Cownie) in this regard has some theoretical support.

Examined more closely, the core element of my 'belief' is the use of knowledge the students already have – the real world referred to above – as a foundation from which to explore the new knowledge covered in my lecture series. Such an approach finds its justification in many of the oft-cited pedagogical texts, including Biggs [12] and Bligh [13], and the innovation in law teaching described by Tribe and Tribe [11] is expressly based upon work done by Ausubel which highlights the value in facilitating learning by building from pre-existing cognitive structures.

The exercise I adopted which most clearly implemented this approach was conducted in my third lecture, which happened to fall St Valentine's Day. To encourage the students to think about the essence of the landlord and tenant relationship, I posited the macabre (and unlikely) scenario that the Capulet family, having no current requirement for *Casa di Giulietta*, were in negotiations with the Montagues who were interested in renting the premises to exploit as a tourist attraction. Students were formed into opposing teams, representing the landlord or tenant, and asked to draw up a list of issues that they, assuming their assigned role, would want to address. The students engaged enthusiastically and although the final result was simply the drawing up of a list of the sorts of conditions (as to rent, user, alienation etc) that tend to be found in leases, this was achieved by working from the students' own knowledge.

2.2 Primary Legal Resources

Another belief which underpinned my approach to course delivery was the importance I placed upon students personally engaging with primary legal resources, particularly reports of judicial decisions. This belief was based on my awareness that these resources provide access not only to the law, but also to examples of practical application, since in each case the tribunal must articulate a view of the prevailing law, and then apply that view to the relevant facts. Consequently I provided significant quantities of detailed case expositions, supported by provision of full transcripts via the Virtual Learning Environment ('VLE').

Whilst undergraduate *law* courses require considerable engagement with primary legal resources, this was a course where law was a subsidiary subject. The QAA benchmark statement for Law [14] suggests that where law is a subsidiary subject, in-depth study will probably be in other areas, and students are expected to engage with secondary resources - text books - rather than with primary legal sources. The same point is made by Soetendorp and Byles [15], who identify that a series of studies indicate the 'inappropriateness of teaching law [to non-lawyers] through the study of primary sources as outlined by statutory and case material'. The alternative approach often implemented is described – though not endorsed - by Soetendorp and Byles as 'prophylactic law' – where students bound for a particular profession or occupation are provided with a simplified set of fixed rules, which provide the bare minimum of knowledge to protect the student from breaching the law when in practice.

One solution to the law for non-lawyers problem posited by Soetendorp and Byles is a case study workshop, designed to encourage students to maximise their existing knowledge of the law and to contextualise it in their subject discipline. The justification for not exposing students to primary legal resources is that the intended learning outcome of the 'micro-module is to encourage awareness of relevance of specific law, not its detailed application'. In the context of my course, this approach is relevant – and resonates with the *Casa di Giulietta* exercise outlined above – but does not seem to offer a complete solution where more extensive learning outcomes are defined.

Allen [16] provides a thumbnail sketch of non-lawyers' responses to learning law. Student feedback indicates that law is considered difficult, with overwhelming quantities of reading, and confusion regarding how to study the subject. There is a certain inevitability that low marks and frustration on the part both of students and lecturers will ensue. However, Allen widens the debate by arguing that what is really at issue is not the characteristics of law *per* se but its position as a discipline secondary to the one which the students chose. This can impact student learning in a number of ways.

First, in terms of motivation, it may not safely be assumed that even the primary subject chosen is one which the student is keen to learn, potentially leaving the secondary subject foundering. Secondly, in terms of understanding, Allen draws on Meyer and Land's 'threshold concepts'. These are defined as 'concepts that bind a subject together, being fundamental to ways of thinking and practising in that discipline' [17]. A student who has succeeded in internalising a threshold concept is better able 'to integrate different aspects of a subject in their analysis of problems', whereas a student who has not internalised that threshold concept will 'have little option but to attempt to learn new ideas in a more fragmented fashion.' [17] Clearly, where a student is studying a number of different disciplines to varying degrees, the risk is that the threshold concepts of the subsidiary discipline are not grasped.

Allen posits that in law threshold concepts include an appreciation that much reading is required, specific disciplinary language (jargon) is used, and a particular approach to both problem-solving and writing is required. If this does represent an effective application of threshold concepts in the legal milieu, the corollary is that focus should be on encouraging students to 'get' these concepts – and that my initial insistence on exposing students to large volumes of primary legal sources may be misplaced; if the students are not guided to an understanding of legal discourse, then little may be gained by repeatedly exposing them to yet more such discourse.

Pickering cites the views of a novice lecture who had intially taken a purist line to lecturing, being reluctant to ‘flog’ his subject to those who were not interested, but his reflection on his first year’s experience indicates a more nuanced position:

> *‘The good students are here because they are interested anyway and they’re not a problem. It’s the students who are here because they weren’t sure what to do after finishing their A levels and they didn’t actually do very well in their A levels and they’re not committed to the subject. . . . And it’s trying to get them interested so that they then become receptive to the ideas and concepts that you’re trying to put across. And so there has to be some interaction so that you can gauge where their interests are. And it varies. . . . And you have to keep probing to see what makes them tick.*[1:326]

There are aspects of my own initial approach that could be described as purist, particularly my insistence on using large amounts of primary legal resources. What prompted my deeper consideration of this, and indeed, all aspects of my approach to the course was the shock of the exam results.

2.3 Exam Results

All but one of the 38 students registered on the course took the exam. I set the questions and marked all papers. The papers were anonymised until submission of marks, but I have since had an opportunity to correlate individual student marks to other data held, notably attendance records, and performance in course work.. Consideration of the data establishes that on average just short of 70% of Building Surveying students attended each session, whereas only just over 50% of PMI students did so, and the only occasion when PMI students outnumbered BS students was in the final revision session.

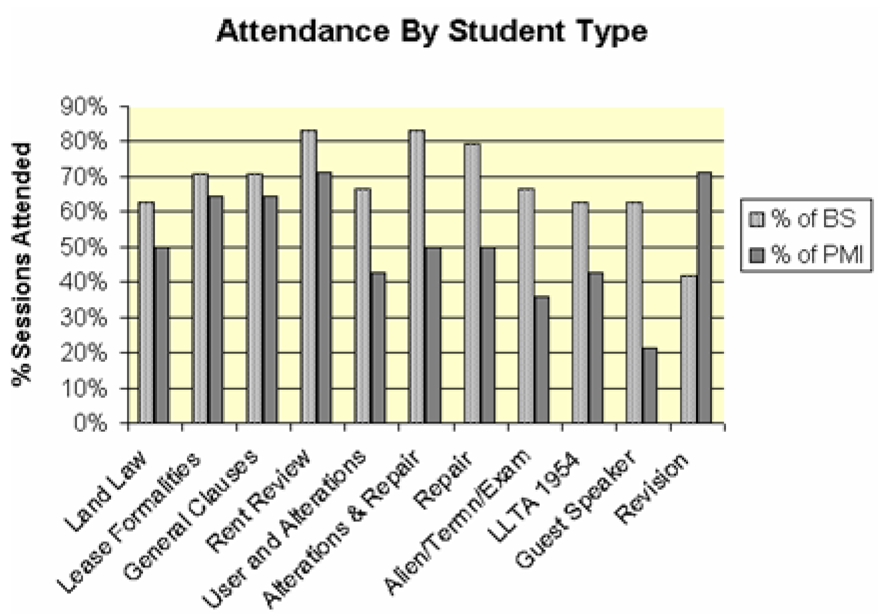

Fig 2. Comparative Attendance Figures

Despite these attendance figures, on average PMI students slightly out-performed Building Surveying students, gaining 56.6% on average as against 55.8%. Building Surveyors did do better in coursework, (63.4% as against 61.1%), but in the exam, whilst neither group did very well overall, PMI students scored on average 47.1% as against 43.6% for Building Surveyors. One interpretation of the figures is that, at best, on average there was no correlation between attendance at my lectures and student performance overall. This is most vividly illustrated in Figure 3:

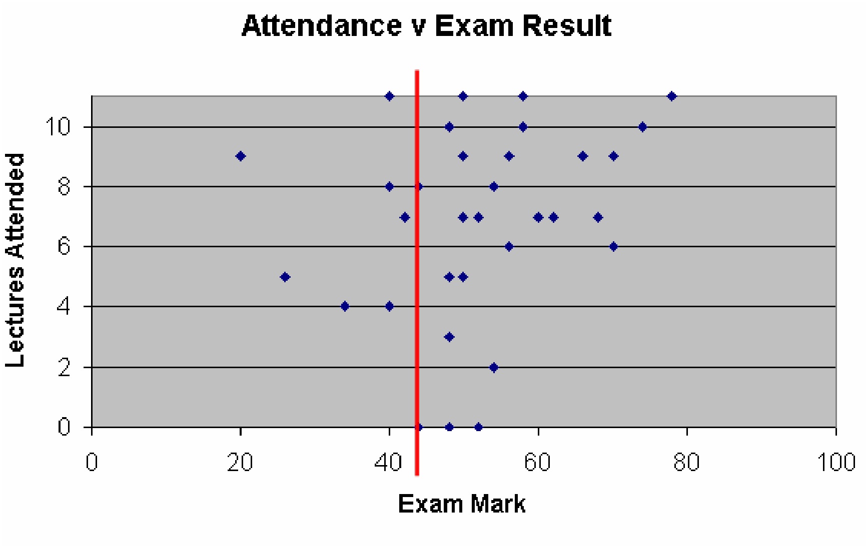

Fig 3. Plotting Lecture Attendance against Exam Result

The 7 results to the left of the red line are those students whose exam performance was less effective than the performance of any of the three students who attended no lectures whatsoever. There could be any number of variables which these figures do not make explicit, but an application of Occam's razor to analyse a situation where one student who attended every single lecture does worse in an exam than three who attended none, does tend to a conclusion that there are aspects of the delivery which could be refined.

2.4 Lecture Practice – The Good Points

Considered reflection on my practice does suggest that my lectures - as lectures - had quite a lot to commend them. Moreover, though they may have been manifestations of belief not theory, and were certainly examples of 'flying by the seat of my pants', along the way I stumbled across quite a few practices that are supported in the literature.

I adopted a pretty informal delivery style. I was keen to get input from the students and tried to bring the subject matter to life as best I could. This type of approach is arguably what Eble describes as a 'generous' attitude towards knowledge [18:207] whereby knowledge is freely shared with students, not retained as mysterious arcana by the academic 'priesthood'. Similarly, research into student attitudes and response to varying teaching styles is strongly in favour of *enthusiastic* lecturers (e.g. Hodgson [19], Coats and Smidchens [20], Murray [21]). As Ramsden notes [22:95], 'truly awful university teaching is most often revealed by a sheer lack of interest in and compassion for students and student learning'.

This is not a criticism that could fairly be levelled at me. During course delivery I captured student views on two occasions. First during the fifth session when I sought views via a stop/start/continue exercise [see Race and Brown 23:34] when 22 of the 38 registered students were present, and around 10 provided feedback; and again in the 9th session when I administered a Module Evaluative Questionnaire ('MEQ'). On that occasion 21 of the 38 students were present and 18 provided feedback. No comments specifically regarding lecturing style were captured on the first occasion, but in the MEQ 78% of the students polled noted as a positive the 'engaging' lecture style. This was the most unanimously expressed view by a factor of around 3; 5 other groups of positive points were noted, but each of these polled at around 30%.

I also structured my lectures carefully using diagrams to illustrate points, and picking images to associate with certain concepts. Research confirms that individuals are better able to recall sentences that have meaning than sentences which do not [24]. At a micro-level, this suggests the importance of lecturers using simple language to explain themselves, whereas at a macro-level it suggests the importance of giving students information in a logical and structured way [13]. Bligh further argues that it is not enough that the material actually has a logical structure, that structure must be shared with the students, and consistently and repeatedly referred back to, in a cyclical 'taking stock' exercise, as, otherwise, students risk losing the thread of the lecture [13:70]. There is also support for the use of visual representations to assist explanations, as these are more likely to be retained in long term memory [25], although the effectiveness of such resources depends not so much on the resource themselves but on how they are used [26]. This implies there must be a clear rationale for the choice of resources and a strategy for how they are to be used within the lecture to enhance student learning.

I also provided hand-outs, generally in the form of powerpoint slide printouts. I did not operate consistently with the timing of the provision of these; sometimes I provided them at the end of the lecture on the basis that I wanted the students to concentrate on what I was saying. Whilst the literature is supportive of the use of hand-outs, it is not supportive of providing them retrospectively in this way. Research indicates that handouts should be used to get students to make notes, not just to write down what is being said or to copy slides [27]. Creativity and variety in handout design, including short learning tasks to encourage interaction, enables students to make good notes in lectures [28]. If intended as a guide to the structure of the lecture with spaces to make notes, there is support for issuing these at the beginning of the lecture [13], whereas Neuble and Cannon indicate that handouts which provide additional or more detailed information should be issued at the end [29].

Whilst there remains considerable room for improvement, it is also encouraging that some of my intuitive approaches can be justified theoretically.

2.5 Lecture Practice – The Bad Points

The belief which arguably did most to shape my approach to course delivery was the belief that I had to cover all of the topics in the Module Specification. This document has a broad reach ranging from the doctrine of tenure, through adverse possession, and on into landlord and tenant law. Despite my belief that I had to deal with all items, fitting all that content into 11 two hour sessions was an impossibility and I rationalised coverage (see Fig 1). Nonetheless, I did endeavour to cover as much of the syllabus as I felt was possible.

In both the informal and formal feedback captures referred to above, a recurring feature was that I went too quickly. 50% of those who completed MEQs expressed this view, and this was the most unanimous negative view expressed; 6 other groups of negative views were provided, but with a frequency ranging between 6% and 33%. Fewer responses were provided in the informal feedback exercise - a total of 18 comments provided by around 10 students – but of the eight 'negative' comments, 3 were heartfelt requests for me to slow down. If additional confirmation were needed, my teaching sessions were observed on 4 separate occasions by 4 separate academic colleagues as part of my study for the University of Salford's Post Graduate Certificate in Higher Education Practice and Research. Each of these observers, while commenting favourably on other aspects referred to above, also noted that I was moving quickly through material.

I did incorporate interactive elements into each of my sessions – and these were well received - but my desire to achieve coverage kept such elements within quite tight bounds. Likewise, I did provide guidance regarding assessments, but did not provide an opportunity – in class time – for students to practise their skills. Large amounts of primary legal material was made available on the VLE, but little guidance regarding how best to exploit it.

Engagement with the literature suggests, to quite an extreme degree, that this is precisely the wrong approach to take in the circumstances of my course. Much pedagogical literature centres around the opposition, posited by Marton, F. & Säljö [30], between deep and surface approaches to learning, with the surface approach being characterised by rote learning, and the deep approach being based on conceptual understanding. Biggs [12] emphasises that a teaching approach driven by a desire to achieve syllabus coverage will tend to encourage a surface approach to learning. Bligh's substantive review of the literature relating to the didactic lecture mode indicates that, on its own, the mode is not well suited to promoting deeper levels of understanding noting that 'little thought can take place in a lecture' [13:129]. Fyrenius identifies two stages in the process of understanding; 'sifting', where information is received and condensed, and 'building', where the information received is related to previous knowledge in order to understand it, own it and eventually reshape it [31]. The didactic lecture typically promotes the sifting stage but does not tend to encourage the building.

In opposition to this, the type of learning which is needed in order to perform to a high level in law is deep learning. Allen cites Cownie et al that 'law is an argument not a statement, it is to be debated and discussed' [16], and to engage in a debate a student needs to have absorbed the arguments, merely pushing superficial facts around will not produce a quality response.

Formalised feedback to students was also not factored into my course delivery, save in relation to the one piece of coursework. Yet, it is considered that formative assessment is crucial to knowing how well students understand and to enable continuing development of effective practices in teaching and learning [28].

A final underpinning – but unarticulated - belief that I brought with me to my course delivery was that of the *teacher* being central to the learning process. This is implicit in the approach to course design which I adopted. There is a considerable body of literature which argues for the reverse with the student being placed at the centre of learning (e.g. Ramsden [22]). Maharg [32] highlights the potentially revolutionary implications for legal education of Rogers' argument that that 'the only learning which significantly influences behaviour is self-discovered, self-appropriated learning.'

3. Conclusion

The reflection on practice informed by theory which this paper represents, however incompletely, enables some conclusions to be drawn which have particular significance for me, as I prepare the next iteration of the Landlord and Tenant module, but which may also have wider relevance for those facilitating the legal learning of other cohorts of non-lawyers elsewhere.

My driving force remains to encourage students to acquire a real understanding of the legal concepts that form the basis of the course; I have no wish simply to dole out 'prophylactic law'. Yet my approach must take into account the circumstances of course delivery, including the amount of student contact time, and the degree of student aptitude and inclination. It is these which must dictate the approach, regardless of the literal extent of the curriculum.

A student-centred approach, in the model of that implemented by Soetendorp and Byles has its attractions. Certainly the focus of delivery should be to encourage the development of understanding in those who struggle with the subject (those to the left of the red line in figure 3). Adopting a less didactic stance, covering less material, but in more student focussed ways, to achieve deeper understanding must be the aim. There must be concentration on encouraging the acquisition of threshold concepts and providing more opportunities for students to practise the skills and knowledge deployment which will be assessed.

It is these considerations which will guide me in my development of the next cycle and this time around I hope not to be 'flying by the seat of my pants'.

BELFAST: Built Environment Law, *Flowing* Assessment.

Tim McLernon,
School of the Built Environment, University of Ulster
(email: t.mclernon@ulster.ac.uk)

Abstract

The formal assessment process acts as an extrinsic motivator of learning in the Built Environment Law curriculum. The old adage "what gets measured gets done" applies. It is widely recognised by teachers in Higher Education (HE) in the U.K. that learning is more enjoyable and meaningful when motivation to learn is intrinsic and accords with Csikszentmihalyi's [1] 'flow' theory; yet the HE system requires formal assessment. Students focus on this assessment for the parameters of their learning. The purpose of the paper is to instigate a dialogue on assessment design for Built Environment Law through an examination of assessment practices, and to report on what works, in terms of promoting student learning whilst satisfying the demands of the HE system. The paper reviews key literature to construct a conceptual framework on why we assess, what we assess, and how to assess. It reports on a longitudinal study of the developing assessment design of an undergraduate Built Environment Law curriculum that focuses on construction contract law and administration, and a postgraduate Built Environment Law curriculum that focuses on legal studies for the construction Project Manager. The paper includes an examination of those factors external to the learning process that impinge on, and shape, assessment design. The prescriptions in the paper are informed by generic findings of data collected from interviews with academics on their constructions of assessment practices, and from focus group interviews with students on their attitudes to assessment. The conclusions highlight those things that create educational difficulties and argue that curriculum design for Built Environment Law, that incorporates only informal assessment with inherent flexibility and freedom, can promote intrinsic motivation to study and promote deeper student learning in this discipline.

Keywords: assessment, flow, motivation, learning, impingements.

1. Introduction

1.1 Background

This paper emanated from a larger study that I carried out to answer the research question: "What are academics' constructions of assessment practices?" The idea for the paper was instigated as a consequence of an in-house teaching and learning debate, in the School of the Built Environment, on student engagement and motivation in construction management subjects. There was a strong consensus that new thinking is required on teaching and assessment methods generally to motivate students to engage more deeply with their learning. It was put forward that textually based subjects, such as Built Environment Law, need particular attention because there is an increasing reluctance to read on the part of many students today. The purpose of the paper is to instigate a dialogue on assessment design for Built Environment Law through an examination of assessment practices, and to report on what works, and suggestions for enhancement, in terms of promoting student learning whilst satisfying the demands of the HE system.

1.2 Data sources

The paper was informed by the general findings of data collected from the larger study. These data were collected from interviews with academics on their constructions of assessment practices, and from focus group interviews with students on their attitudes to assessment. The data on the development of assessment strategies for Built Environment Law was collected from an ongoing longitudinal study of an undergraduate and a postgraduate module in the discipline. The interviews with academics consisted of three distinct stages:

1. The first stage formed the main body of data on which the study was based. This involved in-depth interviews with a sample of 16 academics in order to explore their constructions of assessment practice. The sample was drawn from two ‘different’ universities: one a long-established, red-brick, Russell Group university, and the other a modern university which had its roots as a former Polytechnic. These interviews were designed to be free-flowing with interview questions guided by a prepared interview guide which was used as an *aide-memoire* as opposed to a more strict question schedule designed to elicit responses related only to predetermined questions. On a scale of structured – unstructured interviews, these semi-structured interviews would fall towards the unstructured end of the scale. The rationale for this was to make the interviews more conversational with less stringent boundaries to give the interviewees more scope to introduce issues which would be of importance or significance to them and which otherwise might not have been catered for in an interview.

2. The second stage of the active research was carried out as an extension to, to check and inform this main body of data and to consolidate the findings from the initial 16 interviews. This second stage consisted of five further interviews with three academics from institution A and two from institution B.

3. The third stage consisted of interviews with a further nine academics, who, for pragmatic reasons, were from the Institution A. To effect data for comparison and to facilitate recording of responses in note form, a more structured and briefer approach was taken using a specified set of research questions to be investigated, based on issues which emerged from the initial interviews. The data thus collected were used for triangulation purposes to highlight any significant differences between, or additions to, what emerged from both the main, first stage interviews and the follow-up, more structured interviews.

2. ‘Flow’

The term ‘*Flow*’ as used in this paper, refers to the work of Dr. Mihalyi Csikszentmihalyi [1], a Hungarian-born painter and psychologist who gave the term ‘flow’ a new meaning in his 1990 publication. In an interview with Debold [2], Dr. Csikszentmihalyi explained ‘flow’ as follows:

> ‘*In the early seventies, I spoke with chess players, rock climbers, musicians, and inner-city basketball players, asking them to describe their experience when what they were doing was really going well. I really expected quite different stories to emerge. But the interviews seemed in many important ways to focus on the same quality of the experience. For instance, the fact that you were completely immersed in what you were doing, that the concentration was very high, that you knew what you had to do moment by moment, that you had very quick and precise feedback as to how well you were doing, and that you felt that your abilities were stretched but not overwhelmed by the opportunities for action. In other words, the challenges were in balance with the skills. And when those conditions were present, you began to forget all the things that bothered you in everyday life, forget the self as an entity separate from what was going on—you felt you were a part of something greater and you were just moving along with the logic of the activity. Everyone said that it was like being carried by a current, spontaneous, effortless like a flow. You also forget time and are not afraid of being out of control. You think you can control the situation if you need to. But it's hard because the challenges are hard. It feels effortless and yet it's extremely dependent on concentration and skill. So it's a paradoxical kind of condition where you feel that you are on a nice edge, between anxiety on the one hand and boredom on the other. You're just operating on this fine line where you can barely do what needs to be done… So "flow" seems to be a phenomenological state that is the same across cultures. What people do to get into that state varies enormously, but the experience itself is described in very similar ways.’*

Wikipedia [3] records that Csikszentmihalyi identifies the following as accompanying an experience of flow:

- *Clear goals* (expectations and rules are discernible and goals are attainable and align appropriately with one's skill set and abilities).
- *Concentrating and focusing*, a high degree of concentration on a limited field (a person engaged in the activity will have the opportunity to focus and to delve deeply into it).
- A *loss of the feeling of self-consciousness*, the merging of action and awareness.
- *Distorted sense of time*, one's subjective experience of time is altered.
- Direct and immediate *feedback* (successes and failures in the course of the activity are apparent, so that behavior can be adjusted as needed).
- *Balance between ability level and challenge* (the activity is neither too easy nor too difficult).
- A sense of personal *control* over the situation or activity.
- The activity is *intrinsically rewarding*, so there is an effortlessness of action.

- People become absorbed in their activity, and focus of awareness is narrowed down to the activity itself, *action awareness merging* (Csikszentmihalyi [4] p.72).
- Not all are needed for flow to be experienced.

With the rugby world cup taking place at the same period as the writing of this paper, there have been many references to players and teams ‘*being in the zone*’. I like to think that this is analogous to the flow experience. As a Built Environment academic, I would argue that our Built Environment assessment strategy should be constructed using a goal of transforming the learning experience into one that *gets students in the zone* and engenders the ‘state of flow’ during appropriate and significant learning episodes. Our aim should be establish assessment strategies that focus on instilling a deep learning approach by students so that students retain the requisite knowledge and study skills for their professional careers.

3. Conceptual Framework: why we assess, what we assess and how to assess.

Assessment of student learning in higher education is required to fulfil a multiplicity of purposes and play several different and, possibly, conflicting rôles. The same assessment task can be used in a formative way, in a diagnostic way and in a summative way in respect of the individual student learning. The outcomes of this assessment task can be, and are, also used, individually or collectively, as an evaluation of a module, a subject, a programme or an institution. The variety of purposes and rôles played by assessment of student learning in higher education influences the method and type of assessment used. It is proposed that the design, setting and marking of assessment should ensure that the utility of the key, central function of student assessment is not lost to these collateral purposes and rôles, and is properly dealt with.

The assessment of large student numbers in a semesterised system imposes a heavy burden on academics and the process of assessment can be tedious and slow. Assessment of student learning can become routine and mechanical and it is easy to lose sight of why assessment is necessary, what is being assessed and the best method(s) of doing so. Assessment is often perceived as a mechanism for *measuring* academic achievement. This concept of educational measurement suggests precision and accuracy. Kelly (in Blenkin & Kelly [5] p4) argues that:

> *‘Accuracy of assessment is related inversely to the complexity and the sophistication of what is being assessed. And, since education is a highly complex and sophisticated process, educational assessment can be regarded as measurement only in the remotest of metaphorical senses’.*

Although Blenkin’s and Kelly’s propositions, theories and arguments studies relate to early childhood education and compulsory education, it will be apparent from later chapters that they transfer quite easily to higher education.

Good assessment practice requires considerable thought, preparation and execution on the part of the academic. In today's climate of diminishing resources, the administrative demands made of academics and the requirements for achievement in the latest Research Assessment Exercise, a juggling of priorities is required of both the individual academic and of the institution. Assessment has to be effective and efficient and these two elements should be balanced. However, *if* assessment is viewed as a low priority, or low-status, activity, the weighting may move towards efficiency to the detriment of effectiveness. We need always to be careful that assessment does what it is supposed to do.

Kelly pulls together his propositions and argues in summary that:

> '*Educational assessment, therefore, must be recognised as being a highly imprecise activity at all but the most basic levels, and as being* ***judgemental*** *rather than* ***metric*** *in character, as requiring the making of sound professional* ***judgements*** *rather than of objective, mathematical* ***measurements****.'*
>
> (this author's bold font)

This dichotomous view of whether assessment is a measurement or a judgement or, indeed, a combination of these and, perhaps, other factors is debated in the literature without consensus but it seems that there is a place for both measurement and judgement. In arguing for a more ipsative approach to assessment, Kelly (P6) says:

> *'What is needed … is a recognition that assessment is of personal experience and not merely of individual progress, that it is a matter of judgement rather than of measurement, and that, as a consequence, the standards against which such judgements can best be made are those based on the characteristics and previous achievement of each pupil rather than those of his/her peers or those derived from some external and impersonal concept or definition either of particular subjects or of the educational process itself'.*

3.1 Why assess student learning?

The literature presents an array of the purposes of assessment of student learning in higher education. Two contributions follow:

1. The Quality Assurance Agency for Higher Education in its Code of Practice for the assessment of students [6] states that assessment serves many purposes and that assessment:

- Provides the basis for decisions on whether a student is ready to proceed, to qualify for an award or to demonstrate competence to practice.
- It enables students to obtain feedback on their learning and helps them to improve their performance.
- It enables staff to evaluate the effectiveness of their teaching.

2. Mutch and Brown [7], writing for the LTSN Generic Centre, agree with these set of purposes but expand them further under three categories of purposes of assessment of student learning, viz.: learning; certification and quality assurance. They expand on each of these as follows:

Learning

- To provide feedback to students to improve their learning
- To motivate students
- To diagnose a student's strengths and weaknesses
- To help students to develop their skills of self-assessment
- To provide a profile of what a student has learnt

Certification

- To pass or fail a student
- To grade or rank a student
- To licence to proceed
- To licence to practice
- To select for future courses
- To predict success in future courses
- To select for future employment
- To predict success in employment

Quality Assurance

- To provide feedback to lecturers on student learning
- To improve teaching
- To evaluate a course's strengths and weaknesses
- To assess the extent to which a programme has achieved its aims
- To judge the effectiveness of the learning environment
- To ensure the course is credit worthy to other institutions and employers
- To monitor standards over time

The reasons for assessment are multi-factorial and not solely focussed on the student learning activity.

3.2 What ought to be assessed?

Contemporary thinking in the literature evidences a shift in emphasis in defining learning in higher education away from the traditional accumulation of declarative, or propositional, decontextualised knowledge towards the notion of being competent and able to perform in preparation for the workplace. Work-based learning and problem-based learning have come to the fore in recent years as methods of learning in preparation for the workplace. Assessment too reflects this shift and contemporary thinking in the literature proposes the use of authentic assessment, e.g. Biggs [8], Torrance [9]. Higher education has seen a parallel shift in emphasis from teaching orientated curricula to learning orientated curricula by which is meant that the students now take more responsibility for their own learning. Indeed, Boud [10] (pp27-28), for example, argues that students should become independent of their teachers and should be expected to make decisions about what they learn and how they learn much more than they currently are. What ought to be assessed should be aligned with that which is defined and specified in the learning outcomes.

3.3 How should assessment be carried out?

The approaches to assessment can have a manipulative effect on student learning and it seems that the context of assessment and the beliefs and orientations of the teacher can influence assessment. Rowntree [11] makes the point that 'The teacher … must *plan* and *evaluate* his (*sic*) assessment methods in relation to the *purposes* he is pursuing' (italics in original). It is fundamentally important therefore that the focus is on the purpose of the assessment as defined by those responsible for the assessment. Heywood [12] (p58), arguing for multiple-strategy assessment, illustrates this point using Furneaux's criticism of engineering examinations in which it was identified that the examinations were all measuring the same thing. Rowntree [11] sets out conflicting modes of assessment in a way that provides a useful summary of the issues which should be considered by academics approaching assessment of student learning. These are:

- formal v informal
- formative v summative
- continuous v terminal
- course work v examination
- process v product
- internal v external
- convergent v divergent
- idiographic v nomothetic

To this list can be added from Biggs [8] (p166):Norm-referenced v criterion referenced (and to which could be added: v ipsative)

- Quantitative v qualitative
- Holistic v analytic
- Contextualised v decontextualised
- Teacher assessed v self/peer assessed
- Time constrained v not time constrained
- Invigilated v not invigilated

The link between learning and assessment and the effects of assessment on student learning and student approaches to learning need to be considered when making decisions about assessment and choosing appropriate assessment methods.

3.4 'Traditional' and 'Progressive' assessment.

The literature illustrates a variety of purposes and functions of assessment of student learning, but, although there is overlap, the literature distinguishes assessment as acting in two contexts. The first is assessment that emphasises its purpose and function as a mechanism for determining whether a student should proceed to the next stage of the course or whether the student should have an award conferred. In this case, assessment acts externally to the system of learning as an independent, auditing mechanism. I would refer to such assessment as assessment in the 'traditional' context, or traditional assessment. I would propose that significant features of traditional assessment are:

- The use of the measurement model of assessment in which norm-referencing predominates;
- The use of end of unit assessment methods, usually a time constrained, unseen, written examination with and/or without a choice of questions;
- Minimal use of formative assessment;
- Minimal feedback on formal assessment
- An emphasis on discipline-based propositional knowledge over general transferable, or key, skills

The second context is one in which assessment emphasises its purpose and function as a vehicle that shapes, drives and influences learning. In this context, assessment acts not only as an integral part of the system of learning but to a significant degree, the driving force behind what is learnt and how it is learnt. This second purpose is one that has been the subject of considerable research and opinion over the past couple of decades. It has many advocates and is being promoted through seminars and publications as the way forward in assessment. Assessment in this context differs from the first in that the concern is to do with clear statements of what the student should know and be able to do on completion of the module with methods of assessment designed to drive the learning towards these stated, intended learning outcomes. I would refer to such assessment as assessment in the 'progressive' context, or progressive assessment. I would propose that significant features of progressive assessment are:

- The use of the standards model of assessment in which criterion-referenced assessment predominates;
- The alignment of assessment and learning;
- An inclination towards continual assessment which is sequenced to match the curriculum programme;
- An emphasis on formative assessment;
- A high value placed on feedback;
- The use of authentic assessment by which the assessment task meets the learning objective and assessment is based on performance;
- The integration of general transferable skills with discipline-based propositional knowledge;
- A propensity to include self assessment and peer assessment during the module;
- An inclination towards different modes of assessment.

How assessment should be carried out is driven by the requirement to have as an outcome of the teaching, learning and assessment regime, a number representing academic attainment. The reliability and validity of this number depends on:

1. Whether the assessment is intended to be descriptive, metric, judgmental or a combination of these determinants, and
2. The orientation to assessment of the academic in terms of whether the academic's beliefs are 'teaching-centred' or 'learning-centred.

The prescriptions in the literature recognise that the approach to assessment should relate directly to the purposes of assessment and that appropriate valid and reliable assessment methods are used to achieve this relationship. The practice of assessment may be influenced by the academics' orientations to assessment practice and their beliefs about assessment and its relationship with learning approaches. The type of assessment used is dependent upon the purpose or purposes of the assessment and appropriate methods should be utilised to achieve this purpose or these purposes.

4. Factors that impinge on, and shape, the assessment process.

I would argue that assessment is impinged upon and shaped by factors external to the students learning process and, as a consequence, assessment is a compromise and because of this the learning experience is likewise compromised. Figure 1 illustrates a theory through an analogy of a journey to propose that students' learning, by whatever means, and its assessment should travel smoothly together and in parallel on a learning highway to arrive at a destination of pre-determined learning outcomes with no hold-ups. However, the higher education system creates hold-ups on this learning highway by impinging on it with a variety of barriers. To optimise student learning in Built Environment education, we need to remove these barriers to maintain an effective and efficient learning highway.

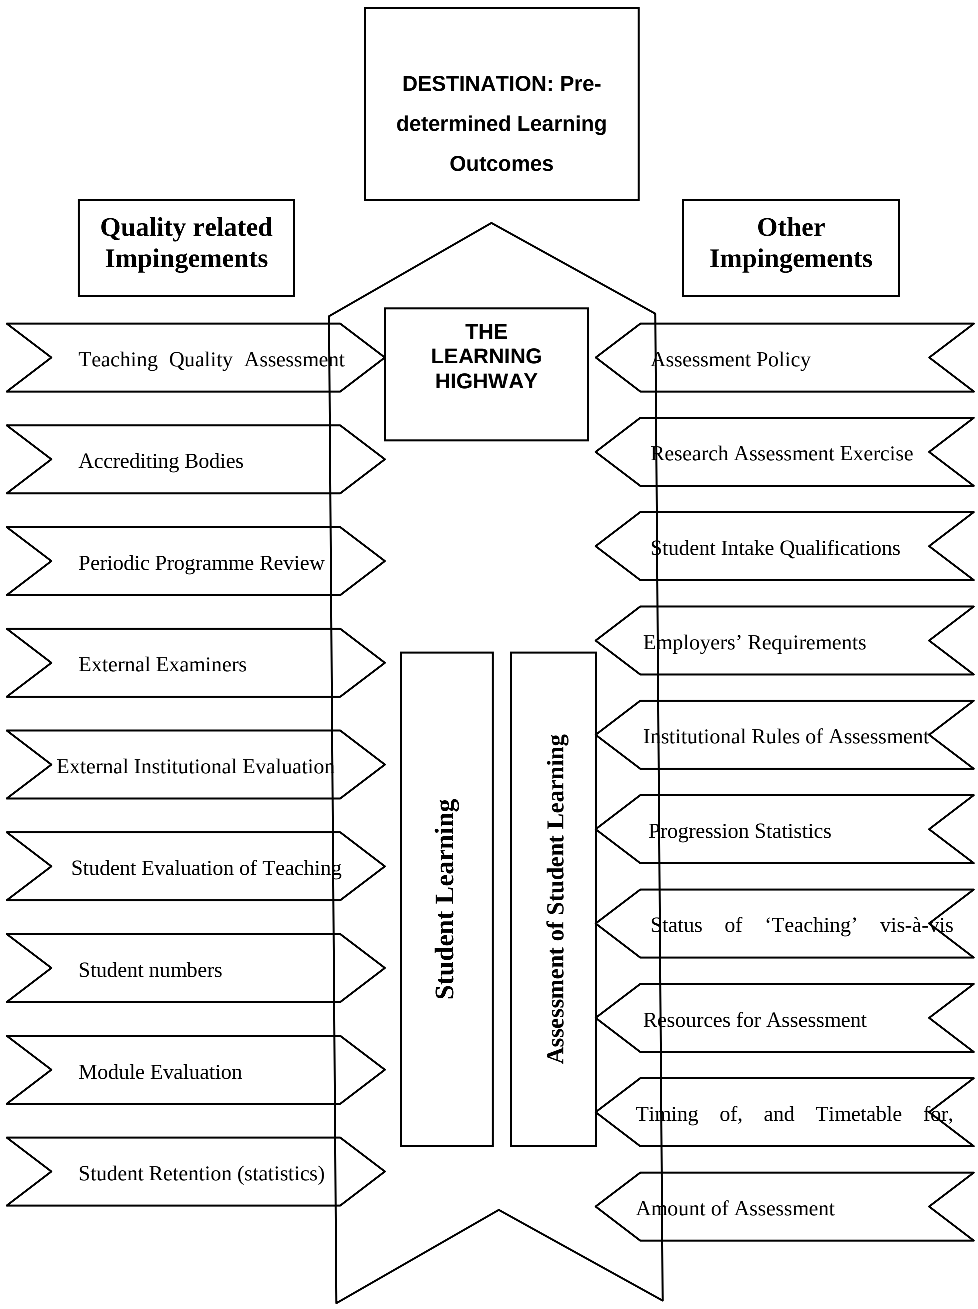

Figure 1- Learning Impingements

5. Longitudinal study of developing assessment design for Built Environment Law

The development of assessment of Built Environment Law over the past ten years has been the subject of monitoring research using an undergraduate module and a postgraduate module. This section reports briefly on the changes and developments of these two modules. The rationale for these changes emanated from a study and presentation by McLernon *et al* [14] in which was coined the term 'disguised learning' to describe a means by which students acquire particular knowledge from carrying out a task not expressly related to that knowledge.

5.1 The undergraduate curriculum

Ten years ago, this module was assessed using ‘traditional’ methods of one essay of two thousand words and an end-of-module, unseen written examination that required the student to answer five questions from an eight-question examination paper. This assessment regime had worked reasonably well up to that point because the module had smaller student groups that benefited from more class contact time and in-class dialogue than subsequently. Owing to the significant changes in student traits and in the higher education system, students were found not to be sufficiently engaged in their studies. The assessment strategy was revised to require the student to engage continuously with their studies and to incorporate employers’ requirements for students to have better presentation and communication skills. The assessment regime developed into the format below:

Assmt	Handout date	Description	Weighting	**Latest** Submission Date
1	Week 1	Semester Paper 1	15%	Week 5
2	Week 1	Semester Paper 2	15%	Week 10
3	Week 1	Reflective Log	10%	Weekly, 1 – 13
4	Week 1	Final Case Study	30%	Week 13
5	Week 1	Construction Contract	10%	Week 6 (in class)
6	Week 1	Duo Seminar Presentation	10 %	As Seminar Prog.
7	Week 1	Individual Sem Presentation	10 %	As Seminar Prog.

Whilst this has worked well, a pilot change has been introduced this year in an attempt to engender more of a **flow experience** into the learning. In essence, the Case Study has been replaced by an assignment which runs in parallel with the module over its duration and which requires students to be creative. Students were given the following initial instructions:

> ‘You are Contracts Manager for a large construction company. You have been asked by the Contracts Director to prepare a training manual for junior staff in the company, ***who have absolutely no knowledge of Law or construction contracts***, on the Law of Tort, the Law of Contract and The Standard Building Contract 2005 Edition with an emphasis on the ‘With Quantities’ version. The design of the manual is left completely to yourself.’

This approach will be evaluated using qualitative feedback from students and student results.

5.2 The postgraduate curriculum

The assessment regime that has worked on a postgraduate module entitled ‘Construction Legal Studies’ has been one that is problem-based and continual. Two years ago, a pilot assessment strategy was introduced to instil in students an element of individual creativity with the aim of making the learning experience more enjoyable through a trial means of encouraging the flow experience to happen during the students' studies. The key aspect of the specification for this assignment directed students as follows:

> ' This assignment requires you to carry out a short research exercise on a legal matter associated with the management of a construction project. The final product should be an A1 size poster, which explains your study, illustrates the research design and research method(s), and shows your findings and the conclusions reached.'

The evaluation of this approach did not find any significant improvement in the student marks for the module. However, the qualitative feedback from the students, on completion of the module, demonstrates that the students liked doing the assignment and learned a lot about the subject through this method of illustration and presentation. The pilot will continue for at least another academic year.

6. Conclusions

Built Environment Law is a vital component of the body of knowledge needed by the construction professional to operate successfully in the commercial world of construction. Those things that create educational difficulties by interfering with the pedagogy and smooth implementation of proven educational practices should be removed from the curriculum delivery. The goal of deep learning is more likely to occur if students are motivated to learn and enjoy their studies. Students need an enjoyable incentive to engage deeply with textual studies such as Built Environment Law. An assessment strategy and regime which encompasses the theory of 'flow', which has an element of informality, and which focuses on the optimal attainment of the pre-determined learning outcomes, goes some way towards the achievement of this goal.

Abstract

Practical applications of principles of law are common in the construction industry. Thus students of construction project management need to acquire relevant basic legal knowledge and practical skills for solving problems with legal implications that they may encounter. Yet, traditional lectures and tutorials still seem to dominate preferred methods for teaching law in construction education at many universities. With the emerging experience gained from the development of legal education, a variety of methods have been experimented with, to facilitate the uptake of legal knowledge and their practice in real-life problem scenarios. One of these is through role-playing.

The University of Hong Kong used role-playing in a group project in a postgraduate course on construction contract claims, for developing an authentic type of learning experience. This paper reviews the above, along with other experiences, such as in mock mediations, as well as in role-playing in non-legal courses. Comparing with traditional teaching methods, this paper illustrates how role-playing can be better used in a group project for enhancing the effective learning of law in construction education. In addition, it also highlights some tested approaches to providing feedback and conducting more reasonable assessments of individual students within such group activities that have proved effective at The University of Singapore. Through this paper, it is expected to share useful examples with other construction educators as well, with a view to enhancing the learning processes and outcomes in our field.

Keywords: Legal Education; Construction Education; Role-Playing; Group Project; Assessment

1. Teaching Laws to Construction Professionals and Students

Construction professionals need to handle much more application of laws now than previously. The regulations on affecting construction professionals are building up [i]; expectations from the society and clients are becoming more and more demanding [ii]; the responsibilities and liabilities on construction professionals are expanding [iii].

The increasing numbers and success of combined engineering and law undergraduate and postgraduate programmes [iv] at universities around the world also evidences a growing awareness among the construction educators, the students and the professionals of the importance to learn and be able to apply legal knowledge in the daily situations that construction professionals need to handle. Yet, teaching laws is challenging in itself. Teaching laws to construction professionals and students [v] can be even more challenging in view of the usual limited time assigned in such programmes [vi], the scope and depth of the topics to cover, and, in many cases, the limited exposure to legal education of construction professionals and students during their prior training.

Construction problems usually call for solution by a combined and balanced use of technical knowledge, management skills and legal principles. Doing this can of itself be complicated. Teaching does not make this easier. Hence, how best to deliver a course that can bring about interactions among the technical, management and legal knowledge and considerations as applied in the construction field in solving and handling the daily problems that construction professions encounter or will encounter is a real-life challenge to most construction educators.

2. Conventional Methods

Like many other countries, lectures are one of the overwhelmingly used methods for primary delivery of course materials for teaching law in undergraduate courses in the built environment in Hong Kong. Similar observations, for example, are made in relation to the learning methods for law in undergraduate courses in construction management and surveying in United Kingdom [vii].

Lectures are helpful in providing the ‘know-how’ and ‘know-why’ on a topic. Apart from delivering knowledge, experience shows that lectures are good to establish the broad outlines of a body of materials and to cultivate students’ interest in a topic or perspective that is relatively new to them. Lectures are also good if the topics to be covered are under heavy time constraints. In an industry like construction, the use of guest lectures can provide favorable results in providing a new way for the students to see and to understand the real-life implementation of theories. There can even be a continuum of format in which lectures are delivered, from a completely one-way scripted mode to a highly interactive mode.

However, effective learning is a highly cognitive activity in which students can engage the task appropriately, meaningfully seeking understanding [viii]. It has also been suggested that, from the students' perspectives, students learn 10% of what they read; 20% of what they hear; 30% of what they see; 50% of what they see and hear; 60% of what they write; 70% of what they discuss; and 80% of what they experience [ix]. For teaching 'soft' skills, it has been recognised that conventional teaching styles such as lectures and seminars alone are not always appropriate [x].

3. Role-Playing as a Learning Tool

In the education and training context, role-playing is a structured, target-oriented technique that uses the acting out of a part in a specified context to give participants a hands-on opportunity to apply knowledge and skills in a classroom setting. Role-playing is an approach for intensifying and accelerating learning. Also, one aspect of role-playing is that of diagnosis or assessment, and a test of how a person would act when placed in an imagined or pretend problematic situation.

Role-playing in education has been gaining popularity with recognition of the benefits that it can bring via combining the use of problem-based learning and collaborative learning principles. It has been engaged, for example, to teach educators [xi], nurses [xii], and government officials [xiii]. Role-playing has been particularly applied to teach courses with a focus on 'soft' skills, like communications, management, planning, problem-solving [xiv], but it is also used in a much wider context in education, teaching in history [xv] , economics [xvi] and even law-making [xvii].

In the context of legal education, role-playing has been widely adopted in the teaching and assessing of advocacy skills in post-graduate courses and professional training of lawyers[xviii]. As regards alternative dispute resolution methods, role-playing is almost universally engaged in the training and accreditation of mediators [xix]; in relation to negotiation skills, role-playing is customarily used for adult or post-graduate learning [xx].

So, why is role-playing so broadly accepted almost everywhere? There are certainly various positive aspects of role-playing. It enables the immediate application of knowledge and skills learnt; it allows the safe and structured practice of knowledge and skills gained and to obtain feedback; both its use and content can be flexible to suit the education needs; and it further offers the opportunity to learn from others, whether as a role-player or observer [xxi]. In relation to learning of 'soft' skills, such as problem-solving, critical thinking or presentation, role-playing has several other benefits. First, it encourages hands-on training, putting students into real-life situations and encouraging more effective application of knowledge, when compared with handouts, lectures or videos. Second, when performed in a group, it helps delivering brainstorming and developing teamwork skills, by students watching and participating in the role-playing sessions. Third, it enables students to approach problems from various perspectives, by the exchange of different points of views, such as from the employer, the architect, the engineer, the surveyor, the contractor and the subcontractor. Fourth, by allowing practices, it provides confidence to students for dealing with similar situations in their real-life work. And, fifth, it can be organised quickly, done inexpensively, performed almost everywhere, operated with very few training materials.

Thus, when properly designed, role-playing is an effective learning method, particular, for adult education since, with the working experience of participants, it enhances learning retention, provides hands-on training and, enables teamwork and communication. Above all, role-playing can also be fun.

Traditional use of role-playing goes through 3 stages --- briefing, role-playing and debriefing, depending on the goals and logistics. The design of a role-playing usually requires students to be briefed either on the situation or by written instructions. At the briefing stage, there is usually a set of common facts to kick off and individual role be may be given the ‘for-their-eyes-only’ additional facts for helping to bring out the problems to solve. Briefing to observing students may be different, for instance, by assigning a list of questions for them to observe and comment. When role-playing is staged, there will be more effective and productive learning by keeping everyone on their assigned roles. The role-playing process can be video-taped for reflective reviews and discussions. It is extremely important that students are debriefed after the role-play has been run. It is preferable to do this immediately following the role-playing is completed, while the verbal interactions are fresh in everyone’s memory. During the debriefing, the focus is placed more on learning by the class as a whole and elements of good practice or bad examples can both be utilized for learning during the discussion. In role-playing for teaching ‘soft’ skills, it may be a good idea for there to be a demonstration and for an opportunity for the students to do it again after the reviews to reinforce on the spot improvements.

4. Experience Sharing

The University of Hong Kong has used role-playing in a group project in a course [xxii] of its postgraduate programme [xxiii] for developing an authentic type of learning experience for construction professionals.

The role-playing group project formed part of the assignment and assessment of the students. The question was modeled on real cases, to stage typical disputes between the employer and the contractor in construction contracts, arguing over the four areas of extension of time, liquidated damages, valuation and payments. These were contained in four self-standing questions to be answered. The role-playing group project took the format of a group presentation. There were some 50 students in the course and they were divided into 8 groups. Each group was assigned to answer one of the four questions but from either the perspectives of the employer or the contractor. Hence, the question for each group was different, either in substantial issues or in perspectives. The group presentation was followed with question and answer sessions from the instructors and peer students from other groups. Each student was also required to submit an individual report, but covering the answers to all of the four questions. As to assessment, each student was given a group mark to represent the quality and substance of the group presentation, an individual mark to show his or her own performance during the question and answer sessions when propped with questions from the instructors and other students, and an individual mark for the written report on the overall answers to the four questions. During the presentation, questions were particularly invited from the students who were answering the same question but from the opposite perspectives and points or reasoning made in the presentation by the opposite group were put to the presenting group for responses and comments [xxiv]. The answers to the questions called for a critical analysis of the facts and the application of the relevant legal principles to the facts. The merits of the case of each side were factually sensitive and assumptions made could have the effects of changing the outcome all together. This was indeed the purpose in the design, with a view to helping students to be aware of the need to investigate these factors and their impacts in the real world.

The students all showed keen interests in participation, both in the preparation of the group presentation and during the question and answer sessions. The presentation indicated that many groups had carried out much more in-depth research for legal arguments than were provided for in the lectures or handouts. Exchange was particularly heated when questions or responses were made or given from the opposite groups answers to the same questions. Most of the students were so ‘in’ their roles and treated the presentation seriously. These seemed to benefit all by brining out all potential arguments for or against an issue for full discussion during the debriefing. There were of course some shortcomings in that students might take the case too personally. Some of the students looked for ways to defend their employer/contractor position by taking up too much of the roles of an advocate; some talked about using other commercial pressure (perhaps as inherited from their jobs) to ‘help’ the opposite side coming to terms with them; some even went a long way to invent new facts into the role-playing scenario to help their arguments. On the other hand, there were also some who gave away their employer/contractor position too easily by agreeing with some invented facts by the opposite group, which of course were adverse to their case. All of these were pointed out during the debriefing for the questions, and were made use of as a learning example from the converse point of views.

The overall feedback from the students on the course was quite positive, though there were some remarks on whether the role-playing group project was a bit too demanding in terms of resources required to be put in.

Apart from using group role-playing at the post-graduate programme, the University of Hong Kong has also recently engaged this model in a course [xxv] at the undergraduate programme of B.Eng in Civil Engineering (Law) [xxvi]. The focus of the learning was on design presentation and communication skills. This time, it concerned two groups of 3 students. They were given a factual scenario of an extension of time and liquidated damages disputes between an employer and a contractor. The groups were required to act an expert witness and prepare an expert report for the employer and the contractor respectively. Each group was required to prepare a fee proposal and inception report, an interim report and oral presentation, and a final report and presentation. At each stage, each student was marked and the overall marks formed the student’s result of the course. To make it more realistic, the two groups were asked to exchange the draft of their final reports so that response and comments to the opposite side’s report could be prepared during the final oral presentation. Again, positive feedback was received from the students who still talked to the instructors about the case and their presentations even a couple of months afterwards.

Another example of beneficial group work and role-play is seen in the course on ‘Engineering Design & Communication’ at the Department of Civil Engineering under the general B.Eng. in Civil Engineering [xxvii]. This involves problem-based-learning where synergistic group work leads to better results. Second years students were assigned in groups of around six to real-life problems from multi-discipline perspectives such as feasibility studies for a potential development for, say, sports stadium, cruise terminal, district-wide cooling system, centralised automated refuse collection system or multi-purpose culture centre. Students in the group would each take up the roles such as ‘architect’, ‘structural engineer’, ‘quantity surveyor’, ‘environmental engineer’, ‘geotechnical engineer’ or professional in other disciplines as needed for the assignment, thereby modeling the work life of a multi-disciplinary consultancy company. Similar to the above, they were required to prepare reports and make presentations to the client (role-played by the academic and industrial instructors).

In another example, year three civil engineering undergraduates are assigned in the groups of eight that include students from the architectural and building services engineering undergraduates to foster an even more real-life inter-disciplinary design project. Judging from feedback, group projects of this sort were welcomed by the students and the valuable learning outcomes were demonstrated by their high quality outcomes.

Role-playing in group projects of this type enables participating students to gain first-hand experiences of the pleasures and pains of working with other disciplines and help aligning their approaches to a project from more than one perspective. The common wish for completing a good project in time also assists the development of team building and co-operating skills.

5. Evaluating Groupwork More Realistically

The experience in Singapore may also provide further thoughts and options in the design of assessments for group projects. Apart from the traditional assessment by the instructors, there were two further initiatives adopted by a course leader at the National University of Singapore --- getting students to evaluate their group-mates and getting students to evaluate their peers’ performance [xxviii].

In group projects, it is not always easy to accurately assess the individual’s contribution to the overall output. One of the chief difficulties is the problem of identifying, or indeed discouraging, ‘free riders’ or ‘social parasites’ [xxix]. They get through the project abusing the extra efforts put in by other group members. Spotting these is not always easy, particularly when the output is represented by a mere report. By getting students to evaluate their group-mates and telling students up-front about this, it can help discourage, if not weed out, such free riders. For effectiveness, maintaining confidentiality in the evaluation by each individual student is preferable. This method can be summarized as getting a student’s own group mates to evaluate his/her performance during the *process* of preparing group project work.

Another method is to get students to evaluate their peers' *output* performance. This entails getting students in parallel groups to evaluate the performance of the group of students who are presenting their project *output* to the class. In order to make peer evaluation meaningful and motivating for student-evaluators, the marks awarded by them account for a significant portion of the student-presenter's continuous assessment marks, and the student-evaluators are given marks for making an objective evaluation. In order to give an accurate evaluation, student-evaluators not only have to read up on the presentation topics prior to the presentation, but they also need to listen attentively to the presenters during the presentations. Students acquire the ability to think critically and evaluate information objectively. As student-evaluators will only score marks if their ratings are within the specified range from the instructor's, they have to think critically, learn to respect other people's ideas and make sure that their evaluations are not affected by leniency or their own biasness. Students who are presenting need to defend their work and 'sell' their ideas; and through this process learn communication skills.

6. Conclusions

Experience in Hong Kong, Singapore and other locations show that role-playing helps in injecting real-life law into the study of construction project management, a subject that calls for the combination of technical, management and legal knowledge in practical applications to situations common in the construction industry. With proper design and sample innovation, role-playing using real-life problem scenarios can readily be adopted and be utilized as a 'learning-effective', interest provoking and initiatives motivating tool for teaching and assessing students in the legal education of construction professionals and students.

This paper provides a review of the experience in relation to the above and some suggestions and feedback on how role-playing, as an education tool, can be better used in a group project for enhancing the effective learning of law in construction education, with a view to enhancing the learning processes and outcomes.

Abstract

The finishing process in any construction project is very important that it takes up over 40% of the whole project. In particular, the outer walls of a high-rise building in the finishing process are often completed through the Curtain Wall method. There is a diverse range of materials and specifications regarding the Curtain Wall method, requiring a close decision-making process between the owner and the designer even in the initial stage of design.

However, the designer is often provided with only architectural design elements in the design-making process and the information on basic specifications of the Curtain Wall, and lacks detailed technical information on Curtain Wall and experience in its specifications.

Such a lack of information and experience often prevents the designer from acquiring the know-how and detailed information on Curtain Wall specifications even after the design documents stage, which often causes the Curtain Wall to be redesigned and follow-up repairs on defects in the latter stages of construction. Therefore, in this study, we aim to establish a product model for Curtain Wall information management with which participants in its design—the designer and Curtain Wall engineer/technician—can share in the decision-making process and design information with one another. The proposed model is a preliminary study for the establishment of a design management system that allows the parties involved in the design to determine the

information flow and conduct a continuous and consistent management in the decision-making process. In this study, we investigated the theoretical concept of collaborative design management system.

Keywords: Curtain Wall, Product Model, Collaborative Management, Design Management System

Background and Goal

The Curtain Wall design process can be divided into two stages: the basic design stage, which is conducted at an architectural design office, and the actual design stage, which is drawn just before the construction and is conducted by a Curtain Wall specialist.

From the process of the basic design stage to the actual design stage, the Curtain Wall design can often be executed by merely focusing on the results, and certain elements such as performance, specifications, and standards are overlooked. Moreover, the unidirectional flow of the decision-making process involved in the design of the Curtain Wall, in which the decision-making process in the latter stage is often overlooked, makes it difficult for parties formulating the design to communicate with one another.

Particularly, the design of the Curtain Wall design, which is conducted in the initial stage of an architectural process, fails to consider the aspect of engineering technology, a Curtain Wall specialist contracted for the actual construction process often have to revise the design or change the specifications, which causes a significant delay in the construction schedule. All of these may lead to insolvent design management of the Curtain Wall and other consequent problems.

Therefore, in this study, we aim at establishing a product model for Curtain Wall information management with which the parties involved in the design—the designer and Curtain Wall engineer/technician—can share and collaborate in the decision-making process by considering in advance the issues in the actual design stage before the Curtain Wall construction.

Research Scope and Process

In order to establish a system in which the architectural designer and the Curtain Wall specialist can collaborate in both the basic design stage and the actual Curtain Wall design stage in the finishing process of a building, we propose a product model for the establishment of a system model and database. The proposed information management product model, which is a preliminary study for establishing the proposed system, allows each party in the design stage to share design information and collaborate in the decision-making process. In this study, we implemented the following methodologies:

(1) performing a theoretical investigation on the collaborate ground for the Curtain Wall design management;

(2) performing a theoretical investigation on the concept of *Problem Alternative Solution*;

(3) establishing a Curtain Wall information model based on the concept of *Problem Alternative Solution* for sharing engineering information and performance D/B in the design stage;

(4) analyzing Curtain Wall design management information; and

(5) proposing a product model using the information created, referred to, and discussed in the Curtain Wall design process based on the analytical results and *Problem Alternative Solution*.

Theoretical Review

1.1 Collaboration in the Architectural Design Stage

Collaboration is a broad concept,[1)] and includes judgment, decision-making, dialogue, and feedback after a decision has been made. Terminology such as collaboration should be considered essential when managing curtain wall work for a high-rise building, which has complex processes that require many participants to communicate with one another frequently.

Therefore, in order to support the active information sharing and decision-making of various participants, such as an architect, a designer, a consultant, and an owner, we analyzed information exchange systems related to design management and collaboration system-building, based on a review of previous studies. The results are shown below.

Since there are many choices to be made in the design stage, a smooth decision-making system and collaboration-based technologies that allow participants to intelligently save and share design information are required to implement the final design choice selected from among the alternatives.

In their early stages, collaboration systems were restrictively used within individual companies via an intranet, for the purposes of database-building and integration of information. However, the idea of collaborative design was not fully utilized or established due to the way work was done in the domestic construction industry prior the early 1990s. As well, there were restrictions in terms of support for communication between participants due to technological constraints.

Since the rapid spread of the Internet in the late 1990s, multiple studies on collaboration systems have been conducted. Moreover, "network-related" functions have been added to CAD

[1] Lee Seong-ryong, "A Review on A Collaborative System, The Korea Operations and Management Science Society, 2003

programs, which make it possible for people to conduct design via the Internet[2]. As a result, many studies on professional systems and information integration systems related with these have actively conducted.

Considering not only domestic but also overseas research trends, studies on collaboration-based design can be largely classified as relating to information management to integrate design information, and support decision-making by each participant. Concept of Problem Alternative Solution

The Problem Alternative Solution is the concept of improving linkage between the existing PMIS (Project Management Information System) and the KMS (Knowledge Management System), to support decision-making in the project being implemented. The PAS derives the optimal solution from the diversity of alternatives suggested, in order to solve the problems that arise during the process of decision-making. Based on the personal knowledge and experience of each participant, the alternatives provided to solve the problems refer to historical data, such as existing similar cases and related literature, in order to create and deliver internal information from each participant, which other participants can use to make the optimal decision. In this way, each participant can accumulate more knowledge and experience, by obtaining knowledge from conventional similar cases and references, in the process of making the optimal decision. Fig. 1 is a diagram of the concept of the information model, based on the Problem Alternative Solution.

1.2 Considerations in Decision Making for the Curtain Wall Performance

This chapter discusses the main decisions to be made related to characteristics of the curtain wall by each participant in the curtain wall design stage based on the curtain wall process model and influential factors on decision making.

Of all the characteristics of the curtain wall, the characteristics that affect the whole building design and the curtain wall design are found as wind pressure, air infiltration, water penetration, sound insulation, thermal insulation, moisture condensation proof, fire resistance, seismic-resisting and smoke characteristics. In calculating the wind pressure, the calculation method recommended by the KS(Korea Standard) takes the region and conditions into consideration, but there are no Standards for other items, or although there is KS for them, people are using the ASTM (American Society of Testing Materials,) AAMA (American Manufacturers Association), and JIS (Japanese Industrial Standards) as shown in Table 4 in order to supplement the KS Standard due to its ambiguity and omissions. There are many factors to be considered in decision making for material resistant. Table 1 show the factors to be considered.

Table 1: Main factors to be considered & Technical requirements for decision making for design Standard

Item	Considerations & Standards
Wind pressure	◆ Taken into consideration in calculation ◆ Whether there is zoning or not
Air infiltration	□ KS Standard(ASTM)
Water penetration	□ KS Standard(ASTM)
Sound insulation	□ KS Standard
Thermal insulation	□ KS Standard(AAMA Standard)
Moisture condensation proof	□ AAMA Standard
Fire resistance	◆ Under the article 2.8 of the Architecture Law ◆ Notification No. 528 announced by the Ministry of Construction
Seismic-resisting	□ AAMA Standard
Smoke characteristics	□ Enforcement Ordinance, Article 35.2 and Enforcement Regulation No. 20

1.3 Curtain Wall Product Information Model

The curtain wall information consists of the standard specification, particular specification, materials to be used, design standard, the curtain wall time, a variety of documents and references. The product model proposed in Fig. 3 comprises of five parts: the curtain wall type class related to the curtain wall type, the curtain wall document class showing the curtain wall drawing and related documents, the engineering performance class showing design standards for the curtain wall, specification class showing specification information of the curtain wall and the reference class used as references in decision making for material and design standards.

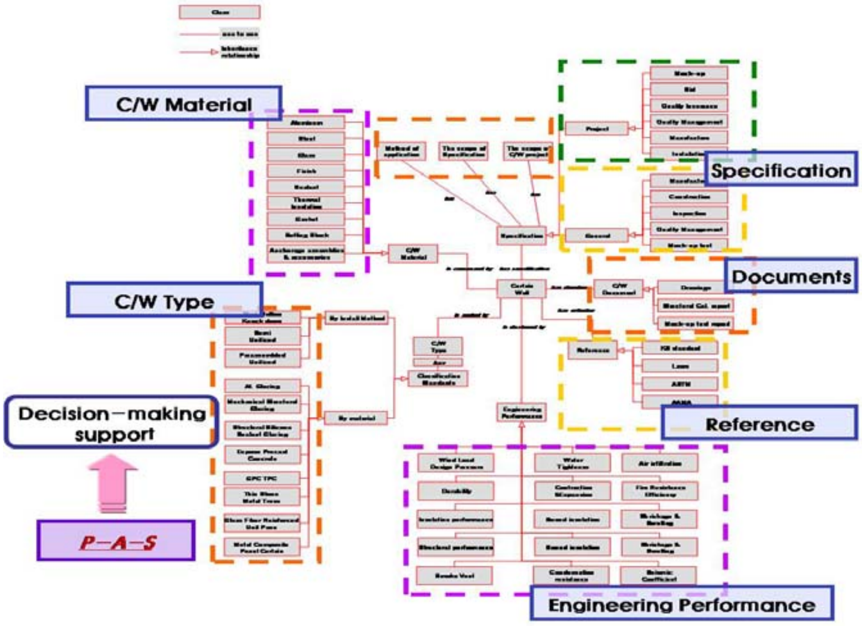

Figure 3: The Curtain Wall Product Information Model

Conclusions

In this study, we proposed a product model with which the participants in the design of the Curtain Wall design and construction process will be able to effectively use and manage the flow of information involved in designing the Curtain Wall. As a follow-up study, we aim at realizing a prototype of the Curtain Wall design information management system based on the proposed product model. The Curtain Wall information management system should have the following functions:

(1) it should store, categorize, and revise effectively the information generated in the design and construction processes;

(2) the stored data should be available for participants to enable them to make effective designs

(3) it should enable the system manager to monitor the proceedings, as well as provide such a manager a document certification function to ensure the participants make no duplicate decisions. This study's key results are the following:

- solutions are proposed to create alternative Curtain Wall design methods based on *Problem Alternative Solution*;

- decision-making items are analyzed with regard to the performance among participants in the design stage, and established an information model based on *Problem Alternative Solution*, which aims at supporting the decision-making process; and
- a product information model is established aiming at sharing and storing information among parties by analyzing the Curtain Wall design information.

The Curtain Wall design information management system proposed in this study for collaborative design can support the management of documents and design scheduling as well as assist in each party's decision-making process. The product information model proposed by this study presented a simultaneous execution method, not a serial design method, in the design process for each design party by proposing a collaborative method through the sharing of information and enhancing the communication in the decision-making process of the Curtain Wall design stage.

Abstract

Freedom of movement from place to place is recognized as a basic human right. Everybody regardless of his/her age and physical condition should have proper and convenient access to certain places in their daily lives. In order to ensure that all residents including those with disabilities can access to places that the public is entitled or allowed to enter or to use, adequate provision of unobstructed access is required. In Hong Kong, Disability Discrimination Ordinance and the code for Barrier Free Access Design are two major pieces of legal control regulating unobstructed access. In this paper, a comprehensive review of these requirements or other relevant regulations is conducted in order to identify whether there is room for improvement in the building laws regulating access for people with disabilities (PWDs), to aim for Universal Design. In addition, this paper also presents the result of a study which has investigated the accessibility of PWDs in public housing estates serving the majority of Hong Kong population. This case study is valuable to identify the inadequacies of current access provisions for PWDs and highlight the areas requiring further improvement. Based on the review of existing legislative controls and the case studies, some possible solutions for improving present building regulations are generated.

Keywords: Barrier free access, Universal design, Public housing estates, Building Regulations

1. Introduction

The main purpose of this research is to review the current regulatory controls on unobstructed access, and investigate the accessibility of PWDs in public housing estates serving the majority of Hong Kong population. By conducting the checkwalk exercises, the accessibility problems in the selected public housing estates representing typical public housing estates built in different periods between the 1970's and the 1990's can be identified, and recommendations to be considered in the future design and construction of public housing estates in order to meet the needs of PWDs can also be highlighted.

2. Controls over unobstructed access for PWDs

2.1 Disability Discrimination Ordinance

The Disability Discrimination Ordinance (DDO) Cap.487 was enacted in 1995 and became fully operative in December 1996. It ascertains that PWDs have their entitlement to an equal right on accessibility. In addition, it prohibits discrimination against PWDs for failing to provide reasonable means of access to any premise that the public or a section of the public is entitled or allowed to enter or to use, or for refusing to provide appropriate facilities. For the purposes the DDO, the issues of accessibility by the PWDs will be considered with reference to the current needs.

2.2 Design Manual: Barrier Free Access

In order to legalizing disabled access requirements, in 1984, disabled access requirements were introduced into the Building (Planning) Regulation under the Buildings Ordinance and a guideline “Design manual access for the disabled” was announced. Since the promulgation of the DDO, an improved design guide called “Design Manual: Barrier Free Access 1997 (BFA)” was introduced. Compliance with the BFA is deemed to have satisfied the statutory requirements for barrier free access under the Building (Planning) Regulations. Basically, the BFA sets out design requirements for new and substantially altered buildings. It aims at providing proper barrier-free access to appropriate facilities in a building for PWDs. In 2006, an updated version of the design manual “Final Draft Design Manual: Barrier Free Access” was issued by the Buildings Department for consultation. The new draft version enhances the design standards to make the built-environment more accessible and aesthetically pleasing. It is still a consultation paper not yet implemented as part of the regulatory control

3. Universal design in public housing estates

The new draft design manual not only encompasses obligatory design requirements but also recommended design requirements to better provide a new concept of “Universal Design” environment for everyone. Barrier free design even with latest technological assistance may also result in separate and stigmatizing solutions. Universal design is a relatively new concept that emerged from "barrier-free" and "assistive technology" [5]. Universal design takes into account of other issues such as the aesthetics and appeals to a wide range of consumers. It provides a broad-spectrum solution not just for people with disabilities, but also for everyone. Experts of the Centre of Universal Design collaborated to establish the Principles of Universal Design to guide a wide range of design disciplines including environments, products, and communications. The following 7 principles may be applied to evaluate existing designs, guide the design process and educate both designers and consumers about the characteristics of more usable products and environments [2]:

- Equitable use

- Flexibility in use
- Simple and intuitive
- Perceptible information
- Tolerance for error
- Low physical effort
- Size and space for approach and use

Therefore, apart from the BFA code used in Hong Kong, this study also referred to barrier free design codes used in other overseas countries to look for ways to better provide a "Universal Design" environment for the PWDs. In this study, the major overseas barrier free design codes that have been consulted are:

- Barrier Free Design in Japan-Code of Practice for Design for Access and working Commission Report 1989, Kanagawa Prefecture
- Barrier Free Design in the United States-ATBC Board 1982, Minimum Guidelines and Requirements for Standards for Accessibility
- Barrier Free Design in Canada, Public Works Canada 1985, Barrier-Free Design: Access to and Use of Buildings by Physically Handicapped
- Barrier Free Design in Netherlands-Provinciale Stichting Gelderland 1984, Requirements for Access
- Barrier Free Design in Singapore-Public Works Department 1990, Code on Barrier-Free Accessibility in Buildings

4. Research methodology

To achieve the aims of the project, a methodology for carrying out this project was formulated and it could be described in 4 stages as follows:

- Establishment of local and overseas regulatory control references
- Selection of typical public housing estates;
- Preparation of checklists;
- Carrying out of checkwalks; and
- Data analysis.

4.1 Selection of typical public housing estates

There are more than 170 public rental housing estates under the direct management of the Hong Kong Housing Authority (HKHA) in Hong Kong. It would not be feasible to carry out a survey on each of them to reveal the accessibility issues for the PWDs. After a thorough desk top study and discussion among the Research Team members, 4 public housing estates were selected. All of these housing estates are located in the same district and the housing estates selected would be of significant value because they represent different types of estates built in a particular period. The 4 selected estates i.e. CH Estate and WH Estate, SL1 Estate, SL2 Estate are built in the 1970s', the 1980s' and the 1990s' respectively, and cover the housing block types i.e. Trident, Harmony, Linear, New Slab, Old Slab and Double H which are the most common building forms observed among estates in the district. Apart from the domestic blocks, a variety of communal facilities e.g. market, mall, car park, ball court and playground equipment provided in each of 4 selected estates were also surveyed.

4.2 Preparation of checklists

With reference to the design requirements in the Hong Kong BFA code and overseas' barrier free design codes to achieve Universal Design, the Research Team studied the building plans of the selected estates to recognize the material characteristics of the housing estates and to identify the critical areas for assessment on site. With a draft checklist developed for discussion with practitioners for refinement, a full checklist was created for the checkwalk exercise on site.

After preparing a draft checklist, the Research Team studied the building plans of 4 selected estates to recognize the characteristics of the housing estates. Then, the Research Team walked through the building plans mentally as users with the benefit of discussion among Architects and Building Surveyors. The checklist is refined and finalized in order to facilitate the checkwalks for assessing the accessible design of built environment in a logical sequence.

4.3 Carrying out of checkwalks

Checkwalks were conducted in 6 separate days to examine accessibility issues for PWDs on site. The Research Team spent 1- 2 days (about 4 - 6 working hours) on each of 4 selected estates in early 2007. In order to ensure that the most common types of housing blocks were covered in the checkwalks and increase the reliability of the survey findings, it was decided that at least 2 housing blocks of each type were selected for study in each estate, and at least 4 floors of each block type were studied. For example, 2 Trident blocks in CH Estate, 2 New Slab blocks and 2 Double H blocks in SL1 Estate, and 2 Harmony blocks in SL2 Estate, and 2 Linear blocks and 2 Old Slab blocks in WH Estate were studied. Equipment employed to measure and to record the relevant data during the checkwalks included a measuring tape for dimensions and a digital camera for recording, etc.

4.4 Assessment criteria and grading

For each estate, the Research Team assessed the accessibility of PWDs on site. Due consideration had been given to any special circumstance on site. The team members are qualified building professionals and had to bear their architectural and surveying expertise to assess items affecting accessibility of PWDs. The assessed items were classified into 4 main categories for data analysis. The first category included those items found to have fully complied with the requirements. The second category included those items found to be totally non-compliant or with no provisions at all. The third category included those items that were not applicable to the estate. The forth category included all other items that were provided on site but were non-compliant with the standards. Within this last category, the items were further graded according to the degree of compliance with the requirements. The grading assessment by the Research Team was based on a set of qualitative criteria including a combination of:

1) For each item provided/ observed along the checkwalk routing, the Research Team estimated the % of that item appearing to be completely non-compliant with the requirements or with no provisions at all;
2) For each item provided/ observed along the checkwalk routing but not classified under the category of total non-compliant, the Research Team assessed the adequacy and the completeness of that item provided on site;
3) The assessment would also take into account of the frequent use of the facilities provided and whether there were alternative provisions which were reasonably convenient.

The grading is not an exact science that could be justified simply by counting, but the grading relies very much upon the Research Team’s professional judgment with reference to the above criteria. The grades are only indicative of the degree of non-compliance with the requirements. The grading provided the Research Team one of the criteria to determine the priority for rectifying the non-complying defects.

5. Data analysis

5.1 Summary of findings for domestic blocks

The housing block types selected for this study are comprised of Trident, Harmony, Linear, New Slab, Old Slab and Double H due to their popularity among estates in the district. Block types of Trident, Old Slab and Linear were all built in 1970s. Both New Slab and Double H were built in 1980s whereas Harmony was built in 1990s.

The different block types are standard designs. During the visit to each of the 4 estates, the Research Team assessed the accessible design for at least 2 blocks of each block type. The rationale for assessment criteria and grading had been discussed in Section 4.4. The main purpose of the grades is to provide a record for the team members to check back in office when assessing the priority for rectifying the non-complying defects. With reference to the grades obtained for individual block in four selected estates, it is possible to obtain an overall grading on the degree of compliance by combining the survey results of all 4 estates for each block type.

After summarizing the survey results of all block types of all concerned estates, the team members found out that block type of Harmony in SL2 Estate, which was built in 1990s, has minimum defects comparatively while the rest of them has some common defects in the aspect of accessible design, for example, substandard ramp at lobby entrance, large door threshold of the flat entrance, deficient signage for exit, no tactile strip at landings and at bottom and top end of staircase, no raised directional signs on handrails, insensitive detection device and no infrared sensor, no audible signal and verbal annunciation for lift car, lack of indication system for lift and no visual alarm signal at prominent locations.

5.2 Summary of findings for communal facilities

Each of 4 selected estates has their own unique arrangement of transportation facilities, commercial complex, wet market, communal facilities and open areas between blocks. Different designs of each estate are due to local landforms, geographic locations, period of time and specific needs.

The overall comments on common defects existing in all 4 estates are shown below:

- Substandard access ramps are found in some locations. Not all handrails have raised directional signs. Dropped kerbs are not sufficient. No tactile strip at head and foot of ramps is provided even if ramps are constructed. Same case happens to staircases in commercial complexes in terms of the standard of handrails and the provision of tactile strips.
- Braille map and tactile guide path, for people with visual/hearing impairment, is missing.
- Some corridors of commercial centers and wet markets are not wide enough to ensure sufficient room of movement or the finished floor is slippery.
- The lifts, as a typical problem in all evaluated estates, were not upgraded to meet the BFA code in terms of the height of control button, the sensitivity of detection sensor and notification of both audible signal and verbal annunciation.

6. Recommendations

6.1 Criteria for prioritizing

Throughout the years, different departments of the Hong Kong Government have published a number of codes, standards and guidelines in order to create or promote a healthy and safe built environment for the local citizens. This study is based on the established document to set out the requirement/ criteria for assessing the accessibility of PWDs in the public housing estates. The assessment is based on the latest standards for the purpose of this checkwalk exercise; however, most of these documents are published in 1990s-2000s and therefore, many of the residential buildings including those of public housing estates built before their effective date may not be able to comply with the new requirements. In this way, the Research Team has to take into account of the constraints of those estates built earlier when making recommendations for rectification of the defects.

In addition, it is not absolutely clear whether the requirements for accessible design also apply to all external areas outside buildings, such as outdoor landscapes, pedestrian paths and areas between housing blocks. Since accessible design for outdoor areas and facilities are equally important and no standard particularly designed for the external areas can be found in the territory, the Research Team makes reference to BFA 1997 when assessing the accessible design of external areas.

Ideally, all items which do not fully comply with the current requirements set out in the checklist have to be rectified as soon as possible. However, it is not possible due to limited human and financial resources. Therefore, it is better to prioritize these items in the first instance in order to make the best use of the scarce resources. With the professional expertise, the Research Team prepares the priority list according to 2 major principles. First, with reference to the grade given to each item, the Research Team can consider a priority ranking for each item. Item with greater degree of non-compliance is given a higher priority. Second, the preliminary priority ranking is qualified with due considerations given to the following factors in the order of deserving higher priority treatment:

- Matter of urgency;
- Ease of rectification;
- Resources required;
- Special circumstances of the estates, such as natural landforms, and
- Promotion of good practice for future designs.

It should be noted that the priority assessment is based on the Research Team's professional judgment with reference to the above qualitative criteria. The details of each priority classification are shown below:

Priority 1: Requirements that are urgently needed for improving the accessibility of PWDs.

Priority 2: Requirements that can greatly improve the accessibility of PWDs without demanding too many resources.

Priority 3: Requirements that can improve the accessibility of PWDs but may require heavy consumption of resources.

Priority 4: Recommended requirements that can provide good guidance for future designs

6.2 Recommended priorities for rectifying defects of domestic blocks

Table 1 and 2 present the recommendations made by the Research Team on the defect rectification for housing block types in order to improve the accessibility design for the PWDs.

Table 1: Recommended top priorities for defects rectification in all block types

Items	Design Requirements
Dropped kerbs	• Dropped kerbs: provide properly designed dropped kerbs at prominent locations

Items	Design Requirements
Ramps	• Gradient: improve slopes to comply with BFA code • Handrails**:** provide properly designed handrails • Tactile strips: provide tactile strips to comply with BFA code
Steps & staircases	• Handrails: provide properly designed handrails • Tactile strips: provide tactile strips at every change of level
Indicative provisions	• Signage: provide clear signage to identify entrances, public toilet & parking spaces • Provisions for people with visual impairment: provide Braille map or tactile guide path • Intercom: Intercoms should be positioned ≤ 1.1m above finished floor level. Level landings in front of intercoms should be provided
Corridor & lobbies	• Projections: reduce projections
Public toilet	• Location: provide a clear space of 1.5m x 1.5m in front of the cubicle • Size: provide disabled toilet of not less than 1.5m x 1.75m • Design: provide properly design water fitment
Lift	• Detection devices: provide detection devices or infra-red sensor to all existing passenger lifts • Control buttons: (i) install indication light for emergency call; (ii) improve control panels to comply with BFA • Notification: provide audible signal and verbal annunciation to all existing passenger lift
Fire services provisions	• Fire alarms: provide visual alarm signal at prominent locations • Exit sign: provide exit signs at prominent locations on each storey

Table 2: Recommended future improvement in all block types

Items	Design Requirements
Level between corridors and rooms	• Doors threshold: reduce level difference to 25mm or provide dropped kerbs
Steps & staircases	• Nosing: use materials in contrast colour for nosing and steps
Corridors & lobbies	• Dead end: provide an area not less than 1.5m x 1.5m for wheelchair users within 3.5m of dead end

Items	Design Requirements
	• Colour: use finishes in contrast colour for floor and wall

6.3 Recommended priorities for rectifying defects of communal facilities

Another section of the research findings is a summary of the recommendations in response to major defects commonly found in the communal areas in 4 selected estates that need priority attention for rectification (Table 3 and 4).

Table 3: Recommended top priorities for defects rectification in communal spaces

Facilities	Design Requirements
Commercial centre & market	• Defects similar to those found in Table 1 for domestic block in terms of Dropped kerbs, Ramps, Steps & staircases, Indicative provisions, Corridor & lobbies, Public/Disabled toilet, Lift and Fire services provisions
Public transport terminal & car park	• Access: provide direct access from public street/ pedestrian way
	• Drop kerbs: provide properly designed dropped kerbs at prominent locations
	• Ramps: provide properly designed ramps if there is a level change
	• Steps & staircases: (i) provide properly designed handrails; (ii) provide tactile strips especially in front of crossings of terminal or car parks
	• Signage: provide clear signage to identify terminal entrance, car park & locations of disabled car parking spaces
	• Disabled car park: at least 1 reserved for persons with disability at each parking level
Leisure facilities	• Ramps: provide properly designed ramps if there is a level change
	• Signage: provide clear signage to major routes & common facilities signal at prominent locations

Table 4: Recommended future improvement in all estates

Facilities	Design Requirements
Commercial centre & market	• Steps & staircases: use materials in contrast colour for nosing and steps
	• Corridor & lobbies: use finishes in contrast colour for floor and wall
Public transport terminal & car park	• Disabled car park: (i) follow recommended size of 3.5m x 5.5m; (ii) provide emergency call bell at each disabled car park space
	• Pedestrian crossing: incorporate ticking-device (audible and tactile) into existing crossing posts

6.4 Recommended Future Improvements

In this paper, priority lists are recommended for existing buildings because the Research Team takes into consideration practical needs, difficulties in rectifying existing works, and any special situation. There is no justification for future newly built public housing estates not to comply with the latest BFA code. In this paper, the Research Team also suggested lists of recommended items for future improvement in all estates. The assessment exercise will also provide feedback to the new development design team to refine or improve their design for new buildings. The recommendations in this paper should be taken up to review the existing standard designs for public housing, and to look for design solutions that could incorporate the recommendations in their future housing designs.

7. Conclusions

This study was a meaningful exercise to investigate the accessibility of PWDs in public housing estates that affected a large proportion of residents in Hong Kong. Assessing the accessibility of PWDs in the public housing estates is a good indicator showing the effectiveness of current controls over unobstructed access in Hong Kong. The Research Team acknowledged the fact that the majority of the estates selected were built before 1997 and this factor had been taken into account in the priority setting for rectification to be made in the recommendations. As this study was constrained by the resources available, the team members tended to limit this study to 4 selected estates representing housing stocks built in the 1970's, the 1980's and the 1990's. In order to ensure that feasible recommendations were proposed, the Research Team had considered the assessment grading, the needs of the residents, technical difficulties, and resources to be consumed. The study was carried out with reasonable sampling for statistical analysis. Apart from relying on statistical data, the research also relies on qualitative assessments and objective site inspection based on the professional experience. The research confirms that those items in the top priority lists are basic need for disabled access and should be tackled as soon as possible. The 2006 new "Final Draft Design Manual" will incorporate more elements of Universal Design. As highlighted in this paper on the recommendations for future design improvement, the conditions of public housing are far from attaining the new ideal concept of Universal Design. These findings prompt the relevant government authority to undertake further pro-active investigation for improvement to achieve Universal Design.

Towards a more ‘robust’ technology? Capacity building in post-tsunami Sri Lanka

Abstract

In fast urbanizing economies such as Sri Lanka, the construction industry tends to fragment into almost separate spheres of production with little or no reciprocal connection in training, know-how and career development paths, and consequent limitations in internal knowledge dissemination and technology transfer. This type of industrial compartmentalization is detrimental to the social acquisition of skills, and restricts the operational frameworks of given technologies, especially in low-cost sectors. Attempts to stretch such boundaries almost inevitably lead to inadequate application or sub-standard performance-in-use of the systems selected.

Set against this background, the paper presents the results of a technical review of a small sample of ideal-type projects in Sri Lanka, developed with the intention of forming an empirical basis to address two key issues: (1) whether strategic planning of specific building technologies could lead to professional frameworks capable of narrowing the gap between high-quality architectural production, middle-quality commercial building and low-quality shelter supply; and (2) whether architecture can act as an engine of social and economic growth for those involved in its production.

Based on government statistics and building output analysis, the paper argues that the above should and can indeed be the case, provided that such an agenda is developed strategically, by examining the industrial base of region, and by defining a design and technological vocabulary that feeds off the analysis of place-specific conditions, limitations, and ambitions. Crucial to this process is the idea of ‘robust technology’, i.e., an approach to the definition of building implementation techniques that can adapt to the level of complexity required and the level of expenditure possible without penalizing the expected performance of the building, neither culturally nor technically.

Key words: developing economies, design practice, robust technology, capacity building, policy definition

1. Reconstruction challenges in Sri Lanka: the post-tsunami situation

The tsunamis that hit Sri Lanka in late 2004 caused an unprecedented natural disaster with huge loss of lives and severe devastation to infrastructure such as housing, roads, railways and bridges. According to the World Health Organization [1], up to one million Sri Lankans were displaced by the tidal waves. In the aftermath of the disaster, Central Bank sources predicted that the rebuilding cost of housing and townships alone would amount to US$2 billion [2]. There were initial pledges for assistance by the world community and United Nations-assisted groups, although many feared that such relief may not reach the displaced due to entrenched political graft and mismanagement. Others, however, believed that the sheer amount of aid pledged by donor countries, combined with the reconstruction effort, would spur the economy and give a fillip to the stagnant construction industry battered by the country's 20 years of war [1].

A more structural question however lingers as to the Sri Lankan construction industry's ability (or maturity) to absorb and put to effective rebuilding use all the assistance received. After almost three years from the day of the disaster, the people who have been made homeless are still residing in refugee camps or temporary structures built closer to their destroyed settlements. The townships are still plagued by damaged buildings and ruined infrastructure. Most of the new buildings that replaced the destroyed ones have failed in quality and character. Above all, the opportunity offered by the disaster to re-think and re-develop the coastal belt to a better vision and substance has been lost in the process.

These reflections gain further resonance when considering that the plight of tsunami refugees cannot be treated as an isolated problem; indeed, it is part of an increasing (and increasingly larger) phenomenon of people displacement, which is particularly pronounced in developing and transitional economies. Reasons vary. The 20-year old civil war in Sri Lanka, for example, has transformed a particular section of the population into what the international community now calls 'internally displaced people', or IDPs. According to 1995 estimates, there were about 85,000 IDPs in Sri Lanka; by 2004 this number was expected to have doubled [3].

Natural disasters and war conflict combine with economic restructuring and urbanization pressures. In Sri Lanka, the extremely limited opportunities offered by the dying economies of internal towns and villages have triggered large migration flows of rural population to Colombo and other significant towns. As a result, the form of many urban centres is losing its traditional shape and functional hierarchy to become part of continuous, over-stretched urban corridors characterized by noise, congestion, formless growth, and massive shortage of housing and infrastructure. A recent survey of the city of Colombo, for instance, suggests that 52% of its night population lives in under-served, informal settlements [4]. This is a staggering figure given that, out of a total population of 20 million in the country, more than 4 million live in the Colombo Metropolitan Region (CMR), and well over 2 million in the Colombo District alone. By 2010, the CMR population is projected to increase up to 6.4 million, placing even more pressure on the demand for building and services in residential areas. Demand for infrastructure by both local and foreign investors within the CMR is also likely to increase in the future [5].

Responding to these challenges is not going to be easy. If one looks at the whole spectrum of activities carried out within the building industries of developing economies, the relationship between product supply and product demand varies highly in social efficiency. Sri Lanka is no exception. Institutional and professional responses to urbanization and population pressures have largely ignored the spatial needs of the poor, and allowed the proliferation of informal settlements as a social pressure-release mechanism. The planning and implementation of social housing and infrastructure — the supply of which was seen as a government prerogative in the immediate post-colonial period — have not risen to the challenge. Market-based commercial development, by contrast, is being strongly encouraged by the government, and facilitated through zoning, land use concessions and tax cuts. Architectural design, for its part, has been limited to few individual buildings identified mostly by high patronage or top-end tourism uses.

This paper is the first result of a thesis-in-progress that, on the basis of the type and amount of building work carried out in Sri Lanka at the moment, is considering ways to overcome the inherent misallocation of intellectual energy behind it.

2. Organizational structure of the industry: Institutional networks and labour pools

The point to start is informal labour. In Sri Lanka, in fact, the formation of construction labour and the consequent transfer of knowledge across the industry occur largely through informal relationships. This is essentially so for two reasons.

The first reason is that the majority of construction work is still organized via traditional networks led by a small-scale, one-man contractor and craftsmen manager, conventionally known as the ‘baas’. These individual contractors establish informal organizations of limited size, assemble a small workforce, and obtain contracts through social contacts which supply them with steady work. They usually rely on a few skilled workers competent in all the aspects of traditional building construction, with a larger team, or work gang, usually formed around them. The acquisition of skills takes place informally on the job, through the relationship between stable and temporary employment, thus generating a tacit working knowledge of building. Although the institutional training of construction workers has grown in recent years, its numbers still remain substantially low compared to informal training.

The second reason is that rural-urban migration has led to a progressive growth of the informal sector by generating a steady supply of unofficial workers, characterized by low capital-labour ratio, lack of job protection, dominance of self-employment, easy entry, and low productivity [6]. The minimum levels of income earned by these workers contribute to entrench their social status and position in the industry: in fact, without spending access to housing and land, they become further confined to the informal sector. In Colombo, squatter residents constitute practically all the informal labour utilized in the building industry, the port and the municipality.

The informal nature of the construction sector can also be explained in light of the large prevalence of self-building activities, where a considerable part of the investment is non-monetised and reliant on sweat-equity. According to the MARGA Institute [7], most of the semi-permanent and improvised housing in Sri Lanka is constructed through family labour and the assistance of informal groups whose members offer help to one another. Within such a process, required materials are obtained locally, and construction work can be extended over long periods according to the availability of labour and resources. In the 1980s and 1990s, this model was even promoted by government under the banner of 'aided self-help programmes' as a reliable mechanism for low-cost housing. Yet the lack of support for users' access to basic resources and knowledge has resulted in the cloning of sub-standard structures all over the island.

It is not difficult to understand why, in such conditions, the evaluation of the true capacity of the construction industry in Sri Lanka has proven to be a difficult task. According to 2003 figures from the Colombo-based Institute of Construction Training and Development (ICTAD), the construction industry provides direct employment to around 300,000 people, who become more than 1,000,000 when considering the informal linkages serving the construction process. These numbers include the staff of around 2,000 ICTAD-registered building contractors, and 100 consultancy/design organizations belonging to state and private sectors. There are also approximately 200 private-sector property development entities, the majority of which, again, operate informally [8]. In addition, over a dozen major institutions provide assistance on construction industry issues [9]. Yet, the industry's involvement in public-sector development has been minimal in recent times, especially when compared to the scale of construction work required to upgrade the battered socio-physical conditions in many parts of the country.

3. Pigeonholing labour by building markets: Fragmentation of construction activity into separate production spheres

The informal nature characterising the social structure of building production in the country combines with the failure of the industry as a whole to respond appropriately to current challenges to suggest that new analytical models of the sector may be needed, not only to appreciate the structural limitations of the present situation but also to delineate adequate policy responses that could help Sri Lanka take advantage of the situation rather than becoming a victim of its own opportunities.

Workforce dynamics are likely to occupy a central place in this discussion. With regard to internal migration patterns, a model introduced by Lewis in the early 1990s foresees a one-stage process of labour transfer where, with unlimited human supply, migrant workers from low-productivity rural jobs are absorbed into high-productivity urban industrial jobs [10]. Other authors, on the other hand, are more inclined to envision a two-stage migration process, whereby migrants first enter the 'urban traditional sector' (informal sector) due to their limited access to the 'modern sector' (formal sector), and then acquire the necessary skills that will eventually enable them to graduate to the formal sector [11].

Yet the research conducted for this thesis in Sri Lanka shows that both positions lack the necessary dose of realism under actual market conditions. The reason is simple: the construction industry is fragmented into almost separate spheres of production, with little connection in training, know-how and career development paths, and consequent limitations in cross-system application of technology transfer. In such a context, the advance of labour from entry-level informal workers to skilled workers does not occur as smoothly as labour scholars may have implied: construction workers tend to find themselves confined to insular activity pockets, characterized by the building markets they serve and the original social status that brought them there in the first place.

In order to arrive at making this assertion, the research employed over a dozen ideal-typical case-studies to examine the way specific building systems — concrete block-work walls, pre-cast concrete beam and column structural systems, and steel structural and roof framings — are developed and erected in Sri Lanka, depending on the building markets in which they are used. Due to space limitations, only concrete block-work will be considered in the following text.

4. The gap between ambitions and reality

To start with, the relationship between particular building markets and the skill base of their labour pool was analysed from a socio-technical viewpoint (Figure 1).

Construction workers for low-cost residential and commercial building activities in Sri Lanka are sourced predominantly from social networks characterized by the use of local materials and processes as well as manual tools, where empirical and ‘conventional’ knowledge constitutes the basis for action and decision-making, and where informal labour structures are built around ‘self-builders’ or small-scale contractors (baas).

The limited level of building know-how available to such construction activities has a direct bearing on the formal, environmental and mechanical performances of the finished products. For example, the formation of roughened surfaces and irregular edges in concrete blocks due to errors in manufacture, assembly and handling are common to most block-work walls built in low-skilled construction sites. High porosity of blocks as a result of irregularities in the concrete mixture and curing process is also commonplace, thus creating failure chains in water proofing and thermal insulation. The mortar joints between blocks often appear ragged, untidy and irregular, and most walls have stained surfaces due to droppings of mortar and bad weathering. Moisture penetration through shoddily built joints is a major concern, while structural failure due to the use of sub-standard blocks is also common.

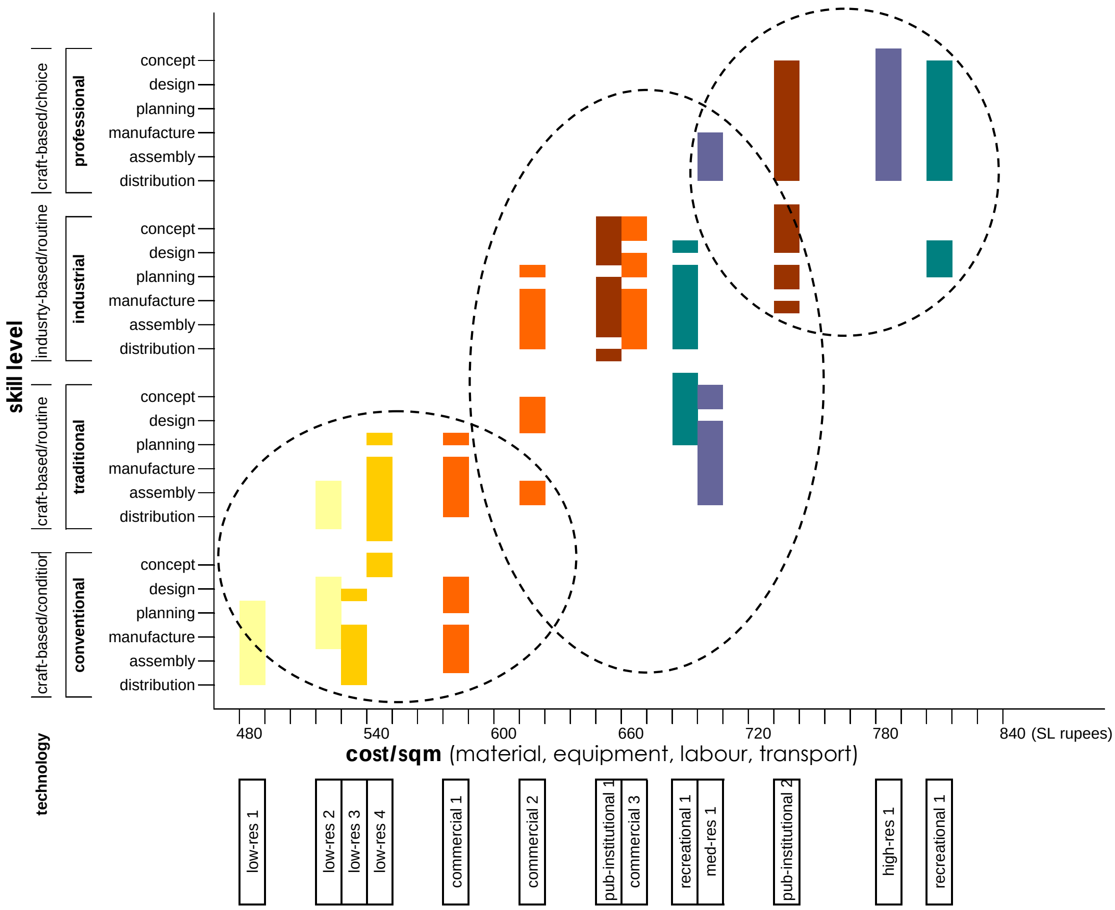

*Figure 1: **Application of block work:** Socio-technical economics*

For most large-scale commercial and industrial buildings, however, industry-based routine processes provide the basis for construction know-how and labour organization. Work in such building markets is often carried out by ICTAD-registered commercial builders or construction companies, supported by a pool of skilled/semi-skilled masons and plasterers. Block-work modules are mostly factory-produced by large-scale manufacturers, using skilled block-makers at their plants. There is a reasonable emphasis here on the use of proper block-laying techniques, although routine production protocols can also give rise to inflexible, and thus potentially compromised, technical solutions. Exposed block-work, for example, is rarely used for higher-end commercial buildings in Sri Lanka; plastering of walls is generally considered essential to cover shoddy junctions and ragged joints.

In buildings of high patronage such as resort hotels, museums or high-end residences, the involvement of design professionals and the set up of a highly craft-based socio-technical framework is deemed necessary, thus implicitly generating a demand for highly honed labour skills and efficient planning of work at the site. Since the architectural ethos informing most of this work finds its inspiration in a picturesque paradigm defined and achieved through high craftsmanship, the lack of precision that characterises building artefacts in low-skilled labour environments is aggressively rejected. Common techniques employed in these more ‘cultivated’ markets include the laying of blocks to different compositional strategies, forms and bonding patterns, and the use of custom-designed block-work that requires special instructions both at the factory and on site. The employment of skilled masons, plasterers and carpenters is seen as both natural and essential to carry out such jobs, thus depriving entry-level informal labour the opportunity to be contracted for higher-end work even as apprentices.

As Figure 1 shows, when construction activity takes place within areas with such dramatic differences in capital expenditure ability, access to materials and systems, and standards of use, technology itself gives rise to separate socio-technical pockets. This make it difficult for the workforce employed within each pocket — particularly the lower ones — to move across boundaries, learn from others, and improve their technical and economic status.

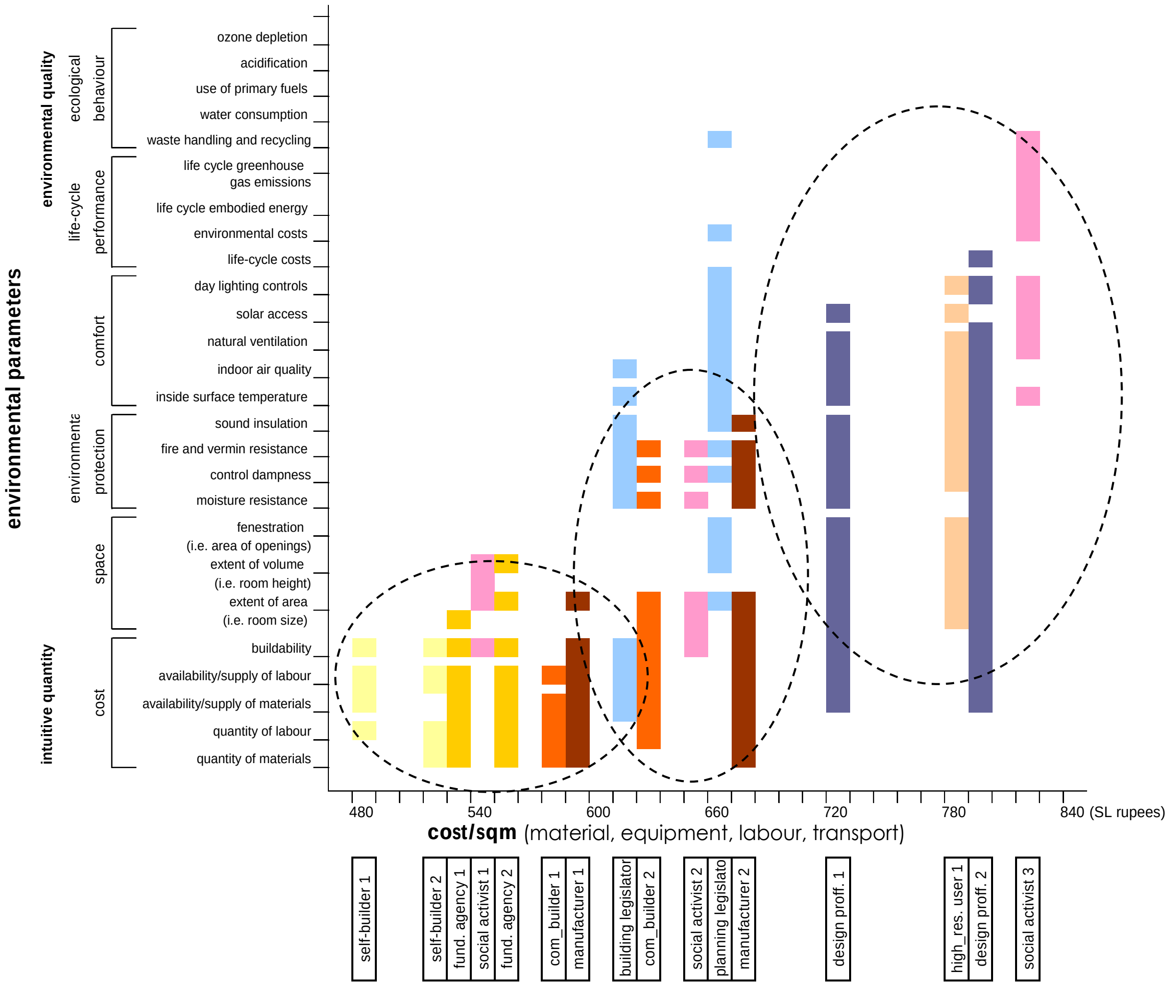

Figure .2: ***Application of block work:*** *Socio-cultural economics.*

5. From technology to ‘sensitive’ technology: Consequences of industrial compartmentalization

After looking at product characteristics as a result of labour skills and material resources, the analysis focused on the socio-cultural definition of acceptable (or expectable) building parameters. In Figure 2, particular technological decisions taken by various parties involved in the construction processes observed – e.g., self-builders, commercial builders, funding agencies, planning and building regulators, design professionals, social activists, etc. - are associated to a set of measurable factors, or ‘values’, which define the complex of surrounding circumstances, conditions or influences in which a person lives or operates. These factors are collectively identified as ‘environmental parameters’, and organized in the diagram under six sub-headings: cost, space, environmental protection, comfort, life-cycle performance, and ecological behaviour.

For the actors performing in the lower-end markets, the parameters related to cost of production — such as quantity, availability and supply of materials and labour, or easy constructability of chosen building systems — seem to be the most crucial and achievable at the same time. The actors involved in the process have neither the economic capacity nor the technical knowledge to respond to higher aesthetic and environmental product concerns. In other words, the environmental parameters pertaining to cost and constructability define the technological framework within which builders, users and facilitators of low-end residential and public projects operate. Even more so, these parameters form a combination of semi-independent constrains that define the real choice available to decision-making subjects in that particular building process. Groak [12] calls the result of this combination the ‘feasible set of available technological decisions’ of a given building program, and argues that attempts to stretch this boundary will result in ‘sensitive’ technological applications that may lead to building failures. For example, the construction of commercial and institutional buildings in Sri Lanka requires the provision of determinate levels of fire and sound resistance to comply with the occupational health and safety parameters set up by planning and building authorities. Due to lack of knowledge, skill and capacity, the lower-end building markets do not adhere to such regulations, thus exposing their buildings to potential failures. On the other hand, attempts to stretch their ‘feasible set’ to accommodate such concerns may result in failures elsewhere – i.e. lack of funds to spend on a proper waterproofing mechanism due to the different allocation of a very tight budget.

By contrast, larger ‘feasible sets’ are available for building markets with higher spending capacity and cultural ambitions. High-end commercial buildings, for example, have both the capacity and the need to facilitate proper response to regulatory requirements such as fire and sound resistance. Yet, concerns for life-cycle embodied energy in buildings, or for their impact to the ecological footprint, are not embraced by commercial builders and manufacturers.

What happens, in other words, is that the stated objectives of construction activity, be they physical, commercial or cultural, differ greatly according to the market. It is therefore unlikely that the knowledge required to respond to those objectives is produced outside the market where it is needed. Attempts to import the objectives without importing the work structure or the resources, then, may result in sub-standard results or relative failures.

The industrial compartmentalization of labour can be further understood in relation to the production systems in use amongst building component suppliers. As explained in Figure 3, concrete block-work wall production in Sri Lanka spans different industrial models. If one adopted Winch's taxonomy of production systems [13], the supply of block-work walls for low-end construction (in both residential and commercial buildings) is generally organized under 'make to order' or 'assemble to order' provisions, where pre-configured systems or sub-assemblies end up being used almost as raw (and thus imperfect) materials, with the understanding that they will be inevitably altered to adapt to the 'feasible set' of technological options. In other words, the 'order' for a standard exposed block-work wall system already allows for construction irregularities that come from both the manufacturing and the application context. The inevitability of formal and mechanical errors is almost accepted as part of it.

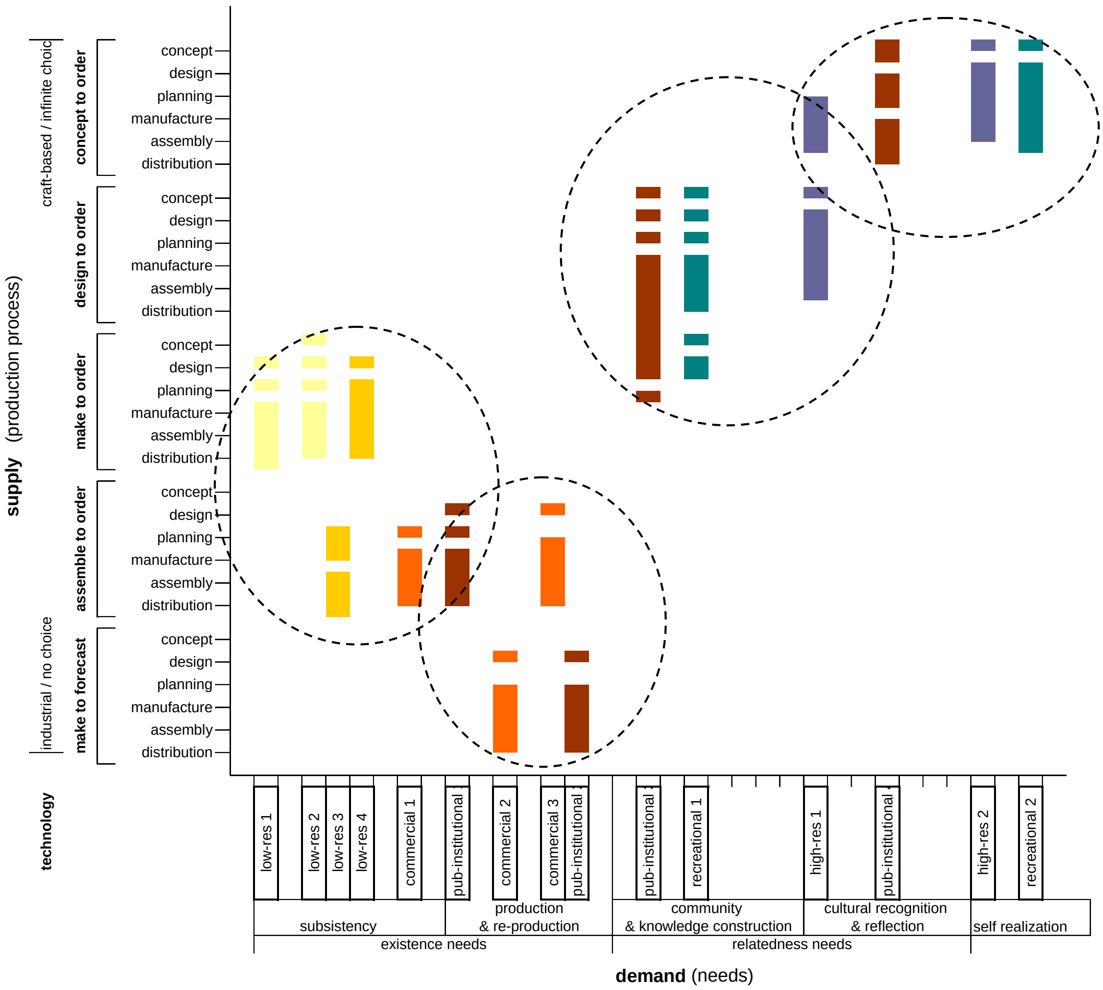

Figure.3: ***Application of block work:*** *Demand-Supply behaviour*

For construction activities based on routine re-production – i.e. commercial, institutional and industrial projects – off-the-shelf procurement is more widely used. Building components are produced for stock and sold after or during manufacture; the final product is always a reasonably well-built, plastered block-work wall.

High-end architectural creations for cultural programs, on the other hand, depend mostly on a supply chain where the client's involvement from early conceptual and design stages appears to be essential. In such a 'designed to order' process, significant design work — for example the laying of blocks to a particular pattern, or the manipulation of wall texture through the exposure of aggregates or particular pigmentation — is required even to conceptualise the basic product.

6. Planning for controllable failure

Succinct tough it has to be, the description highlights the contradictions that pervade construction activity in socio-economic environments such as Sri Lanka's, with a large portion of the workforce employed in the sector officially unaccounted for and yet central to the operations, and ultimately the outcome, of many of its sub-markets. The technical review undertaken of different projects depicts an industrial landscape, even at building system and component level, characterized by highly diverse demands, labour skills, achievable objectives, and conception-and-implementation horizons, which is structured and functions essentially as a series of separate socio-technical environments. The more internally efficient (or optimised) each of these environments becomes in terms of product definition and delivery, the less permeable its boundaries will turn out to be for the productive passage of labour force from other environments, particularly lower-end ones. This may not be critical to the ultimate realization of building structures (although it can lead to both better and worse construction results depending on actors' understanding of the requirements); but it is certainly critical to the building of technical capacity and, ultimately, the existence of social development paths.

The theoretical conclusion arrived at in the thesis, and currently under investigation through a series of pilot projects, is that the integration of technological development and broad socio-economic growth can be facilitated by 'open' (or 'incremental') industrial design strategies: rather than planning for design solutions and structures of production perfectly self-contained in their limitations and potential, from emergency shelter-relief work to sophisticated iconic hotels, it would be advisable to recognize that technological contamination and compromise can increase the rate of participation of the labour force to their own progressive training. What is proposed, in other words, is the definition of a broad technological framework at industry level that is both flexible and adaptable, and can therefore be used to expand the options available within any given project, helping the latter perform as training grounds.

Using building projects as training opportunities without losing productivity, however, means that the technologies employed must have latitude for errors and non-optimal application ― i.e., they must be inherently 'robust' as opposed to precise and therefore more 'sensitive'. In practical terms, this objective translates in the definition of technical options that can tolerate changes in the economic variables of projects on the one hand, and manage the intricacy of buildings' cultural and technical attributes on the other. A framework, that is, which can adapt to the level of complexity required and the level of expenditure possible in a project without penalizing the expected performance of the building, neither culturally nor technologically.

There are examples of the type of intellectual and technical robustness argued for above in the work of several Modern Architecture masters, who defined design and technological languages able to travel and develop consistently across markets to facilitate diverse spatial and cultural needs. Le Corbusier, for instance, designed the Maisons Jaoul in Paris in 1955 — possibly one of the most expensive small residential projects in France at that time — and then developed social housing structures in Chandigarh, India, a project built with much sweat-equity, without compromising his architectural ethos or the relative result. Eladio Dieste's church in Atlantida, made of reinforced concrete and post-tensioned brick tiles is the most renowned building in Uruguay, but his municipal bus terminal in Salto and the sheds for Massaro Agro-industries in Canelones use analogous solutions and are equally poetic and glorious. The India International Centre in New Delhi, designed by Joseph Allen Stein, has a monumental effect achieved by the unity of form and material. Yet, Stein's industrial structures for a bicycle manufacturing plant in Kerala have similar quality and character, but in a different sense of materiality as allowed by the limitations of its financial and cultural program.

7. In lieu of conclusions: the elements of a robust paradigm

Yet the construction of a pervasive robust framework cannot rely on the work of isolated masters taking advantage of discrete opportunities; rather, it has to be developed more 'generically' from the bottom up, by looking at the industrial base of region and defining a design and technological vocabulary that feeds off the analysis of place-specific conditions and limitations. Within this perspective, the architecture of a robust framework must incorporate, normatively, a series of performance parameters. Operating 'robustly' requires:

(1) The ability to save money and time

Scarce, expensive and labour-intensive materials and processes should be avoided, thus making the components and subsystems cost-effective compared to other systems available in the market. Clarity of design and the performance of technological systems should not depend on excessive craftsmanship so that flexible and economic use of labour across building markets can be achieved. A flexible programming of building process should be implemented to facilitate different demands of production, while easy-to-erect connection techniques and modular design for easy handling should be preferable engineering options to allow faster erection and use of cross-market labour.

(2) The ability to allow greater flexibility in production, assembly and use

Components and subsystems should be scalable, and subject to be coupled/decoupled as required to accommodate specific design and technological performances. Having the capacity for demountability, disassembly and reuse will allow systems to be used for different production requirements. Systems and subsystems should be also designed in such a way that discrete unit processes can be replaced with upgraded and enhanced technology as it becomes available through transfer from higher sectors.

(3) The ability to provide high tolerance for human errors of design, manufacture, assembly or use

To allow easy transfer across markets, resolution of a problem should be achieved via logic of construction and clarity of erection, without the need for care and precision in the making. When joining sub-systems together, different junctions should be allowed to accommodate diverse labour conditions. Strategies must be in place to prevent the failure of one module or element of a system from triggering a chain of failures.

(4) The ability to allow greater adaptability to social circumstances

Different permutations of products and processes need to be established, so as to give rise to different but equally valid solutions in terms of functional and social make-up of technical objects. Balancing of resources in the construction industry should be allowed, particularly by allowing users to take advantage of other users' investment in production, labour, land and machinery, thus optimizing factors' productivity. The capacity for disassembly and reconfiguration in components and subsystems should be supported, so that the same technology can respond to the changing needs of its users as well as to changing users across building markets.

(5) The ability to build workforce capacity

By implementing a mix of labour-intensive and capital-intensive processes for building production, less skilled labour can be used through limited training and modular breakdown of activities. Labour productivity should be increased by enforcing better health and safety standards, and by diminishing the extent of job casualization, fragmentation and traditional skill demarcations in the industry. The gap between operative and professional/technical skills (or informal/formal) should be reduced by translating explicit knowledge into tacit knowledge, and vice versa.

(6) The ability to establish organic links

Finally, organic cross-industry links, naturally connecting or acknowledging all participating actors, must be in place to facilitate easier transfer of knowledge across the construction sector.

Abstract

The renovation project of an apartment building can be classified into four processes: ordering the project stage, planning stage, examination and judgment stage, design stage and construction stage. However, in the domestic renovation business, the project performance process has yet to be made systematic by stage. Of the stages involved in renovation, the design stage is the one that involves very complex roles and business processes of those involved in the project, including the project manager, architect, resident and engineer. In particular, in the design stage, the insufficiency in the ability to utilize the input information by project participants and improper decision making cause various problems in the subsequent construction and ultimately make it difficult to accomplish a renovation project that fully satisfies the residents. Therefore, the design of renovation is a very important stage to ensure a comprehensive understanding of the project performance process as well as the recognition of the design management technology. For this purpose, we aim to provide design work process in integrated respects and the role and responsibilities of every participant in the project, subject to the renovation design stage.

Keywords: Renovation Project, Cooperative Design Process, Participants Roles, Decision Making

1. Background

1.1 Research Objectives

A construction renovation project has various advantages, including cost savings, reduced project duration and minimal production of wastes in terms of resource recycling. In particular, an important factor of the performance of the renovation business is the provision of an opportunity to increase the value of the asset and create benefits through the performance improvement. On the other hand, as renovation should be performed under the controlled conditions of the utilization of existing resources, there is a limit on work space and methodology, along with the fact that recycling of the existing system should be considered and compatibility ensured. Therefore, the special, highly demanding field of building renovation requires complex factors and concrete process planning in the design stage. The major difference between renovation design and new construction design is that it is difficult to obtain the design information of an existing building, and any change in the design information occurs in the minute examination and judgment process. Moreover, the design of the structural reinforcing methodology is necessary to be progressed in detail from the design development stage. In this respect, the design management of a renovation project goes through a complex design process in which major requirements are simultaneously considered in the planning stage and the renovation workability in the construction stage.

Therefore, in this study, we aim to propose a basic project performance system for design management by analyzing the information the design work process subject to the planning →feasibility study→ design stages with various participant respects. The major contents proposed in this study are the following. First, we aim to set specific roles and responsibilities for all project participants and propose a general process for such projects in this study. Second, we will aim to establish a utilization method for the input information in order to propose an effective information management system for the renovation design in the after study.

1.2 Research Scope and Process

In this study, we aim to examine the basic process involved in a project in the renovation design stage and analyze the role and responsibility in the project of those in charge by each progressive stage. The performance method and the progress of this study are described in next paragraph. (1) Study of the process in the renovation design stage, (2) Comparative analysis work flow in the new construction design and renovation design, (3) Analysis of the roles and responsibilities of project participants at each renovation stage, (4) Constitute integrated renovation design process.

2. Design Cooperative Process and Participants

2.1 Renovation design process

A renovation design project can be classified into four stages: project ordering stage, planning stage, examination and judgment stage, design stage and construction stage. First, the examination and judgment stage involves the establishment of the remodeling requirements, preliminary examination and feasibility assessment, after which the design process begins. Renovation design has various limitations as compared with general new construction design. Unlike in new construction design on land, the considerable part of the structure of the existing building has to be maintained and the compatibility of the existing structure and facilities systems should be reviewed in consideration of performance improvement. Also, the range of renovation could be readjusted according to new conditions and situations that occurred with respect to social and economic demands. In this case, the design plan, construction technique, methodology, selection of materials should be comprehensively considered. Renovation design process differs according to the characteristics of the project and it can be always examined by design stage through job site investigation. In particular, the accuracy of the understanding of the current state regarding job site investigation is very important as it avoids later changes of order in the design and reduces such risks as reconstruction and removal, thereby ensuring an efficient performance of the project. The following Table 1 describes the major business details of the general renovation business.

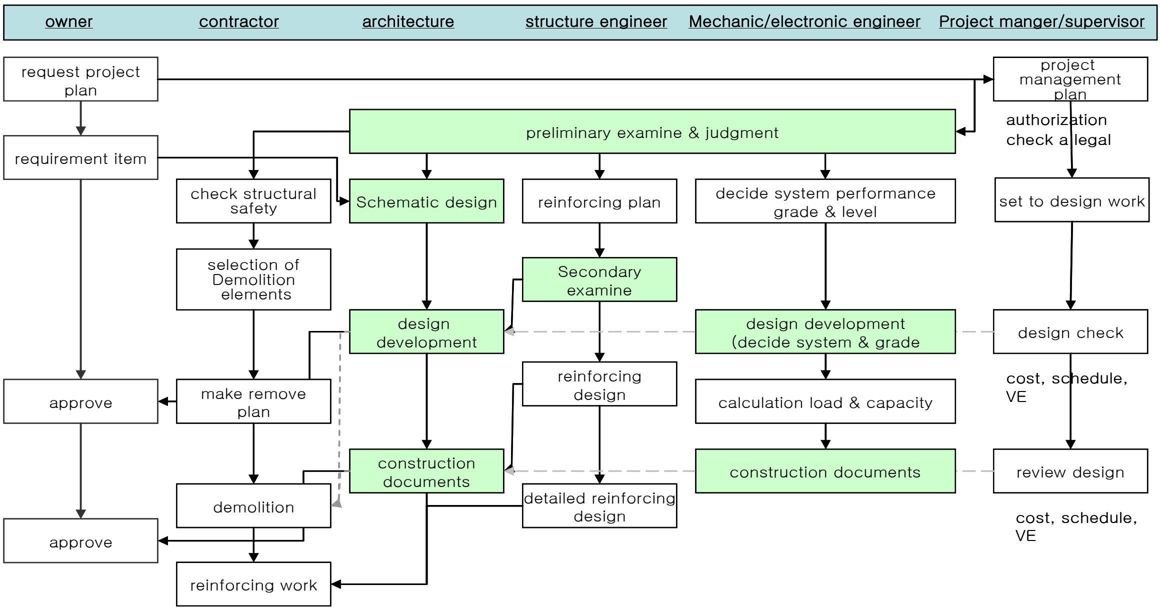
Table 1: Major business details by renovation design stage

Stage	Major Work Contents
Schematic Design	- Understanding of the renovation requirements - Review of the current status of the existing structure, performance and the plane figure - Checking of the renovation policy and plan-related items : Consideration of the pace suitable for the uses and goals of users and the establishment of the construction plan (e.g., Changing the type of stairs, extension of the floor, vertical extension and extension of the restroom and installation of new elevators) : Repair and structural reinforcement plan for structural problems arising from obsolescence. (e.g., alternative structural plan) : Setting the performance improvement rate of facilities, electricity and communication (e.g., adjusting the course of repair work and changing the plan according to the machinery facilities) - Need to review the adaptability and workability of the plan and relevant laws and regulations - Others, such as the setting of the establishment scale of the common basement space
Design Development	Concretely making the major details of the design plan - Review of the actual measurement of the plane of the jobsite and understanding of the major details of building components and checking of the bill of quantities of machinery facilities - Setting, review and application of alternatives for the plan for the removal work, change of the structural deign (e.g., drawing of the removal plan and establishment of the standards) - Advanced adjustment of the construction, structure, engineering, facilities and electricity by construction work types as well as the review of the structural design of the cooperative deign among construction works, and planning and review about the structural reinforcement methodology. (e.g., Extension of the floor structure, plan of beam and column, vertical extension, location of the stair hall, use of reinforced concrete structure or steel structure according to the parallel extension) (e.g., Establishment of new subordinate materials, enlargement of concrete placing of the section, adhesive methodology and prestressed methodology of the structural reinforcing materials) (e.g., Setting of the standards for vertical and horizontal piping and duct)
Construction Document	- Confirmation and approval of the details of the basic design - Confirmation of the uniformity and budget with the finishing methodology and structure of the design plan in various construction work areas - Determination of the structural reinforcement system and design of the structural section - Drawing and collection of bills of quantities, various other bills and specifications - Equipment and export planning related to the removal and construction

2.2 Design Process in New Construction and Renovation

Project participants in each stage of the renovation design have their own responsibilities and roles and the work is performed in consideration of their professional relationships in terms of cooperation, direction and supervision. In particular, regarding the architect, the relevance between the construction design part and the structural design is very important and structural supervision is performed separately to ensure a consistent structural review during the construction. Depending on the structural condition of the building, the extension, repair and remodeling plan is drawn and the appropriate structural construction methodology and the adhesive joints design are determined. Regarding the detailed design stage, the primary structural reinforcing plan is established in the schematic design stage. In the design development stage, structural reinforcing design is concretely made as secondary accuracy, examination and judgment, and further details are confirmed in the construction documents stage later. However, although all the aspects of the structural design are confirmed, as it is not possible to understand everything in the job site, changes and adjustments are usually undertaken during the construction, so that the exactitude of the information regarding accurate examination and judgment are considered very important. The goals and requirements of the renovation are established in the planning stage for the facilities and electrical parts. And based on the primary understanding of the project's current status, the scope and level of the renovation are determined. Eventually, the basic design alternative is established in consideration of various alternatives for system selection, assessment, and the maintenance and management afterwards. Considering the energy cost and load, among other factors in the construction documents, the plan is finally confirmed. Also, the owner and the project manager perform a design review and VE throughout the progress of the design and it finally goes through the VE review and the owner's approval. Removal works generally proceed with construction documents stage together to reduce the project's duration. In this case, a special construction methodology review for the removal of building elements related to remodeling and extension of the renovation should be considered prior to the construction documents stage. Figure 1 shows a diagram of the basic business cooperative design process of project participants.

Figure 1: Comparative Analysis Work Flow in the New Construction Design and Renovation Design



2.3 Roles and Responsibilities of the Project Participants

For the implementation of the renovation project, each project participant will have particular responsibilities and level of authority by work stage. The work to be done by the project participants must be classified so that the efficient implementation of the project can be ensured. It is difficult to implement the new construction and renovation designs without the cooperation of the project participants. Therefore, for the accurate implementation of the design, the work involved in the renovation project planning must be shared by institutions. Through this, the architect can more efficiently promote the design work and the sharing of information about the design, and the project manager can review and approve the results of the project. The following table (Table 2) outlines the responsibilities and level of authority of the project participants in the renovation design stage.

Table 2: Role and Responsibilities of the Project Participants

Phase	Work Contents	owner	project manager	architecture	contractor	occupants
Schematic Design	architecture programming	A/I	A/C	R	C	I
	make alternative plan	A	A/C	R	C	I
Design Development	decision methodology	A	A/C	R	C	I
	cooperate management	-	A/C	R	C	I
	design development VE	A/I	R	C	C	I
Construction Document	material & method decision system	A	A/C	R	C	I
	construction document VE	A/I	R	C	C	I

Explanatory notes: R: Responsibility, A: Approval, C: Consulting, I: Information

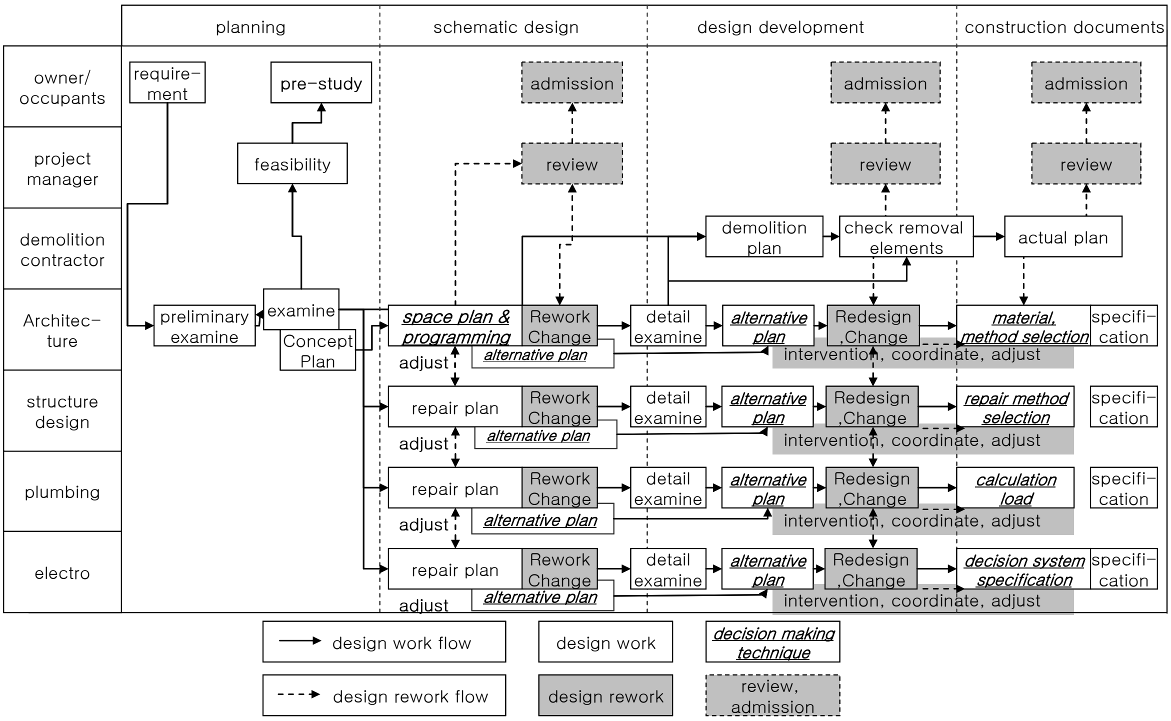
2.4 Cooperative Design Process

In the renovation planning stage, the promotion of the project is confirmed after considering the required design information as well as the results of the primary examination and judgment, and of the feasibility assessment. The schematic design stage is promoted afterwards, focusing on the construction area. The major contents of the project involve making the design concept concrete through the space plan and programming. In this process, the alternatives of each design item are determined and assessed by the architect again, and are reviewed and confirmed by the owner and the project manager. Also, the feedback process takes place in the review and confirmation stages, and the rework or change of design necessarily occur simultaneously. These serial processes are directly related to the performance and quality of the schematic design. Therefore, appropriate decision-making from the early design stage is the best preventive measure for the change of design well into the project, going beyond the projected construction cost, rework, etc.

In the basic design stage, which follows the schematic design stage, detailed secondary examination and judgment are conducted. The design work progresses by pre-screening the dimension, column space, floor elevation, and compatibility of the systems, and by considering the structure, engineering, electricity, communication, etc. in the construction work, along with the architect.

At this time, cooperative design is promoted by necessarily checking the mutual interference among construction works. Figure 2 shows a diagram of the design process's serial work process in integrated respects and by design stage.

Figure 2: Cooperative Renovation Design Process



3. Conclusions

Currently, the renovation business faces many problems due to the absence of a comprehensive evaluation system and performance assessment of a project. The design stage in the renovation phase is an important stage, to manage the quality and hit the targets of the entire project. Therefore, this study aimed to implement renovation design management system as it proposes the business processes by project performance stages focused on the design stage. As major contents of this study, it determined the roles and responsibilities of the project participants. And it presents a base study on design work process with various participant respects.

Renovation business is promoted in very various forms according to its conditions such as the characteristics of the project, the owner's ability and the job site conditions etc. Therefore, this study is expected to be utilized on the whole or in parts according to the characteristics of the project's requirement subject to apartment buildings. It is expected that consistent performance of the study will contribute to the improvement of the efficiency of the design work as it informatizes the project management system of the renovation business as well as systemizes the utilization process of the design information by the project participants.

This research performed a basic study to propose a prototype for the design management, which will boost and activate rational renovation.

INTERNATIONAL AND COMPARATIVE LAW IN THE BUILT ENVIRONMENT

Special Features and Experiences of the Construction Industry- Arbitration in Sri Lanka

M.D.T.E Abeynayake

University of Moratuwa
Sri Lanka
(abey92@hotmail.com)

Abstract

The construction industry in Sri Lanka covers a complex and comprehensive field of activities involving many operative skills and conditions, which vary considerably from one project to another. The dispute might arise at any point during the construction process. Generally, there is a low standard of contract formation and of contract administration in the construction industry, which lead frequently to unnecessary problems and disputes. The contract parties usually enter into a dispute as a result of differing expectations or misinterpretations of the contract documents.

Arbitration is a voluntary procedure available as an alternative resolution to litigation but not enforceable as the means of settling disputes except where the parties have entered into an arbitration agreement. In such cases the right of either party to have disputes resolved by arbitration will no doubt be beneficial to the country in the context of construction law and the foreign investment. Construction claims tend to be of the most technical nature - intensive and multifaceted than most other commercial disputes. Hence construction industry needs a fast and cost effective means for dispute resolution. The desirable features of arbitration is fast, inexpensive, fair, simple, flexibility, confidentiality, minimum delay. The main feature of arbitration is that it is consensual in nature and private in character. Sri Lanka Arbitration Act No 11 of 1995 stated various concepts or arbitration principles and UNCITRAL Model Law.

Keywords: Arbitration, Construction Industry, Special Features

1. Background

Disputes in the construction industry in Sri Lanka are normally those that arise under contracts for the procurement of supplies and services and the installation of equipment. In the early days of construction industry in Sri Lanka most disputes were settled on the job site at an informal meeting between the client and contractor with residential engineer on handshake. Nowadays construction disputes are more lengthy and complicated than ordinary civil cases in Sri Lanka. Most Arbitration Acts of world (including those following the UNCITRAL Model law) usually allow parties to change the substantive law to be applied, if it is a transactional contract. The Arbitration Act of Sri Lanka goes a little further.[1] The Sri Lankan courts refused to incorporate the arbitration agreement into a subcontract.[2] **(**Courts will in each case examine or interpret the language of the contracts in question to see whether general principles of construction are applicable. Arbitrators may keep away from writing reasons for the award and only the final decision of the Arbitrators will be enough for a valid award. This will be very useful for the settlement of disputes relevant to construction industry. Sri Lanka arbitration process has become very adversarial and very expensive. It is important to review and improve the process.

1.1 Conflicts, Claims and Disputes in Construction industry

Conflict has been defined (Collin – 1995) disagreement and argument about some thing "Serious important" and also as a difference between two or more beliefs, ideas an interests' since, conflict is 'inevitable in human relationships' (Rhys Jones) it is predictably preponderant in projects where human relationships proliferate as in construction. Figure 1 illustrates the many interacting potential sources of conflict in construction. Despite the potentially unpleasant connotations and consequences of conflict, beneficial aspects of conflict have also been recognized and conflict management has been said to be a major component in construction project management (Gardiner and Simmons- 1999).

Claim will be used to mean simply a request, demand, applications for payment or notification of entitlement to which the contractor, rightly or wrongly at that stage, considers himself entitled and in respect of which agreement has not yet been reached. Some construction claims are unavoidable and in fact necessary to contractually accommodate unforeseen changes in project conditions or unavoidable project conditions or unavoidable changes in client's priorities. While such claims may be settled amicably the prior presence of unhealthy conflict can trigger degenerations into unnecessary disputes. Such sceneries can in turn generate unnecessary and unreasonable claims that further escalate unhealthy conflict and disputes.

The possibility is also illustrated in Figure 1, which sets out the basic relationships between conflicts, claims and disputes in construction sceneries, Disputes are taken to imply prolonged disagreements on unsettled claims and protracted unresolved conflict.

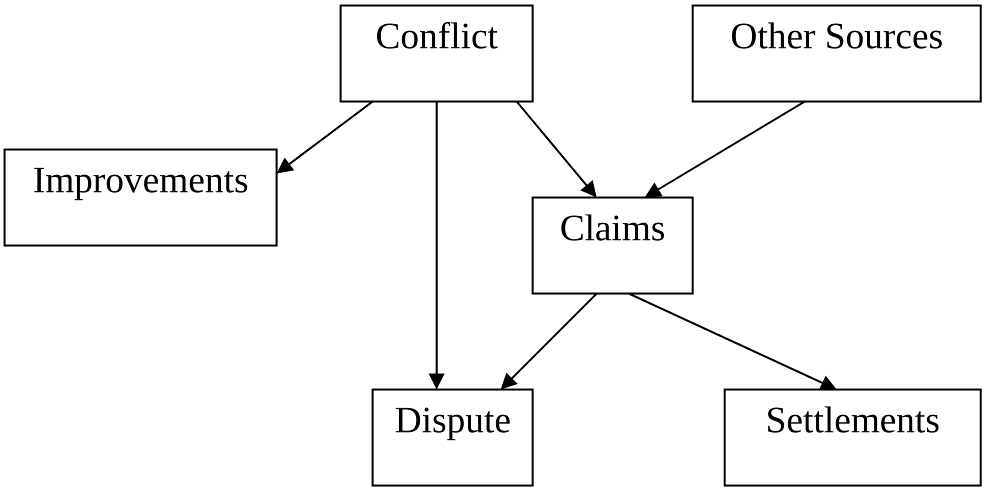

Figure 1: Basic relationships between conflicts ,claims and disputes

1.2 Reasons for construction industry disputes in Sri Lanka

Disputes in the construction industry in Sri Lanka are normally those that arise under contracts for the procurement of supplies and services and the installation of equipment. Main Reasons for disputes in Sri Lanka construction industry are namely,

- Breaches of contract by any party to the contract.
- Inadequate administration of responsibilities by the owner or contractor or sub contractors.
- Some plans and specifications that contain errors, omissions and ambiguities.
- Sudden tax and cost increase.

In the early days of construction industry in Sri Lanka most disputes were settled on the job site at an informal meeting between the Resident Engineer or owner or contractor by a handshake. Nowadays construction contract disputes are notoriously more lengthy and complicated than ordinary civil cases in Sri Lanka. Most construction disputes are resolved by negotiation. However , a dispute cannot be resolved only by negotiation between the parties. Resolution of the matter can be facilitated by the use of Arbitration techniques. Most of the contractors of Sri Lanka are unaware of the arbitration process, its benefits and low cost. Foreign investors particularly with foreign construction companies were reluctant to enter into contract agreements with local contractors due to an absence of an easy , accessible construction arbitration institute as well as specialised construction arbitrators in the country. As projects increase in size and complexity so the risks of cost and time overrun, which invariably lead to disputes.

1.3 Remedies for Breach of construction Contracts

When there is a breach of construction contract the following remedies may be available.

- A right of action for damages (the most common remedy)

- A right of action on a quantum meruit.
- A right to sue for specific performance
- A right to for an injunction.
- A right to ask for rescission of the contract.
- A refusal of any further performance by the injured party.

Construction Contract Law is part of civil law and concern the enforceability of agreements entered into between two or more persons. While all contracts are based on an agreement, all agreements may not result in contract. A construction contract is a legally binding and legally enforceable agreement. Whenever there is a breach of contract by one party, the other is entitled to bring an action for damages which is calculated in accordance with the special circumstances. Damages are the common law remedy consisting of a payment of money and are intended as compensation for the plaintiff's loss and not as punishment for the defendant. The plaintiff should not be put in a better position than if the contract had been properly performed. The aim is to put the injured party in the same financial position as he would hare been if the contract had been performed according to its terms. The client is trying to achieve the best – finished product possible within budgets, time and quality. The builder is trying to achieve this with the economic and market forces while trying to maintain builders profitability. If either party feels that the other party is hindering their goal a dispute may arise. Hence arbitration is a voluntary procedure available as an alternative to litigation but not enforceable as the means of settling disputes except where the parties have entered into an arbitration agreement. In such cases the right of either party to have disputes resolved by arbitration will no doubt be beneficial to the country in the context of construction law and foreign investment .

2. Disadvantages of litigation

Construction contract litigation is so common at present that District courts in Sri Lanka and the two Commercial High Courts in Colombo , Sri Lanka are unable to scope with the large volume of cases . The result is that today our courts are not in a position to dispense justice expeditiously to those litigants who have recourse to them .Construction claims tend to be of the most technical nature - intensive and multifaceted than most other commercial disputes. Hence construction industry needs a fast and cost effective means for dispute resolution. In this regard the Arbitration Act of Sri Lanka was enacted by Parliament of Sri Lanka, which became law on 1st August 1995. It expects to make the arbitration process more definitive, streamlined and effective. Today Arbitration is an alternative to litigation in Sri Lanka . It originated as a method of resolving disputes quickly and without legal formality.

Sri Lanka's court system and litigation method is based primarily on the British judicial system modified to some extent to suit our country's needs. After independence in 1948, the court system and litigation system was reformed to a great extent by the Administration of justice Law of 1973. Later, the Constitution of 1978 made several important changes for litigation method and these changes apply today.

District Courts have unlimited original jurisdiction in all civil litigation matters such, claims for breach of contracts ,breach of bonds and guarantees, applications for damages such as construction tort cases.

All too often the effects of litigation is ,

- Long – drawn – out proceedings (lengthy hearing)
- Cost of litigation are far too high (High legal cost)
- Wastage of the client's managerial time
- Damaged commercial relationships
- Some times judgment that is impossible to enforce .
- Use of deliberate delaying tactics by a defendant or respondent who knows how to play the system .
- Parties must comply with formal rules of procedure or evidence for litigation
- Possible over – simplification of complicated technical and legal issues

3. Advantages of Arbitration

There are several advantages in certain instances for the parties to dispute to refer it to arbitration rather than to commence an action in the courts. The principal advantages are,

- Economical – Arbitration is cheaper than a court action.
- Simplicity- Arbitration procedure is simple.
- Mutual agreement- Arbitration meetings can be conducted anywhere and at any time which is suitable for the parties. Parties do not have to wait for the court's free dates.
- When the dispute concern a technical matter such as a building contract, person chosen to arbitrate generally possess the appropriate special qualifications.
- The process can be speedier than a court case.
- There can be a saving in costs.
- Unwanted publicity can be avoided.-The arbitrator can view the subject in dispute at any reasonable time.
- Private- The entire hearing takes place in private.
- Speedily- Arbitration is speedier. A court action will take at least one or two but in arbitration can be agreed to settle the disputes within 6 months.
- Expertise- Arbitrator is normally selected for his expert knowledge but the judge will not have the knowledge of technical side of each field.

The desirable features of Arbitration is, Fast, inexpensive, fair , simple, flexibility, confidentiality , minimum delay. The main feature of arbitration is that it is consensual in nature and private in character. The concept of "Party autonomy" associated with arbitration not only allows the parties to select their arbitrators, the seal of arbitration and the rules of procedure to be followed by the arbitrators. (Article 10, 19 & 20 of the UNCITRAL Model Law) UNCITRAL – Arbitration Rules) The composition of the arbitral tribunal is critical for a good arbitration. The ability the parties have to choose their arbitrator taking into consideration *inter alia* their special expertise in the relevant field. Most countries have legislative provisions which enjoin the court to facilitate the process of constituting the arbitral tribunal. [3]

4. Arbitration Act of Sri Lanka and its Procedure

The Arbitration Act of Sri Lanka No. 11 of 1995 provides for a legislative framework for the effective conduct of arbitration proceedings as well as the most practicable or methodical mechanism for the enforcement of arbitral awards thereby making arbitration a viable and expeditious alternative to litigation for the resolution of commercial disputes. This Act treats arbitration in the field of construction without taking in to consideration the value of contract or the disputed amount.

A stated in the preamble of this Act, one of its objects is to make “Comprehensive legal provisions” for the conduct of arbitration proceedings and the enforcement of arbitral awards. The second object is to make legal provision to “give effect”, to the principles of the convention on the recognition and enforcement of foreign award of 1958 (The New York Convention).This Sri Lankan Act to a great extent follows the UNCITRAL Model Law. The Sri Lanka Act Provides that by an agreement “any dispute” can be determined by arbitration “unless the matter in respect of which the arbitration agreement is entered into is contrary to public policy or is not contrary to determination of Arbitration. [4]The Sri Lanka Act provides that an arbitration agreement shall be in writing. It can be contained in a single document or in an exchange of letters telexes, telegrams or other means of telecommunication which provide records of the agreement. It mentions challenge to jurisdiction, duties of the arbitrators , corrections and interpretation etc.

Most Arbitration Acts (including those following the UNCITRAL Model law) usually allow these parties to change the substantive law to be applied, if it is a transactional contract. The Arbitration Act of Sri Lanka goes a little further. The material part of section 24 (1) provides “An arbitral tribunal shall secede the dispute in accordance with such rules of law as are chosen by the parties as applicable to the substance of the dispute”. The construction industry appears to favour the resolution of disputes by arbitration proceedings. These proceedings enable a determination by a respected person usually from a discipline apartment from the dispute, and will be resolved in a manner, which reflects the contractual and commercial aspects of the project.

Applicable law will be the Sri Lankan Law and the proceedings should be held in the English language. Therefore parties can carefully draft an Arbitration Agreement to include Arbitration Clauses. It has to be done after careful scrutinizing the clauses that are in the English language . When there is an arbitration clause the aggrieved parties concerned cannot seek a remedy in courts because in such case the jurisdiction is ousted by virtue of the arbitration agreement. [5]

An arbitration agreement must be in the duly prescribed up or formulated form . There should be in the form an arbitration clause in Institute of Construction Training and Development/ICTAD condition of contract category provides an arbitration clause No.67 for building disputes). According to the arbitration agreement recommended by ICTAD the period for commencement of an arbitration must take place within a maximum of 90 days and in accordance with the ***Federation Internationale Des Enginieurs*** /FIDIC the maximum period to appoint an arbitrator is 154 days to arrive at the final decision. Sri Lankan present

Act does not specify a time limit .Section 48.1 of the Bidding document of the ICTAD (Guidelines of the Government of Sri Lanka) provides Arbitration clause for construction contracts . In Sri Lanka all disputes arising out of contract agreements should be dealt with in accordance with the provisions of Arbitration Act No: 11 of 1995.

FIDIC condition 1999 has introduced Dispute Adjudication Board (DAB) system as a pre-Arbitration requirement. Accordingly dispute between employer & contractor shall be referred to Dispute Adjudication Board as a pre-Arbitral step before reference same for arbitration –Clause 20 of FIDIC 1999. When there is no settlement before DAB only the same dispute can be referred for Arbitration.

As far as the nature of some contracts are concerned, involvement of more parties than two in a single dispute can be seen, e.g. involvement of employer, contractor and number of sub-contractors in construction contracts and disputes relevant to them. Construction projects usually involve sub contractors and a common problem is whether the term in a main contract, including the arbitration clause, have been incorporated into a sub contract.

The Sri Lankan courts refused to incorporate the arbitration agreement into a subcontract. Courts will in each case examine or interpret the language of the contracts in question to see whether general principles of construction are applicable.

Arbitrators may keep away from writing reasons for the award and only the final decision of the Arbitrators will be enough for a valid award. This will be very useful for the settlement of disputes relevant to construction industry. However, if the parties do not agree, the Arbitrators shall give reasons for the award under section 25 (2) of the Arbitration Act of Sri Lanka No: 11 of 1995.This Sri Lanka Arbitration Act treats arbitration in the field of construction on the same basis without making any distinction in the value of contract or the disputed amount

4.1 Arbitration institutes in Sri Lanka

Arbitration is a private means of dispute resolution whereby the parties agree to be bound by the decision of an arbitrator of their choice whose decision is final & whose award has the legal force of a high court judgment or order. In Sri Lanka there are several arbitration .They bonded with obtain the rules& they are guide how to arbitrate matters related to any field.

Same of them are,

- Institute for the Development of Commercial Law & Practice (ICLP)
- (Sri Lanka National Arbitration Centre (SLNAC)

ICLP is set up in 15th march 1995 as separate body but in 1992 it established in as corporate body under the companies act of No: 17 of 1982 of Sri Lanka. This is non-profit organization funded by sum private sector companies in Sri Lanka.

The centre provides free general information on dispute resolution by arbitration & maintains a growing library of books & publications which are available for reference to interested members of the public. The **Centre** is able to assist and make names available to potential parties who are unable to decide on suitable Arbitrators. In the event where the parties fail in agreeing on the appointment of a sole Arbitrator, the **Centre** shall act as the appointing authority. A list of qualified Arbitrators who have registered with ICLP is available for selection of arbitrators.

The Sri Lanka National Arbitration Centre is the institution in the country in the administrations of arbitration for the resolution of construction and commercial disputes. It was established and incorporated in the year 1985. The fundamental responsibility of the centre is to popularize the operation and practice of arbitration matters .

This is service by the ICCSL in Sri Lanka. The panel of SLNAC is consisted with,

- Retired judges of the court of appeal.
- Supreme Court & high court judges.
- Other professionals (Attorney-at-law, Engineers, Quantity surveyors)

5. New Trends by case decisions in Sri Lanka

Mahaweli Authority of Sri Lanka Vs. United Agency Construction (Pvt.) Ltd.[6] case was an appeal to the Supreme Court from an order of the Commercial High Court under section 37 of the Arbitration Act No: 11 of 1995 and it decided the time period necessary for leave to appeal.

In **Southern Group Civil Construction (Pvt.) Ltd Vs. Ocean Lanka (Pvt) Ltd.** Case [7] application for setting aside arbitral award under section 32 of the Arbitration Act of Sri Lanka . The need to set out in the application the grounds for setting aside the award period for making the application – whether grounds set out in written submission after lapse of that period can be considered.

These two cases were developed arbitration procedure of Sri Lanka . Hence we have seen Arbitration is a voluntary procedure available as an alternative dispute resolution method to litigation and disputes resolved by arbitration will no doubt be beneficial to the country in the context of construction law and foreign investment .

6. Loopholes of Arbitration and Recommendations

Sri Lanka arbitration process has become very adversarial and expensive. It is important to review and improve the process.[8]

Become very expensive. It is important to review and improve the process since construction is a process where people come together for a short period of time and then disburse after the construction. The proper appointment of the arbitrators with concurrence of the two parties, agreeing of the costs of arbitration. In the submission of the claim the parities have adhered to the procedure. Most professionals are not fully aware of the arbitration process. When we consider about disputes in the construction field, concerning or involving subjects relevant to Architecture, Engineering and Law , appointment of a Lawyer, Architect and an Engineer to the Arbitral tribunal may be very appropriate.

The serious criticisms against the arbitrations in Sri Lanka is the time factor. The Arbitration agreement incorporated in the ICTAD category of contract under clause No. 67 stipulates that the period within which the award should be made in 4 months, although the Arbitration Ordinance of 1948 stipulates a period of 3 months . The present Arbitration Act does not specify a time limit. Parties are free to fix a desired time period for proceeding and award the agreement. However this may be an extension if done with the consent of the parties. According to the arbitration agreement recommended by ICTAD the period for commencement of an arbitration must take a maximum of 90 days and in accordance with the FIDIC the maximum period to appoint an arbitrator is 154 days. Hence the time factor remains a major drawback in the arbitration process. Also, there are no facilities for construction arbitration other than in Colombo- the commercial capital city in Sri Lanka .

Arbitration Act of Sri Lanka (1995) should promote the formation of an association of arbitrators whose objective is to educate and train professionals in the field of arbitration and also promote special continuing development of skills of arbitrators . For example when Sri Lanka consider about disputes in the construction field, concerning or involving subjects relevant to Architecture, Engineering and Law , appointment of a Lawyer, Architect and an Engineer to the Arbitral tribunal may be very successful.

7. Conclusion

Alternative Dispute resolution methods are most popular dispute resolution methods in any legal system. Among those methods Arbitration is one of the best methods. Because of its flexibility wide range of disputes can resolve, not only the construction industry disputes, but every kind of commercial disputes without going to the court system. Flexibility in the sense, privacy & the time are the most important factors. Everyone in the business field likes to solve their controversies by having privacy to that problem & as soon as possible. So the arbitration is one of the most suitable ADR methods. Cost for the arbitration process is considerably high, but it hides automatically with its number of advantages. Sometimes there may be problems when hearing the Awards from arbitration tribunal. However clauses in arbitration act clearly describe how to react when having unexpected situations from tribunal. Arbitration is the most effective & famous method in resolving international disputes in any kind of corporation.

The EU model: An integrated approach to water protection and management in the built environment?

Julie Adshead,
Salford Law School, University of Salford
(email: j.d.adshead@salford.ac.uk)

Abstract

The environment that buildings occupy cannot be divorced from the structures themselves and it is vital that consideration is given to the impact of the construction process and the subsequent occupation and operation of buildings upon the environment. Regard needs to be given not just to the physical impact of these activities, but also to the potential social and economic consequences. In the context of water protection and management, new approaches have recently been adopted that look at a more integrative approach. In particular, the Water Framework Directive represents a revolutionary shift in the way the European Union addresses water legislation. This paper considers two aspects of the Directive's possibilities to act as an integrative force. Firstly, it examines the provisions for river basin management in the Directive, in the light of modern definitions of 'integrated river basin management' and secondly, the paper aims to identify features within the Directive that contribute to effective inter-instrumental integration, integration between the individual media and inter-agency integration; all of which have been identified as key elements in achieving an overall aim of internal integration.

Keywords: Regulation, Environment, Water, Integration, River Basin Management

1. Background

The river basin concept is by no means a new one, indeed, management of water resources within a river basin framework can be traced back thousands of years to the fluvial civilisations of the Nile and Tigris-Euphrates [1]. The river basin unit provides a natural division for the consideration of water use and protection and planning in catchment areas has been a feature of legislative measures over a long period of time. One of the earliest pioneering river basin enterprises, and one that provided the prototype for others worldwide, was the Tennessee Valley Authority in the United States. This unique body took the form of a government corporation with wide-ranging powers of planning, development and operation of all kinds of projects and had, among its aims, the achievement of economic and social development goals [1]. The early ventures into river basin management featured highly autonomous corporate bodies with separate funding, responsible to central government and, although they led to a general acceptance of the river basin entity, they did not allow for the integration of stakeholders [2]. Valley authorities of more limited scope, dealing with just water supply and pollution abatement were established subsequently throughout Europe [2]. Characteristic of the European model is a composition of both local authority representatives and private enterprise and a two tier structure co-ordinated at national level but decentralised at regional/basin level [3]. The river basin concept is not alien in the United Kingdom, where administrative units have long been based upon river basins and the 10 regional water authorities created in 1973 were similar in nature to those in existence elsewhere in Europe.

Since the early days of regulating activities in river basin units, when management was purely for exploitation and usually single-use orientated, the notion of management of the river basin and its ambit and aims have changed significantly. As advances were made in engineering and technology and reliable data became available for stream and eco-system modelling, the management of water resources took on a more comprehensive character. An awareness of the interrelationships between ecological, socio-economic and political priorities and an increased ability to balance these competing interests brought still further elements into the management of the basin [4]. Over a period of time, management of the river basin unit came to adopt an eco-system approach. Following the Stockholm Conference of 1972 its scope was extended to include groundwater, and both the 1992 Dublin Conference on Water and the Environment and the 1992 Rio Conference called for comprehensive management of resources using the river basin as a focus. This theme was echoed at the World Summit on Sustainable Development at Johannesburg in 2002. River basin management entities generally now aim for 'integrated river basin management', although the terminology used is varied and somewhat confusing. Some commentators prefer to use the terms 'comprehensive' or 'holistic' [5] management and others draw distinctions between the different terms [6]. For the purposes of assessing the plans for river basin management within the Water Framework Directive, 'integrated river basin management' will be taken to include the five basic components identified by Downs et al [7], namely, water, channel, land, ecology and human activity. In addition, integrated river basin management should require consideration of all dimensions of water (surface water, groundwater, quality and quantity), the interaction between the water system and other systems (e.g. land and air) and its interaction with social and economic development [6]. This not only reflects an eco-systemic approach but also recognises the relationship between land use and water resources. Quite evidently, the idea of integrated river basin management, as it has developed and expanded in scope, has become increasingly complex, with a requirement to consider and to balance a multitude of often competing factors. In fact, it has been argued that this difficult and unwieldy task has led to disappointing results in effective management [5] and that a less comprehensive approach is necessary to gain practical success [6].

2. River basin management in the Water Framework Directive

Space does not allow for an exhaustive account of all the provisions for river basin management contained in the Directive but, in summary, the Water Framework Directive requires Member States to identify river basins and assign these to river basin districts. A competent authority with responsibility for river basin districts is also to be identified. River basin management plans are then to be produced, for which some technical specifications are provided in annex VII of the Directive. The plans are to include an initial analysis of the characteristics of the river basin, a review of human activity impact on surface and groundwater and an economic analysis of water use as required by article 5. Special protection areas are to be identified for drinking water, habitat protection, bathing water etc. and monitoring programmes put in place to provide an overview of water status. Details of the programme of measures required in article 11 to achieve the environmental objectives for good water quality status are also to be included in the plan. In essence, the plans are to provide an evaluation of existing legislation, highlighting any deficiencies and thereby indicating the measures required to address these shortcomings. They also allow for an evaluation of the cost-effectiveness of improvement measures, provide information and allow for public participation both before and after the plan production stage. The programme of measures that is to be drawn up for each river basin district will clearly be of significant importance. While seeking to attain the environmental objectives of the Directive, the programme will also take into account the analysis of the river basin district characteristics, the review of human activity and analysis of water use. However, there is no clear indication exactly what the measures contained in the programme should be. There is an obligation to include ‘basic measures’, for which a fairly comprehensive list is provided; these are clearly designed to meet the specific legislative objectives of the Water Framework Directive and other existing EU water law. ‘Supplementary measures’ are also to be adopted in cases where the ‘basic measures’ are inadequate to achieve the ‘good water status’ objective. Part B of annex VII to the directive gives a non-exclusive list of ‘supplementary measures’ with a final category of ‘other relevant measures’.

3. Integrated river basin management

It should be remembered that the outline for river basin management provided in the Water Framework Directive makes no claim to be integrated in any sense. However, the need for an integrated approach is acknowledged in the preamble of the Directive. Preamble 18 calls for co-ordination and integration of the overall principles and structures for protection and sustainable use of water, and Preamble 34, for the integration of qualitative and quantitative aspects of surface water and groundwater. Also the ‘Common Strategy on the Implementation of the Water Framework Directive’ sets out a clearly defined integrative role for the river basin management plans. How then do the provisions of the Directive contribute to the development by Member States of systems for river basin management that will be along the line of the modern, integrated approach? There is no doubt that the river basin management scheme outlined in the Directive is, in many respects, limited. In the first instance, it is restricted to water only and there is no consideration of the water system interacting with other systems. The key omission here is of any acknowledgement of the inter-relationship between water use and land use planning. The only concession to land use considerations within the Directive itself is a requirement to include, in the programme of measures, any measures required by the Environmental Impact Assessment Directive. The necessity to consider land use issues is, however, clearly identified in the guidance documents and it is also recognised by the Environment Agency in the United Kingdom in their call for ‘a clear and statutory interface between land-use planning and river basin plans’[8], which they see as ‘critical for the successful implementation of the Directive’ [8]. Specific inclusion of land use in the Water

Framework Directive was, however, always going to be problematical given the firm position traditionally adopted by individual Member States on retaining state control of planning issues, reflected in the requirement for unanimity for land use planning measures in article 175(2) and the strong reliance on the subsidiarity requirement in this area. In terms of considering the interaction between the water system and other systems, therefore, the provisions of the Directive do not contribute greatly to this feature of integration in river basin management and it will be in the hands of the individual Member States to legislate in order to tie land use into river basin management and to follow the non-binding EU level guidance in this respect.

Turning to the two other manners of contemplating integrated river basin management outlined by Mitchell [6], the Directive does, to some degree, succeed in considering all dimensions of water; both surface water and groundwater fall within its ambit, as well as transitional and coastal waters. Also, in terms of good groundwater quality, as required by article 4(1)(b)(ii) of the Water Framework Directive, status is to be determined by the poorer of its quantitative and chemical status and, as previously indicated, there is clear direction in the Directive's preamble to consider qualitative and quantitative aspects of both groundwater and surface water. It can be argued that the interaction between the water system and social and economic development is also recognised within the Directive itself. There is a requirement for the review of human activity impact and an economic analysis of water use, as well as recognition of the role of economic factors in attaining the goal of good water quality. However, the economic analysis is restricted to the carrying out of calculations to enable recovery of the costs of water services under article 9 and the impact review, although its requirements are fairly wide-ranging, looks only at the anthropogenic pressures on surface and groundwater and does not consider the social benefit or disbenefit of water protection and management. Also, a true view of the interaction between water and social/economic development would, once again, require land use planning issues to be incorporated. Clearly then, the framework for river basin management set out in the Water Framework Directive does embrace some of the features of the modern day concept of integrated river basin management. However, there are some glaring omissions, most notably a specific requirement to consider the interaction with other media, in particular with the land. Also, importantly, there is no elaboration within the instrument on how the river basin plans and programmes of measures are to serve the integrative aim. It should, however, be remembered that more comprehensive systems of integrated river basin management have been criticised for their complexity and lack of practical workability. Indeed, it has been suggested that, certainly at operational level, although an integrated approach is necessary, attention should be directed to a smaller number of variables that account for a large proportion of the problem [6]; an approach that may well be adopted by the Environment Agency in the United Kingdom. Nonetheless, land use planning should not be regarded as an expendable consideration when selecting the variables to be taken into account in river basin planning and management.

3.1 Internal integration

The framework for river basin management outlined in the Water Framework Directive could not, therefore, be said to fully match the modern approach to integrated river basin management. However, although there is no specific requirement for inter-media integration within the river basin management planning process of the Directive, there is potential for this to be fostered through various other facets of the legislation. The remaining part of this paper assesses the Water Framework Directive's potential contribution to the general end of 'internal integration'. This aim should be distinguished from that of 'external integration', which is the most common usage of the term integration in EC law terms and refers to the integration of environmental considerations into other sectoral policies and activities. Faure defines 'internal integration' as cross-media integration in decision-making [9] and contends that this is crucial for effective environmental protection [9]. He identifies two key aspects of internal integration: cross-agency integration (both vertical and horizontal) and instrumental integration. As identified above, there are undoubtedly features of the river basin management framework in the Directive that will contribute cross-media integration, but how does the Water Framework Directive deliver in terms of these other two key aspects?

3.2 Inter-instrumental integration

In order to gauge the Directive's role in inter-instrumental integration, it is necessary to step back in time and take a brief look at prior approaches to water quality law by the Community. Traditionally the EU approach was a sectoral one and legislation tended to be based on one or more of three control techniques: Where substances were considered inherently dangerous, an emissions control approach was adopted. Otherwise, quality objectives were employed and waters classified by end use (e.g. shellfish waters and bathing waters). With this second category of instruments the emphasis was on the impact of pollutants on a specified quality standard. A third group o f measures sought to regulate the activities that can result in water pollution (e.g. treatment of sewage). The first phase of early EU water legislation introduced quality objectives for drinking water, freshwater fish waters, shellfish waters, bathing waters and ground waters. The Dangerous Substances Directive on the other hand, primarily adopted an emission control approach but with a parallel alternative option for Member States to work with limit values for quality. By 1988, it was recognised by the European Commission that there were gaps to be filled. The second phase of water legislation, therefore, addressed sewage and agricultural sources through the Urban Waste Water Treatment Directive and the Nitrates Directive. Drinking water quality objectives were further tightened in a revised Drinking Water Directive of 1998. The only measure, however, that reflected an integrated approach and consideration of cross-media impacts came in the form of the 1996 Integrated Pollution Prevention and Control Directive, which looked at the impact of pollutants on all three environmental media.

The need for a more comprehensive approach to water legislation, was identified by the Council of Ministers, in 1988 and the Council then exerted pressure on the Commission who finally accepted a request to develop a new EU water policy made by the European Parliament and the Environment Committee in consultation with the Council of Environment Ministers in mid 1995. A dichotomy was recognised in the approach to EU pollution control between control at source and receiving environment quality objectives. Both approaches revealed problems; source control, on the one hand, can result in cumulative pollution load from multiple sources, whereas quality standards, on the other hand, rely on scientific knowledge as to the effect of the pollutants on the ecosystem. The Commission acknowledged that a combined approach was needed. The Water Framework Directive was the instrument designed to achieve this and to draw together and build on existing legislation in order to attain greater legislative coherence and to gain greater integration in the practical implementation of the law. In this instrument the legislators specifically aimed to achieve integration between; water quantity and water quality issues, surface water management and groundwater management, water use and environmental protection, control of pollution through emission controls and through quality objectives and between water policy and other policies.

There is a clear aim and role for the Water Framework Directive in contributing to inter-instrumental integration. The Directive, as its name suggests, sets a framework for attaining good water quality in all nature of water bodies and, therefore, consolidates by repealing (in due course) a number of existing measures dealing with specific water environments. A good many legislative instruments are kept in place, although these are firmly tied to the Water Framework Directive. The requirement to identify and make provisions for the protection of drinking water and protected areas is illustrative of the inter-instrumental integrative capacity of the Directive. Areas for conservation of habitats and species are also to be identified and dealt with under river basin management plans and, likewise, Member States are directed to ensure that waters used for the abstraction of drinking water meet the requirements of the drinking water Directives. It is interesting to note, however, that proposals to link more closely a new bathing water Directive to the Water Framework Directive have recently been rejected. The overall approach taken in the Directive, in order to tackle point and diffuse source pollution, is one of attaining the stricter standard between the legislative instruments that remain and the Framework Directive, thereby assuring a good level of integration between different pieces of water legislation. The Directive also takes a dual approach to protection of the water environment, requiring whichever is the stricter of emission standards or quality objectives to be met.

As previously noted, there is little in the Directive to link the regulation of the water system with that of other media and it is this feature of inter-instrumental integration that is crucial to the overall goal of internal integration. Apart from the consideration given to the IPPC Directive, there is no requirement to refer to legislation in the spheres of air and land and, despite the Commission's commitment in the Sixth Environmental Action Plan to the 'greening of land use planning and management decisions', there is little to tie the Water Framework Directive with instruments governing environmental impact assessment and strategic impact assessment. Once again the guidance documents are documents are not silent on these issues and advocate instrumental integration across the boundaries of the media. Whether this guidance is heeded or not will of course be a decision entirely in the hands of the individual Member States and one that will no doubt be informed by local pressures, policies and politics.

3.3 Inter-agency integration

Inter-agency integration in both directions is fundamentally dependent on the inclusion and participation of relevant stakeholders. The provisions for public information and consultation contained in article 14 of the Water Framework Directive will, therefore, be of key significance in attaining successful integration in this regard. Essentially there are three forms of public participation contained within the Directive each entailing a different degree of stakeholder involvement; information supply, consultation and active involvement. The first two of these are to be ensured and the latter encouraged. Annex VII – which dictates the content of river basin management plans - requires a summary of the public information and consultation measures taken, together with the results and any consequential changes to the plan and article 14 requires publication and availability for public comment of; timetable, work programme, statement of consultation measures, interim overview and draft copies of the plan. Background documents are also to be available on request and six months is to be allowed for comment. In terms of actual stakeholder participation in the planning process, the Directive encourages the active involvement of interested parties.

To what degree then will this stimulate inter-agency integration in the two necessary directions? In terms of vertical inter-agency integration, this can potentially be achieved by the means of active involvement of stakeholders on a multi-level basis (e.g. representatives of national, regional and local authorities) and likewise horizontal integration can be achieved by engaging stakeholders and the public in active involvement, but, as noted above, there is no absolute requirement for such a level of involvement in the Directive. The only obligations are for consultation and the provision of information, neither of which will be certain to foster inter-agency integration. Admittedly, it is difficult to legislate for the compulsory participation of stakeholders and how Member States approach the issue of encouraging active participation will be crucial in attaining the necessary inter-agency integration.

4. Conclusions

In summary, the scope of the Directive, in terms of contributing to internal or inter-media integration, is limited by its focus almost exclusively on one medium. Arguably, the Directive does have the potential to deliver on the European Commission's integrative aims in terms of bringing in all elements of water and consolidating existing legislation under a new and comprehensive piece of legislation, but it fails to succeed in inter-instrumental integration by virtue of failing to recognise the inter-relationship between water, air and, in particular, land use. The Directive does address the issue of stakeholder involvement. However, as is the case with so much of this framework measure, the comprehensive guidance on best practice in this respect is to be found in a non-binding guide to implementation. Reservations expressed by the UK Environment Agency suggest that the level of active involvement of stakeholders on either a horizontal or a vertical plane is likely to be limited.

The system of river basin management in the Water Framework Directive does not call itself integrated, but there are clear indications from both the Directive itself and the implementation guidance that an integrated system of management is envisaged. However, the task of introducing modern practices of integrated river basin management is mostly left in the hands of individual Member States, as is the option of incorporating land use issues in the planning process. It may, of course, be that there are valid practical considerations in operation here. Experience in existing river basin authorities has indicated that problems are likely to be encountered when too comprehensive an approach to river basin management is adopted at an operational level [6]. Not least of these is the time element involved and, given the timetable imposed by the Directive for production of the first river basin management plans, a fully holistic approach may well be unrealistic. Almost certainly, political concerns have been influential in the steer away from explicit mention of land use planning in the framework for river basin management provided in the Directive. It is to be hoped that some kind of statutory provision is adopted to allow for this in Member States and, of course, given the long, staged, implementation period, there is plenty of time yet to introduce more detailed requirements in future legislation. Although there is excellent and comprehensive guidance in place at EU level on integrated river basin management, it is inevitable that the systems ultimately adopted by individual Member States will vary considerably depending on the local environment and pressures.

The systems of river basin management that evolve in EU Member States may well serve the goal of ensuring that all environmental media are considered in decision-making and planning and thus achieve the internal integration that is crucial (along with external integration) for the protection and sustainable use of our water environment. However, to do so there must be integration between legislation in place in all the environmental media. Once again, measures to ensure such integration will fall to be adopted at a national level, albeit with some guidance from the European Union. The Water Framework Directive provides a skeletal outline of possibilities for stakeholder involvement that could serve the remaining key aspect of internal integration (inter-agency integration). Yet, once more, it is left to Member States to put flesh on the bones and practical difficulties and time constraints will almost certainly limit the degree of active involvement by agencies, authorities and the public. Without such involvement and the opportunity to draw in all interested stakeholders, it is unlikely that the goal of inter-agency integration will be achieved. As previously observed, these are early days in terms of the river basin planning process and it waits to be seen how systems of river basin management will develop and the degree to which Member States will make a determined effort to integrate legislation cross-media and allow active involvement of stakeholders. However, it is likely that across the European Union practice will diverge considerably as will the degree of internal integration achieved. The Water Framework Directive provides the potential, implementation guidelines fill in the gaps, but it will be in the hands of Member States to decide how best to serve the protection and management of their water resources for the future.

Causes of Insolvency and Unethical Practices of Contractors In Pakistan Construction Industry

Dr. Faisal Manzoor Arain
Academic Chair, Construction Project Management, Southern Alberta Institute of Technology (SAIT), Calgary, Canada.
Email: faisal.arain@sait.ca

ABSTRACT

A construction project traditionally involves two major professionals in the construction industry. These two professionals are the designer and the contractor. Within the industry, the contractors appear to be most at risk player. This study identifies the causes of insolvency in the construction industry and the unethical practices that may lead to such causes of insolvency in the industry. As contractors are the players who are most at risk, their inputs regarding the above issues were examined. To achieve the study objectives, a questionnaire survey was carried out to collect the relevant information. Questionnaires about issues relating to causes of insolvency and unethical practices were sent to 90 contractors. 30 questionnaires were eventually returned and ten face-to-face interviews were completed. After checking through the completed questionnaires, 30 questionnaires were found to be suitable for the data analysis. Eleven causes of insolvency were identified from the literature review in this study. These are diversification, absence of barriers, family firms, management buy-outs, cash flow problems, overtrading, poor financial control, knock-ion effect, overwhelming contract claims, imprudent diversification and onerous conditions of contract. Five issues that significantly caused insolvency of contractors in the industry were identified and explained. These are absence of barriers, cash flow problems, poor financial control, knock-on effect and onerous conditions of contract. It appears that all these five causes, with the exception of absence of barriers, can be caused by unethical practices. The study suggests that the construction industry should pay heed to ethical behaviour and practices in order not to jeopardize the financial stability of contractors in the supply chain. Special attention should be paid to the five significant causes of insolvency highlighted in this study to render the construction industry less onerous for the contractors.

Keywords: Construction, Contractors, Insolvency, Unethical practices, Pakistan.

1. Introduction

Projects are complex because they involve many human and non-human factors and variables [1]. The project process can be influenced by changing variables and unpredictable factors that could derive from different sources. These sources include the performance of the parties, resources availability, environmental conditions, involvement of other parties and contractual relations [2]. As a consequence, the projects may face problems possibly causing delay in the project completion time. It is commonly accepted that the construction industry has for many years been criticized for not developing consistent projects that are on time, within budget and with high quality standard [3]. Generally, failure to deliver successful projects has been considered in relation to schism between design and construction, lack of integration, lack of effective communication, uncertainty, changing environment, and increasing project complexity [4, 5].

Construction is a complex industry in which disputes are common, uncertainties and risks are inevitable, individual interests of parties are natural, delays are routine and cause huge loss of resources, and aggravations are an everyday occurrence [1]. Among the project players, construction contractor is the person who has to carefully look into all these matters and ensure that the project completes on time, within budget, and according to expected quality standards [6]. Most of the disputes, as numerous researchers have established, are due to lack of communication and coordination interface management in the design phase [7]. This deficiency leads to difficult access of working area and conflicts in the requirements of various subcontractors during construction, and a design that does not deliver an end product that satisfies the Client [8, 9].

The term “insolvency” means the financial failure of individuals and companies and their position before and after the start of a formal insolvency procedure [10]. There are two different categories of insolvencies, namely short term insolvency and long term insolvency. The former means that there is a cash flow crisis where not enough money is coming in to meet a company’s outgoings and the latter means that the company is able to pay its debts as they fall due but its balance sheet shows a deficiency of assets over liabilities [11].

Contractors in the building industry are known to have low profit margins, low fixed assets and low capital but high cash flow and high return on capital employed [12]. Financing of contractors is generated internally from positive cash flow and retained profits and externally from short term finance, which is usually an overdraft repayable on demand. The short term finance will be able to support items such as working capital, stock and work in progress. However, for growth, there is a need for long term external finance in the form of equity investments and long term loans.

The unique nature of the construction industry has caused a large number of insolvencies each year [6]. Due to high interest rates and a generally poor economic climate, significant financial pressures are imposed on many companies in the construction industry. Companies with high levels of borrowing and an insufficient capital base are therefore forced into liquidation. The construction industry always ranks high among the annual number of liquidation. There are two striking features of insolvency in the construction industry [13]. Firstly, a fifth of the bankrupts were builders. Secondly, the building trade is the only sector that has displayed obvious vulnerability towards insolvency.

Within the industry, the contractors appear to be most at risk player. A study by Burnett [14] suggests that apart from being one of the easiest industries to join, the construction industry is also one of the easiest in which to fail. It can also be safely assumed that the highest proportion of failures is in small sub-contracting companies.

Besides coping with economic and financial pressures, the contractors must also tackle profit squeezing from main contractors who abuse their rights to set-off, give late and insufficient interim payments and the introduction of onerous clauses into the forms of sub-contract [15]. In addition, the sub-contractor is less able to manage his accounts accurately. Furthermore, if the main contractor becomes insolvent, the sub-contractor will become an unsecured creditor and hence may also become insolvent due to cash flow problems.

The objectives of this study are first to identify and examine the causes of insolvency in the construction industry and second to identify and examine unethical practices that may lead to causes of insolvency in the construction industry in Pakistan.

2. Causes of Insolvency

Eleven causes of insolvency in the construction industry were identified [16, 17, 18]. These are discussed below:

2.1 Diversification

Many contractors diversify in order to use the cash earned from contracting higher profits, create assets as security for loans and seek financial stability by venturing into businesses that are counter-cyclical to construction. Whether the move was into property or into sub-contracting and materials supply, failed acquisitions undermining the financial health of a group were common [1, 19].

2.2 Absence of Barriers to Entry

Due to the ease of entry into the construction industry, there is a proliferation of small firms with little management expertise in the industry. In addition, the general lack of financial barriers to entry has created an industry where market forces are most ruthless [1, 19]. There are just too many contractors in the industry. This leads to the tendering of projects by small contractors who are not capable of doing the job. They become insolvent when they cannot manage the job.

2.3 Family Firms

Given the absence of a need to raise equity funds from shareholders, there are many family firms of contractors in the industry. The predominance of family firms has also contributed to a significant level of financial failure in the industry. This is because ingrained attitudes lead to financial complacency and an inability to adapt to a changing construction market [19, 20].

2.4 Management Buy-Outs

Management buy-outs have been a common exit from receivership as these provide a more feasible solution than in other industries. However, there have been cases where a management buy-out was soon followed by receivership due in part to the high level of debt that is required to finance. It may be possible to plan the receivership by appointing receivers to the parent company, allowing the target company to continue trading while a buy-out is negotiated [5].

2.5 Cash Flow Problems

Nearly all companies that went into solvency do so because of cash flow problems. Cash flow is more of a problem in the construction industry than in any other industries due to the fact that when tied to a fixed price contract, normal market forces are immobilized [5, 14]. It has been shown that cash flow problems are largely responsible for the high level of insolvency in the construction industry [21].

Construction is a labor intensive industry. Whether the contractor has been paid or not, the wages of the worker must still be paid. Cash flow is the lifeblood of the industry. Too often, people concentrate on whether they are making a profit. However, if this profit is tied up in debtors or work in progress and there is not enough left over to pay the bills, then that profit is of little utility.

Contractors frequently experience sharp decline in demand leading to reduced turnover and loss of cash flow. In the economic recession of the 1990s, excessive competition has forced many contractors in the UK to tender at below cost. Tenders for long term contracts were based on prices for contractors and materials whose prices have rose thereafter. These shortfalls cannot be sustained by the unstable sources of finance used by the contractors. Cash reserves built up in previous years were lost and contractors have to turn to their bankers and shareholders for support [19].

The situation for contractors is very much similar to the main contractors. It can even be worse especially when onerous contract clauses such as “pay-when-paid” and the “right to set-off” are in operation.

2.6 Overtrading

Another avenue, which small companies, like the contractors, can run into serious cash flow problems is when the company is growing faster than the capital base it can support [5]. A sub-contractor may or may not be receiving the monthly interim payments from the main contractor. However, during the month, he still needs to pay for materials, hiring of plants and equipments, overheads, labor wages, as well as loan repayments and other debts. The funds need to be drawn from the capital base since most of the sub-contractor’s money will be tied up in stocks, trade debtors and work in progress [14].

There can be a situation where the company has expanded so quickly that it finds that all its cash are tied up in stocks, trade debtors and work in progress. As a result, the contractors will have no money left to pay for additional materials, labor wages, hiring of plants and equipment and to make loan repayments to the bank. Although the company's assets may outweigh its liabilities, it is however unable to pay its debts and hence become insolvent [14, 20].

2.7 Poor Financial Control

Successful contractors do well in cash control and management. They employed highly sophisticated techniques of cash flow forecasting and monitoring. A well managed contractor maintains detailed financial, cost and management accounts which allocate cost in as much details as possible to specific contracts and to individual elements within them. Unfortunately, many contractors in the industry fall short of this practice [4].

Many contractors become insolvent due to the lack of proper accounts in their organizations. They fail to collect debts, especially retentions; thus allowing these to accumulate until their delays made them difficult to collect later. The adage of strategic cash flow is to "collect early and pay late". However, late payment is a two-edged sword [4]. It is serious problem and a contributory factor to the large number of insolvencies in the construction industry [19].

2.8 The "Knock-On" Effect

The majority of contractors in the industry are small firms with just a few employees. Small firms often fail because of the financial failure of another company which is further up in the supply chain. A significant number of insolvencies occurred as a direct result of the insolvency of another party [20]. This is known as the "knock-on" effect. There are three aspects related to this effect.

First of all, the knock-on effect is felt up and down the supply chain. The insolvency of a contractor in the chain may bring down a series of contractors and suppliers. However, it may also cause the failure of an employer due to the contractor's failure. Secondly, the effect can be felt across different companies in the same group. As for the third aspect, the effect can be experienced across industrial sectors to cause a major impact on the country's economy. The construction industry is cyclical and experiences boom as well as bust periods. A sharp decline in the market will reduce the demand for construction work which will cause insolvency among the contractors. The decline will be felt by contractors, suppliers and manufacturers of plants and equipments. Hence, a slump in house-building will inevitably lead to a contraction in demand for home furnishings, household appliances and Do-It-Yourself (DIY) services [19].

2.9 Overwhelming Contract Claims

If a construction contract goes wrong, it will go badly wrong. An exceptional claim against the contractor under one contract can be enough to cause insolvency. One such example is liability for liquidated damages due to failure to complete works on time. The greatest danger is when management is forced to concentrate on one problem contract and the effort to extricate the company forces it to draw resources from the rest of the company or group [2, 19].

2.10 Imprudent Diversification

Many contractors look to other sectors and businesses in search of higher profits. During the 1980s, many contractors were tempted into property development for this reason but have since withdrawn from the sector or worst of all, become insolvent [19]. Diversification can also be achieved by moving from one method of procurement to another. Insolvency could also result from an acquisition which turns out to be a financial liability. Substantial sums can be incurred in supporting a new subsidiary, even by means of orderly wind down of its activities, and in litigation to recover losses from the vendor. For some, the urge to build an empire in the industry is just too strong. Hence, much insolvency has resulted from corporate aggrandizement.

2.11 Onerous Conditions of Contract

When a sub-contractor submits a quotation for a contract to be "as per standard form of sub-contract", he will often receive an acceptance that is "subject to standard terms and conditions" of the main contract. Many a times, the sub-contractor does not want to be burdened with the conditions of the main contract. However, because he does not want to lose the job, the sub-contractor frequently has no choice but to accept [14]. Some examples of onerous conditions include use of "pay-when-paid" clauses; making contractors liable for their works until practical completion of main contract works; excessive retentions and discount percentages; and right to hold back money on one contract for unproven faults on other sub-contracts.

3. Unethical Practices

There has always been a general agreement that insolvency will result in a loss of time and cost [4, 22, 23, 24, 25]. However, this view does not appear to be universally accepted. One client asserted that he could actually make money out of a contractor's insolvency during the course of the contract [26, 27]. This could come about in three ways. Firstly, since clients usually pay in monthly installments, there would frequently be some payments outstanding at the time of the contractor's insolvency. Hence, a client who has doubts as to the contractor's financial position may well have deliberately withheld payments. The outstanding amount, coupled with the value of work undertaken since the last monthly valuation, means that the client is typically in possession of a six-week "buffer" [26].

Secondly, the client may be legally entitled to claim for its management time expended in dealing with the problems caused by the contractor's insolvency and to set-off this amount against the funds held, before handing them over to the judicial manager. Many clients appear to have done so [26].

Thirdly, there are contractors who are keen to impress new clients and may often take on the completion of a contract at cheaper rates for works that have been stopped due to a contractor's insolvency. The procedure adopted by the receiver of an insolvent contracting company is that the bids are invited from other contractors to buy the workload of the insolvent contractor. This means that the successful bidders will have to pay the receiver for the right to take over the insolvent contractor's part-completed contract, either through a process of novation or by entering into a separate contract for the outstanding items of works. Under a novation, the successful bidder will take on the responsibility to the client for the work already carried out by the insolvent contractor but if this is unacceptable, a separate contract will be used. However, in either circumstance, the contract under which the new contractor buys the workload from the receiver is entirely separate from the construction contracts between the new contractor and the clients, who will not normally be aware of the price agreed [27].

Normally, the receiver will insist that all the unfinished contracts must be taken over. The receiver will also attempt to tie each bidder to a "confidentiality agreement" which prevent them from making a direct approach to the clients under the relevant contracts. In deciding on how much to offer, the contractors will have to assess the value of the unfinished contracts to them. This value usually consists partly of the money representing work already carried out which is still held by the employer. There may also be resources on site which belonged to the insolvent contractor and the receiver may be prepared to include them in at an advantageous price. The new contractor will not take any responsibility for debts due to contractors or suppliers. These parties will take their place as unsecured creditors of the failed contractor [26]. From the client's point of view, the advantage of the procedures described above is that it enables completion of the contract works and in some occasions, it may be possible to secure completion at the same price and at the original or a sensibly re-negotiated date [2, 27].

4. Research Methodology

The research instrument used in this study is a questionnaire. Section A of the questionnaire is the demographic information section. Section B of the questionnaire consists of eleven causes of insolvencies in the construction industry. The survey was carried out only on contractors in Pakistan. Because the population of contractors in Pakistan is too large to be covered completely, sampling has to be carried out first before the survey can be conducted. Before the actual survey was carried out, the questionnaire was pre-tested with two contractors. The selected respondents have industrial experience of more than five years. The purpose of the pre-test was to obtain feedback on the questionnaire. Amendments like rewording, reconstruction of the sentences and omission of repetitive questions were made to improve the questionnaire.

A total of 90 questionnaires were sent to contractors randomly chosen, together with a covering letter explaining the purpose of the study and assuring them of anonymity. A self addressed, postage paid envelop was supplied with each questionnaire. The questionnaires were mailed to the president, vice-president, general manager or estimating manager of each company. Recipients of the letters were asked to complete the questionnaire themselves or to pass it to someone else in their company who are qualified to respond.

In addition to sending out the questionnaires, ten face-to-face interviews using the questionnaires were also used to ensure that all questions are answered and the respondents have a chance to clarify any doubts with the interviewer. 30 questionnaires were eventually returned and ten face-to-face interviews were completed. After checking through the completed questionnaires, 30 questionnaires were found to be suitable for the data analysis. This yielded a response rate of about 30%.

Descriptive statistics such as cross tabulation and mean ranking were used to describe and summarize the data. In addition, one-sample-test was employed to compare and find out the most significant issues that may cause insolvency in the construction industry.

5. Background of Respondents

32 contractors responded to the survey and 10 face-to-face interviews were completed. After checking through the completed questionnaires, 30 questionnaires were found to be suitable for data analysis. This yielded a response rate of about 33.33% as shown in Table 1.

Table 1 Survey response rates

Respondents	**Questionnaires sent**	**Responses received**	**Working experience**	**Valid responses**	**Percentage**
Contractors	90	32	1 – 4 yrs	3	10%
			5 – 10 yrs	12	40%
			11 – 15 yrs	11	36.66%
			15 yrs <	4	13.33%
Total	90	32		30	100%

Of the 30 respondents, 21% were Grade 1 contractors and 79% were Grade 2 contractors. Only 13.33% of the respondents were in the group of 1 to 4 years working experience. A majority of the respondents fall in the group of 5 to 10 years experience in the construction industry, which is about 40%. About 36.66% of the respondents were in the group of 11 to 15 years experience and 13.33% were with more than 15 years experience in the construction industry. Respondents who were in the group of more than 11 years of working experience in the construction industry were very likely to be better able to assess the causes of inconsistencies between the design and construction more realistically. As for those who were in the group of 1 to 10 years working experience, their assessment of the causes of inconsistencies was also a good representation.

As shown in Table 2, 60% of the respondents were project managers. 30% of the respondents were senior managers. 10% of the respondents were directors of their organizations. As a majority of the respondents were professionally positioned at management level or higher, a certain level of accuracy in the data collected was assured.

Table 2 Professional respondents' statistics

Respondents	Appointments	Responses received	Percentage
Contractors	Directors	3	10%
	Senior Managers	9	30%
	Project Managers	18	60%
Total		30	100%

6. Analysis Of Issues Causes Insolvencies

The questionnaire listed eleven issues that may cause insolvencies in the construction industry. Each respondent was asked to rate each issue according to how frequently they thought the issue will occur in the construction industry. In addition, the respondents were also asked to rate whether unethical practices will lead to the occurrence of each issue.

For the causes of insolvency, a score of 1 means that the issue never happen and a score of 5 means that the issue happens very often. The mean scores of these eleven issues are shown in Table 3. Of the eleven issues surveyed the five most frequently occurring issues that may cause insolvency are: diversification, imprudent diversification, management buy-outs, family firms and overtrading. Both diversification and imprudent diversification have the highest mean of 3.63. This may be because many local construction companies appear to lack commitment in their core businesses. Many local companies have become insolvent because they do not focus on their core construction businesses. They tend to diversify into other construction-related works. Worst still, the moment they have made enough profits, they will diversify into an area of work which is not related to construction at all. Many local construction companies appear to be very profit-oriented in the short term. Management buy-outs rank in third place with a mean of 3.57. Many construction firms, especially the larger ones, have become insolvent after they acquired another company with financial difficulties. The associated debts were simply too much for them to bear.

Table 3 Frequency of causes of insolvency

Causes of Insolvency	Mean	Variance	t-value
Diversification	3.63	0.37	5.64
Absence of barriers	3.23	1.15	1.19
Family firms	3.53	0.60	3.76

Management buy-outs	3.57	0.25	6.15
Cash flow problems	3.27	0.75	1.68
Overtrading	3.50	0.67	3.34
Poor financial control	3.30	0.97	1.66
Knock-on effect	3.27	0.82	1.61
Overwhelming contract claims	3.43	1.15	2.21
Imprudent diversification	3.63	0.79	3.89
Onerous conditions of contract	3.27	0.89	1.54

Many construction companies are actually family firms that have been around for many years. Firms that are family-run seem to be more resistant to changes. This resistance may be a cause for insolvency.

The critical point for t-distribution, having a degree of freedom of 29 and level of confidence of 95 percent, is 1.699. Table 3 shows the t-value results that have been generated using the one-sample t-test. From Table 3, it can be noted that out of the eleven possible causes of insolvency in the construction industry, only five of them are significant. These are absence of barriers, cash flow problems, poor financial control, knock-on effect and onerous conditions of contract. All these five causes have t-values lower than the critical value of 1.699. These five significant causes of insolvency are discussed below.

6.1 Absence of Barriers

Absence of barriers to entry in the construction industry has always been an important issue because of the ease of entry into the industry by companies who are not even professionally trained to do construction related works. 22 respondents viewed the absence of barriers to entry as a characteristic that does occur frequently within the industry that may cause insolvencies. Only 27 percent of the respondents opined that it rarely occurs within the industry.

Unlike other economic sectors, the construction industry does not restrict players from entering the industry although the Pakistan Engineering Council (PEC) maintains a registry for contractors in Pakistan. This registry is only for companies to list themselves for them to know which category of public sector projects they are financially qualified to tender for.

During a boom period, many companies will be keen to have a slice of the pie in the construction industry. However, in an economic downturn, companies which are not financially strong and do not have enough technical expertise in this area of work risk ending up insolvent.

The survey suggests that the absence of barriers to entry is a significant cause of insolvency in the construction industry.

6.2 Cash Flow Problems and Poor Financial Control

The next two significant issues that may cause insolvency in the industry are cash flow problems and poor financial control. Cash flow problems have always been a critical issue in the construction industry. The results from the survey showed that many respondents felt that cash flow problems have a higher chance of causing insolvency than other issues listed in the questionnaire.

80 percent of the respondents agreed that the cash flow problem is indeed occurring and that it has caused insolvency in the construction industry. Similarly, 73 percent of the respondents have rated poor financial control within companies as a significant contributing factor that may cause insolvencies. Out of this 73 percent, 37 percent of them rated it as a factor that often leads to insolvencies, especially during an economic recession. The reason is that subcontractors are unable to get their money back from the main contractors. Consequently, this leads to cash flow problems which eventually cause the bankruptcy of small contractors.

6.3 Knock-On Effect

The next contributing factor that may cause insolvency of contractors is the knock-on effect. This is a factor that is felt especially by contractors along the supply chain of contracts.

The downfall of a main contractor leads to the subsequent downfalls of other contractors. This is because the survival of contractors is usually dependent on the main contractors. The main contractor will usually tender out parts of the main contract to various contractors. Most contractors are paid on credit basis. Therefore, if the main contractor becomes bankrupt, the contractors, being unsecured creditors, will not be able to get their money back for any work done earlier. Hence, they may end up insolvent as well. 80 percent of the respondents felt that the knock-on effect is indeed one of the significant contributing factors affecting insolvency in the construction industry.

6.4 Onerous Conditions of Contract

The last contributing factor rated by the respondents for causing insolvency is onerous conditions of contract. 77 percent of the respondents linked onerous conditions of contract to insolvency. This is because the contractors will receive an acceptance of his offer to work as a sub-contractor for the main contractor "subject to standard terms and conditions of the main contractors".

Although the sub-contractor does not want to be burdened with such onerous conditions, he frequently has no choice but to accept them. Otherwise, he risks losing the job by objecting to them. Subject to such onerous conditions, many contractors were unable to survive and eventually become insolvent.

Some onerous conditions of contracts include “pay-when-paid” clauses, the contractors being liable for their works until practical completion of the main contract works, excessive retentions and discount percentages and last, but not least, the main contractor’s right to hold back money on one contract for yet to be proven faults on other contractors.

The “pay-when-paid” clause is one of the most onerous conditions of contract. It transfers the risk of a client not paying the main contractor to the sub-contractor. It provides some form of protection for the main contractor should the client becomes insolvent but at the expense of the contractors.

7. Unethical Practices And Insolvencies

Besides asking the respondents to rate their opinion on which issues they think would mostly cause insolvency, they were also asked to rate whether unethical practices will lead to the occurrence of these issues. The results from the survey are shown in Table 4 where it can be noted that out of the 30 respondents, 21 of them who think that absence of barriers to entry into the industry has caused insolvency in the industry have also felt that unethical practices do not lead to the occurrence of this issue.

Table 4 Cross-tabulation of causes of insolvency and unethical practices

Causes of Insolvency and Unethical practices	**Unethical Practices**		
	Yes	**No**	**Total**
Absence of barriers	9	21	30
Cash Flow problems	25	5	30
Poor financial control	20	10	30
Knock-on effect	27	3	30
Onerous conditions of contract	21	9	30

From Table 4, 25 of the 30 respondents felt that the issue of cash flow problems may be due to unethical practices within the construction industry. This is because cash flow problems have always been a critical factor that affects insolvency in the industry. Furthermore, cash flow problems within companies often occurred due to unethical practices such as failure to get back the debts owed etc.

From Table 4, 20 out of the 30 respondents felt that unethical practices have caused poor financial control resulting in insolvency. Like cash flow problems, poor financial control is often due to unethical practices as well. Some examples of these include the deliberate delay of payment by the main contractor even though the sub-contractor has finished the work and submitted the claim.

The frequency of unethical practices leading to the knock-on effect is high. In Table 4, 27 respondents, or about 90 percent, hold this view. This is because knock-on effect is a factor that occurs when one's action will affect another party. Hence, main contractors who are unethical in their daily scope of work will affect the survival of the contractors who are at the bottom of the supply chain. One example is payment delays by the developer to the main contractor who will then not be able to pay the contractors.

As shown in Table2, 21respondents felt that unethical practices do lead to onerous conditions of contract. This is because the respondents, who are contractors, felt that they were bound by onerous conditions of contract such as "pay-when-paid" clauses, making them liable for their works until practical completion of the main contract, excessive retentions when they accept the offer from the main contractor, etc.

The mean rankings of the six unethical practices for the five significant causes of insolvencies are shown in Table 5. For quantifying unethical practices, a score of 1 means "most likely" and 6 means "most unlikely" were used.

From Table 5, it can be noted that for "absence of barriers" to entry, the respondents felt that it is likely to be caused by an unethical practice that fail to reconcile with the sub-contractor's concerns (mean score of 2.81). As for "cash flow problems", the respondents felt that these are likely to be caused by the unethical practice of the main contractor deliberately delaying payments (mean score of 1.93).

As for "poor financial control", the respondents may feel that it is likely to be due to the misrepresentation of financial status by the main contractors (mean score of 2.17). This suggests that the main contractor may have created an impression for the contractors in making them think that they are financially stable when in actual fact, they are not.

Table 5 Mean scores relating to issues of unethical practices

Causes of Insolvency and Unethical practices	**Absence of barriers (Mean Rank 1)**	**Cash flow problems (Mean Rank2)**	**Poor financial control (Mean Rank3)**	**Knock-on effects (Mean Rank4)**	**Onerous conditions of contract (Mean Rank 5)**
Delaying of payments	4.19	1.93	2.71	1.67	3.24
Mishandling of sensitive information	2.94	4.41	4.13	4.59	3.38
Improper estimating practices	3.00	4.10	4.17	3.56	4.10
Abuse of resources	4.13	4.03	3.83	3.70	3.38
Failure to reconcile with subcontractor's concerns	2.81	4.34	4.00	3.67	3.05
Misrepresentation of financial status	3.94	2.17	2.17	3.81	3.86

The respondents may feel that "delaying of payment" is likely to have resulted in the "knock-on-effect" which in turn, caused insolvency in the construction industry. As shown in Table 5, this has a mean score of 1.67. Every player in the construction industry is somewhat connected contractually. Hence, if one of the players, especially the main contractor, deliberately delays payment to the contractors, this may result in the contractors running into cash flow problems and becoming insolvent. Last but not least, the respondents suggest that the failure of the main contractor to reconcile with sub-contractor's concerns has resulted in the occurrence of "onerous conditions of contracts" with a mean score of 3.05 in Table 5. This appears to be the case because most main contractors are profit-oriented to the detriment of others.

8. Conclusion

Out of the eleven possible causes of insolvency in the industry, five were identified as most significant causes by the respondents. These are the absence of barriers to entry, cash flow problems, poor financial control, knock-on effect and onerous conditions of contract. All these five significant causes have a response rate of more than 70 percent.

In addition, the respondents also perceived that all these five significant issues that will cause insolvency may occur because of unethical practices. According to the respondents, unethical practices such as deliberately delaying payments, misrepresentation of financial status, etc. are likely to lead to the occurrence of insolvencies among contractors.

On another note, 70 percent of the respondents have also rated the overall behavior in the construction industry as unethical and that this seems to be a major problem in the industry. In addition, more than 70 percent of the respondents have rated main contractors as unethical. Hence, it appears that some causes of insolvency arose because of unethical practices.

The research revealed that unethical practices are major cause of insolvency of contractors in Pakistan construction industry. It is therefore important for the construction industry as well as main contractors to pay heed to ethical behavior and practices in order not to jeopardize the financial stability of contractors in the supply chain. Special attention should be paid to the five significant causes of insolvency highlighted in this study to render the construction industry less onerous for the contractors. Further, it is also strongly suggested that proper code of ethics and professional conduct be developed. This would assist in addressing the undesirable state of the construction industry in Pakistan.

Finally, as this study only surveyed contractors, future works can be extended to survey the consultants on the ethical behavior and practices of the client.

Abstract

Cash flow is the lifeblood of the construction industry worldwide. Yet, unlike many other jurisdictions, Hong Kong does not yet have any security of payment legislation or any solid plan for the same. Hence, the right of contractors to stop work and terminate the contract in case of non-payment is essentially a matter still regulated by the ambit of the common law. In the circumstances, such unique features of Hong Kong also present a case worthy of investigation from a comparative perspective, in respect of the contractor's dilemma as to whether to continue working without payment.

Through reviewing recent case examples in Hong Kong and other jurisdictions, this paper examines and compares the legal landscapes regulating the right to stop work on the part of contractors in non-payment situations. In addition, it also seeks to highlight those factors affecting the exercise of such a right that those who find themselves in such situations, or those who need to deal with such situations should be alerted to, in order to guide appropriate approaches to their resolution.

Keywords: Non-payment; Security of payment; Repudiation of contract; Hong Kong

1. Lifeblood in Construction Industry

The construction industry in Hong Kong has gradually recovered from the economic recession in the past 3 years. This however does not necessarily mean that getting paid the right amount in a timely manner, will no longer be a problem for contractors. Indeed, there are some common features inherent in the worldwide construction industry, that make securing cash flow a vital aspect to the survival of every contractor in the business. The construction industry is an industry characterized by operations often with limited capital backing. Construction activities are often subject to a high level of risks and tender prices are inserted with significant uncertainties on the basis of technical and financial assumptions affecting the ultimate pricing; contractors are paid in arrears and capital funding for the works by overdrafts, trade credits or other interim means as the works progress is almost unavoidable. Most of the contractors are unsecured creditors of the parties whom they have contracted to work for, and, hence the cascade of payments from the project owners from the top downward is critical for the cash flow to all concerned. Indeed, as in many other jurisdictions, the typical organization of construction projects in Hong Kong is somewhat pyramid-like in structure. The project owner enters into contract only with a main contractor that sub-contracts out some or a substantial part of the actual works to various sub-contractors while retaining in itself the administrative and supervisory tasks. The various sub-contractors may well in turn further delegate the actual tasks of execution of the works to others. This chain of sub-contracting can go on much further. As observed in a April 2005 paper of the Environment, Transport and Works Bureau to the Hong Kong Legislative Council, it is remarked that: "*Sub-contracting is a common practice in the construction industry. If properly managed by contractors it will facilitate the execution of works in a cost-effective manner with efficient use of resources. However, in the absence of proper management, uncontrolled subcontracting could have adverse impact on the progress and quality of works, not to mention the adverse public image on Government.*". Thus, the inherent features of the construction industry, when coupled with the extensive use of further sub-contracting, renders cash flow critical for most small and medium sized contractors these days and, if payments are held up, it can be enough to tip them over the edge. This is the case in Hong Kong; this is also the case elsewhere [i].

'Non-payment' here is meant to cover situations where there is lack of correct or timely payment or refusal of total payment from the employer or upper tier contractor during the progress of the works, whether such payments are genuinely disputed or otherwise. When faced with the situation of non-payment during the progress of the works, the contractor has a huge dilemma to handle. Some standard forms of contracts in Hong Kong have provided for the termination by the contractor's giving notices to the employer in cases on non-payment. However, similar provisions are seldom found in sub-contracts in Hong Kong and it is not uncommon for such provisions to be deleted from the contracts in some private sector jobs. The contractor may naturally wish to suspend or stop the works pending receipt of proper payments. This, without express contractual entitlement to do so], is often a breach or even a repudiation of the contract. Repudiation means a fundamental breach that goes to the root of the contract and has the effect that, once validly accepted by the innocent party, it discharges the innocent party from further performance of the contract and to sue for damages immediately. As laid down in the case of *Hongkong Fir Shipping Co. Ltd. v. Kawasaki Kisen Kaisha Ltd.* [ii], as held by Diplock L.J., the test on whether an event which discharges one of the parties from further performance of his undertakings is this: "*Does the occurrence of the event deprive the party who has further undertakings still to perform of substantially the whole benefit which it was the intention of the parties as expressed in the contract that he should obtain as the consideration for performing those undertaking*s?".

Hence, in such circumstances of non-payment, there are competing considerations. Many construction contracts in Hong Kong do provide that disputes are to be resolved by arbitration and arbitration shall not be proceeded with until the completion of the works. See, for example, the Agreement and Schedule of Conditions of Building Contract for Use in Hong Kong (1976 Ed.) by the Hong Kong Institute of Architects and Royal Institution of Chartered Surveyors (Hong Kong Branch), which is still popularly used in the private sector. Also, with the nature of some payment disputes, they are not always suitable for resolution by summary judgement even if the disputes can be brought before court. Thus, on the one hand, if progress payments are not forthcoming, the disputes over such payments may need to be referred to litigation or arbitration, which can take months, if not years to resolve [iii]. Also, payment disputes are also complicated by the use of "pay-when/if-paid" clauses in the construction industry, allegations of defective works or delay to completion of the works, and set-off or abatement claims for contra charges or other deductions [iv]. This means effectively that such disputes cannot be resolved within a short time and no cash flow can be inward coming. Therefore, the contractor has to rely on its own means to finance the works if to continue the works. On the other hand, the contractor is often still under an ongoing obligations to proceed with the works with diligence to meet the agreed progress or programme. Failure in meeting these obligations is usually visited with deduction of damages for delay, whether liquidated or otherwise, and a right of the employer or upper tier contractor to terminate the contract and sue for consequential losses, where the contractor simply suspends or stops working on site. In such circumstances, instead of getting paid for the works done, the contractor may be held liable for damages for the delay and extra costs for the completion of the works by others. Accordingly, 'invalid' suspending or stopping the works all together, can expose the contractor to disastrous consequences.

2. Legal Landscapes for Right to Stop Work

This dilemma arises from the common law position as regards the right (if any) of a contractor to stop work, treating the contract as terminated, if not getting timely and correct progress payments as agreed in the contract. The starting point for this can be that there is no general right in common law to suspend work if payment is wrongly withheld. This is illustrated in the classic case of *Lubenham Fidelities & Investment Co. Ltd. v. South Pembrokeshire District Council* [v]. The employer in this case withheld interim payments by deducting liquidated damages on wrongful advice by the architect. The contract was in the JCT 63 form. The contractor wrote to terminate the contract for such a breach and ceasing work on site. This led to the employer sending out determination notices for the contractor's ceased works without reasonable cause and the contractor also served notices to terminate the contract for the employer's failure to effect interim payments as certified, also issuing a writ. The UK Court of Appeal held that the contractor, who was indeed the bondsman who choose to take over the contract to perform it rather than paying on the performance bond, had repudiated the contract by ceasing works without reasonable cause notwithstanding that the employer were wrong in deducting liquidated damages at that stage. Thus, by serving the notices of termination for non-payment and issuing a writ thereafter, the contractor was held to have indicated an intention not to be bound by the contract, leaving the employer with no alternative but to accept the repudiation. In giving the judgment of the court, May LJ said: "*Whatever be the cause of the under-valuation, the proper remedy available to the contractor is, in our opinion, to request the* *architect to make the appropriate adjustment in another certificate, or if he declines to do so, to take the dispute to arbitration under clause 35…*".

Also, in *Mersey Steel and Iron Co. v. Naylor, Benzon & Co.* [vi], it was held that on the facts of the case the party which had postponed an installment payment under erroneous advice had not shown an intention to repudiate the contract so as to release the other party from further performance. In the judgement of Earl of Selborne L.C., it was stated that "*You must look at the actual circumstances of the case in order to see whether the one party to the contract is relieved from its future performance by the conduct of the other; you must examine what that conduct is, so as to see whether it amounts to a renunciation, to an absolute refusal to perform the contract, such as would amount to a rescission if he had the power to rescind, and whether the other party may accept it as a reason for not performing his part.*" Therefore, how the legal consequence of a breach is to be ascertained is regarded as a matter to be determined primarily from the terms of the contract itself, and the facts and practical results of the breach have to be examined to see whether it will go to the root of the contract and accordingly amount to repudiation. As noted in *Decro-Wall International S.A. v. Practitioners in Marketing Ltd* by Salmon L.J: "*The contract may state expressly or by necessary implication that the breach of one of its terms will go to the root of the contract and accordingly amount to repudiation. Where it does not do so, the courts must look at the practical results of the breach in order to decide whether or not it does go to the root of the contract.*"[vii].

This approach has support from also the New Zealand case of *Canterbury Pipe Lines Ltd. v. The Christchurch Drainage Board* [viii] where McMullin J. held that: "*It is true that where a stoppage in payments is temporary only, in the sense of being no more than delayed rather than withheld, the contractor's rights may not extend beyond a right to sue the employer. There may be some cases in which the contractor can treat the stoppage as repudiation. Much will depend on the facts.*"

However, the difficulties associated with this approach for an innocent contractor is that non-payment, in itself, does not normally amount to a repudiation that can be relied on to discharge the innocent party from further performance of the contract. All the circumstances have to be assessed to search for an intention not to be bound by the contract on the part of the defaulting party. Indeed, a contractor in such situations is further faced with the risks and consequences of a wrongfully terminated contract or stopped work, when the non-payment is merely a breach and not sufficient to become a repudiation, whereby entitling the innocent contractor to sue for damages for the breach associated with the non-payment and, normally, merely to recover interest for late payment. . In that case, the 'innocent' contractor can be liable for wrongful repudiation of the contract by its act.

Uncertainty and complications in this regard are further highlighted by the cases like *James Shaffer Ltd. v. Findlay Durham & Brodie* [ix], *Sweet & Maxwell Ltd. v. Universal News Service Ltd.* [x] and *Woodar Investment Development Ltd. v. Wimpey Construction U.K. Ltd.* [xi], which firmly lay down the principles that a party who *bona fide* relies upon an express provision in a contract in order to rescind or terminate a contract, should not, by that fact alone, be treated as having repudiated his contractual obligations if he turns out to be mistaken as to his rights.

Partly to cater for these problems associated with non-payment, legislative solutions have been introduced in various common law jurisdictions, starting from the enactment of the UK Housing Grants, Construction and Regeneration Act 1996. A statutory right to suspend works on non-payment of contractual sums otherwise due is conferred on a contractor engaged in a construction contract by virtue of section 112 this 1996 Act. When a sum due under a construction contract is not paid in full by the final date for payment as regulated by Sections 109 to 113 of the 1996 Act, this right becomes exercisable by giving 7-day notice of intention to suspend performance, stating the ground(s) on which it is intended to suspend performance, unless an effective notice to withhold payment has been given to the contractor. This right to suspend work continues until the party in default makes payment in full of the amount due. For calculating time under the construction contract, any period during which performance is suspended in pursuance of the right conferred by this section shall be disregarded in computing for the purposes of any contractual time limit the time taken, by the party exercising the right or by a third party, to complete any work directly or indirectly affected by the exercise of the right. By requiring the use of notice to withhold payment, no one may withhold payment of money due to the other party without giving him advance notice of the intention to do so [xii]. Further, contract conditions which provide that pay-when/if-paid arrangements are also prohibited except in circumstances where the non-payment arises from insolvency of the upper tier payer [xiii]. Coupled with the use of statutory adjudication for interim binding resolution of disputes [xiv], the 1996 Act aims at reducing disputes in construction contracts and moving them upstream for resolution as early as practicable, on a provisional interim basis [xv].

Since 1996, legislation similar to the above have been enacted in various other common law jurisdictions. These include the Building and Construction Industry Security of Payment Act of 1999 in New South Wales, of 2002 in Victoria, of Queensland in 2004, and the Construction Contracts Act 2004 in Western Australia; the Construction Contracts Act 2002 in New Zealand; and of the Building and Construction Industry Security of Payment Act 2004 in Singapore. In Malaysia, a legislative move towards the enactment of the Construction Industry Payment and Adjudication Act 2007 is also in progress. Though operational details differ, all of these models of legislation have, *inter alia*, one common feature --- a mechanism to confer a statutory right on the contractor to a construction contract to suspend carrying out of the works when payment due is not effected in time [xvi].

Of course, every solution can breed new problems. For instance, in respect of the UK Housing Grants, Construction and Regeneration Act 1996, disincentives for exercising the right to suspend work are observed. These are centered on the costs of suspension and include considerations for the costs of suspending and remobilising performance, under a construction contract, the inconvenience and cost of remobilising immediately upon payment of the outstanding debt, and the inconvenience and cost of having to suspend all obligations under the contract [xvii]. Reviews and ways for improving the current legal regime created by these legislation are indeed ongoing [xviii]. However, the popularity of security of payment legislation being adopted across various jurisdictions indicate that payment problems, while not unique to the construction industry, are often seen to be worse in this industry than in others. The multi-tiered industry hierarchy, the low capital backing of contractors, the heavy reliance on cash flows to sustain business, and the not uncommon criticism for not maintaining consistently high standards of ethical conduct in the worldwide construction industry also are features of the construction industry in Hong Kong [xix]. However, as the matter now stands, Hong Kong does not yet have any security of payment legislation or any solid plan for the same. Hence, from the perspectives of common law principles, Hong Kong is a case worthy of investigation, from a comparative perspective, in respect of the contractor's dilemma as to whether to continue working without payment.

3. Approach in Hong Kong

Obviously, the starting point of a contractor's right to stop working on non-payment must be the contract.

As an illustration, clause 26 of the Agreement and Schedule of Conditions of Building Contract for Use in Hong Kong (1976 Ed.) by the Hong Kong Institute of Architects and Royal Institution of Chartered Surveyors (Hong Kong Branch) ("the HKIA/RICS Form") provides for the usual two-notice procedure for determination of the contract by the contractor for non-payment of certified payments. This entitles the contractor to give to the employer the initial notice stating that a notice of determination will be served if no payment of the certified amount is made within the next 7 days and the sending out of the notice of determination thereafter. There is a proviso that no such notices can be served unreasonably or vexatiously [xx]. To validly exercise such a right to bring the contract to an end, the contractor is generally required to strictly comply with all the stipulated procedural requirements, e.g. as to the timing and format of the notices [xxi]. Termination of the contract under clauses like this is often described as contractual termination, as distinct from common law termination, when repudiation exists to discharge the innocent party from further performance of the contract. . It is well settled that contractual termination co-exists with common law termination, as illustrated in *Trident Engineering Company Limited v. Mansion Holdings Limited* [xxii] ,where, applying *Lockland Builders v. Rickwood* [xxiii], it was held that, in deciding clear express words must be used to rebut the presumption neither party intends to abandon any remedies for its breach arising by operation of law.

In respect of terminating the contract at common law, the Hong Kong Court of Appeal has in a recent decision reviewed the governing legal principles. This is the case of *Creatiles Building Materials Company Limited v. To's Universe Construction Company Limited* [xxiv], an example of repudiation at common law arising out of non-payment of progress payments. The facts of the case arise from a sub-contract to apply spray coating to a building. The spray was to be applied to the four elevations of the building in five coats on each wall. Under the sub-contract, the contractor was to pay a 10% deposit upon signing of the agreement, 30% upon materials delivered on site, and the "…*balance by each 14 days interim payment during work-in-progress*". There was no problem with the deposit and the 30% payments. After commencement, the contractor did not settle the sub-contractor's debit note for 20% of the balance of the contract price due based on the progress of the spraying works, in breach of two subsequent promises to pay. Through its lawyers, the sub-contractor wrote to the contractor stating that if payment was not made by a certain time, it would treat the sub-contract as having been repudiated by the contractor. No payment was effected but the contractor wrote back stating that the reason for non-payment was that all five coatings to one elevation had to be completed before the sub-contractor could claim payment. The sub-contractor therefore left the site and claimed for repudiation of the sub-contract on the part of the contractor. At first instance [xxv], it was held that the non-payment by the contractor amounted to repudiation, entitling the sub-contractor to terminate the sub-contract. The contractor appealed arguing that the non-payment was not a fundamental breach amounting to repudiation and that the mere fact that it had insisted on its rights, even though it might have been wrong about them, was not to be treated as evincing an intention to repudiate the contract.

In the judgement of Cheung JA, the Hong Kong Court of Appeal re-affirmed the general principle, as a starting point, that there was no general right in common law to suspend work if payment was wrongly withheld but also accepted that the authorities clearly recognised that a deliberate refusal to make an interim payment was capable of amounting to a repudiation of the contract. After review of cases in other jurisdictions, the Court of Appeal concluded that "*…[u]ltimately one has to examine the facts of the case to see whether the non-payment amounted to a repudiation*", stating that "*…[t]he principle is to consider whether the circumstances of the non-payment show an intention not to be bound*". In applying this approach to the case, the Court of Appeal took into account the facts that the contractor was clearly required to make interim payment every 14 days; that the contractor was in breach of its promises twice to effect the interim payments; that the contractor, by its letter in response, expressed a clear refusal to pay for the work by unilaterally changing the payment method under the sub-contract. It was also observed in the judgement that: "*While it would not pay for the interim payment, it would expect the plaintiff to carry on with the work. In other words, the payment term would be changed from cash payment to that of credit payment. This clearly entitled the plaintiff to treat it as a repudiation.*" To the defence that the contractor was merely insisting on its own, although mistaken, interpretation of the sub-contract, the Court of Appeal was of the view that "*…it may not be a repudiation for one party to put forward his genuine, but bona fide, interpretation of what the contract requires of him but that where that party performs in a manner which is not consistent with the terms of the contract, it is no defence for that party to show that he acted in good faith*". In this case, the Court of Appeal also observed that, when the sub-contractor started work, the contractor was obviously aware that the plaintiff's method of working was to apply one coat to all the four elevations first before applying the next coat; and the contractor had never indicated that this method of work would disentitle the plaintiff from receiving the interim payment even after the debit note was presented. Thus, the defence of the contractor was rejected as there was indeed far from being a *bona fide* misconstruction of the terms of the contract and the reasons given were considered to be spurious reasons.

The approach of *Creatiles Building Materials* has been considered in a subsequent case of *Hongkong Underground Engineering Ltd. v. Welcome Construction Co Ltd* [xxvi], which concerns a specialist sub-contractor in underground tunneling work. The facts of the case are not uncommon. Under the sub-contractor, interim payment arrangement was to be effected via invoice submitted before the end of each calendar month with payment to be paid within 30 days of receiving invoice. The sub-contractor applied in its first invoice for HK$324,400 and the contractor, via its own assessment, calculated an amount of HK$169,800 but paid only HK$100,000 eventually. In likewise manner, the contractor paid over HK$150,000 for the second invoice, which claimed for HK$338,000 and was assessed by the contractor to be HK$288,000. For the third invoice, the contractor paid in full its assessed amount but with a delay for more than 2 months. No further payments were made in the fourth and fifth invoices. The sub-contractor wrote to the contractor stating that its non-payment evinced an intention no longer to be bound by the contract. To this, the contractor indicated that reasonable sums were withheld for liquidated damages that might be imposed.

In his judgement, Sakhrani J was of the view that the figures of HK$100,000 and HK$150,000 were without contractual basis and, using his words, "*…simply a figure plucked out of the air without any calculation…*" and, applying *Shyam Jewellers Ltd. v. Cheeseman* [xxvii], it was held that the 'potency' and legal effect of the concerned breach was to be judged in the light of the seriousness of the breach and its effect upon the continuing performance of the contract and this involved an examination of the circumstances of the breach itself as well as its implications for the future of the contract and any likelihood of repetition. In finding that the contractor did evince an intention not to be bound by the contract, it was also stressed, in doing so objectively, the court could only concern itself with the reasonable perceptions and reactions of the party asserting a repudiatory breach and it would not take into account concerns or fears, which, however naturally entertained, were not justifiably grounded in the actions and intentions manifested by the party alleged to be in repudiatory breach.

4. Factors for Review

The legal approach that can be drawn out from the above cases is quite clear, though the application may be more complicated as being highly facts-sensitive. What matters most in deciding whether there is a repudiation for non-payment, thereby capable discharging an innocent contractor from continuing the work, depends on an evinced intention not to be bound by the contract, rather than the mere fact of non-payment itself.

From the above, there appear to be certain indicators or factors to watch out for when practitioners in Hong Kong are facing the dilemmas highlighted in this paper, and risk consequences as a result of not getting paid in respect of interim or progress payments. These factors will be extracted from a range of cases and presented in another forum, given space limitations herein. The factors derive themselves from common law and, as such, should also be applicable or of guidance effects in other common law jurisdictions, which have enacted security of payment legislation though it is expected that the need to resort to common law termination in non-payment situation should not be frequent in those jurisdictions. However, some examples of the key factors and indicators to consider from a Hong Kong perspective are highlighted as below. It is stressed that these are neither meant to be nor capable of being exhaustive.

Examples of the above factors are:-

- Whether there is clear indication of refusal or inability to effect future payments;
- Whether there is a repeated pattern to pay the correct amount despite warnings;
- Whether there is a repeated failure to pay on time despite warnings;
- Whether payments already effected is of amounts with certain contractual basis;
- Whether there is response or reasonable response to support the refusal or default in payment;
- Whether there is prior or subsequent inconsistent knowledge or conduct against the alleged *bona fide* reliance upon the payment term to refuse timely or correct payment, based on mistaken understanding of the concerned term;
- Whether the reliance upon the understanding of payment term to refuse timely or correct payment is or otherwise can be *bona fide*;
- Whether there are other consequences evincing an intention not to be bound by the contract.

5. Conclusions

Among the common law jurisdictions, Hong Kong remains one of the few that does not yet have any security of payment legislation. The right of contractors to stop work and terminate the contract in case of non-payment is essentially a matter still regulated by the ambit of the common law. From reviewing recent case examples in Hong Kong and other jurisdictions, some factors affecting the exercise by the contractor of the right to stop work in non-payment situations can be identified and are presented in the format of a checklist of questions. In view of the uncertainties and risks surrounding the exercise of such a right, it will be prudent for those facing such dilemmas to prepare such a checklist, based on the contract conditions, governing legislation and precedents, in order to better assess and respond to such situations, avoiding pitfalls and effectively protecting the legal rights and interests of themselves or their clients.

Impact of the ‘Security of Payment’ Act in New South Wales on clients, contractors and subcontractors

Abstract

The *Building and Construction Industry Security of Payment Act 1999* (NSW) (‘the Act’) was introduced primarily to improve security of payment for small scale subcontracting firms. Nevertheless, the aim of the study was to examine the impact of the Act on subcontractors, contractors and clients in New South Wales (‘NSW’). Data for the study comes from a review of relevant literature by authors in the ‘security of payment’ field, on-going research by the authors, data collected and published by the NSW Department of Commerce, and face-to-face interviews conducted by the authors with three expert adjudicators in NSW. From subcontractors’ perspective, the impact of the Act has been largely a positive one with subcontractors’ being highly successful at adjudication. Contractors’, on the other hand, have been exposed to ‘ambush’ claims by subcontractors, which is viewed as an unintended result of the strict time demands the Act places on the parties. Whilst no direct evidence is available to reliably establish the impact (if any) of the Act on client organisations, there is an emerging trend that clients’ most commonly schedule to pay $nil in response to payment claims. Further research is needed to establish the reasons for this trend.

Keywords: Adjudication, Impact, New South Wales, Security of payment

1. Background

1.1 Introduction of the Act

The main reason for the introduction of the *Building and Construction Industry Security of Payment Act 1999* (NSW) (hereafter referred to as ‘the Act’) was to improve security of payment of small scale subcontracting firms by eradicating the practice of clients and contractors of arbitrarily delaying or denying payment [1]. While subcontractors are seen as the main benefactors of the Act, the provisions of the Act also extend to contractors, suppliers of materials and suppliers of services, who also experience security of payment problems. The only party excluded from the provisions of the Act are clients who enter into a construction contract for the carrying out of residential building work whereby the client resides in, or proposes to reside in, the residential building.

It is generally accepted that parties to the construction industry who seek payment under a construction contract for work carried out, services rendered or materials supplied experience consistent failure in receiving payment [2]. This practice not only affects profitability of those parties but it also causes serious cash flow problems particularly to smaller firms [3].

The Act sets out to "ensure that any person who undertakes to carry out construction work or who undertakes to supply related goods and services under a contract is entitled to receive, and is able to recover, progress payments in relation to the carrying out of that work and the supplying of those goods and services" [4]. The provisions of the Act are designed to reduce or eliminate delay in payment by introducing a range of revolutionary measures such as: a statutory right to progress payment; the use of default provisions for progress payment in the absence of express contractual provision; nullifying the effect of 'pay when paid' and 'paid if paid' clauses in a contract; introducing a fast process of notification and adjudication where a claim is disputed; giving security for a disputed payment when so determined by an adjudicator; and giving a claimant a statutory right to suspend work and the right to lien over unfixed materials [5].

The Act is the first security of payment legislative scheme introduced in Australia. It is based on the philosophy of rapid adjudication of payment claim disputes introduced in the UK in the form of the *Housing Grants, Construction and Regeneration Act 1996*. However, the NSW Act is substantially different in its structure and operation from its UK counterpart. Following the NSW example, similar legislative schemes have since been introduced in Victoria, Queensland, Western Australia, New Zealand and Singapore, with Malaysia planning to introduce its own legislation in the near future.

This paper examines the impact of the Act on the main parties to the New South Wales construction industry, namely, subcontractors, contractors and clients. Data for this paper comes from the literature review, on-going research by the authors and the information on the operation of the Act published by the NSW Department of Commerce.

1.2 Overview of the Act

The Act establishes a law that operates separately from, but in parallel with, a construction contract. A claimant of a progress payment claim may elect to seek a payment claim under the contract or under the Act. A payment claim, which is not endorsed as a claim under the Act, is processed strictly in accordance with the provisions of a contract. However, a payment claim endorsed as being made under the Act gives the claimant access to powerful provisions of the Act, which, in some cases, over-ride terms of a contract. The parties are unable to 'contract out' of the Act [6]. The Act applies to any construction contract, whether written or oral, or partly written and partly oral [7]. The provisions of the Act include, *inter alia*: a statutory entitlement to progress payments regardless whether the relevant construction contract makes provision for progress payment [8]; nullifying the effect of 'pay when paid' and 'paid if paid' clauses in a construction contract [9]; imposing a fast process of notification leading to adjudication of a payment claim where a claim is disputed [10]; giving a claimant a statutory right to suspend work [11]; and giving a claimant a statutory right to exercise a lien over unfixed plant or materials supplied by the claimant [12].

The Act provides a mechanism for resolving payment claim disputes in a quick and inexpensive 'adjudication'. This involves having the matter determined by a neutral adjudicator and ensuring that an adjudicated amount of payment claim is recoverable by the claimant.

The Act intended that an adjudicator's determination as to payment of a progress claim was to be merely interim pending final determination of the dispute in other proceedings. The intent was, however, misunderstood by the NSW courts in the first few years of the operation of the Act, insofar as the courts regarded an adjudicator as a quasi-judicial tribunal and decisions of adjudicators as final. For reason of error of law the courts set aside many adjudication determinations. The decision of the NSW Court of Appeal in *Brodyn Pty. Ltd. trading as Time Cost and Quality v Philip Davenport & Ors* [2003] NSWCA 394 reinstated the original intent of the Act and consequently removed the possibility of setting aside adjudication determinations for reason of error of law. However, respondents have been successful in exploited other apparent ambiguities in the Act upon which the courts continue to declare adjudication determinations void. This issue lies outside the scope of this paper and will not be discussed any further. The evolution of the security of payment law in the NSW construction industry can be found in Uher & Brand [13].

The Act requires that if the respondent disputes the claimant's payment claim, which the claimant endorsed as a claim under the Act, the respondent is required to provide the claimant with a 'payment schedule' within 10 business days of the claim being served. The payment schedule is a written response to the payment claim in which the respondent details the reasons for withholding payment. If the respondent chooses not to provide a payment schedule and not to pay the claimed amount by the due date for payment, the claimed amount becomes a 'statutory debt'. The claimant may then either: (a) proceed to recover a statutory debt due in a court of competent jurisdiction; or (b) to have the dispute determined by an adjudicator.

In case the claimant chooses to have a payment dispute determined by an adjudicator, the claimant is required to issue a notice to the respondent that the claimant intends to have a payment claim dispute referred to adjudication. By virtue of the notice, the respondent is given a second chance to provide a payment schedule within 5 business days. Thereafter, the claimant would lodge and adjudication application to the Authorised Nominating Authority (ANA) within the time specified in the Act. The ANA will appoint an independent adjudicator to determine the payment dispute. Only if the respondent has issued a payment schedule, the respondent is permitted by the Act to substantiate the reasons for withholding payment in an adjudication response lodged with the adjudicator. Not later than 10 business days of the adjudicator's acceptance to adjudicate the matter, the adjudicator will issue to the parties an adjudication determination.

If the respondent fails to pay the adjudicated amount to the claimant within the time specified by the adjudicator, the claimant may request the ANA to issue a certificate of adjudication. When filed in a court of competent jurisdiction, the adjudication certificate automatically becomes judgement for the adjudicated amount, without the need for a summons or a hearing.

Furthermore, the Act provides a claimant with a right to suspend work pending payment, and a right to exercise a lien over unfixed plant or materials supplied by the claimant to the extent of the unpaid amount of the progress claim.

Observance of the strict time constraints in which claimants, respondents and adjudicators are required to operate is the essence of the Act. The consequence of non-compliance with the time constraints may result in rights, otherwise available to claimants and respondents under the Act, being lost [14].

2. Impact on Subcontractors

The underlying objective of the Act is to give subcontractors (as claimants) a right to make, and a process to recover, progress payments. Subcontractors, particularly the small ones, are expected to benefit most from the provisions of the Act. Because of their limited financial resources, they are commonly unable to pursue recovery of progress payments through arbitration, litigation or other dispute resolution mechanisms under the contract and apart from withdrawing labour services, have no other means of recovering delayed payments. Needless to say, unscrupulous contractors are able to take full advantage of financially weak subcontractors by delaying or devaluing payments without good reason.

Payment claims that fall under the provisions of the Act are those that have been endorsed as payment claims under the Act. Thus, claimants are free to decide whether or not they intend, should the need arise in the future, to rely on the Act in pursuing recovery of a progress payment.

To be able to exercise the option of either endorsing or not endorsing a payment claim under the Act, a claimant needs to be familiar with the Act and its provisions. According to Brand & Uher [3] this is not always the case as small sized subcontractors are often the least knowledgeable group of claimants of the essential requirements of the Act. They reported that only 33% of the subcontractors surveyed endorsed payment claims under the Act.

Accepting that the aim of the Act was to improve security of payment of predominantly subcontracting firms operating in the NSW construction industry, it was anticipated that subcontractors would be the most frequent claimants under the Act. This hypothesis was verified by the literature. Two surveys carried out by the authors in NSW show between 53% and 71% of all claimants to be subcontractors [15]; [16], while in Queensland, where almost an identical security of payment legislation operates, subcontractors account for around 63% of all claimants [17].

While subcontractors are mainly claimants under the Act by virtue of being near or at the end of the supply chain, it is possible that where they further sublet work under their subcontracts, they may become respondents to payment claims made by their sub-subcontractors. The Queensland experience shows that this occurs in only about 4.7% of cases. No statistics on this issue are available for NSW. However, unpublished research by the authors suggests that subcontractors account for up to 10% of respondents.

Statistics published by the NSW Department of Commerce [18] show that claimants are highly successful in adjudication under the Act. The data shows that claimants are fully successful (i.e., they receive the full amount claimed) in about 43% of all adjudication determinations and that they receive at least a half of the claimed amount in about 74% of all adjudication determinations. On average, for all adjudication determinations made in NSW, claimants receive around 70% of the claimed amount.

The Department's statistics also show that claimants making smaller claims are more successful than those making larger claims; see Table 1. For example, for payment claims less than $5,000 in value claimants recover on average around 89% of the claimed amount, while for large claims of over $750,000 in value they only recover on average 24% of the claimed amount.

Table 1: Average claimed, scheduled and adjudicated amount

Range of claims determined (AUD)	Av. Claimed (AUD)	Av. Determined (AUD) (% of Av. Claimed)
< 5,000	2,920	2,604 (89.2%)
5,000 - 9,999	7,318	6,582 (89.9%)
10,000 - 24,999	16,688	13,300 (79.7%)
25,000 - 39,999	31,968	25,816 (80.8%)
40,000 - 99,999	63,634	44,714 (70.3%)
100,000 - 249,999	159,381	99,446 (62.4%)
250,000 - 499,999	350,963	256,112 (73.0%)
500,000 - 749,999	620,672	327,014 (52.7%)
≥ 750,000	9,456,585	2,291,368 (24.2%)

Considering that a majority of claimants are subcontractors, the above statistics clearly confirms that subcontractors are highly successful in adjudication under the Act, particularly those making smaller payment claims.

Because of their high rate of success in adjudication, subcontractors (as claimants) are not expected to pay a high share of the adjudication fees. Although no statistics are available for NSW, Uher & Brand [16] reported that only around 5% of claimants and 79% of respondents were required to pay the full amount of adjudication fees. In the remaining cases the parties shared the cost of adjudication. They also reported that it is common practice among adjudicators to require the losing party to adjudication to pay the full amount of adjudication fees. The Queensland experience suggests that claimants pay on average 23% of the adjudication fees and, for payment claims under $5,000, as low as 1.42% [17]. The Queensland statistics shows that claimant's share increases with an increase in the amount claimed. For example, claimants' share of the adjudication fee with regard to payment claims in excess of $50,000 is on average around 30%. This indicates that claimants are less successful in securing a satisfactory outcome from adjudication of large payment claims.

In-depth knowledge of the Act not only help subcontractors (as claimants) to comply with relevant provisions of the Act in their effort to improve the probability of a successful adjudication outcome, but it may also encourage them to use the Act to their advantage. Kennedy [19] alludes to the 'ambush' scenario employed by claimants in the UK construction industry. He describes two instances of ambushes: (i) when a payment claim is made against the respondent at the most inconvenient time for the respondent or (ii) when a claimant makes a payment claim prepared over a period of time, which is supported by a large volume of information and documentation.

There is no published information available which would confirm presence of the above two instances of ambushes in NSW. However, there is no shortage of anecdotal evidence indicating the prevalence of ambush claims being made under the Act.

For the purpose of gathering data on the issue of ambushes, the authors conducted face-to-face interviews with three expert adjudicators in NSW. The adjudicators interviewed agreed anonymously that the practice of ambushes is ripe in NSW. Specifically, they identified the period just prior to Christmas shut-down period as being popular for the lodgement of payment claims. Since a respondent has only 10 business days to provide a payment schedule in response to a payment claim, and in consideration of the fact that January is a common holiday period for construction industry organisations, the possibility that a respondent may fail to provide a payment schedule is being exploited. The expert adjudicators agreed that this practice is employed by both subcontractors and contractors.

They also agreed that there is evidence of the use of elaborate payment claims prepared by claimants over a long period of time with the assistance of claim consultants. When such a payment claim is made, the respondent has only 10 business days to prepare a payment schedule and, after the claimant lodges an adjudication application, only 5 business days to prepare a detailed adjudication response. Clearly, while the claimant is able to prepare a claim over a long period of time, the respondent is constrained by the Act in preparing a detailed defence within a relatively short time frame. According to the expert adjudicators, this practice is perpetrated mainly by contractors.

Another example of the alleged abuse of the Act by claimants is referred to as 'adjudicator shopping'. Davenport [20] reports that when a claimant is dissatisfied with the result of an adjudication determination by one adjudicator, the claimant is free to submit the same claim to a second adjudicator, hoping for a better result. The Act attempts to prevent 'adjudicator shopping' by requiring that, in determining the adjudication application, the adjudicator gives the work the same value as that previously determined. For example, if the first adjudicator determines the value of work to be $10,000, in a subsequent adjudication the second adjudicator is required to give the work the same value of $10,000 unless the adjudicator is satisfied that the value of the work has changed. However, if the first adjudicator rejects a variation claim because in the adjudicator's opinion the alleged work was not a variation, it is arguable whether or not the first adjudicator actually determined the value of that claim. It may well be that the second adjudicator may allow the claim if deciding that it was a valid variation. Whilst Davenport [20] does not explain whether 'adjudicator shopping' is wide spread, he points to a number of legal cases that indicate that this practice is being employed by contractors.

While it has been shown that subcontractors experience success in pursuing payment claims through adjudication under the Act, Uher & Brand [15] reported that only about a half of subcontractors, who have pursued a payment claim under the Act are satisfied with the adjudication process, particularly in relation to its time and cost efficiency. This finding may, at the first glance, appear to be surprising considering that subcontractors have largely been successful at adjudication. However, in the context of the results of the authors' previous research [3], which uncovered low level of knowledge and understanding of the adjudication process among subcontractors, it may well be that subcontractors have an unreasonably optimistic expectations of what the Act can deliver. The Act neither guarantees payment to subcontractors of the full amount claimed nor does it guarantee any payment. It only provides a powerful mechanism for a rapid and inexpensive resolution of payment claim disputes. It prescribes the manner in which claimants must prepare and serve payment claims and adjudication applications, and the time frame for making them. Non-compliance with such provisions may invalidate a payment claim or some parts of it, or may reduce the claimant's entitlement to payment. It is suggested that subcontractors' satisfaction with the adjudication process under the Act could be greatly enhanced through improved level of knowledge of the main provisions of the Act.

In conclusion it is evident that subcontractors are benefiting from the Act. More effort is however needed to enhance knowledge of the Act among particularly small sized subcontractors to improve their awareness of the benefits of the Act.

3. Impact on Contractors

The role of contractors as claimants under the Act was briefly referred to previously. Under the main contract, contractors make progress payment claims against clients, and those claims when endorsed under the Act, may be pursuit through adjudication. Although the NSW Department of Commerce does not report the proportion of adjudication applications submitted by contractors (as claimants) against clients, the research of Uher & Brand [16] suggests that contractors represent around 22% of all claimants. However, the predominant role of contractors under the Act is that of respondent.

It was previously established that claimants, as both subcontractors and contractors, are generally highly successful in adjudication of payment claims. It emerges from Table 1 that claimants of larger payment claims, who presumably are contractors, have been less successful than claimants of smaller claims.

The reason for large payment claims being less successful in adjudication than smaller claims is unclear. Assuming that large payment claims are predominately made by contractors, it may well be that such claims are either more vigorously defended by clients, or inflated, or both.

Brand & Uher [3] reported that the cost of preparing large payment claims (in terms of their dollar value) is considerably higher than the cost of preparing small claims. Although no data is available on the cost of responding to payment claims, it seems plausible to assume that such cost would be relatively high for large payment claims.

Brand & Uher [3] reported that claimants are assisted by law firms or claim consultants in the preparation of large payment claims. If claimants' seek assistance of lawyers or claim consultants, it is logical that respondents would do the same. The presence of lawyers or claim consultants in mounting a response to a large payment claim would support the proposition that large payment claims are more vigorously opposed, which could account for their lesser success at adjudication.

Furthermore, the expert adjudicators interviewed by the authors confirmed the presence of 'ambushes', particularly those involving very large payment claims supported by voluminous written submissions. Although respondents have only a very limited time to respond to such claims, with the aid of specialist law firms they are able to mount a formidable defence. According to the expert adjudicators, the potential for uncovering parts of such large payment claims which, for example may over-value the work claimed, or may include unapproved variations, or may be unsubstantiated, is relatively high. Assuming that adjudicators are consistent in arriving at their determinations irrespective of the amount claimed, the authors are inclined to conclude that a vigorous defence mounted by respondents in defence against large payment claims is a contributing factor for such payment claims being less successful for claimants at adjudication.

Based on the data in Table 1, which shows that the average adjudicated amount is about 70 percent of the average claimed amount across the whole range of claims determined, and taking views of the expert adjudicators into account, there can be no doubt that claimants attempt to inflate payment claims, particularly in the case of larger claims. To what extent small payment claims are inflated (if at all) is unclear. Considering that small size subcontractors' working knowledge of the Act and its requirements is generally only superficial, and that they do not generally seek assistance from lawyers in making payment claims and lodging adjudication applications [3], it may well be that the reason for the reduction in the value of small payment claims at adjudication is the failure of claimants to fully substantiate payment claims. While the Act has over its first six years of operation in NSW markedly improved security of payment, it has thus far been ineffective in preventing claimants from inflating and respondent from undervaluing payment claims.

Uher & Brand [15] reported that contractors (as claimants) are generally satisfied with the operation of the Act. However, the authors' unpublished survey of a small sample of respondents suggests that in the role of respondents to payment claims, contractors are less satisfied with the Act. This is not an unexpected result considering that as respondents contractors are largely unsuccessful at adjudication.

The reason for contractors being more successful as claimants than respondents at adjudication is unclear. As a potential claimant and respondent, they would be expected to be familiar with the Act and have in-depth knowledge of the Act's various provisions. It is open to conjecture as to why contractors, as respondents, generally fail at adjudication. It may well be that contractors simply have little or no time to respond to payment claims endorsed under the Act and may well be due to a large number of payment claims being made in the same claim period. Since contractors are required to issue a payment schedule within 10 business days of receiving a payment claim, the sheer number of claims and the limited time available for their processing may require contractors to focus on defending larger payment claims as their top priority at the expense of smaller ones. This may also explain why contractors, as respondents, fail to issue a payment schedule.

The failure to issue a payment schedule dramatically weakens respondents' ability to defend against a payment claim because the Act bars respondents making a submission to the adjudicator in the form of an adjudication response. Based on a research sample of 98 adjudication determination, Uher & Brand [16] reported that about one quarter of the respondents did not issue a payment schedule in response to a payment claim. Of those respondents, 77% were required by adjudicators to pay to claimants the full amount of payment claim; the consequence for not issuing a payment schedule is clearly an onerous one.

Another interesting outcome of Uher & Brand's research [16] is that when respondents provide a payment schedule, they most commonly schedule the amount that they are prepared to pay as $nil; see Table 2. The least preferred amount that respondents are prepared to pay is the full amount of a progress payment claim. They found that clients are more likely to schedule to pay a $nil in a payment schedule when responding to a payment claim from contractors than contractors who respond to a payment claim from subcontractors. They explained that the reason for that trend is likely to be related to contractors' superior knowledge of contract conditions, which enable contractors to make a realistic assessment of subcontractors' entitlement to payment under the contract. It may also be that contractors' superior knowledge of the Act helps them to realise the futility of denying payment in the presence of powerful provisions for recovery of payment in the Act.

Table 2: The amount of payments specified by respondents.

Scheduled amount as a % of claimed amount	**Frequency**
0% (nil payment)	45 (62.5%)
< 100% (partial payment)	21 (29.2%)
100% (full payment)	6 (8.3%)
TOTAL	72 (100%)

Probably the most detrimental provision of the Act from the contractors' point of view is barring of a 'pay when paid' provision in a construction contract. Contractors have relied extensively on a 'pay when paid' clause in subcontract conditions to improve their cash flow to the detriment of subcontractors. Although contractors continue to insert such a clause into subcontracts documents, they are unable to rely on it in an attempt to delay payment to a subcontractor, when a payment claim is endorsed under the Act. Contractors are therefore required to more carefully plan and manage their cash flow considering that they may need to pay their subcontractors prior to receiving payment for the same work from the client. They also need to ensure that the terms of payment are defined in subcontract documents; otherwise the default provisions of the Act for making a payment claim and for the due date for payment, which are the last day of the named month and 10 business days respectively, would apply.

In sum, the unique role of contractors under the Act as both claimants and respondents gives them the opportunity to better understand the operation of the Act and its various provisions, and use that knowledge in better defending against payment claims from subcontractors and maximising the adjudicated amount of progress payment claims served on clients.

4. Impact on Clients

No published information whatsoever is available on the impact of the Act on client organisations. The authors will attempt to extrapolate the data from their previous research studies to draw some inferences of the likely impact of the Act on clients. They will also rely on the expert advice provided by the three adjudicators interviewed.

As discussed previously, the frequency of issuing a payment schedule by clients is similar to that of contractors. However, it was noted that clients most commonly schedule to pay $nil in response to a payment claim. The reason for this is the subject of speculation. It is common knowledge that construction clients often withhold payment as a result of a dispute with a contractor under the main contract, whether that dispute is related to a progress payment claim or not. It is possible that clients employ the same approach even when a payment claim is endorsed as a payment claim under the Act. It may be that they are not aware of the fact that since the Act is only concerned with payment claim disputes in relation to a construction contract, other disputes between the parties cannot be used as a reason for withholding payment. This conclusion is plausible considering that respondents will, on average, pay at least 24% of the claimed amount in adjudication; see Table 1. It may also be that clients' reason for scheduling to pay $ nil in the payment schedule is their reaction to what they perceive to be an ambit payment claim. Further research is needed to provide an objective explanation of this trend.

An interesting aspect of the Act is that it excludes construction contracts for carrying out of residential building work where a client or owner of that residential building resides in or proposes to reside in. The rational behind this is that residential clients may not be familiar with the Act and its provisions, and thus could potentially fail to issue a payment schedule, the result of which could have serious consequences to such clients. However, while a payment claim made by a contractor against a client residing in a residential building is not a valid payment claim under the Act, payment claims of subcontractors against the contractor are, provided they are endorsed under the Act. It means that while subcontractors may rely on the adjudication process under the Act to recover payment, the contractor is denied assess to the Act. Perhaps this imbalance will need to be redressed in future revisions of the Act.

5. Conclusions

From subcontractors' perspective, the impact of the Act has been largely a positive one. Subcontractors (as claimants) have been highly successful at adjudication under the Act, particularly those making smaller payment claims. However, despite the positive impact, subcontractors generally have been shown to have a low level of working knowledge and understanding of the adjudication process. Thus, the extent of the positive impact is unclear.

The impact of the Act on respondents, both contractors and clients, appears to be much less positive; respondents' success rate at adjudication is relatively low while respondents' share of the adjudication fees, as determined by the adjudicator, is higher than that of claimants'.

Of concern for respondent contractors and clients is the emerging practice of claimants to submit 'ambush claims', which arise by virtue of the strict time constraints imposed on the parties by the Act, and the practice of 'adjudicator shopping' by unsatisfied claimants to a previous adjudication. Both of these practices, whilst not illicit under the Act, were clearly not intended to arise.

Finally, no direct evidence is available to reliably establish the impact (if any) of the Act on client organisations. In addition to being subject to ambush claims and adjudicator shopping in the same way as respondent contractors, it emerges that clients most commonly schedule to pay $ nil in response to payment claims. Reasons put for this trend are that clients are likely to have superior knowledge of contract conditions and superior knowledge of the Act than contractors. However, further research is needed to firmly establish the reasons for this trend.

The meaning of the protection of the architects title in European countries

Abstract

The title ‘Architect’ is legally protected in many countries. Only designers who have successfully completed the required academic education can be registered in the Architects’ Register and use the title. The purpose of this regulation is to give some basic quality assurance to consumers when hiring an ‘Architect’ for their design work. This should also contribute to the general quality of the built environment. In addition, it enables architects to work more easily in other EU countries. However, the requirements for registration as Architect differ considerably in the various countries. In some countries just the academic education is required, in others registration can only follow after a certain period of working in practice, sometimes with a prescribed programme. An extensive survey under young Dutch Architects that took part in a structured practice programme and others that just started in the working at the ordinary way, made clear that some years of experience adds considerably to the competences.

Keywords: Architects, title protection, profession, education

1. Introduction

In most countries not everyone that designs buildings is allowed to call himself an Architect. The title is then legally protected. The requirements for registration vary among countries. Sometimes candidates can register with their diploma of the appointed academic courses. In other countries an additional post-academic period is needed in which the candidate architects gain experience in the architects practice and may have to follow some additional courses. The purpose of this regulation is to give some basic quality assurance to consumers and also some basic contribution to quality of the built environment in general. In addition, it also enables architects to work more easily in other EU countries. Since 1985, EU Directive EEC 85/384, also known as the European Architects Directive [1] has regulated the legal position of architects in the European Union. The directive’s greatest asset is its provision for the mutual recognition of qualifications in architecture in EU Member States. The purpose of this provision is twofold: to safeguard the freedom of movement of architects within the EU, and to guarantee that architects from the different member states have the same basic skills and competences.

Since the requirements for registration varies in the countries, it is useful to examine the value of the post-academic requirements. What is the contribution to the competences and skills of the young architects of some years of practical experience and how should this be structured? These questions arose in discussions about the functioning of the Dutch law to protect the title of Architects. The responsible secretary of state had the intention to abolish his responsibility for the quality of the professions of Architects. He initiated an evaluation [2]. The conclusions were very clear: most of the people in the field were positive about the use of the legal protection, but they also found that the quality requirements of the protected title should be expanded with practical experience and 'life time learning', a professional code of conduct and indemnity insurance. Since then a study was undertaken to get an overview of the regulations in fifteen EU countries. This was followed by a series of discussions by a group of some 15 Dutch top architects to define the required qualifications of young architects to be ready to work as a professional. In 2003 an experimental structure for professional experience of young architects was set up by the State architect. About 40 young architects followed a programme that consisted of working in practise, the mentorship of an experienced architect and a series of workshops. After The Experiment was finished it was evaluated [3]. The opinion of the participants of The Experiment and mentors were compared to those of young architects working in ordinary architects' practice without any specific programme. This paper is build upon the results of the above mentioned studies. The purpose is to present some striking evidence of the use of a structured period of professional practice or internship that is of great value for young architects.

2. Professional requirements for architects in member states of the European Union

Although the European Architects Directive provides a common basis for the mutual recognition of diplomas and certificates from certain educational institutions, we encountered wide variations in the requirements regulating the (quality of the) architectural profession in different Member States. (See, for example, Orbasli and Worthington 1995 [4]; Dankelman; 1999 [5]; and Priemus et al 2001 [2]). This section focuses on the how the current European Architects Directive is implemented in the Member States? A comparative overview is given of the similarities and differences between the 15 Member States in this study. More than 350,000 architects are now active in the 15 member states, but their legal position varies greatly. We summarise the situation within 15 (old) member states of the European Union in table 1. Table 2 contains more elaborate information about legal requirtements. The EU member states can be divided in five groups with regard to the legal position of architects (see table 1), varying from a wide ranging regulatory system (group A) to no legal regulations.

Group A. Belgium, Germany, Luxembourg, and Portugal

In this first group not only the title is protected, but also the profession of architects. This means that the submission of building plans to the local authorities for obtaining a building permit is restricted to architects. To become a registered architect in Belgium it requires five years of study and an additional two years of internship. The National Order of Architects issues the licence to practice, manages the architectural register, determines the duties and rights of architects, and is responsible for (the formulation and execution of) disciplinary rules. The obligation for professional insurance is laid down by (public) law. In Germany architects are registered by the State Chambers of Architects. Architectural education can be obtained at universities or academies. After completing the educational requirement, a minimum internship period of two years is required before registering as an architect. Once registered the architect is subject to the professional and disciplinary rules of the chamber. In Luxembourg architects (and civil engineers) must register with the Order of Architecture and Consulting Engineers. To become registered, the aspiring architect must have a degree as defined in the EU Architects Directive plus one year of practical training. In Portugal the requirement to become a member of the Portuguese Association of Architects is a degree from a university of architecture as well as an additional period of two years practical training. Once registered a member has the right to practice architecture and to use the title of architect.

Table 1: Characteristics of the legal position of architects within the EU

	Finland				

Group B. Spain, France, and Italy

In Spain a person is authorised to practise architecture by registering at a College of Architects. In order to register, a candidate must have a university diploma. Only registered architects may authorise and sign blueprints. Internship is not required to register. Architects in France must be registered at one of the regional Councils of Architects. After completing a course of study, no internship is needed to register. For buildings with a floor area that exceeds a certain number of square meters architects are required. In Italy architects register at one of the provincial rolls of architects. After completing a course of study, the candidate must pass a government qualifying exam, which is usually taken at least half a year after obtaining the degree.

Table 2: Overview of the main characteristics of the legal position of building architects in the fifteen EU member states in 2004

	Number of architects (approx.)	Number of architects per 1 million inhabitants	Educational institutions total	universities	academies	Minimum years of study	Protection of title	Protection of profession	Obligatory registration	Internship required (months)	Disciplinary code	Insurance required

+ yes; - no

Group C. Austria and the United Kingdom

In Austria registration at the federal Camber of Architects and Consulting Engineers is obligatory, and a minimum three-year internship is required (following five years of professional education). Furthermore, the regulations of the disciplinary code and professional insurance are mandatory. In the UK it takes five years of academic study and two additional years of practical work to become registered at the Architects Registration Board (ARB) [6]. The registered architects must comply with ARB standards of conduct and practice. This means that they must carry adequate professional indemnity insurance and that they must maintain their professional competence.

Group D. Greece and the Netherlands

In Greece the law requires architects to be licensed. Graduates of a five-year course of study from one of the two recognised universities of architecture are eligible for registration at the Technical Chamber of Greece (TEE). In the Netherlands architects register at the Architects Registration Bureau. Architects are eligible for registration if they have a degree from one of the two recognised five-year universities of technology or one of the six four-year, part-time academies of architecture. These academies admit students only after four years of vocational training. There are no legal requirements for practical experience or vocational training yet. This is going to change soon. The Architects Title Law will be renewed and will contain also requirements for 2 years internship, permanent education etc…..

Group E. Ireland, Denmark, Sweden, and Finland

In Ireland the Royal Institute of the Architects of Ireland (RIAI) is the representative body for professionally qualified architects. A member of the RIAI must have a degree from a recognised university, two years of approved practical experience, and pass an examination in professional practice. It is also possible to become an associate member or an architectural technician member. Some 80 per cent of the qualified architects are members of the RIAI. Irish architects are liable for the projects they carry out, but professional insurance is not obligatory. The Federation of Danish Architects is a private non-profit organisation of architects with qualifications that conform to the European Directive. Minimum length of study is five years. Student members are also admitted. The federation represents about 80 per cent of the Danish architects. In Sweden the National Association of Swedish Architects (the SAR) is responsible for the quality of architects. To become a member, the candidate must have a diploma from one of the recognised architectural training centres (at least four and a half years) and one year of additional experience as an apprentice architect. Approximately 80 per cent of Swedish architects are members of the SAR. In Finland a degree in architecture (representing five years of study) from one of the three recognised universities is required to be permitted to use the title of architect. No professional experience is needed. Almost all of the building architects are members of the Finish Association of Architects.

One of the goals of the European Architects Directive was to improve mobility for architects in the EU member states. Reliable figures on this are lacking, but the Dutch Architects Registration Board (SBA) believes there is a great deal of ‘free exchange of architects’. The Dutch experiences show that this process does not always run smoothly, however. Every year the SBA has to assist Dutch registered architects obtain their legitimate rights to practice elsewhere in Europe. And the Registration Board (SBA) believes these are not isolated incidents. The Architects Directive is interpreted very differently in different European countries. Although this variable interpretation has gradually improved, there are still some difficulties. An example can illustrate this point. Some years ago relatively many Austrian architects enrolled in the Dutch register. Austrian Law requires three years of practical experience before an Austrian architect can register. The market for architects is tight in Austria, so it is difficult to gain practical experience. Thus, Austrian architects are able to practice their profession in the Netherlands but not in their home country.

3. Experiment with structured internship in the Netherlands

In 2005, a two-year experiment came to an end in the Netherlands in which young architecture graduates were given the chance to gain experience in a structured way in every field of architectural professional practice. It was known as The Experiment and was organised by the Atelier of the State Architect. The initiative was the result of the evaluation of the Architects' Title Act. In a series of discussion meetings involving a group of leading Dutch architects in 2001-2002, besides the earlier intentions of giving more meaning to the title of Architects also consideration was given to what was needed to strengthen the role of the architect in the construction process. This led to the plan to offer young architects a programme of experience on a structural basis for two years, under the guidance of a personal mentor and a series of study meetings. The Experiment was evaluated [3]. This involved questioning the young architects and mentors taking part, as well as a large comparable group of young architects who entered regular practice without following any specific programme. It is precisely that comparison between participants and non-participants which has provided an insight into whether a period of structured practical experience offers added value. This section presents the evidence found in the Dutch Experiment for the added value of various elements of eduction and gaining experience. This can be compared to the results of other international studies. See e.g. Glasser, D. E. 2000 [7], Jones, C.B. 2006 [8], Nicol, D. and Pilling S. 2000 [9], and Quinn, B.A. 2003 [10].

In The Experiment, around forty recent architecture graduates were given the opportunity of acquiring experience at architectural firms where they would be supported by a mentor. For the practical side, a list of aspects of the profession of architects was drawn up, ranging from the initiatory phase all the way to the implementation phase of the construction process, with the intention being that the participants gained sound experience throughout. At the same time, several tools were deployed to lend the process structure and to monitor it. They included Personal Six-Month Plans, which laid down agreements between the young architects and their mentors about the activities to be undertaken in the six-month period. The architects kept a logbook of their progress, their findings and the results of their work. Visits were also made by the organisers of The Experiment to the place of work of the participants to discuss their programme. In addition to this practical part, The Experiment consisted of a joint programme. This took the form of a series of meetings with an educational character, during some of which the participants held project presentations on the designs they had been involved in. The other meetings were of an informative nature, and here the focus was on matters such as rules and regulations, local authority procedures, contract negotiations, and procedures for selecting construction companies. The research consisted of questionnaires completed by the young architects and mentors, and a comparative group of recently graduated architects who have worked in regular practice, but not specifically in a structured way. Around 80% of the young architects responded to the questionnaire, while the figure for the mentors was 65%. We looked at the added value of the structure of The Experiment by polling the comparative group. For this purpose, we sent a questionnaire to every architect who graduated between January 2001 and December 2003, and who is registered in the Architects Register (about 500). There was a remarkable large response, with some 200 completed forms being returned. It showed that these young architects that were not in anyway involved in the project, were very driven to answer this long questionnaire. The questionnaires revealed a great deal of information as to what degree architects working over a period of time acquired practical work experience in the various aspects of the profession of architects and to what degree they considered themselves able to perform in those aspects independently.

In general, the mentors and young architects were highly satisfied with the content and organisation of The Experiment and joint programme of study meetings. The relevance and the quality of all aspects were judged positively, while the score given by the architects to the importance of the meetings fluctuated from important to very important, around the eighty to ninety per cent mark. Of the architects in the comparative group, about sixty five per cent said they would have been interested in informative meetings after their studies that dealt with the subjects covered by The Experiment. The quality of the introductions to the joint meetings was, according to the young architects, very good, and although the quality of the accompanying documentation met with approval, this was to a lesser degree on average. They were less satisfied by the time given to the subjects being covered. The quality of the assignments, the expertise and availability of the mentor at the office was judged positively. Three quarters of the architects, and nearly seventy per cent of the mentors, thought that the number of projects they were involved in during The Experiment was sufficient to enable them to gain experience in all aspects of the architectural profession. Remarkably, the score of the comparative group was higher, with almost ninety per cent of them saying that they had worked on enough projects to gain experience with every aspect of the job. The difference is probably due to varying levels of expectation. The use of the Personal Six-month Plan, the logbook and the appraisal interviews were generally considered positive by architects and mentors alike. Finally, more than ninety per cent of the participating architects and mentors described the quality of the overall programme of The Experiment as good to very good.

Table 3 shows that the meetings on Construction methods versus budget, Local authority procedures, Construction process and Contract negotiations were considered as most important by the architects, while the meetings on Research at architectural agencies, the Programme of Requirements and the Mentor meetings were thought in relative terms to be the least important. The mentors were most enthusiastic about the Start meetings, the Project presentations and Building Decree (building regulations), describing them as important to very important. They were not as keen on Research at architectural agencies or the Programme of requirements. About sixty to seventy per cent of the architects in the comparative group indicated that they would have been interested in information meetings after completing their studies, in particular where Contract negotiations, Office and design management and Construction methods versus budget were covered, all of which scored well.

Table 3: The average scores for study meetings

	Participants	Mentors	Comparative group
Start meetings	4.1	4.5	-
Workshop project presentation	4.0	4.5	-
Building Decree (building regulations)	4.3	4.2	3.1
Office and design management	4.0	4.2	4.0
Social position of architects	4.0	4.2	1.7
Research at architectural agencies	3.7	3.6	3.0
Selection procedures	4.0	3.9	1.9
Contract negotiations	4.3	4.2	4.6
Partnership relationships	4.1	3.7	3.0
Giving direction in the construction process	3.9	4.0	2.9
The programme of requirements	3.9	3.6	2.7
Construction methods versus budget	4.4	4.2	3.8
Local authority procedures	4.4	3.9	3.4
The construction process	4.4	4.1	2.6
Positioning of the agency and publicity	4.1	3.7	3.2
Mentor meetings	3.8	3.7	1.7
Average	4.1	4.0	2.9

(average scores on a scale of 1-5: 5 = very important, 4 = important, 3 = neutral, 2 = not very important, 1 = not important at all)

The research produced a great deal of information about whether experience was gained with the different areas of architectural practice and to what degree the respondents felt they had a sufficient grasp of those areas in order to be able to carry them out independently. This was all highlighted by the questions of whether they could work as an independent architect and were experienced enough to run an agency of their own. We have pooled a lot of the information that emerged from these questions and worked out average scores in order to gain insights at a higher abstract level. This has led to the following observations: for the participants in The Experiment and the architects in the comparative group, the period of practical experience has made a significant contribution to their being sufficiently competent in the different areas of architectural practice. Before working in practice, there was already a reasonable grasp of the areas in the design phase, while this was much less the case in the assignment, construction preparation and construction process phases. The period of acquiring experience was useful for each phase in approximately equal measure. The result was that, after participating in The Experiment or gaining practical experience elsewhere, most respondents mastered the different areas of the design phase to the extent that they can carry them out independently. This does not apply to the other three phases. Based on the information received, it has not been shown that organising practical experience in the form of The Experiment gives added value when compared with experience gained in a conventional practical environment. Indeed, in some areas the comparative group scored better than those taking part in The Experiment. The question remains, though, to what degree the group of participants is comparable to those in the comparative group. However, there is no indication among the various characteristics of either group to suggest that one is ‘qualitatively’ superior to the other. The self-perception of both groups as to their own level of experience before working in practice was also very similar.

The mentors and architects taking part in The Experiment, as well as the architects in the comparative group, attached great value to a structured approach in gaining experience, with the former being very convinced of the added value it offered. The comparative group, too, believed that being involved in a structured programme may have provided greater opportunities for gaining experience than being in regular practice, although they were in fact satisfied with their own period of practical experience. Regarding the question of whether the respondents had gained enough experience to begin their own company, the comparative group scored noticeably higher than the participants. A possible explanation for this could be that the group of participants, by being involved in The Experiment and therefore focusing more attention than otherwise would have been the case on all the different fields of the architectural profession and analysing whether they had a sufficient grasp of them, had a more critical view of themselves than the average young architect.

The experience acquired by the young architects in The Experiment in the different areas of architectural practice, and the degree to which they, and the members of the comparative group, now have a good mastery of those areas, were measured extensively (see table 4). This covers the opinions of the young architects themselves and is therefore not necessarily an accurate reflection of the actual abilities of the respondents.

For both groups the period spent in practice made a very large contribution to gaining a good grasp of the different areas of the profession. Before starting work in practice, there was already a reasonable mastery of the various aspects of the *design phase*, while for the *assignment*, *construction preparation* and *construction process* phases there was only a very limited level of competency. The experience gained during the relevant period was spread fairly evenly over all the phases. The result was that most respondents, either after taking part in The Experiment or acquiring experience in practice, have a sufficient grasp of the aspects of the design phase to be able to perform them independently. This did not apply to the other three phases. From the research it appeared that those in the comparative group built up a similar level of experience of architectural practice to the participants in The Experiment. In some areas, the comparative group actually scored more than those in The Experiment. The question remains, though, to what degree the group of participants is comparable to those in the comparative group. There is however, as has already been stated, no indication among the characteristics of either group to suggest that one is ‘qualitatively’ superior to the other. The self-perception of both groups as to their own level of experience before working in practice was also very similar. On the basis of this information it therefore cannot be demonstrated that organising practical experience in the form of The Experiment (the mentors and the Personal Six-Month Plans) lends any added value when compared to gaining experience in regular practice. The architects and mentors involved in The Experiment, as well as the architects in the comparative group, believed there is great

Table 4: Percentages of respondents that are able to carry out the aspects of the profession of architects independently before and after the period of practical experience

Delivery report	3	6	9	37	13	43	88	57
AVERAGE	14	16	48	54	62	70	38	30

P = participants in The Experiment; C= architects in the comparative group merit in gaining experience according to a structure. The former group were convinced of the added value it brings, while the latter thought that being part of a structural process could have given them more experience than being in regular practice. The members of the comparative group, however, were nonetheless satisfied about their own period in regular practice. With regard to the question about whether they now considered themselves to have enough experience to start their own agency, the comparative group scored markedly higher than the participants in The Experiment. A possible explanation for this could be that the group of participants, by being involved in The Experiment and therefore focusing more attention than otherwise would have been the case on all the different fields of the architectural profession and analysing whether they had a sufficient grasp of them, had a more critical view of themselves than the average young architect.

4. Conclusion

The answer to the question of whether there should be regulations that deal with the legal position of architects on a European level is ‘yes’. The work of architects affects the daily life of many Europeans, a fact that is appreciated by the European Council (Council of the EU, 2001). As we have seen, however, the current directive does not require a uniform standard of education and quality for architects. It has flaws with respect to ensuring the quality of architects as well as for the free movement of these professionals. These flaws will become far more important when the new directive on the internal market comes into effect. The aim is to require that an architect working in a country other than his own should comply with the regulations of his country of origin. But the current patchwork of national regulations will make this very difficult, not only for architects, but also for the (quality of) the built environment and for consumers. The recent expansion of the EU will undoubtedly contribute to a more complex (or even unworkable) situation. Therefore, it is important to regulate this professional group with a certain consistency across the continent. The current EU regulatory framework fails to realise this consistency. The directive should focus more on the essential demands on the quality of architects. The educational institutions and their respective degrees that are recognised in the EU member states should be reconsidered. Although the member states have various educational systems, in general the title of architect can be obtained in one of two ways: either through a university course of study or attending a school of (higher) vocational education. University education contains only a relatively small component of practical experience, while schools of vocational education place a relatively strong emphasis on practical components. The directive should acknowledge this situation (as it now does), but should also look at the details of the curriculum in the various educational institutions. It is highly unlikely that a vocational education alone (four years following secondary education) can provide all the training required to develop highly skilled architects. The same is true of a five-year university education that includes only limited practical experience. The directive should sketch more clearly the paths that can lead to the title of architect. On average it will take seven to eight years to become a skilled architect. Not only the educational demands but also the demands on practical experience should be established in the Architects Directive. Only architects who fulfil these educational and practical; experience qualifications are accepted in the architects register. In order to protect the consumer and the quality of the built environment the directive should ensure also that the knowledge, skills, and experience of a registered architect maintain a certain standard. To guarantee these qualities additional requirements can be made in the directive concerning continued education, a professional code of conduct and indemnity insurance. The member states should recognise this new and updated directive and include it in their legal system. States may set additional requirements, but these requirements must not go counter to the directive's ‘spirit’ or substance. Only registered architects should be permitted to use the title and freely practice architecture in all member states.

An American perspective of the suitability of the SOCL's Protocols provisions for dealing with concurrency on Australian construction projects

Peter Ward,
School of Architecture and Built Environment
University of Newcastle
Australia
(email: P.Ward@newcastle.edu.au)

Abstract

Concurrent delays on construction projects have been described as being the most conceptionally challenging aspect of delay analysis. Few of the standard forms of contract commonly used give guidance as to how the issue of concurrency should be addressed, or analysed. Two organisations (the UK's Society of Construction Law and the USA's Association for the Advancement of Cost Engineering International) have produced guidance documents in the form of a Protocol and a Recommended Practice respectively, aimed at addressing the issues associated with delay and disruption on construction projects that contains an approach for dealing with concurrency. The aim of this pilot research, which was supported by the Chartered Institute of Building Australasia, was to carry out semi-structured qualitative interviews with those involved in the production of the USA's recommended practice to obtain their opinion of the adequacy of the clauses of the standard forms of contract for dealing with concurrency, and the suitability of the Protocol's proposed method for dealing with concurrency, for adoption and use on Australian construction projects. Results indicated that the overall approach of the protocol was considered to be correct, but its content needed to be expanded to address some of the issues in more detail, suggesting that an agreed overall standard approach would be beneficial for the industry.

Keywords: Claims, concurrency, delay, extension of time, protocol, recommended practice.

1. Introduction

Concurrency is a major issue should delays occur on construction projects. It has implications concerning the awarding of liquidated damages (LD's) and the granting of extensions of time (EOT).

When a single event occurs on a construction project that results in delay and/or disruption to the project completion date, one party is normally entitled to compensation typically in the form of an extension of time (EOT), and/or a claim for loss and/or expense due to prolongation, or entitlement to liquidated and ascertained damages (LAD). Entitlement is normally dependant upon establishing who was responsible for the delaying event, determining how the risks have been allocated by the provisions of the contract, and determining an amount of compensation in the form of time (EOT) or money (loss and/or expense/LAD) as appropriate compensation.

Typically, if the contractor is responsible for the event, and they have agreed to accept the contractual risk, and provided the contract stipulates, the contractor would incur liquidated damages in accordance with the contractual provisions as a result of any delay to the project completion date (known as an inexcusable [1] or non excusable delay [2]).

If the client or owner is responsible for the delaying event, and it is one in which they have agreed to accept the contractual risk, and provided the contract stipulates, the contractor would be entitled to an EOT in accordance with the contractual provisions for a period equivalent to the delay to the project (excusable delay [1]). They may also be entitled to a claim for any loss and/or expense incurred as a result of the prolongation of the project caused by the delaying event (compensable delay [1]).

Where the delaying event is the responsibility of neither party (a neutral event), and one where they have both agreed to share the contractual risk allocation, and provided the contract stipulates, the contractor would normally be entitled to an EOT equivalent to any period of delay to the project, but not a claim for any loss and/or expense (excusable delay [1], [2]).

Individual occurrences of such events are normally dealt with in this way.

1.1 The concurrent position

Difficulties arise where two or more events occur at exactly the same time or sequentially, that have the effect of delaying and/or disrupting the project completion date. This is known as concurrent delay, and has been defined as "*two or more delays that occur at the same time, either of which had it occurred alone, would have affected the project completion date*" [3], and has been described as "*probably the most conceptually challenging aspect of delay analysis*" [4].

True concurrency, where events occur at exactly the same point in time is considered to be rare [5], but the concurrent delaying and/or disrupting effects resulting from events occurring in sequence, or overlapping is common and cause many disputes. The difficulty is in apportioning responsibility for the combined effects of the events on the construction project in terms of time and money, in accordance with contractual provisions that rarely recognise or address the issue of concurrency sufficiently and adequately. Things are further complicated due to the fact that each of the concurrent events could have a different degree of consequence on the project, making it difficult to quantify and apportion damages (in terms of time and/or money), again with little guidance from the terms of the contract as to the most appropriate method of analysis. The range of techniques that are available for use in quantifying the effects of concurrency adds to the problem. Taken individually, each event could result in a different amount of delay and/or disruption to the project. When combined, the difficulty is in determining what proportion of delay and/or cost should be allocated to each event?

2. Protocols and recommended practices

In an attempt to rectify the lack of clarity that exists in standard forms of contracts for dealing with such issues, two organisations (the UK's Society of Construction Law (SOCL) and the USA's Association for the Advancement of Cost Engineering International (AACE)) have produced guidance documents in the form of a Protocol and a Recommended Practice.

2.1 Delay and disruption protocol

In October 2002, the UK's Society of Construction Law (SOCL) published a Delay and Disruption Protocol (the protocol) aimed at addressing the issues associated with delay and disruption on UK construction projects in the context of the UK's legal system and standard forms of construction contracts. Concurrency was one of the issues that the protocol attempted to clarify and provide guidance.

The protocol is not put forward as a benchmark of current good practice, but as a general statement and guide whose recommendations are to be applied with common sense. The protocols objective is to "*provide useful guidance on … the common issues that arise in construction contracts*" [6], whilst its purpose "*is to provide a means by which the parties can resolve these matters and avoid unnecessary disputes*" [6]. The protocol is not intended to be a contract document, and its contents are not meant to take precedence over the express terms of a contract, nor is it intended to be a statement of law. It is a proposed "*scheme for dealing with delay and disruption issues*" [6] in a balanced and viable way that is available for:

"Adoption by the parties to a construction contract, in order to provide the means to avoid extension of time disputes;

An aid to deciding issues that are not clearly covered by an existing contract;

An aid to decision makers … in dealing with delay issues" [7].

Implementation of the protocol is intended to be by agreement between the parties by whatever administrative procedures they consider suitable and acceptable. Where the parties have agreed to use the protocol as an aid to the management of the contract, the protocol is to prevail over any conflicting case law, but where the protocol is in conflict with any of the terms of the contract, the contractual terms are to take precedence.

The protocol [6] defines true concurrent delay as "*the occurrence of two or more delay events at the same time, one an employer risk event, the other a contractor risk event and the effects of which are felt at the same time*", and suggests that the term 'concurrent delay' is often used to describe the concurrent effect of sequential delay "*where two or more delay events arise at different times, but the effects of them are felt (in whole or in part) at the same time*".

Contained within the provisions of the protocol is an approach for dealing with concurrent delays as a means of minimising their affects on construction projects.

The distinction of the protocols approach with other approaches is:

the requirement for pre-agreement between the contracting parties;

i. that any contractor delay to completion that occurs concurrently with employer delay should not reduce any extension of time due.

2.2 Forensic scheduling analysis recommended practice

In July 2007, the USA's Association for the Advancement of Cost Engineering International (AACE) launched their Recommended Practice No. 29R-03: Forensic Schedule Analysis (FSA) in an attempt to "*provide a unifying technical reference for the forensic application of critical path method (CPM) of scheduling*" [8].

The AACE International is an industry independent organisation and is considered to be the leading professional society for cost estimators, cost engineers, schedulers, project managers, and project control specialists in the USA. It has been in existence since 1956 and has more than 5,500 members in 78 countries worldwide. It is considered to be the largest organisation serving the entire spectrum of cost management professionals.

Forensic scheduling analysis is "*the study and investigation of events using CPM or other recognized schedule calculation methods for use in legal proceedings*" [8] and is described as both "*a science and art*" relying upon professional judgement and expert opinion.

The RP is a taxonomy of schedule analysis methodologies. By defining terminology, identifying, and classifying methodologies being used, and then describing uniform procedures the AACE hope to increase transparency of the analysis methods and the analysts thought processes as a means of increasing the accountability and testability of the analysts opinion with the intention of minimising disagreements over the technical implementation of accepted techniques as a means of resolving disputes over substantive or legal issues.

3. Aim

The aim of this research was to obtain the opinions of members of the AACE's consultation panel who were involved in the development and production of the FSA concerning the provisions of standard forms of contracts and the suitability of the protocol's provisions for dealing with concurrent events on construction projects as a means of assessing the protocols suitability for adoption and use by the Australian construction industry.

3.1 Methodology

The research was conducted in accordance with the Commonwealth of Australia's National Statement on Ethical Conduct in Human Research [9], following procedures approved by the University of Newcastle's Research Ethics Committee.

Semi-structured qualitative interviews with members of the AACE's Recommended Practice consultation panel involved in the development of the FSA were carried out to obtain their opinions of the suitability of the protocols provisions for dealing with concurrent events on Australian construction projects, and their suitability for adoption and use by the Australian construction industry.

Details of those who were interviewed are contained in Table 1.

4. Common approaches to concurrency

Two issues prevail when trying to resolve concurrent delays:

(i) Who has caused the 'overall' delay?

(ii) How much delay is attributable to each of the delaying events?

One of the problems of determining responsibility for concurrent delays is that there is no singularly agreed or accepted approach for determining causation [10]. A number of approaches have been recognised and utilised by practitioners and authors in an attempt to apportion and quantify responsibility for the effects of concurrent events on projects, with varying degrees of support from the courts and industry, however, pre-agreement as to the most suitable or "best" approach to use is rare.

4.1 The protocols approach

McCredie [7], investigating how the protocol was likely to be received by the UK construction industry identified concurrency as being one of the main issues associated with delay and disruption. The protocols approach is for the contracting parties to pre-agree:

In terms of concurrent delay, that "*where contractor delay to completion occurs concurrently with employer delay to completion, the contractor's concurrent delay should not reduce any extension of time due*" [6].

Table 1: Background details of interview participants

Participant	Background
USA01	A director and co-founder of a specialist American construction and asset cost consulting Quantity Surveying Practice with expertise in commercial construction, procurement, and dispute resolution.
USA02	A lawyer, architect and schedule (programme) consultant specializing in forensic schedule analysis.
USA03	A forensic claims consultant and expert witness with some 35 years of experience in construction claims specializing in schedule delay and soft cost damage issues throughout North America, Egypt, China, Kazakhstan, and Trinidad & Tobago.
USA04	A project controls engineer with over ten years of experience of developing and monitoring schedules and provided expert forensic schedule analysis and testimony for contractors and owners in the highway, power, and commercial construction industries.
USA05	A world-renowned scheduling expert, author of a best-selling professional text on construction scheduling, and founder of an international company providing scheduling products and services to the global construction community.
USA06	A lawyer and claims consultant with over 30 years experience of resolving national and international construction claims disputes.
USA07	A certified planning engineer with over 15 years of experience of developing, monitoring, and resolving construction disputes on international projects.
USA08	The principal of a construction management consulting firm who is a certified planning, scheduling, and cost consultant involved in the resolution of construction disputes, with over 25 years of experience and involvement in the commencement, execution, and completion of commercial, public, and government projects.

4.2 The recommended practice approach

The RP describes the process of identifying and quantifying concurrency as "*the most contentious technical subject in forensic schedule analysis*" [8] and recommends that both parties agree on the theory employed. Where no agreement is reached the RP recommends that the analyst should become aware of the theory adopted by the adversary.

One of the major factors identified by the RP as having a significant impact on the determination of concurrency is contractual definition. The general rules, exceptions and considerations of the RP are applicable to the extent that they do not directly contradict contractual definitions and specifications.

In addition to the contractual variable, the RP lists a further five factors that influence the identification and quantification of concurrency:

Whether concurrency is determined literally or functionally;

Whether concurrency is determined on the cause or the effect of delay;

The frequency, duration and placement of the analysis interval;

The order of delay insertion or extraction in a stepped implementation;

Whether the analysis is done using full hindsight or based on knowledge-at-the-time.

The use of CPM concepts for the reliable identification and quantification of concurrency is stated within the RP as being universally accepted, and as such the RP's approach is heavily influenced by the various CPM techniques available.

The RP also introduces the concept of 'pacing' delay.

4.2.1 Literal concurrency vs. functional concurrency

The distinction between literal concurrency and functional concurrency is that literal concurrency is considered to be where events "happen at exactly the same point in time", whilst functional concurrency is where events (that may occur on different network paths) concurrently impact on the project.

Literal concurrency is considered to be a function of the planning unit used and is recognised by the RP as being unachievable since time is infinitely divisible.

Functional theory is considered to be more liberal in identifying and quantifying concurrency and more attuned to the workings of the critical path.

4.2.2 Cause of delay vs. effect of delay

This issue is described within the RP [8] as a "*philosophical dichotomy that complicates the evaluation of concurrency*" and is the difference between the proximate cause (as opposed to an ultimate or root cause) of the delay and the effect of the delay based on the observation that there is no delay until the planned duration has been exhausted.

4.2.3 Frequency, duration and placement of analysis intervals

The frequency, duration and placement of the analysis intervals are considered to be one of the "*most significant technical factors that influence the determination of concurrency*" [8].

4.2.4 Order of insertion or extraction in stepped implementation

The RP [8] states that "*the order of the insertion or extraction of the delay will affect the identity of potentially concurrent delays and the quantification of such concurrency*" and that if the chronological order of events are ignored, the resulting analysis "may not yield the data necessary for reliable determination of concurrent delays".

4.2.5 Hindsight vs. 'Blind-sight'

The RP identifies two schools of thought for recreating a partially statused schedule.

The hindsight method concerns the performance of the analysis after the project has been completed and involves the use of actual performance data to recreate the updates.

The 'blind-sight' method involves the analyst performing a retrospective analysis using only the data and information that was available to the original scheduler at the time the project update was actually being prepared, and thus requires the analyst to 'simulate' the schedulers mindset at the time of the original project update.

The difference in approach will affect the identification and quantification of concurrent delays due to the updating of the CPM schedule being partly dependent upon the value of remaining duration of activities at the data date.

4.2.6 Pacing delay

Pacing delay is described by the RP [8] as a delay in an independent activity that is the result of a "*conscious and contemporaneous decision to pace progress*" against a subject delay and is considered to be a "*real-life manifestation of the principle that work durations expand to fill the time available to perform them*". The distinction between a pacing delay and a concurrent delay is that a pacing delay is the result of a conscious decision by a performing party to pace the work, whilst a concurrent delay is a delay that is involuntarily delayed by factors independent of any problems arising from the subject delay.

5. Results

The responses obtained from the members of the AACE International's consultation panel who were involved in the collaboration and production of the RP are considered to be representative of those who were interviewed and are not put forward as being representative of the AACE International as an organisation.

Clarifying statements contained in the questionnaire, the questions, and relevant edited and responses from the participants are included below:

Statement 1: The AACE recommended practice states that contractual definition is one major factor having significant impact on the determination of concurrency.

Question 1: What is your opinion of how the clauses of the standard forms of contract deal with this issue?

Generally the respondents were in overall agreement that the clauses of the standard forms of contracts that they were familiar with did not adequately address the issue of concurrency.

Participant USA01 was critical of how the clauses of standard forms of contracts dealt with determining concurrency stating "y*ou're lucky if you even see a definition of it ... I don't think most contracts are that sophisticated, even with big consumers of construction … they are still back in the Stone Ages on some of these specifications*". This was reinforced by Participant USA02 who stated that "*they deal with it terribly and they primarily don't address what is actually a concurrent delay*".

Participant USA03 expressed an opinion that the lack of contractual definition was the cause of a number of issues, not just those concerned with concurrency, stating that "*most contracts in the United States are silent on the issue of ownership of float, and most are silent on the issue of concurrent delay, all are silent on the issue of pacing delay, and many of them are silent on the issue of what we call an impact as a result of the delay, not necessarily a delay to the critical path*" and that "*standard form contracts would … be great if they start dealing with the issues*" and this "*would go a long way to solving our problems*".

Participant USA04 stated that the contracts "*don't treat it, … giving cursory treatment if any treatment at all*", but admitted that it was "*a tough issue to treat in a contract*", and suggested that "*a reference to the SCL protocol would be a fair way to treat it or a reference to another standard document*", and that "*If we could develop more of a standard in terms of how these things are treated*". It was suggested it "*would be better for everybody, … and if you want to put something in your contract I would say you reference that standard … What would be nice is to see the owners acknowledge the standard and even go so far to reference it and say we are fully aware of the standard and that's what we're going to apply*".

Participant USA06 was of the opinion that generally "*the contracts are written terribly, the specifications are even worse*" and that "*we're starting to see more and more specifications which get incorporated by reference where the issue of float is addressed … you don't see concurrency mentioned very often at all. I've never seen pacing delay mentioned in a spec*".

Participant USA07 considered this to be "*one of the big issues*" but was reticent about how contractual clauses could address the issue stating that "*if I really want to get out of the claim and protect myself, I can play with it and find my loophole to get around it … I don't think there's anything where everybody is ever going to be able to fix it*".

Participant USA08 was also critical of the way standard forms of contract deal with the issue stating that "*generally what I've seen in various contract documents has been somewhat vague, and if anything they have been skewed or imbalanced a little bit towards the owner or employer, so I don't think they really explain fully the rights and responsibilities of both parties*".

Statement 2: Concurrency concerns the effects of an employer delay and a contractor delay occurring at the same time or sequentially causing concurrent delay. With regard to extensions of time, the protocol recommends that: "*Where contractor delay to completion occurs concurrently with employer delay to completion, the contractor's concurrent delay should not reduce any extension of time due*" (Society of Construction Law, 2002).

Question 2: The participants were asked to state their opinions of how the protocol deals with the issue of concurrency.

Overall there was a general appreciation of how the protocol approached the issue of concurrency, however, most of the participants were of the opinion that the protocol could have dealt with concurrency (and other issues) in more detail.

Participant USA01 was in general agreement that concurrency was one of "*the biggest issues*" and considered it to be "*another one of those issues right along with float we have to go in and look at the different philosophies regarding concurrency*", and was mildly critical of the way the protocol dealt with it in that it "*didn't deal with it enough*", but acknowledged that the protocol brought "*awareness of the concurrency issue to those who really haven't encountered it before*".

Participant USA02 agreed with the protocols description of concurrency "*as far as it goes*". Concern was raised at the apparent lack of how the protocol dealt with actually determining concurrency, and that this was considered to be "*a greater issue … that's where the fight is: not what is the meaning of concurrency but what is in fact concurrent*".

Participant USA03 was more cautious about the way the protocol addresses the issue of concurrency stating that "*concurrent delay is not a protocol issue in the United State's*", it was "*a legal issue*" with "*a whole series of court cases on what you do with things like concurrent delay where one is excusable and another one is compensable*", and that despite the production of documents like the protocol, in the USA at least, "*the courts will pretty well continue doing what they want … I don't think any society rule will change their mind*".

Participant USA04 was "*in agreement*" with the protocols approach in that "*if there's true concurrent delay then the contractor should be entitled to an extension of time. It's a one-for-one for the period of concurrency, it shouldn't be reduced*", *whilst* Participant USA05 considered the protocols approach to be very "*basic*" but "*in principle … very close to right*".

Participant USA06 stated that the issue of concurrency was a "*combination of factual and legal*" and that the courts in the USA were "*very protective of their ability to determine issues of law,* *and the resolution of concurrency and whether or not there is entitlement turns, as much, frequently on the legal issue as it does on the factual*".

6. Conclusions

Concurrency is considered to be one of the major issues involved in delay and disruption disputes, but was not seen solely as a protocol issue, but a legal issue governed by caselaw and precedent.

The courts in the USA are unlikely to be influenced by documents such as the Protocol and its approach and recommendations concerning concurrency (and other issues) and will continue to develop and follow legal precedent on a case by case basis.

The current clauses of the standard forms of contract rarely address the issue of concurrency adequately.

The protocols approach was considered to be fundamentally correct, and that it has raised the profile of concurrency as an issue in relation to delay and disruption claims, but its content needs to be expanded to address concurrency (and other issues), and include a suitable means of determining concurrency rather than simply defining what it is.

The development of a recognised industry standard approach to concurrency (and other issues) in relation to delay and disruption claims acknowledged and recognised by owners and contractors would be beneficial for the industry.

ENVIRONMENTAL MANAGEMENT

Methodology to manage the sociological interplays of actors in sustainable urban projects

Abstract

We developed a methodological framework allowing us to model the actions carried out collectively and individually by the project group. This methodology takes its origin from the strategic analysis suggested by Crozier and Friedberg. It aims objectively to anticipate convergences or "interplays of co-operation" and divergences or "interplays of conflicts" between the main participants in urban development. The project group, as a sociological system, exists by the interdependence of participants and actions whose objectives can converge or diverge. Individual strategies are analysed to determine the collective actions necessary for success. The municipality can then organize the running of the project in accordance with the participants' inherent stopping points. Our approach places each player within the environmental management of an operation. The tool developed on this methodological basis makes it possible to display several sociograms representing direct influences between participants and the impact of each participant on the objectives of an operation.

Keywords: Environmental management, strategic analysis, sociology of organizations

1. General context of the study

Since the launch of the programme “Ecology and Habitat” by the “Construction and Architecture Plan” in 1993, operators in the field of construction have progressively mobilised to promote the environmental quality of buildings. Once the first completed projects finally saw the light of day and a very large number of operations were currently in the design or construction stage in France, the formalisation of a system of certification for these operations - HQE”® - based on a clarified normative framework was called for and has been a tangible reality since 2005.

However, although the operators in the field of construction wish to make a real response to the challenges laid down during the United Nations Conference on the Environment and Development held in Rio de Janeiro in 1992, the environmental management of HQE® operations is no longer in itself sufficient at the level of buildings alone, but must perceive itself in a wider global concept of the “ habitat” at urban level. Our “Habitat” may indeed play a decisive role in bringing out new forms of association making it possible, on a daily basis, to reconcile preservation of the environment with economic efficiency and social equity. Such are the challenges that the 21st century habitat should be meeting.

Taking into account the significant number of housing developments or Designated Development Zones classed as “sustainable” currently being set up or under construction, recent years have seen an increase in the expectations of planners and municipalities that a systematic framework should be put forward, based on assessment tools adapted to suit the context of each urban project.

Our work places us at the meeting point of these expectations regarding:

- the widening of the field of environmental quality in buildings at urban planning level,
- the promotion of the consideration of environmental or socio-economic themes in development projects,
- the setting up of operational tools for assessing sustainability to be used by players in the field of urban planning

The work presented within the framework of “BEAR 2008” forms part of the direct consequences of research developed from the project “ADEQUA “ and the expert reports commissioned by a number of municipalities.

2. Proposal for a system of management by participants

Many pieces of work have focused on the compilation of sets of indicators making it possible to assess the results obtained in quantitative or qualitative terms. Now, the initial feedback shows that obtaining these performance figures depends largely on the management of the operation. However, the methodological questions regarding urban management have hitherto rarely been approached. It therefore appears essential to consolidate a proposal for a system of management that is integrated, structured and organised so as to articulate the questions of sustainable development during the various stages of a development operation

Our initial investigations clearly highlight the importance of developing, within a context that is often contentious, tools making it possible to assist a municipality in its decisions or negotiations. The proposed methodology aims to place the participants at the heart of our approach before moving on to the technical performance levels that are to be achieved within the framework of this type of operation. We will draw our inspiration from the theory of the strategic player as well as the strategic forecast. The strategic analysis proposed by Crozier and Friedberg allows us in effect to model the actions led collectively and individually by the project group. The individual is here included as both the actual person and the body that he represents within the project team. Each action or system of concrete action calls upon a set of mutually interdependent participants. The system exists through the very interdependence of actions and participants, whose own objectives may converge or diverge. Our method of analysis aims objectively to anticipate the convergences or "interplays of cooperation" and the divergences or "interplays of conflicts" between the principal players in the urban development operation. This analysis therefore starts with each participant and their individual strategies, and then makes it possible to put together the collective actions necessary for the success of the operation. It must allow the municipality to organise the running of the project according to what are likely to be the participants' inherent stopping points.

By starting from the premise that each participant is a key element in the sociological organisation of the urban development operation, we recognise that the project team is made up of interdependent participants playing a role that is defined in contractual terms. The actions of each participant have a direct influence on those of the others, thus obliging everyone to adapt to new interactions. In this way, the action of some feeds the action of others, even if they have opposing interests. Divergence becomes complementary, which leads to some complexity and involves new, endlessly repeated adaptation. As stated by P. BERNOUX in the sociology of organisations, each player is a strategic being seeking to satisfy his own needs. He acts according to his own logic, rationality, and individual strategy. By creating his own room for manoeuvre, he adapts his own resources to meet the expected objectives depending on the operational environment in which he finds himself. It is because he is in a relationship with the other participants that he will conceive that he may have priorities (for example, between the short term, which concerns this project, and the long term regarding another project).

The method of analysing the set of participants that we propose to use is based on the MACTOR method developed at LIPSOR, (Laboratory for Investigation into Prospective

Strategy and Organisation. This mathematical tool, that can be found in companies' long-term planning, has the principal advantage of being highly operations-focused, even with a large number of participants, as is the case within the framework of a development operation. This tool makes it possible to display a number of sociograms, schematic representations of the relationships between the players, ie. disputes, alliances, dependences, etc. We should point out that the quality of the data provided through the goodwill of the participants has a strong influence on the results. For this reason, it seems to us essential to show a zone of uncertainty corresponding to the faults of the system and producing zero-quality results, whether this is due to the pressures and deadlocks involved in the project, to professional habits … or quite simply to the fact that a participant does not yet know how he will position himself. The use of this tool requires the collection and entry of the following data:

- description and list of participants
- description and list of objectives
- entry of data in matrices for Direct Influence of Participants (MID)
- entry of data in matrices for Participants' Objectives (MAO).

The application of the Mactor method makes it possible to obtain two types of information: the direct influences between players and the valency of each participant regarding the contractual objectives of the operation.

The results drawn from the matrices of entered data are represented in the form of a matrix of Direct and Indirect Influences (MIDI) summarising the interactions between the participants. This matrix is obtained by taking into account both the degree of direct and indirect influence of each player by counting the direct and indirect influences of the player, and the degree of direct and indirect dependence of each player by counting the clear direct and indirect dependences of the player.

By taking account of these influences and dependences, we can then determine the 'balance of power' held by each participant. Furthermore, it is also possible to describe the valency of each participant with regard to the objectives of the operation.

3. Case study: the Mérigotte NEIGHBORHOOD in Poitiers

The neighborhood of Mérigotte, figure 1, is situated close to the centre of Poitiers, between Artillery Park in the west and the railway and the slopes by the Clain to the south. The urban project designed by AUP provides for several spaces that provide structure, reinforced pedestrian walkways, three viewpoints opening up the perspectives and, above all, a green corridor linking the town with the environment.

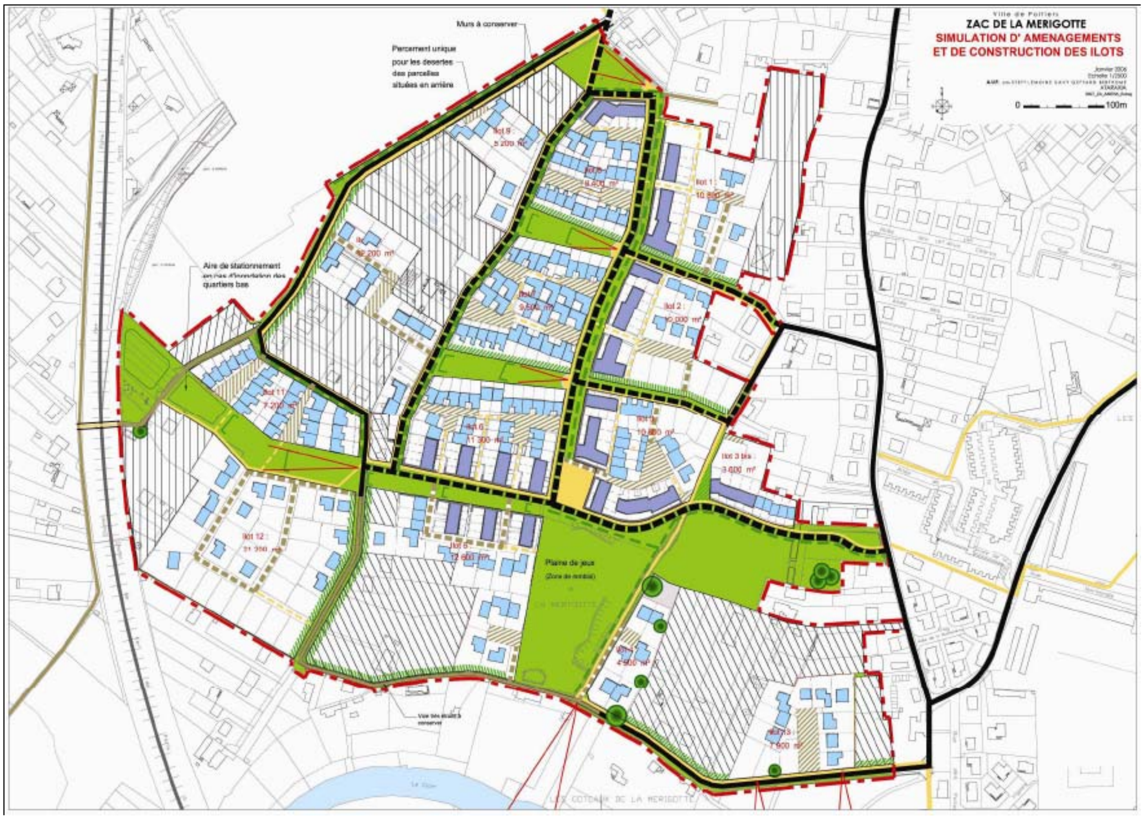

Figure 1. Development plan produced by AUP in January 2006.

In order to put together the table of players' strategies, we have identified a number of participants and initial objectives:

- The municipality, the Town of Poitiers (CP)
- The developer, ATARAXIA Development (A)
- A sample of private and public developers from amongst the principal players: OPARC, SIP, RAGONNEAU Foncier, FONCIER Service, ERMES, (P1, P2, P3).

Each player selected has been identified by means of a non-directive interview making it possible to specify his goals and objectives, plus his strengths and weaknesses.

OBJECTIVES	Conditions of contract for transfer/sale of land – DDZ
Energy efficiency	HPE label (*High Energy Efficiency*)
Management of water	Management of waste water for each plot Promote reduction in consumption of drinking water
Air quality / Health	Choose products listed as Class F + (fungistatic) Class B+ (bacteriostatic) R+ (very low radioactive emissions) C+ (very low chemical emissions) Alkyd paints or those meeting French environmental norms
“Green” building site	Organisation of site Checks and monitoring Keeping riverside residents informed Ensuring personnel’s awareness Limitation of nuisance Limitation of health risks Limitation of pollution Selective handling of waste products

Figure 2. Contractual objectives of the Mérigotte Neighborhood.

The first result that we can draw concerns the influences and dependences between the principal players selected for the study. In Figure 3, we may observe a significant dispersal between the participants. Overall, the role played by the Town of Poitiers within the framework of this operation is highly decisive, more so than that observed on the part of the main or subsidiary developers. The coordination and monitoring of the sustainable development process is therefore wholly incumbent on the municipality. In contrast to other operations in which the developer plays the role of an intersecting player, in this case the Town of Poitiers combines the functions of coordination, steering, negotiation, monitoring, etc., of the process that it plans to carry through itself.

The net balance of direct and indirect influences places the developer in particular outside the other participants, taking into account his potential for influence. The graph of convergences between players, figure 3, also shows the closeness of interests shared by the municipality and the developers. This represents an important guarantee of success in all the objectives linked directly to the “building” level. What is more, divergences on this subject are zero !

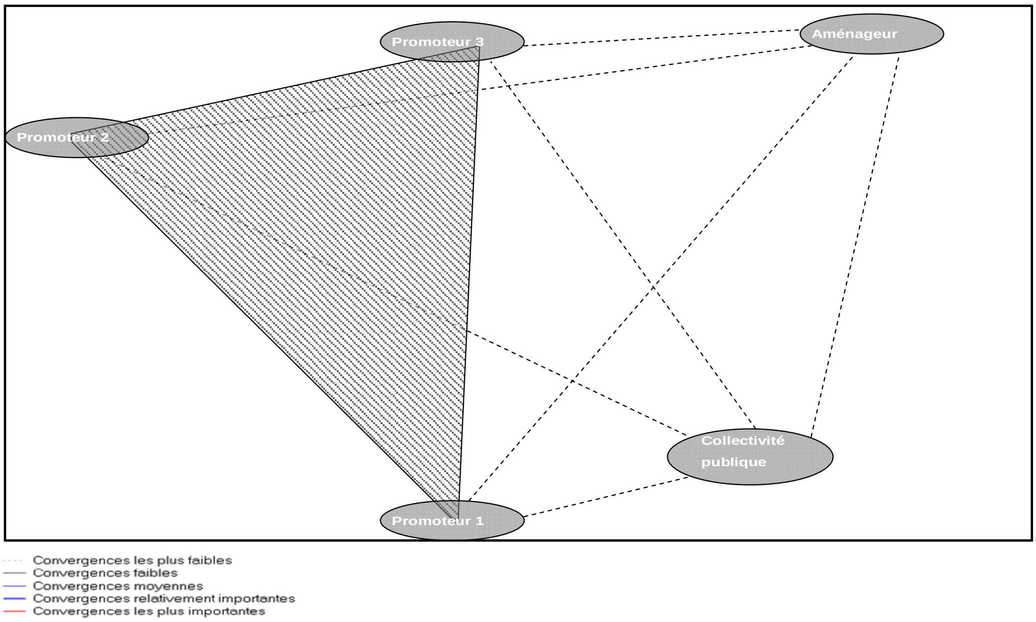

Figure 3. Graph of convergences

On the basis of non-directive interviews, we have also been able to draw up a histogram, figure 4, showing the involvement of all the participants in relation to the selected objectives. The favourable results obtained show a very good appropriation of the approach desired by the municipality, above all in matters relating to water and energy. The measured divergences are here also negligible. This would seem to demonstrate a fairly good level of cohesion between the participants with regard to the approach proposed by the municipality.

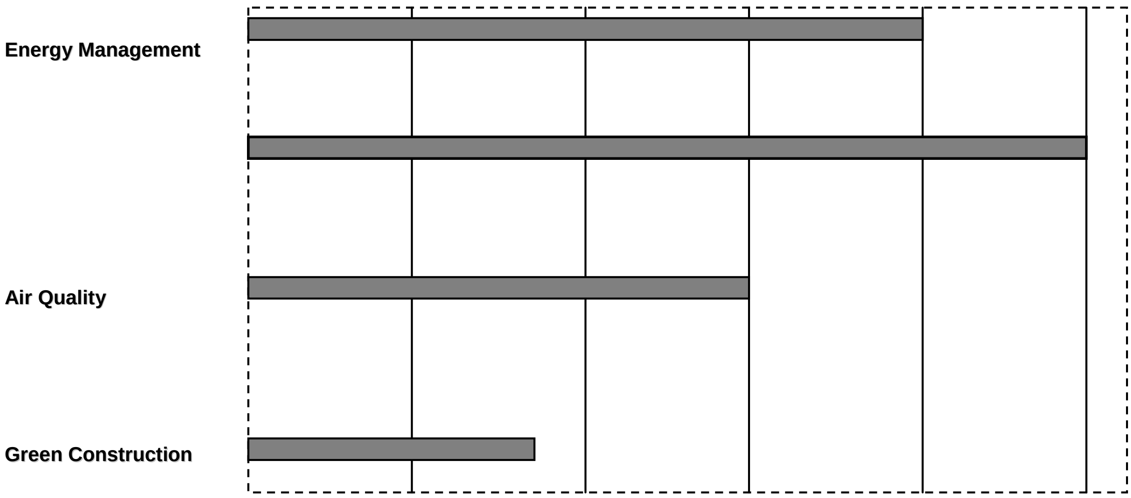

Figure 4. Histogram showing involvement of participants with regard to objectives

We must also point out that here is no ambivalence on the part of any of the participants, which reinforces our reading of the above results. The level of convergence and the appropriation of the approach to sustainable development have brought all the participants together in a highly positive manner.

The few sustainable neighbourhoods carried out in France were it within the framework of well defined operational procedures. These procedures make it possible the community to fix rules of urbanization complementary to the general code at the commune. It facilitates also the financing of the public equipment (roadway system, public space, schools…) by the promoters. Spaces external and envelopes of the buildings like certain internal characteristics. We identify three important phases during the which presence and the interests of the actors can change :

- Creation of the neighbourhood : the municipality and the developer work out the project which is finalized by a plan (see figure 1) and specific code of construction (see table 1). During this stage, promoters are sometimes consulted without there being no contractual relation with the promoters,
- Sale of the grounds to be built, general design of the buildings and detailed design of public spaces: this stage is completed by the delivery of the permit building by the municipality with the promoter and the final sale of the pieces by the developer. It starts with discussions between the developer, the municipality and the promoters interested,
- Detailed design and construction of the buildings: completed by the arrival of the inhabitants, the promoter is the principal pilot of this stage. The munipality and the developer take care of the respect of his engagements. Their influence is juridically limited, but it depends in fact of their capacity to slow down or accelerate the real project and to have later on other grounds interesting the promoter.

The study presented corresponds overall to the second stage. The perimeter of the actors is delimited gradually : during this phase, a first contractualisation is tied between the promoter and the developer in the form of a commitment to sell of the piece subject to obtaining the permit building delivered by the municipality. This stage the decisive actors are identified, but the promoters can still disengage themselves or to be isolated project.

The method suggested supposes a permanence of the logic of actor and interest with the various topics. In fact the renouncements of devices of environmental quality or energy performance prove to be frequent between the initial intention of the promoter and the finalization of the project. Several reasons can explain it:

- an initial ignorance of the benefit and costs of the constructive provisions innovating by the actors,
- a tactic of the promoter consisting in simulating an initial adhesion with the objectives of the developer and municipality while knowing that the principle of realism will precede at the times of the detailed design and financial figuring.

Do the projects of sustainable neighbourhood present sufficient technical and organisational innovations so that their design concerns a collective training during which, knowledge on the devices increases largely. A provision which an actor could considered initially as favorable to his interests can prove to be contrary at the stage design, in particular at the moment of the comparative economic analyses. Because of these multiple uncertainties, the protagonists can hope for an indulgence with respect to their renouncement.

4. Conclusions and prospects

This first application confirms our faith in the feasibility and relevance of our approach. We planned to model various development operations in this way in order to acquire and give structure to knowledge regarding the drawing-up of projects. Our objective is not to rationalise the action being taken. Modelling is not seen here as a predictive model, in other words for putting things in order. The objective is to acquire a better knowledge of the conditions under which the project is put together in order to improve organisation, in the knowledge that each project is unique.

We are seeking to model practices, to understand how decisions are organised and what the rules are governing actions and deliberations. If, within a project, each participant has the right to speak, one may wonder about the value attributed to it according to its origin, about the hierarchical structure and how it is constructed.

Abstract

Is it possible to avoid ecological impacts on built environment instead of battling with the consequences? This paper is focused on mutual impact of environment and building from the viewpoint of selecting the appropriate management strategy. In order to create a built environment harmonizing with the natural world, it is important to manage related information in an adequate way. Systematic approach and methods of simulation modelling enable to assess environmental impacts and establish the balanced interactions between: building and environment; construction process and environment; maintenance and environment etc. The damage of buildings and infrastructure caused by disasters has caught the attention of the world. Even in such geographically calm region as Estonia there have been incidents that compel us to pay more attention to the environmental issues while designing and maintaining buildings. One of the aims of European and Asian Infrastructure Advantage (EURASIA) research project is to find out whether and how the prevention of ecological risks enables to minimize such damage.

Keywords: Built environment, reciprocal environmental impact, environmental risks.

1. Introduction

Building is an essential expression of human activity. Since the beginning of the society humans have shaped the environment by creating, changing and removing various structures. The built environment is a multi-faceted concept, including the natural, artificial, cultural, socioeconomic, political etc. components. It can be stated that buildings can not exist without the environment, but natural environment can exist without buildings as it has been for millions of years before the man. Thus natural background is a basis and human activity has to fit delicately into it. In a long run nature impacted by built environment is changing dramatically.

The assessable influence of each building is localized in various parts of environment into considerably smaller spheres of impact, and the impact outside these boundaries can be considered as marginal. We can find both objective and subjective components of impact, with the latter not being any less significant – e.g. in case of building the architectural attractiveness.

The environment with all its components in turn exerts reciprocal impact on the buildings. In the present paper the following questions are discussed:

- the phases of the life span of a building;
- the reciprocal impacts of the building and environment;
- why and how should the reciprocal impacts be identified;
- possibility of foreseeing and preventing harmful impacts.

The aim of the paper is to provide the starting points for future research in the field, enabling to develop the strategy of assessing the impacts at a more detailed level.

2. Reciprocal Impacts of Building and Environment

2.1 Phases of Life Span

It is possible to differentiate between various phases of building activity as: idea generation and specification; data collecting; initial task and drafting; preliminary assessment; design and planning; construction process; maintenance; the phase of depletion of the lifecycle of the building and its demolition; and finally utilization of waste or the spontaneous utilization of the building in the environment. The length of building life span might be very different as it depends on numerous factors, including both, the environment where it is erected and decisions made in the idea generating and planning or maintenance phase. Some buildings have a life span of hundreds and thousands of years in the form of extensions and rebuilding or architectural memorials, another building can complete its cycle already after a few years of its existence due to being erected in a discord with the environment or other human decisions, incidents, accidents etc. There are always numerous buildings in different phases of life span in the same observed area.

2.2 Classification of Reciprocal Impacts

The reciprocal impacts of the building and environment can be identified throughout all the phases of life span, concentrating most from the phase of construction process to the utilization phase as the impact in the design stage of a building is relatively small. On the other hand, the influence of waste dispersed after utilization has been less researched as well as the impact of the expired but un-utilized buildings. Therefore we have to treat the influence of the building and the activity inside it separately. In this paper general aspects and the reciprocal impacts of the building and environment, depending on the life span of the structure are differentiated as:

- the impact of the building on the environment;
- the impact of environment on the building.

The building affects the environment mainly by: placement, time of being located in an environment, the architectural and structural design, building materials used, suitability of the intended use, size and capacity indicators, building technology and intensity of construction, duration of construction period, intensity of usage, preparedness to environmental changes, labour intensity ratio of utilization etc. The harmful impacts and danger factors of the building on the environment include for instance: delays of planning and increase of cost; the logistic load of building, high energy and resource cost, disorders in waste and recycling arrangements, hazardous building materials, unsuitability of architectural decisions, high energy cost at the maintenance stage, leaking of heat, noise level, irresponsibility of energy saving, demolition waste, etc.

Environment (as a natural, artificial, cultural and socioeconomic entirety) influences the buildings by the location conditions, duration of stay in the environment, human activity, cultural and socioeconomic and political aspects of the environment. The location conditions and harmony of intended use of building and its parameters are here most vital. Out of natural harmful impacts for example the climatic circumstances not corresponding with the qualities of the building can influence the latter as well as the temperature, rainfall, winds, ground conditions, the groundwater level and its quality, fluctuation of water bodies, tides, seismic activity, harmful gas (radon, methane etc.), UV-radiation etc. Besides the artificial factors of the environment and impacts caused by human activity also other buildings, their insufficient infrastructure or energy supply, water, atmospheric and surface pollution etc. can prove to be detrimental to the observed building. The regarded building can become disharmonious with the cultural and socioeconomic and political components of the environment for example by cultural background, evaluations, convictions, human skills, expectations and needs, economic, social and technical conditions and opportunities, as well as strategic and political decisions and choices of individuals or human groups. Impact chains of various range, complexity and intensity result from the reciprocal impacts of the building and the environment, where the cumulating impacts and indirect reaction can be indirectly noticed (Environmental overview, 2005 [5]).

2.3 Significance of Reciprocal Impacts by Phases of Life Span

The extent and intensity of reciprocal impacts come from the properties of the building and environment. As the environment is a background to the building, we can state broadly that environmental impact on the building is the stronger and more intense, in a bigger disharmony the building has been erected with the surrounding environment. In case some essential environmental aspects of the building have been ignored at design, construction process or in maintenance phase, a contradiction will emerge at a definite moment of life span, exerting negative impact on the building and eventually on human health and welfare. The time of appearance of the harmful factor, its severity, possibility to discard it, cost and expediency will be an issue. In course of assessing the extent of the impact by different factors and stages of life span, the following indicators could be used:

- extent of impact,
- duration of impact;
- intensity of impact,
- significance of impact.

In purpose to create a comprehensive picture of the significance of different impacts of the building and to discover the harmful and aggressive impacts at the initial stage of assessment, the rating system has been suggested in the framework of the present research. In table 1 an example of rating sheet for sample building is presented. The impacts are graded as follows:

- "4" – severe influence;
- "3" – high influence;
- "2" – medium influence;
- "1" – low influence;
- "0" – no influence.

Table 1: Significance of Reciprocal Impacts of Building and Environment by stages of life span

Description of Impacts		Significance of Impact											
		Design Stage			Construction Process			Maintenance			Utilization		
		Extent	Duration	Intensity	Extent	Duration	Intensity	Extent	Duration	Intensity	Extent	Duration	Intensity
a) Impact of the building on the environment													
1.	Labour consumption	1	2	3	3	3	4	3	4	4	2	2	1
2.	Logistic load	1	1	1	3	3	3	4	4	4	2	2	2
3.	Construction waste	0	0	0	3	4	2	1	2	2	0	0	0
4.	Demolition waste	0	0	0	1	2	2	2	2	1	2	3	4

3. Assessment of Reciprocal Environmental Impacts

3.1 Environmental Impact and Environmental Risk

Environmental impact is usually described as an impact that can accompany human activity and is expressed by changes in natural environment, cultural heritage or assets. According to its common definition environmental risk is a risk where the environment and through that human health, welfare and/or assets are endangered (Morris and Therivel, 2001 [7], Peterson, 2006 [8] and Põder, 2006 [10]. The regular definition of environmental impacts has been focused first of all to the impact proceeding from the building on the environment, leaving the reciprocal influence of the environment on the building as secondary. The definitions contain also no references to the impact division proceeding from the life span of the building.

In purpose to find information regarding the influence of the intended building on the environment and minimize the risks, most countries have adopted a routine to conduct a mandatory preliminary assessment; which can be done within legal framework and legislation, usually called the **assessment of environmental impacts (AEI)**. Focused on the dangers proceeding primarily from the building to the environment, typically the threats proceeding from the environment to the building are handled secondarily and only when it is required by legal instructions. In the present paper the AEI is considered as integral process, including reciprocal (mutual) impact assessment, i.e. assessment of impact exerted by building and *vice versa*, considering the life span of the building. The voluntary assessment of impact for research and knowledge obtaining purposes is also very important besides the legislative due.

3.2 Purpose of AEI (Assessment of Environmental Impact)

In purpose to determine a broader goal of AEI a systematic method should be applied to that. The framework of assessment existing in most countries at a legal level provides good assumptions to it. According to the concept of AEI the assessment is an administrative-regulating measure, characterized by its systematic, reproducible and interdisciplinary nature with a goal to provide the interested parties with competent information of environmental impact of all realistic versions and suggest the optimal solution. Assessment of environmental risk is thereby an activity used to assess the probability and severity of negative impacts proceeding from a source of risk, being exerted to a certain part of environment or by a part of environment to human health or property, as described by Põder, 2006 [10]

In a broader approach of environmental impact and risk assessment it is necessary that impact assessment is meant on one hand map the impacts and their ranges for research purpose (value of knowledge) and on the other hand to help the decision makers, so that all the interested parties might value the results of decisions (practical value). Therefore AEI should have planning and promoting the long term sustainable development by the life span phases of the building as its next essential goal (Peterson, 2006 [8] and Estonian National Strategy of Sustainable Development [6]).

3.3 Method and Procedure of AEI

It is possible to assess the reciprocal impacts and rate actual alternatives by method including the following activities:

- choosing possible alternative versions for AEI;
- identifying the reciprocal environmental impacts of chosen alternative versions;
- ranking the priority sequence of impacts;
- rating the extent, intensity, duration and significance of the impacts by phases of life span as shown in table 1;
- estimating the quantitative values of specific impacts or providing their qualitative assessments;
- analysing the results, selecting actual alternatives of construction and maintenance of the building,
- suggesting on sustainable development, risk level, priorities of impacts etc.

In most countries environmental impact assessment is regulated by legally set principles. Mutually complemented and reckoned environmental, planning and building laws and codes provide a general framework for AEI. Assessment of environmental impact is generally related to two procedures differing in their content and form as depicted in Peterson, 2006 [8] and Estonian National Strategy on Sustainable Development [6]:

- applying and issuance of activity licences (building permits, waste permits, pollution permits, water-special usage permits) and
- composing and validation of strategic documentation (plans, strategies, projects).

The possibilities of AEI on various levels are illustrated in Figure 1.

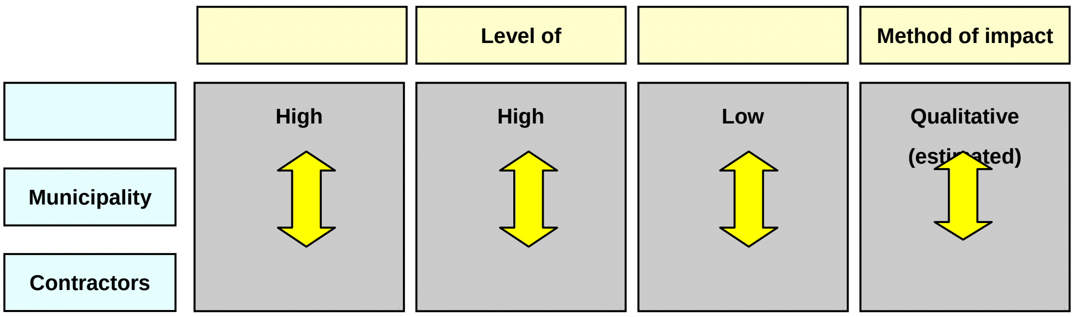

Figure 1: Possibilities of Environmental Impact Assessment on Various Levels

Different countries use different approaches to decide about the need for AEI. For example in Estonia the general conditions of a need for environmental research are provided by legislation as Building Act [7], Act of Environmental Impact Assessment and Environmental Management System [11] and Planning Act [12]. The most significant condition of environmental impact assessment procedure is that it has to be open to public. A special process has been foreseen for disclosure. Disclosure brings forth full preparation of planned activity, its strengths and weaknesses and enables people to track the decisions influencing their living quality. The involvement of the general public improves also the quality of assessment. In order to engage the general public a suitable set of methods excluding information noise and excessive conflicts in accordance with legally set boundaries will be selected.

The assessment of strategic impact should be differentiated from assessment of environmental impact. Environmental risk assessment is a separate measure in addition to regular AEI. Based on current investigation and findings of Peterson, 2006 [8], Põder, 2006 [10] and Veinla, 2006 [13] the present paper provides an outline of basic AEI procedure as shown in Figure 2.

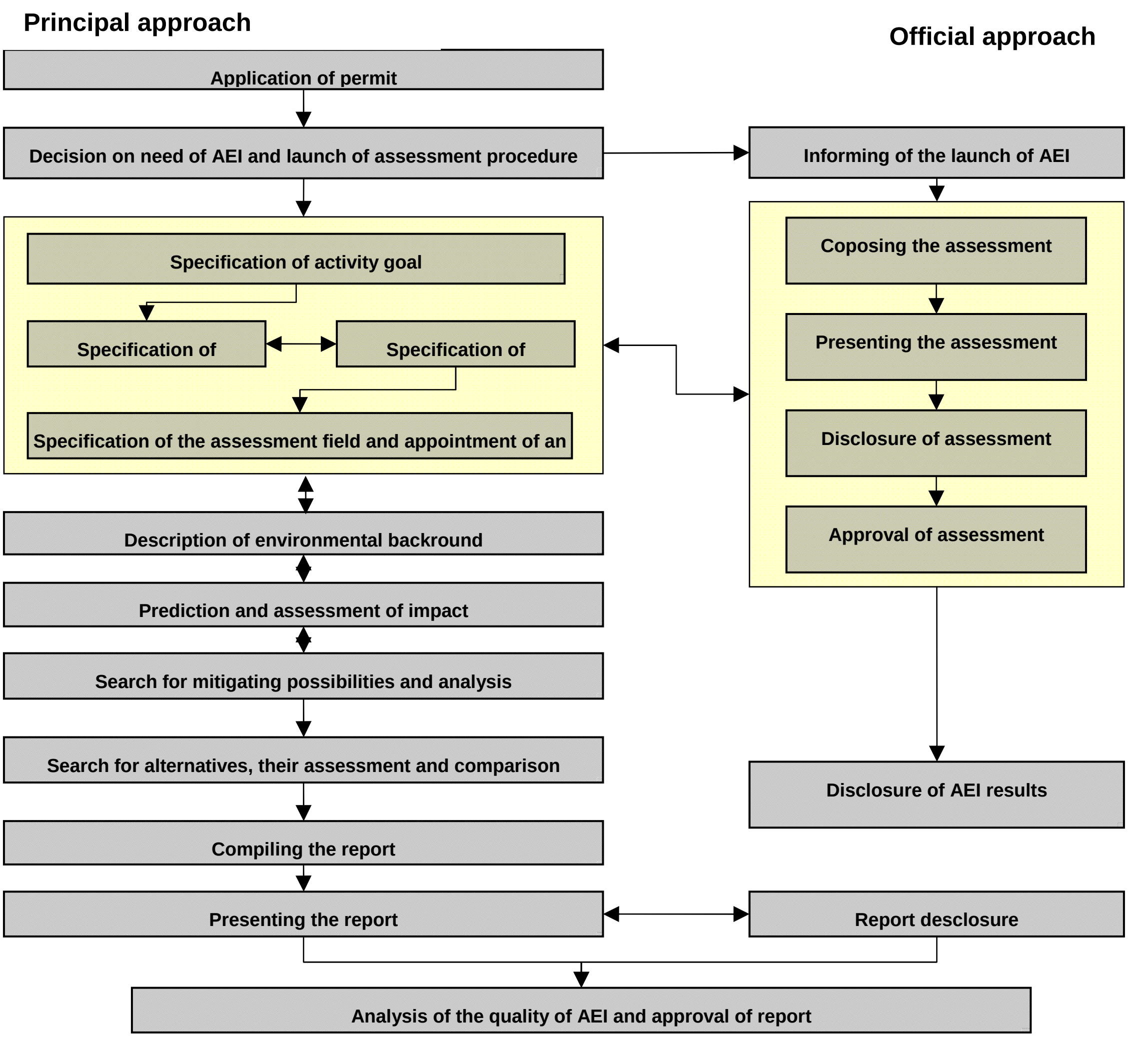

Figure 2: Procedure of Assessment of Environmental Impact (AEI)

3.4 Assessment of Indirect Impact

In the process of AEI one should always consider that besides the direct reciprocal impact the assumed indirect impact has to be specified also. The indirect impact of activity is formed by relational reason-result chains between different parts of environment. They can be manifested far from the immediate locality. The indirect impact can develop as a consequence of direct influences in the long run and it could hardly be predicted during the regular AEI. Impact chain is one of the resources to determine the indirect and cumulative impact. The whole environmental impact is completely specified when all the impact spheres, presumable direct impacts and chains leading to indirect impacts and according results have been ascertained. The field of impact can often be found only at the end of AEI when modelling regarding the distribution of pollutants, water regime alteration, range of changes in socioeconomic environment etc. have been made. The description of environmental background will be taken as the base point of simulation modelling and its parameters will provide an overview on the condition of the influenced object (environment or building) before the beginning of the process. Different environmental aspects and parameters will be described by appointing relevant indicators for the assessment process.

In order to determine the parameters special studies, environmental audit or expertise will be carried out or they will be derived from preliminary analogue projects or case studies. In principle the environmental impact can be assessed both as a by qualitative expert assessment or by mathematic quantitative simulation. The selection of prediction method depends on technical possibilities and nature of impact. The goal and the object will be specified during the simulation process. For modelling a sample model of ecosystem or building will be prepared, where the boundaries of the system, system elements and reciprocal relations of the elements, external factors and exchange processes with the other systems will be specified.

When the elements and relations of the system are determined, the next stage in creating the model includes the description of relations by mathematical equations, proceeding from the law of conservation and balance of systems. The simulation model consists from mutually related sub modules where the motion of critical process is defined. The solutions will be found as analytical or numerical answers, for example by appointing the network of calculation points to the system under investigation. The calculation ratios are used to characterize the intensity and run of the researched processes, using the approximate relations describing the processes. The values of model ratios will be required at calibration where the calculation results will coincide with the measurements. Calibration has to cover ignorance, revealing the limitation of the theoretical principles of the model.

4. Planning Strategy of Sustainable Development

4.1 AEI as a Method for Planning Sustainable Development

Following the AEI it is important to estimate the quality of completed assessment by checking if the evaluation of impacts met all the set terms. After picking up the reciprocal environmental impacts identified as a calculation model the next step will be to consider the mentioned impacts in every possible way at planning the activity in sustainable development. The respective activity in its initial stage is called spatial planning. According to Estonian National Strategy on Sustainable Development [6] and Development Plan of Estonian Country Life [4], the spatial planning is a long term planning of three-dimensional development, co-ordinating and integrating development plans of different fields, considering the tendencies and needs of the economic, social, cultural and natural environment. The goal of sustainable development can be defined also as understanding that our present actions would not endanger the welfare of posterity. Sustainable development is not a goal in itself, but a measure to balance the activity of mankind with its surroundings in a longer run (Sustainable Development Program of Estonian Fund of Nature: [12]).

The arrangement of strategic impacts in the framework of general planning is an essential starting-point of planning the strategy of sustainable development. The goal of preliminary and general planning is to determine the main tendencies and conditions of the territorial development of the area, prepare the underlying basis for detailed planning to set the land use and building terms. Assessment of strategic impacts creates thereby assumptions for the best application of the most vital environmental factor – the suitable location already in the general planning stage when the likely locations of buildings of specific purpose will be specified. Based on general plans it is possible to proceed to a more detailed level in the stage of detailed plans and to the resulting issuance of building and activity permits, by constituting the required conditions for sustainable development.

4.2 Management Strategy for Prediction of Harmful Impacts

The transition from general to the individual (more detailed) and considering the impacts of every activity should be an integral part of the management strategy in the course of assembling a general plan. Management strategy includes the developed systematic activities proceeding from a national policy covering the stages of from general to detailed plans, followed by building permit issuance and concluding with deliberate methods at construction, maintenance and utilization of the building in harmony with environmental sustainability. AEI must always precede the planning in accordance with the degree of detail. Building site management should be conducted according to the impacts of various phases of life span; considering the traffic scheme, infrastructure and engineering supplies. Various alternative versions from the viewpoint of the most suitable environmental solution should be reckoned over when selecting the architectural and structural design.

The natural factor of the environment is one of the strongest and most valid factors besides the artificial, social and economic components. The natural component of the environment deserves separate regard, as in spite of hidden agents the impact might be unpredicted and destructive, posing a direct hazard to a man as well as to the nature itself. In order to avoid the harmful effects exerted by natural environment the impacts must be gradually mapped, considering the functional and constructive alternatives of the building and searching for mitigating possibilities already before the planning of the structure or in the course of construction process. The dangers related to existing structures can be minimized to a certain extent by identifying potential impacts in various stages of life span and planning according protection measures. In case of the most vital aspect ─ the unsuitable location of the building, it must be considered that there might not be so many options at human residential areas to accommodate the desired building.

Natural impacts can be divided into general and local ones. The strongest general impacts are the climate, temperature, precipitation, winds, seismic activity and level of water bodies and its fluctuation etc. The local and weaker impacts are the impact of groundwater, ground conditions, harmful gases etc. Neglect of general impacts can cause large scale, fatal results to humans; in case of local impacts the effect will be more localized. For example the analysis of major natural disasters occurring in the past years all over the world (hurricanes, earthquakes, tsunamis, floods) and their destructive impact has revealed that often there has been insufficient knowledge in the planning of the buildings as probability of endangering hazard or destructive impact of cumulating events was not considered. According to Atwater et al, 2005 [1] it might be possible to forecast both ─ the most devastating disaster of the new millennium ─ the tsunami of South-East Asia in 2005 and the hurricane Katrina, that destroyed New Orleans. These resulted in thousands of victims and a very big economic and environmental damage by dangerous substances proceeding from buildings and ruins. One conclusion of the analysis of the disasters stated that even relatively realistic danger visions obtained by the time spent on predicting the impacts and fiscal means were unable to make the general public react beforehand in a sufficiently active manner with the present management system, economic model and level of responsibility due to traditions, decision making habits, political demands and support of the law between the short term (aggressive, planned to increase progressively) and long term (stable, sustainable) developmental strategy. The key words are versatile awareness of the participants in a decision making mechanism and willingness, resourcefulness and adequacy at searching the mitigating measures, fiscal policy reckoning with priorities and juridical framework sets guaranteeing the certainty of decision making.

As example from Estonia the establishment of buildings on the shore of coastal areas during the real estate boom of 2005-2006 can be brought; which is not negative in itself if all the reciprocal impacts would be considered. The environment influences the buildings located at shore areas mainly by stable water level, probable tides due to gales and wind, as well as the structure and stability of ground. Seismic activity and impact of precipitation have thereby been relatively small. Yet there are developmental areas in Estonia, where short term business interests hold a priority at development and where the dwelling houses and the infrastructure supporting them are established literally to shallow marshland, to the same height with the sea level. The rise of sea level that occurred in Pärnu, Estonia during the January storms in 2005, resulting in major water damage to buildings and facilities located even within a kilometre from the coastal area, let alone the damage to the property and indirect damage to nature, testifies of the insufficiency of danger prevention measures. According to Soomere, 2005 [11] the tsunami caused by earthquake will be also in future improbable in Estonia, but there might be a rise of water level again due to atmospheric phenomena. Therefore building to coastal areas is always an activity of enhanced risk level, that should be preceded already in the planning stage by a versatile analysis of strategic impacts to specify the suitability of building areas at coastal and shore areas and conduct the preliminary assessment of the adequacy of possible mitigation measures. When building to coastal areas one should particularly reckon with relevant foundation, increasing the water and wind resistance of structures, volume-spatial project solutions considering also the probable rise of water level, architecturally used water and wind resistant building materials and improved technologies, as well as the resistance of infrastructure and communications to the impacts of water and wind. The respective research requires more support and recognition, which enables to use derived knowledge already in the design and construction stage of the buildings. This demand nationally regulated policy and increased awareness of decision makers, but also programs and training at the local authority level.

5. Conclusions

The present paper provides a basic overview on the stages of the building life span, reciprocal impacts of the environment and building, their distribution in lifecycle stages, identification of impacts and structure of procedures.

It is important to acknowledge that the environmental impacts can be foreseen already on the planning stage of the building. The following gaps in common assessment of environmental impacts are revealed on the basis of current study:

- as a rule environmental impact assessment involves only the phase of construction process and maintenance, while design and utilization phase of construction life span are almost ignored;
- while impact of the building is usually accepted the reciprocal impact of environment is considered to be insignificant;
- the peculiarity of reciprocal environmental impacts by different phases of life span has not earned deserving attention.

In purpose to continue this research besides fulfilling the gaps mentioned above a list of the reciprocal environmental impacts should be established and a simulation model reflecting the dependences of the sets of reciprocal impacts created.

Knowing the direct and indirect impacts and impact chains it is possible to plan the built environment fitting into nature so that in each planning and building stage reciprocal discords will be minimized. Thereby it has become evident that only increasing the awareness of the general public and decision makers and creating the system of nationally recognized rules, balanced management methods and financing policy, can lead to a result where environmental impacts will be considered at planning stage in purpose to ensure a sustainable development.

Abstract

The use of fly ash in concrete is desirable because of benefits such as useful disposal of a byproduct, increased workability, reduction of cement consumption, increased sulfate resistance, increased resistance to alkali-silica reaction and decreased permeability. However, the use of fly ash leads to a reduction in early strength of concrete. The use of quarry dust in concrete is desirable because of benefits such as useful disposal of a byproduct, reduction of river sand consumption, and increased strength. However, the use of quarry dust leads to a reduction in the workability of concrete. Therefore, the concurrent use of quarry dust and fly ash in concrete will lead to the benefits of using such materials being added and some of the undesirable effects being negated. The decrease in early strength by the addition of fly ash is ameliorated by the addition of quarry dust. The decrease in workability by the addition of quarry dust is reduced by the addition of fly ash. This paper investigates quantitatively the workability and strength of a concrete mix at 3-day, 7-day, and 28-day age containing 0% - 45% of fine aggregate as quarry dust and 0-30% of cementitious materials as fly ash. These findings guide the practitioner in selecting fly ash and quarry dust contents to meet strength and workability requirements of a concrete mix. The concurrent use of the two byproducts will lead to a range of economic and environmental benefits.

Keywords: Fly Ash, Quarry Dust, Economic, Concrete, Workability

1. Introduction

Concrete is the most popular building material in the world. However, the production of cement has diminished the limestone reserves in the world and requires a great consumption of energy. River sand has been the most popular choice for the fine aggregate component of concrete in the past, but overuse of the material has led to environmental concerns, the depleting of securable river sand deposits and a concomitant price increase in the material. Therefore, it is desirable to obtain cheap, environmentally friendly substitutes for cement and river sand that are preferably byproducts. Fly ash (pulverized fuel ash) is used extensively as a partial replacement of cement. Fly ash is a byproduct of coal consuming power plants but has not gained popularity in Sri Lanka as yet because the material is not generated in Sri Lanka, and transportation costs make fly ash not significantly less costly than cement. However, the material may gain popularity in the future with the commissioning of the Norochcholai coal power plant. More fly ash may also be produced worldwide in the future with the establishment of many coal power plants due to the rapid rise in petroleum prices. However, though the inclusion of fly ash in concrete gives many benefits, such inclusion causes a significant reduction in early strength due to the relatively slow hydration of fly ash. Nevertheless, fly ash causes an increase in workability of concrete. Quarry dust has been proposed as an alternative to river sand that gives additional benefit to concrete. Quarry dust is known to increase the strength of concrete over concrete made with equal quantities of river sand, but it causes a reduction in the workability of concrete. When examining the above qualities of fly ash and quarry dust it becomes apparent that if both are used together, the loss in early strength due to one may be alleviated by the gain in strength due to the other, and the loss of workability due to the one may be partially negated by the improvement in workability caused by the inclusion of the other. This paper is generated from a research project designed to determine whether such benefits could be obtained by the use of these two materials together, and to quantify such benefits. Positive results will lead to the possibility of using the two byproducts in large quantities, while reducing the dependency on chemical admixtures.

2. Properties of Fly Ash and Quarry Dust

The spherical shape of fly ash particles causes an improvement in the workability, and the particles alter the flocculation of cement, with a resulting lowering of the quantity of water required [1]. The addition of fly ash causes a reduction in the water required for a given slump, typically in the order of 5-15 % when compared with a Portland cement only mix. However, coarse fly ash with high carbon contents can adversely affect workability [2]. Fly ash in a mix has a retarding effect, typically of about 1 hour, which may be especially advantageous in hot weather such as those prevalent in Sri lanka, while on the other hand, in cold weather, an accelerator may be required. Only the initial set is delayed by the inclusion of fly ash, and the time between setting and final stiffening remains unaffected [3]. The improvement in ultimate strength obtained with the use of fly ash is due to its pozzolanic action and the ability of small fly ash particles to fit in between cement particles [3].

The reaction (hydration) of fly ash does not start until some time after mixing, and in the case of Class F (low calcium) fly ash, can be delayed as much as one week or more. An explanation offered is that the glassy material in concrete is broken down only when the pH in the pore water is at least about 13.2, which means that an amount of Portland cement must have hydrated [3]. Once the reaction does occur, products of hydration are formed around the fly ash particles, and with time diffuse away and precipitate within the capillary pores, causing a reduction in the capillary porosity. Conversely, Class

C (high calcium) fly ash reacts directly with water to some extent. Because the reactions of fly ash take a long time, extended curing times are required [2,3].

Fly ash causes an increase of strength because of the “packing” of the fly ash particles at the aggregate-cement interface, but the beneficial impact of fly ash on both strength and workability is not extended beyond 20 % of the cementitious material. Unlike in the case of strength and workability, fly ash does not affect the properties of creep and shrinkage [3] , though some authors state that the drying shrinkage is increased with the inclusion of fly ash [2]. As a result of the longer setting time for concrete containing fly ash, it is more permeable at a young age, but with time, the permeability drops down to very low values [3].

The median pore size becomes smaller when fly ash is included, and consequently the permeability is lowered; therefore, the use of these cementitious materials improves the durability of concrete [3]. However, Dias et. al [4] found that sorptivity, and hence, water permeability increased with increasing fly ash content in concrete that had not been cured at all. Amarasiri [5] showed that water permeability of concrete containing fly ash is significantly affected by duration of curing. However, the sorptivity of concrete that had been cured for 7 days or greater were independent of percent of fly ash content. Thus, it is possible that concrete containing fly ash, which hydrates slower than cement, needs longer curing times to become durable. In fact, it has been shown that concrete containing fly ash tested after 56 days of curing had smaller sorptivity than control mixes without fly ash. Researchers found that the carbonation of concrete containing fly ash was not significantly greater than in control specimens without fly ash. Significant benefits in resistance to chlorine ingress were noted, while slight increases in sulfate ingress were found. However, resistance to sulfate ingress was not adversely affected by the inclusion of fly ash, presumably because of the decrease in C_3A and $Ca(OH)_2$ in such concrete [4]. The evaluation of the effects of fly ash, and optimizing mix designs is complicated by the variability of the quality of fly ash, even though it may be obtained from the burning of coal at the same power plant. The periodic variations in the operation of the power plants and differences in the coal used causes changes in the particle size distribution and chemical composition of the fly ash produced. Conversely, ground granulated blast-furnace slag, and silica fume are byproducts of highly controlled processes, and have much more consistent properties [3].

Quarry dust is made while blasting, crushing, and screening coarse aggregate. Quarry dust has rough, sharp and angular particles, and as such causes a gain in strength due to better interlocking and a concomitant loss in workability. The use of quarry dust sometimes causes an increase in the quantity of cement required to maintain workability. A survey of samples from 6 quarry dust suppliers in the Galle region of Sri Lanka revealed that they were all more well-graded than the river sand provided by a supplier from the same region. The quarry dusts contained more fines smaller than the 200 μm sieve than the river sand (about 20% for quarry dust compared with 5% for river sand) [6] According to the guidelines for mix design according to the Department of the Environment of the United Kingdom [7], the finer the fine aggregate used in concrete, the higher the requirement of free water to maintain workability. However, the mix-design procedure limits the analysis of fines content of a fine aggregate to % passing 600 μm sieve. Therefore, the guidelines should clearly be used with trial mixes when inserting quarry dust.

3. Research Methodology

One mix design was used for this research with a target strength of 30 N/mm^2. River sand was replaced by 0 (i.e. totally river sand), 15, 30, and 45% quarry dust, whilst cement was replaced with 0, 15, and 30% fly ash. The slump of the resulting mixes and the strength at 3-day, 7-day, and 28-day age were obtained by testing three replicate 150 mm compressive strength cubes for each combination of mix and testing age. Ordinary Portland Cement from a leading manufacturer was used as it the widely used cement for construction in Sri Lanka. Gneissic crushed coarse aggregate of maximum size 20 mm was used. River sand was used as the primary fine aggregate, and gneissic quarry dust was used to partially replace it to find the effects of including quarry dust. One mix design was used for the entire research project and it was as follows per cubic meter of concrete..

Cement 362 kg
Water 210 kg
Fine aggregate 818 kg
Coarse aggregate 985 kg

The moisture contents in the stockpiles were 1.83% for river sand and 2.00% for quarry dust, and corrections were carried out for the differing moisture contents when partially replacing river sand with quarry dust.

The combinations tested were as shown in Table 1. For all test series, 3 replicates each were made for the three testing ages of 3 days, 7 days, and 28 days.

Table 1: Testing programme

Fly Ash Content (% replacement of cement)	**Quarry Dust (% replacement of river sand)**			
	0	**15**	**30**	**45**
0	Series 1	Series 2	Series 3	Series 4
15	Series 5	Series 6	Series 7	Series 8
30	Series 9	Series 10	Series 11	Series 12

A power driven drum type concrete mixer with revolving drum was used to mix the concrete, while weight batching was used. Steel moulds were used to prepare concrete specimens of 150 mm x 150 mm x 150 mm for strength determination for each test. The slump was also tested of the fresh concrete immediately after mixing. The concrete specimens were demoulded 24 hours after they were cast and continuously moist cured in a curing tank unit the time of test.

4. Results and Discussion

The average strengths and slumps obtained from the above tests are shown in Table 2. For ease of comparison and insightful analysis of the effects of replacement, the average strengths of the concrete with replaced materials are reported as ratios of the average strength of the control without river sand

and cement replacement. The strengths of the control mix at the three ages tested are shown in the first row of data.

Table 2: Test results as strength ratios between the control mix and mix with cement and river sand replaced

PFA (%)	Quarry dust (%)	Slump (mm)	Age (days)		
			3	7	28
			Strength ratio to control mix		
0	**0**	80	20.21 N/mm^2	25.31 N/mm^2	33.47 N/mm^2
	15	50	1.17	1.12	1.12
	30	35	1.20	1.13	1.13
	45	20	1.24	1.20	1.16
15	**0**	105	1.00	0.95	1.04
	15	58	1.05	0.99	1.09
	30	48	1.10	1.00	1.15
	45	25	1.10	1.04	1.15
30	**0**	88	0.85	0.86	1.05
	15	78	0.86	0.86	1.05
	30	55	0.83	0.82	1.03
	45	30	0.92	0.90	1.10

Examining the strengths at 3-day age, it can be seen that the increasing of quarry dust content from 0 % to 45% has caused an increase of strength for fly ash contents of 0% and 15%. The increase is not that consistent for 30% fly ash, though there is a distinct increase of strength for the concrete with 45% quarry dust compared with other quarry dust contents for concrete containing 30% fly ash. Interestingly, the increase of strength with increase of quarry dust content is most apparent in the concrete without fly ash, where a strength gain of 24% has been recorded by increasing the quarry dust content from 0% to 45%. When combining all contents of quarry dust, the concrete with 15% fly ash is about 8% lower in strength and concrete with 30% fly ash is about 25% lower in strength than concrete with no fly ash at 3-day age.

Examining the data obtained at 7-day age, it can be seen that the increasing of quarry dust content from 0% to 45 % has consistently caused an increase of the strengths of concrete containing 0% fly ash and 15% fly ash. Again the gain in strength with increase in quarry dust content is not as clear cut for concrete containing 30% fly ash. The increase in strength with increase of quarry dust content is most apparent for concrete containing no fly ash. When combining all contents of quarry dust, the concrete with 15% fly ash is about 11% lower in strength and concrete with 30% fly ash is about 23% lower in strength than concrete with no fly ash at 7-day age.

Examining the data obtained at 28-day age, it can be seen that, in general, there is an increase in strength with increasing quarry dust content though the increase is not as much as at 3-day age. Thus, the addition of quarry dust affects concrete at 3-day age (early strength) more than concrete at 28-day age. When combining all contents of quarry dust, the concrete with 15% fly ash is about equal in strength and concrete with 30% fly ash is about 4% lower in strength than concrete with no fly ash. According to some guidelines for mix design, only 30% of the fly ash should be considered when calculating the water-cementitious material ratio for estimating the strength of a designed mix. It can immediately be seen when examining the current data that this factor certainly underestimates the contribution to strength from fly ash, and how difficult it is to make generalizations regarding the effects of including fly ash in a concrete mix.

Considering the slump data, it is apparent that there is a rapid loss of slump with the addition of quarry dust, but the increase of slump with the addition of fly ash is not as significant. For the purposes of selecting fly ash and quarry dust contents to meet a certain slump requirement, the data was processed to generate a plot of equal slump lines, as shown in Figure 1.

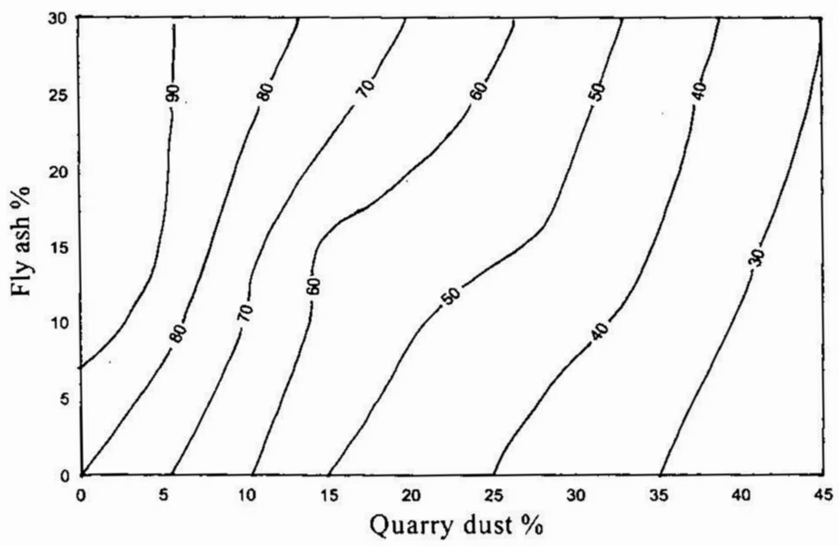

Figure 1: Equal Slump Lines (mm)

From Figure 1, it can be seen that if a slump of 80 mm is required, using the above mix design it is possible to use 0 % quarry dust and 0 % fly ash, or about 5 % quarry dust and 7 % fly ash, or 10 % quarry dust and 22 % fly ash. The question then arises, how will these variations affect the concrete strength at early age, say 7-day age. Then, based on data shown in Table 2 and interpolation, the 7-day age strength would be approximately 25.3 N/mm^2 for concrete with 0 % fly ash and 0 % quarry dust, 26.0 N/mm^2 for concrete with 5 % quarry dust and 7 % fly ash, and 23.3 N/mm^2 for concrete with 10% quarry dust and 22% fly ash. The last type of concrete is understandably weaker than the control, because fly ash inhibits the rate of early strength development. If the strength at 28-day is being targeted, it would be approximately 33.5 N/mm^2 for concrete with 0 % fly ash and 0 % quarry dust, 35.1 N/mm^2 for concrete with 5 % quarry dust and 7 % fly ash, and 35.6 N/mm^2 for concrete with 10% quarry dust and 22% fly ash.

From the above discussion, it is apparent that the concurrent use of the two materials is possible, causing environmental, monetary, and some durability benefits, while preserving the workability and slump requirements of the concrete mix. Gaining the required strength at 28-day age even though fly ash is included is feasible for all contents of fly ash and quarry dust tested. However, the loss of early strength (at 3-day age) due to the inclusion of 30 % fly ash has not been entirely compensated by the inclusion of up to 45 % quarry dust. Similarly the loss of strength at 7-day age due to the inclusion of fly ash has not been entirely compensated by the inclusion of up to 45 % quarry dust. The loss of strength at 3-day age and 7-day age due to the inclusion of 15 % fly ash can be fully negated by the inclusion of quarry dust.

However, making quantitative statements regarding the ability to use fly and and quarry dust concurrently is hampered by the variability of fly ash, even from a single batching plant [3]. Similarly, the presence of very fine particles in the fine aggregate causes the cement to disperse and increases hydration [8]. Therefore, two approaches are present to generalize the research showed herein for any fly ash and quarry dust. One approach would be to develop a large database of test results so that many types of fly ash and quarry dust are covered. Another, more practical solution may be to carry out limited testing on a particular fly ash and quarry dust that is to be used at site. The data presented in this paper may be valuable in estimating the ranges where substitution is practicable. The use of the second approach over a period of time, and the publication of the results obtained will lead to the data needed for the first approach being automatically generated.

5. Conclusions

Fly ash is a byproduct that can be used in concrete to obtain durability, cost, and environmental benefits. However, its use has a drawback in that early strength is adversely affected. This is due to the slower hydration of fly ash than cement. Quarry dust is a byproduct of quarrying, crushing, and sieving aggregate. It is a very good replacement of river sand, which is in short supply currently. However, the use of quarry dust causes a loss in workability of concrete. This paper looked at the concurrent use of the above two byproducts, with the expectation that the decrease in early strength by the addition of fly ash is ameliorated by the addition of quarry dust. The decrease in workability by the addition of quarry dust is reduced by the addition of pulverized fuel ash. The loss in early strength due to the addition of 15 % fly ash can be completely negated by the addition of 30 % quarry dust. The strength at 28-day age has not been adversely affected at all by the addition of up to 30 % fly ash. The addition of quarry dust causes a loss in slump; though such loss in slump can be significantly reduced by the addition of fly ash.

Abstract

As a developing country, Sri Lanka has already launched major development projects such as highways and major road development projects, airport projects, harbour expansion projects and other larger construction projects, therein utilizing undesirable grounds due to limited spacious land. Normal practices such as removing and replacing of soil as well as pile foundations in overcoming undesirable conditions of ground may not be economically and environmentally feasible for a country like us. At the same time, solid waste management is becoming a major concern all over the world as it appears with many issues. Waste reduction, reuse and recycle have become major issues in recent days. As a major coconut producing country in the world, Sri Lanka produces annual net waste of coir dust around 527,800 tons [1].

Having considered the means of reducing and optimizing waste in a useful manner, the applicability of soft ground improvement with an introduction of coir dust in vertical drains as a filling material with sea sand was studied in this research. Permeability characteristics of mixed materials of coir dust and sea sand as well as sea sand alone were analyzed and the consolidation behaviour of high plasticity clay with vertical drains under two conditions, vertical drain filled with sea sand and the drain filled with mixed materials as well as without vertical drains were analyzed. It was observed that the coefficients of permeability of mixed samples were within the range of 10^{-2} (cm/s), which is a typical value for sand drains. The consolidation experimental results showed that with the introduction of coir dust in vertical drains, coefficient of consolidation of high plasticity clay was increased compared to the case without vertical drains.

The optimum percentage of coir dust to be used in vertical drains with sea sand as filling materials was figured out as the final outcome by considering permeability and consolidation characteristics as well as the cost analysis for practical applications.

Key words: Coir dust, Consolidation, Ground improvement, Sand, Vertical drains, Waste reduction

1. Background

Sri Lanka has encountered undesirable ground conditions with major development projects such as Southern highway, Katunayake highway, major road development projects, Weerawila airport, Hambantota harbour project, Colombo port development project and other larger construction projects. Normal practices such as removing and replacing of soil as well as pile foundation in overcoming undesirable conditions of ground may not be economically and environmentally feasible for a developing country like Sri Lanka. At the same time, solid waste management has become a major concern all over the world as it appears with many issues such as aesthetic appearance, financial problems in removing and treating, loosing an income and affecting human health etc. Hence, waste reduction, reuse and recycle have become major issues recent days. As a major coconut producing country in the world, Sri Lanka produces annual net waste of coir dust about 527,800 tons (i.e. 2150 m3) [1]. Since coir dust is a waste, it is needed to seek the possibilities of using profitably so that it will minimize some of waste problems in Sri Lanka.

Figure 1: Coir dust dumped aside at Hikkaduwa

Coir dusts are huge wastes and one of the major environmental problems in the coastal zone of Sri Lanka especially Hikkaduwa and southern coast line of Sri Lanka. It is a national need to utilize these wastes in a productive manner. So far no steps have been taken to use these wastes for the ground improvement in Sri Lanka. Sand drains are commonly used in the ground improvement projects. However, the present situation shows that river sand is a high costly material and a limiting material in Sri Lanka where river sand mining has become a major environmental issue. At present, one cube of river sand costs around Rs. 6000 whereas purified sea sand costs around Rs. 3550 mainly in suburban areas, especially in Colombo [3]. Therefore, it is a timely needed investigation to search whether coir dust can replace some amount of sand which is used in the sand drains.

Weak soils such as soft clay and peaty clay are low permeable and have high water content and thus cause excessive settlement when subjected to loads. While ground improvement helps to reduce settlement, increase the bearing capacity and decrease permeability etc., some ground improvement methods like preloading alone for the types of weak soils takes long time to get consolidated but preloading with vertical drains together accelerates the consolidation process.

2. Ground improvement techniques

It is obvious that structures should be constructed on good quality ground. The ground conditions of construction sites due to lack of suitable ground, however, have become worse than ever during recent decades throughout the world. It is often encountered to dredged soils, highly organic soil ground, loose sandy ground when any type of infrastructures is constructed, where large ground settlement, stability failure is anticipated. Lot of ground improvement techniques have been developed and applied in many construction projects. They can be classified into four categories generally as replacement, drainage, densification and admixture stabilization [4].

Under drainage, compression of soft soils prior to construction by means of static loading is widely applied in practice to achieve the required consolidation and proper strength increase, if sufficient time is available. In the method, a pressure (preload) equivalent to or exceeding a contact pressure of superstructure is applied to the ground in advance of the construction of superstructure. The consolidation of soft soil by the preload will increase the shear strength of the soil and hence reduce the residual settlement. Normally such a preload can not be applied all at once to soft ground. Thus, the preloading must be performed in several stages while confirming the strength increase of the ground.

In accelerating the consolidation of low permeable soil, the existing techniques are:

1. Preloading on ground surfaces.
2. Preloading with sand vertical drains.
3. Preloading with prefabricated vertical drains.

The slow rate of consolidation of a loaded cohesive soil is accelerated by providing horizontal drainage in addition to the normal vertical drainage by means of installing vertical drains, commonly use sand drains. The vertical drain method has been frequently adapted to gather with the preloading, surcharge or vacuum method to accelerate the rate of consolidation by shortening the drainage path. In general, vertical drains have been used with pre-compression technique on a wide variety of applications to increase the rate of consolidation of clay, results in a reduction of time required for primary settlement to take place and the increased rate of gain in shear strength of the clay enables the load to be applied more rapidly.

Sand drains are vertical columns of sand or other pervious material inserted through a compressible stratum. They enhance consolidation process by decreasing the drainage path and quite often taking advantage of a higher coefficient of consolidation in the horizontal direction and provide supplementary outlets for the expelled pore water. The Sand drains are mainly used in consolidation of extensive areas of loading such as airport runways, highway embankments, large storage areas and reservoirs etc., over compressible soils to ensure that most of the settlement will occur during and not after the construction. The diameter of sand drains vary in practice from 300mm to 600mm and the spacing vary from 1.5m to 4.5m. To be effective, the spacing of sand drains should be less than the thickness of the consolidating layer. The depth of sand drain is governed by the sub soil conditions such as the depth of the firm layer below the ground surface. Perhaps sand drains have been installed to depths of up to 45m [10].

3. Ground improvement using wastes

Different kinds of waste materials were used in ground improvement in the world such as oyster shell as mixed material of sand compaction pile (Okumura, 1995), wood chips as mixing material for back fill of retaining walls (Pradham, 1993) [7 and 9] and particularly coir dust in different applications.

Coir dust is very similar to peat in appearance. It is light to dark brown in colour and consists primarily of particles in the size range 0.2-2.0 mm (75-90%) [5 and 6]. Cresswell, G.C. (1992) has done studies on coir dust. According to his studies, coir dust is a spongy, peat like residue from the processing of coconut husks for coir fibre. Also known as coco peat, it consists of short fibre (<2mm) around 2-13% of the total and cork like particles ranging in size from granules to dust. Coir dust strongly absorbs liquid and gasses. This property is due in part to the honeycomb like structure. Coir dust is also hydrophilic (attract water) which means that moisture spreads rapidly over these surfaces [2]. Coir dust has better capillary wetting properties. Capillarity is the property that enables water to be drawn from a saucer or a capillary bed towards the top of the post. Capillarity is needed to distribute moisture already absorbed. In this way, it influences the maximum rate water from surround is absorbed as it drains throughout mix, the water retention efficiency. Therefore, coir dust can help to establish a capillary connection to fully wet the mix.

Non woven coir used in the manufacture of basket liners, mulching mats, grow sticks, cultivation mats for plants, roof green applications, portable lawn or instant lawn and many more applications. Non-woven erosion blanket protects the soil from effective erosion and creating microclimates and mulching action. The blankets will be much suited for dry lands and low fertile soil. The applications are road embankments; rail embankments, river embankments and hill slide slopes [8].

In Sri Lanka only 60 to 65% of annual yield of coconut husks is used for coir products with no waste and the remaining 35 to 40% is totally a waste. A coconut husk with an average weight of 350g consists of 150g of coir fibre and 200g of coir dust. One of the special features of coir fibre is that its durability which is unlimited under dry conditions and about 2 to 5 years under wet condition. Another important factor is coir dust has a moisture capacity of about 550% (Information from Industrial Development Board, Sri Lanka). Coir dust accumulates in large piles or "dumps" outside of the mills, which process the husks for extraction of the industrial valuable long fibres. The high lignin and cellulose content of the pith prevents the piles from breaking down further [5 and 6].

4. Materials and methods

Sampling and Preparation of Materials

The main materials; coir dust, sea sand and clay sample that classified as high plasticity silt (MH) were taken at closed proximity to the Faculty of Engineering, University of Ruhuna, Galle, Sri Lanka throughout the research work. The places of intake of those samples are given in Table 1. The places of intake of coir dust and unimproved clay are shown in Figure 2 and Figure 3 respectively.

Table 1: Details of collected materials

Material	Place of intake
Sea Sand	Coast of Galle fort area
Coir Dust	Nugaduwa Fibre Mill, Akuressa road, Nugaduwa, Galle.
Unimproved Clay	Southern Highway site (Chainage: 15 + 000 from Kurundugaha Hetekma)

Figure 2: Intake of coir dust at Nugaduwa Fibre Mill, Nugaduwa

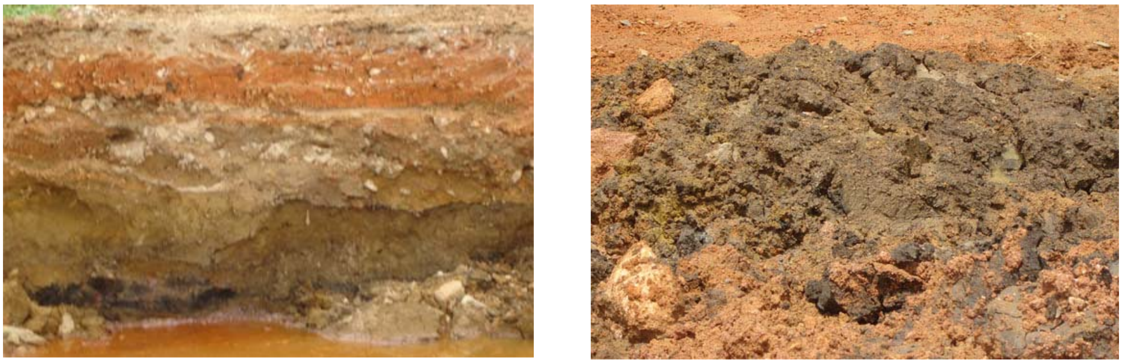

Figure 3: The intake of unimproved clay at the Southern highway (CH: 15+000 from Kurundugaha Hetekma)

Normal field samples kept under general environmental conditions at the laboratory were taken for mixing. Coir dust and sea sand were mixed based on weight and the percentages of individual materials are shown in Table 2. The maximum percentage of coir dust in the mixture was 50% as beyond that percentage the mixture experienced to separate as layers when allowing to get full saturation. The mixing of coir dust and sea sand was done by a mechanical mixer as shown in Figure 4 and each sample was mixed for 5 minutes and the usages of materials for different experiments are shown in Table 3.

Table 2: Percentage of coir dust in mixtures

Mix sample	Percentage of coir dust (%)
1	05 (18)
2	10 (32)
3	15 (43)
4	20 (52)
5	30 (65)
6	40 (74)
7	50 (81)

(Note: Percentage by volume is in brackets)

Figure 4: The mechanical mixer

Table 3: Various forms of material samples for different uses

Sample	Usage
Oven dried	To determine particle size distribution curves for sea sand and coir dust To use in Atterberg limit tests for unimproved clay sample
Fully saturated	To use in permeability analysis (Constant head) To use in consolidation test
Normal field	To mix materials to obtain various mixed proportions

4.2. Determination of Material Properties

Sieve analysis tests were carried out to analyse the particle size distribution of coir dust and sea sand. coefficient of uniformity (C_u) that indicates the spread (or range) of particle size and the coefficient of concavity (C_c) that indicates the shape of the curve between D_{60} and D_{10} grain sizes for both materials were obtained from the grading curves with the help of following equations.

$$C_u = D_{60}/D_{10} \qquad (1)$$

$$C_c = D_{30}^2/(D_{10}\ D_{60}) \qquad (2)$$

where, D_{10} is the diameter at 10% of weights are finer, D_{30} is the diameter at 30% of weights are finer and D_{60} is the diameter at 60% of weights are finer. The particle size distribution curves are shown in Figure 5.

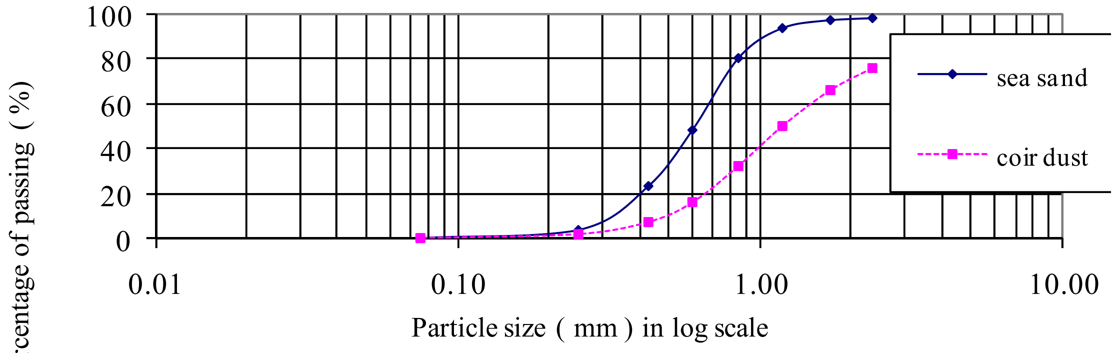

Figure 5 : Particle size distribution curves

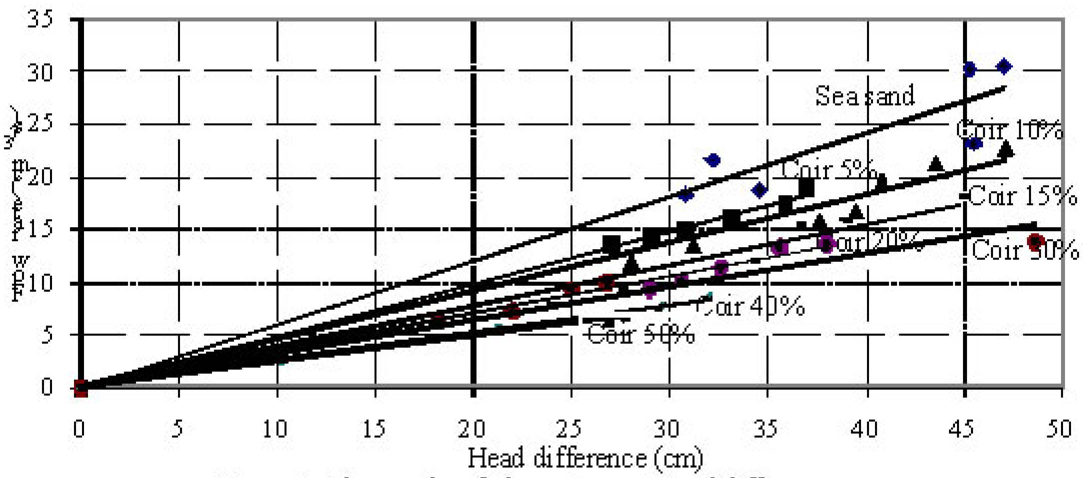

Figure 6: The graphs of Flow rates vs. Head differences

Series of constant head method of permeability tests were done to determine coefficient of permeability of materials due to both materials used for the research works are porous materials. Sea sand and mixed samples of different proportions were analysed under the same test conditions. Materials samples were packed in the apparatus under three layers and each layer was subjected to five blows with a rod while adding same amount of water so that to avoid formation of larger size air voids inside the specimen. Each test was allowed to get fully saturation as water flows through the specimen. Since there was no significant temperature variations observed, each analysis was done under normal room temperature of 30 ^{o}C. Using observation of each analysis the graph of flow rate vs. head difference was plotted as shown in Figure 6.

Laboratory one dimensional consolidation tests were carried out to study the consolidation behaviour and the effect of vertical drains on the settlement of unimproved clay sample. Diameter of the sample tested was 50mm and the thickness was 20mm. Graphical methods (logarithm of time method and square root of time method) proposed by Casagrande and Taylor were used to determine coefficient of consolidation (c_v).

A simple model for the application of vertical drain in the clay sample was prepared with an introduction of a cylindrical hole at the centre of the unimproved clay specimen (Figure 7). Two experiments were done with a vertical drain at the centre of the clay specimen, as one experiment was done as the vertical drain filled with sea sand alone and the other experiment was done as the vertical drain filled with mixture of coir dust and sea sand. As a typical sample, the mixture of 50% of coir dust mixed with sea sand based on weight was tested. The clay specimen without a vertical drain was also analysed to determine the coefficient of consolidation. The coefficient of consolidation was determined by using the following equation.

$$c_v = T_i H^2 / t_i \qquad (3)$$

where; T_i is Time factor, t_i is corresponding time for T_i and H is length of the drainage path.

Figure 7: Introduction of vertical drain in clay specimen

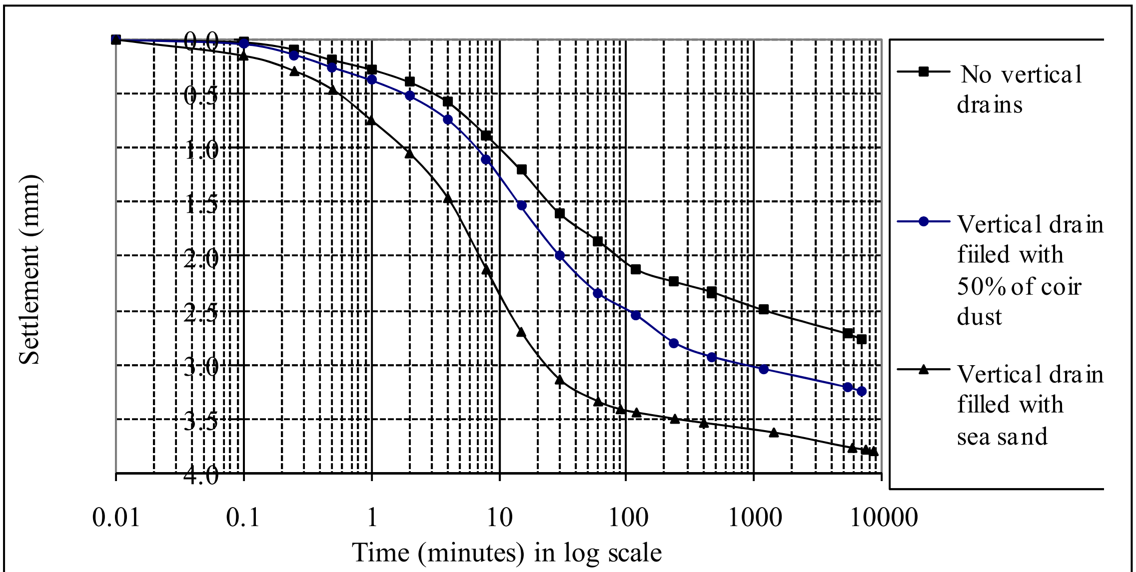

Figure 8: The graphs of settlement vs. log Time

The relevant graphs of settlement vs. time were drawn for three sets of test specimens used for the research works and shown together in Figure 8.

Engineering behaviour of fine grained soils depends on factors other than particle size distribution and it is influenced primarily by their mineral and structural composition and the amount of water in it. Fine grained soils can exist in any several states depending on the amount of water in the soil system. Atterberg limit tests were carried out to classify the type of clay sample used for the research. The plastic limit, liquid limit and plasticity index were determined in order to identify the type of clay and the clay sample was classified according to Unified Soil Classification System.

5. Results

The coefficient of uniformity and coefficient of concavity for both materials have been obtained and summarized in Table 4 and the observations from permeability analysis were processed to obtain coefficient of permeability from the graphs of flow rate (q) vs. head difference (Δh). These graphs were developed for material samples of coir percentages from 0 to 50% mixed with sea sand by weight (Table 2). The coefficients of permeability determined from the graphs in Figure 6 are shown in Table 5.

Table 4: Sieve analysis results

Material	C_u	C_c
Sea sand	2.11	1.04
Coir dust	3.04	0.96

Table 5: The coefficients of permeability

Material samples		k (cm/s) x 10^{-2}
Percentage of coir dust in the mixed sample (%)	0	12.06
	5	09.80
	10	09.08
	15	07.74
	20	07.00
	30	06.40
	40	05.20
	50	04.78

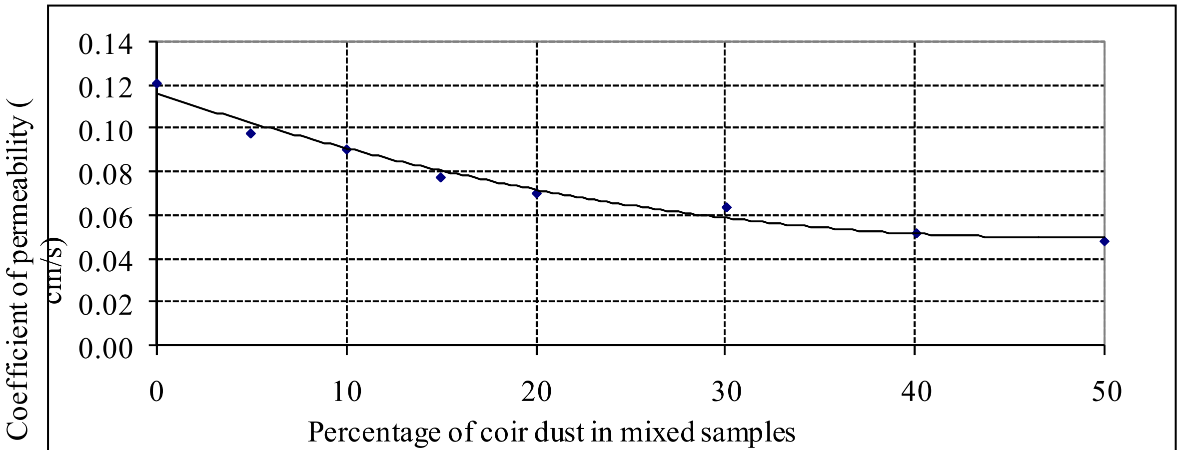

Figure 9: The graph of k vs. percentage of coir dust by weight

The graph of coefficient of permeability vs. percentage of coir dust measured on weight basis in the mixture is shown in Figure 9 and the same graph with the percentage of coir dust measured on volume basis is shown in Figure 10.

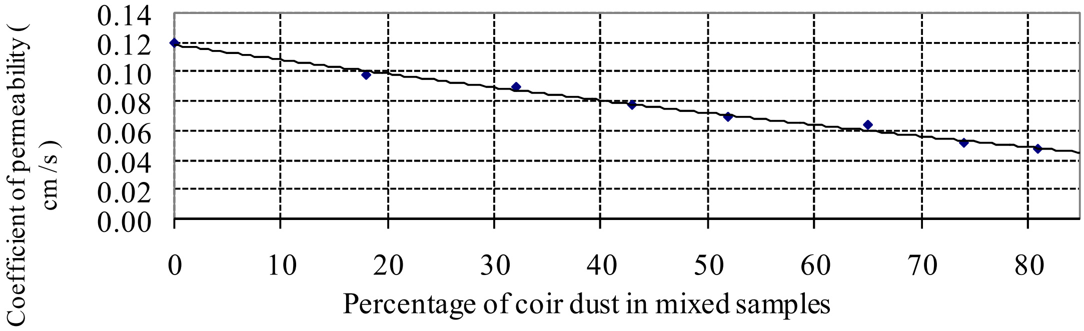

Figure 10: The graph of k vs. percentage of coir dust by volume

The coefficients of consolidation for three test specimens were determined using equation (3) for the graphs in Figure 8 and the results are shown in Table 6.

Table 6: The coefficients of consolidation

Test specimen	c_v (mm^2/min)
High plasticity silt	1.446
High plasticity silt with vertical drain filled with mixture of coir and sea sand	1.973
High plasticity silt with vertical drain filled with sea sand	3.457

The liquid limit, plastic limit and plasticity index were determined from Atterberg limit test and the results are shown in Table 7. The clay used for the research was classified as High plasticity silt (MH) according to Unified Soil Classification System.

Table 7: Results of Atterberg limit tests

Tests	Results (%)
Liquid Limit (LL)	67
Plastic Limit (PL)	40
Plasticity Index (PI)	27

6. Discussions

The permeability tests indicated that the coefficients of permeability of the mixed samples are decreased with increasing of coir dust in the mixture up to around 50% of coir dust based on weight. The 50% of coir dust by weight basis consists of approximately 80% of coir dust by volume in the mixture (Table 2). The coefficient of permeability for sea sand was 12.06 x 10^{-2} (cm/s) and it was 4.78 x 10^{-2} (cm/s) for 80% of coir dust by volume in the mixture. Those coefficient values showed that the introduction of coir dust as a substitution for sea sand in vertical drains did not reduce coefficient of permeability reasonably. Although coefficient of permeability is increased beyond the 50% of coir dust in the mixture, the samples were experienced to separate as layers. Due to practical difficulties to use higher amount of coir dust in the mixture (more than 80% by volume) it is recommended that the maximum coir dust percentage in the mixture applicable as filling materials for vertical drains, can be around 80% by volume.

The introduction of vertical drains for unimproved clay indicated that coefficient of consolidation increased significantly (Table 6). The vertical drain filled with sea sand gives a faster consolidation and it is more than twice as without vertical drains. The introduction of coir dust in vertical drain reduces the consolidation compared to vertical drain with sea sand but still gives reasonable higher consolidation. The introduction of coir dust in vertical drain is justifiable with time and economic considerations.

The particle size distribution curve for coir dust indicated that the percentage of coir fibres (more than 2 mm) was around 23% (Figure 5). The presence of coir fibres in mixed samples of coir and sea sand increases the durability and strength characteristics of vertical drains.

The justification of introduction of coir dust as a substitution for sea sand as well as for river sand to be used as a filling material for vertical drains largely depends on economical and environmental considerations. Table 8 shows approximate costs involvements for filling materials. Typical dimensions for vertical drains were assumed as 450mm diameter, 5m spacing and 15m depth. The total volume of filling materials per hectare was approximately 950 m^3. It shows that introduction of mixture of 80% of coir dust by volume instead of river sand in vertical drains reduces the cost more than 90% and reduces the cost 80% with compared to drains filled with sea sand.

The maximum amount of coir dust that can be used practically in vertical drains was justified as 80% by volume based. Since coir dust is still a waste in Sri Lanka, the introduction of coir dust in vertical drains reduces the filling materials costs significantly.

Table 8: Cost comparison for filled materials of vertical drains

Cost	Materials		
	River sand	Sea Sand	Mixed sample (80% coir by volume)
Per cube (Rs.)	6000	2000	400
Per hectare (Rs.'000)	2014	671	134

7. Conclusions

Although the coefficients of permeability are decreased slightly with increasing coir percentage initially, it is not significant as coefficient of permeability values are still in the range of 10^{-2} (cm/s) which is considered as a typical value for sand vertical drains. Consolidation tests showed that significant improvement of ground with vertical drains filled with sea sand. Although vertical drain filled with mixture of coir dust (80% by volume) and sea sand was not given the same consolidation rate as drain filled with sea sand, it gave reasonably higher consolidation with mixture of coir dust and sea sand compared to without vertical drains.

The usage of coir nets (or gunnies) in the vertical drains increases the possibility of using higher amount of coir dust in the vertical drains as it helps to maintain the drain dimensions. An application of coir net in vertical drains proposed is shown in Figure 11.

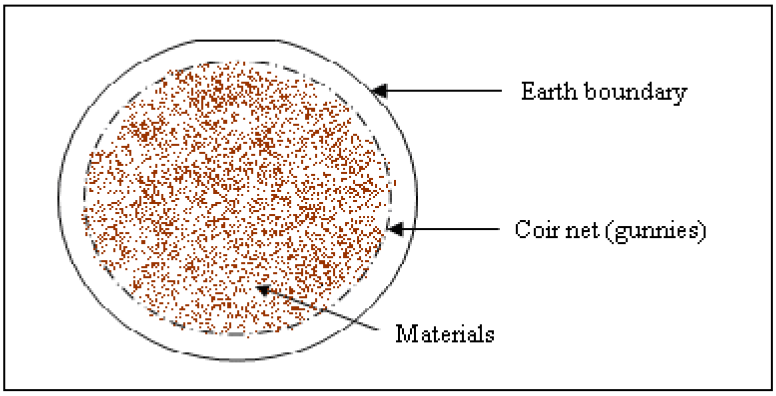

Figure 11: Plan view of a vertical drain covering with coir net

The required percentage of coir dust in the mixture can be determined using the graph of coefficient of permeability vs. percentage of coir dust (Figure 10) in the designing of vertical drains. The steps should be followed as;

- Calculate the required k for the vertical drain design depending on site conditions.
- Find the appropriate percentage of coir dust in the sample from the graph.
- Necessary precautions such as coir net should be included depending on coir percentage used.
- Proper mixing of coir dust and sea sand should be done.

The introduction of coir dust as a substitution for sea sand in vertical drains saves the cost as well as some environmental problems simultaneously.

8. Acknowledgements

Authors would like to express deepest gratitude to Dr. U.P. Nawagamuwa, supervisor of the project for his guidance and encouragement towards the successfully completion of the project and thanks are extended to personnel of the Faculty of Engineering, University of Ruhuna and outside who helped the authors in numerous ways for the successfully completion of the project.

Abstract

A computer based numerical model, which can simulate the propagation of the tsunami wave, was developed for the coastal area of Galle city. TUNAMI N2, a computer code developed in Japan (2006) was used as the base model. Model includes bathymetry, fault and stability sub modules other than the main module. Bathymetry sub module was used to store all the co-ordinate data of the required area. Fault module was developed to create the initial wave due to the fault with the fault parameters. Stability sub module was prepared to check the stability of the prepared grids. Main module calculates the propagation of the tsunami wave. For that it requires the initial wave due to the fault as well as the prepared bathymetry data. The time series of water surface elevations at the given locations and water surface elevations at the given time steps are the main outputs of the model. Mathlab and surfer software were used for the interpretation of output files in pictorial form. Outputs of the model after applying the parameters of the fault, which caused tsunami in 26 December 2004, were verified with the observations. Under that the water levels in Colombo and highest wave arrival times at south and west coast areas were used. Model results were found to be matched with the observations. The model was applied for different tsunamis with different fault origins with different magnitudes. Different propagation patterns were obtained.

Key words: Tsunami, Earthquake, Propagation, Simulation, Numerical model

1. Background

1.1 Introduction

Gigantic tsunami waves, triggered by an under sea quake in Sumathra, battered Sri Lanka's eastern and southern coastal areas on Sunday 26^{th} December 2004 killing an estimated 50,000 people in what is believed to be the islands worst natural disaster to the date. Of all the countries hit by the tsunami, Sri Lanka has undoubtedly suffered the most byway of loss of livelihood, loss of housing and public infrastructural facilities. With the huge disaster of the recent tsunami most people in Sri Lanka tend to study about the tsunamis. Even though tsunamis are new to Sri Lanka countries like Japan, Indonesia and USA frequently face this type of tsunamis. As the awareness increases, damage due to the tsunami disasters are expected to reduce. It will be useful for Sri Lanka, if tsunamis can be predicted early. Further the knowledge about different tsunami scenarios will also help to reduce the risk. This research includes a preparation of a computer based numerical model which can forecast the tsunami wave propagation due to an earthquake around the coastal area of Galle City.

1.2 Literature review

Several attempts of tsunami propagation modeling were reported in literature. Several computational models are being used in the National Tsunami Hazard Mitigation Program, sponsored by the National Oceanic and Atmospheric Administration (NOAA) to produce tsunami inundation and evacuation maps for tsunami hazard zones in USA. These models are also used to design and operate early warning systems (Titov and Synolakis (1998)). The computational models include MOST (Method Of Splitting Tsunami) developed originally by researchers at the University of Southern California, Liu et al. (1994), COMCOT (Cornell multi-grid coupled tsunami model) developed at Cornell University and Imamura (1996) TUNAMI developed at Tohoku University in Japan. Most of the above models adopt a modified leapfrog finite-difference scheme to solve (both linear and nonlinear) shallow-water equations.

However most of these results require further validation by experimental results. Even though there are different types of modeling for tsunami propagation coastal area near to Galle city never had any of these modeling for the tsunami propagation as the tsunami had not happen in Sri Lanka during last few decades when the modeling of tsunami propagation developed rapidly.

2. Methodology used in developing the model

2.1 Theoretical background of tsunami propagation modeling

Tsunamis, which are mainly generated by the movement of sea bottom due to earthquakes, belong to long waves. In the theory of long waves, the vertical acceleration of water particles are negligible compared to the gravitational acceleration. Consequently, the vertical motion of water particles has no effect on the pressure distribution. It is a good approximation that the pressure is hydrostatic.

Based upon these approximations and neglecting the vertical acceleration, the equations of mass conservation and momentum in the three dimensional problem are expressed by shallow water wave theory.

Based on the shallow water wave theory the computer code has been prepared. Mainly it consists of 3 sub modules named Fault, Bathymetry and Stability other than the main module, which simulates the tsunami wave propagation.

1.1 Preparing bathymetric data around Galle city area

Bathymetry data of Indian Ocean covering Sri Lanka and possible tsunami generation locations were obtained from the etopo2 satellite data. Bathymetry data were stored as randomly spaced data files and those were converted into evenly spaced grid files using surfer as the first step.

Computational domain includes the origin of the tsunami and the area of interest (Galle in Sri Lanka) as shown in the Figure 1 and Figure 2.Through a mathlab code the selected area was taken as grid A in ASCII format. Since there is a larger number of values in order to run the program faster a nested grid system was used as shown in the Figure 3 and Figure 4.

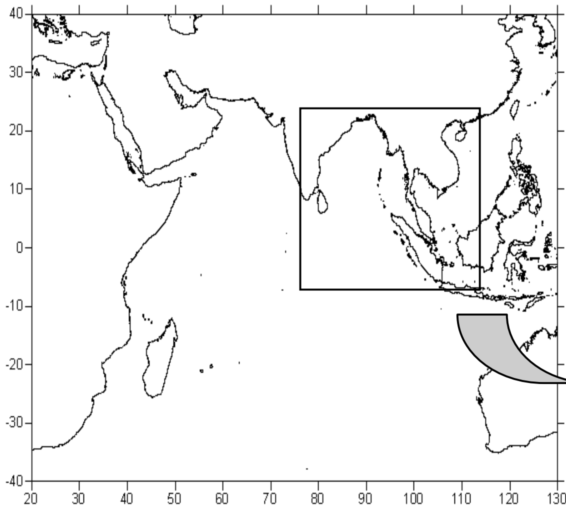

Figure 1: Map obtained from Etopo2

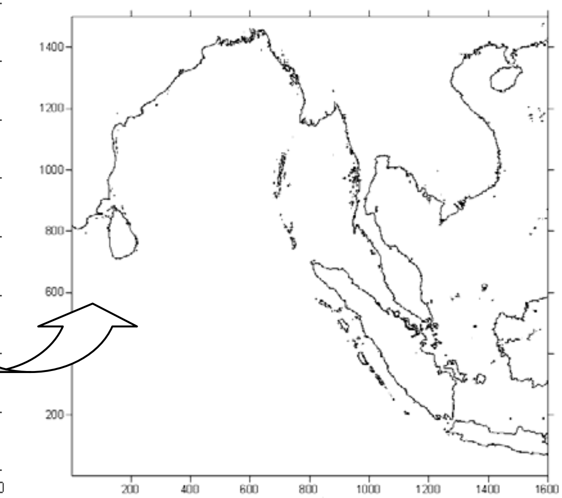

Figure 2: Selected areas for the model (Grid A)

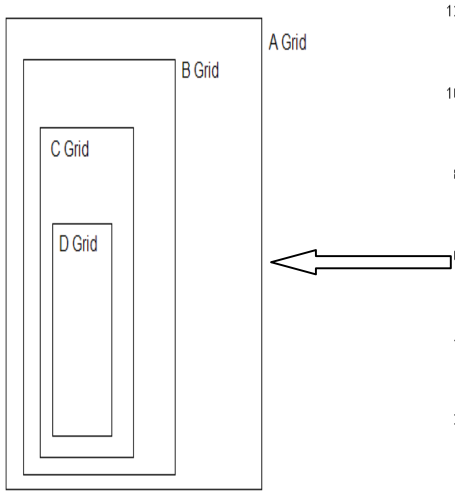

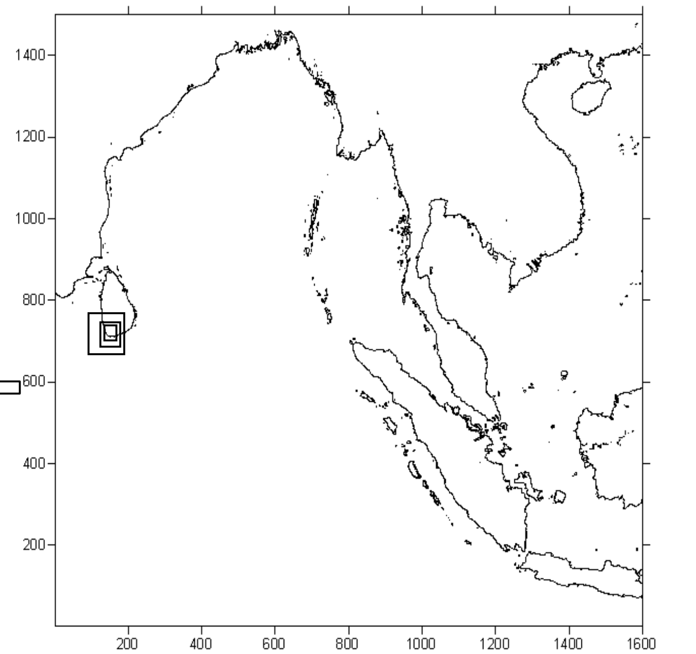

Figure 3: Nested grid system

Figure 4: Nested grid system in the map

2.2 Preparing sub modules

Apart from the main module in order to enter the information of the tsunami, several sub modules have to be prepared. Outputs of those sub modules are the inputs to the main module. Those are the computer codes to enter fault data and to check for stability.

2.2.1 Sub module fault

This is the module, which generates the initial wave due to the earthquake. Here the fault parameters are given as inputs. Using the input information it generates the initial disturbance of the water column. That was entered into the main module as an input. Fault parameters of December 2004 are as in Table1.

Table 1: Fault parameters-26th December 2004

Parameter	Value
Origin	3.30N,95.78E
Slip Magnitude(m)	20
Fault Length(m)	500000
Fault Width(m)	150000
Depth of the Fault(m)	20000
Dip Angle(degrees)	11
Rake Angle(degrees)	90
Strike Angle(degrees)	370

2.3 Preparing the main module

This module is prepared to calculate the propagation of the wave and run-up. It will do the numerical simulation with linear wave theory in deep sea, shallow water wave theory in shallow sea and on land. The main outputs of the model are time series of water surface elevations at given gauge locations and the water surface elevations in the given time steps.

2.4 Interpretation of output files

Since this is a numerical model all the results obtained as data or grid files. However in order to present the results effectively those are needed to be converted into graphical form, which can be easily visualized. Mathlab and surfer software are used to convert output data files into graphical form. Figure 5 to 10 are the propagation of the tsunami wave due the earthquake occurred in 26th December 2004.

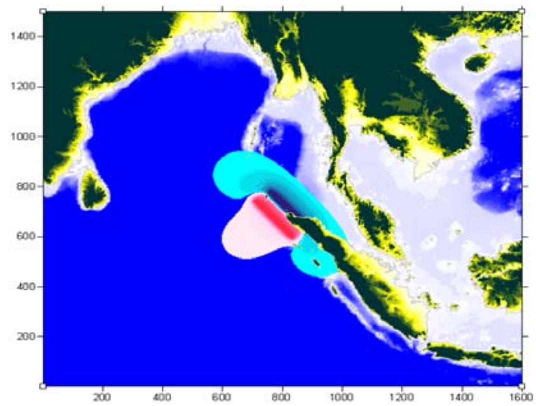

Figure 5: Just after the earthquake

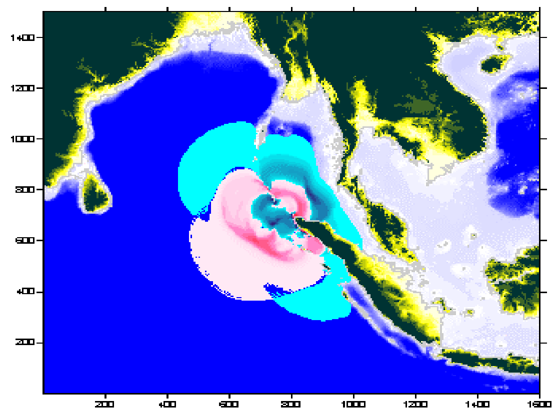

Figure 6: 0.5 hour after the earthquake

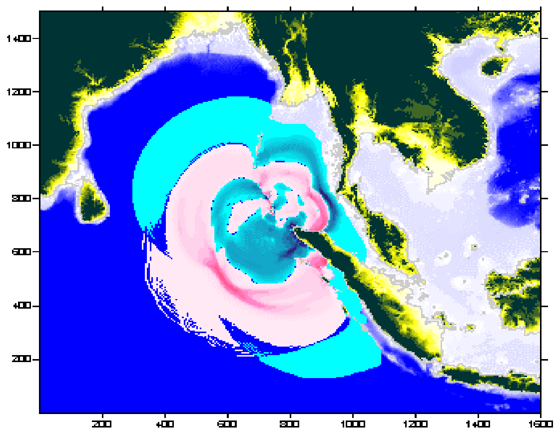

Figure 7: 1 hour after the earthquake

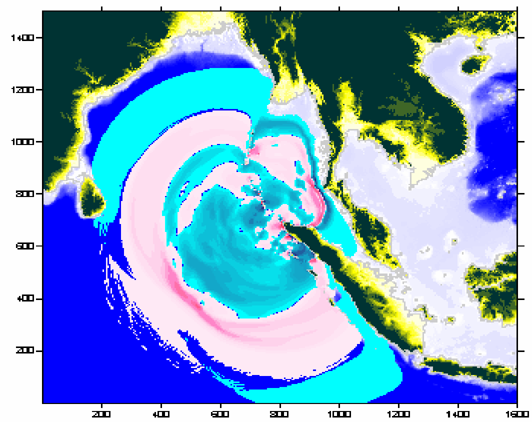

Figure 8: 1.5 hours after the earthquake

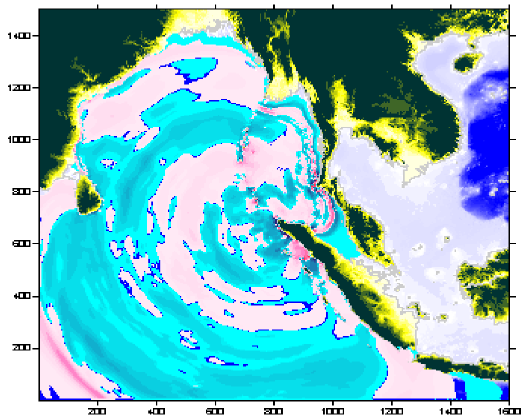

Figure 9: 2.0 hrs after the earthquake

Figure 10: 3.0 hours after the earthquake

3. Verification of the model

Here the values obtained from the model with the observed data (arrival times of the waves to the shoreline and the way they have arrived) during the recent tsunami December 2004 were compared. The propagation of the wave within nested grid system was clearly understood with the model. Observed water surface elevation during the December 2004 tsunami was available only at Colombo and that data was used for model verification.

As shown in Figure 11 the measured values and values obtained from the model for Colombo area was plotted. By comparing the two values obtained from the model and measured values obtained from Colombo the shape is nearly same. However there is slight mismatch in some of the figures. It can be due to the approximations used to simplify the governing equations. The values reasonably match up to 3.5 hours. However after that there are changes. The reason for that is, after 3.5 hours the reflected waves from India and Maldives have arrived. For the measured values it is accounted but for the values obtained from the model those were not accounted.

Other than that the first wave arrival time and highest wave arrival time are exactly matching with the model results as shown in the Table 2. The sea level drop due to the oncoming tsunami wave was clearly understood with the plots. Wave shoaling is always associated with water level reduction in the front side. In Galle area, Balapitiya, Hikkaduwa etc there were that type of waves before the arrival of tsunami wave. From the model also the same type of waves were obtained.

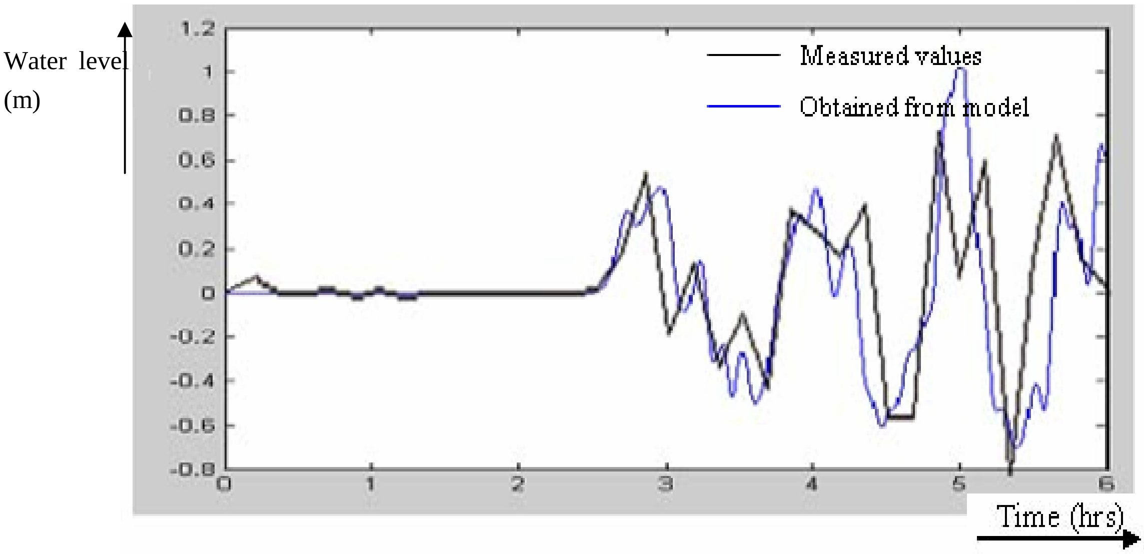

Figure 11: Water levels at Colombo - (Source: Lanka Hydraulics Institute)

Table 2: Highest wave arrival times to Sri Lankan coastal areas

Area	Real Values	Obtained From Model
Hambanthota	9.20 a.m.	9.15 a.m.
Matara	9.40 a.m.	9.45 a.m.
Galle	9.50 a.m.	9.30 a.m.
Hikkaduwa	10.0 a.m.	10.05 a.m.
Benthota	11.05 a.m.	10.05 a.m.
Kaluthara	11.30 a.m.	10.10 a.m.

After verifying the model it can apply to anywhere in the world with certain modifications. Since the model gives mostly correct values the model could be verified.

4. Study the different propagation patterns around Galle city area

Tsunami generation and propagation due to earthquakes with different fault parameters were studied. Different propagation patterns were obtained. Table 3 shows one of the possible tsunami source, which was used to study the propagation patterns.

Table 3: Source parameters

Fault parameters	Values
Co-ordinates	2.076N,97.025E
Fault depth	30 km
Length of fault plane	200 km
Width of fault plane	150 km

Strike, Dip ,Slip	300°,13°,90°
Dislocation	15m

(Source: USGS 2007)

Figures 12 to 17 present the propagation of the tsunami wave due to an earthquake as given in Table 3 which was different to that of earthquake occurred on 26 December 2004.

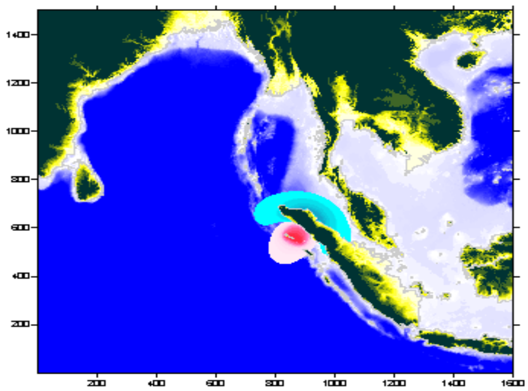

Figure 12: Just after the earthquake

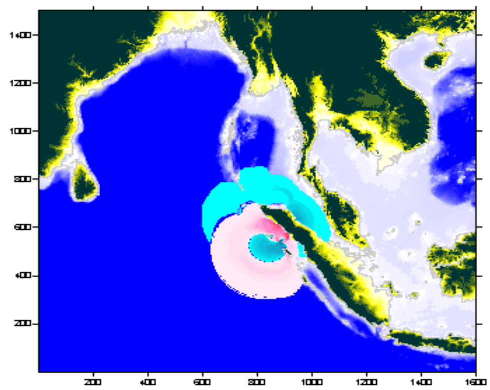

Figure 13: 0.5 hours after the earthquake

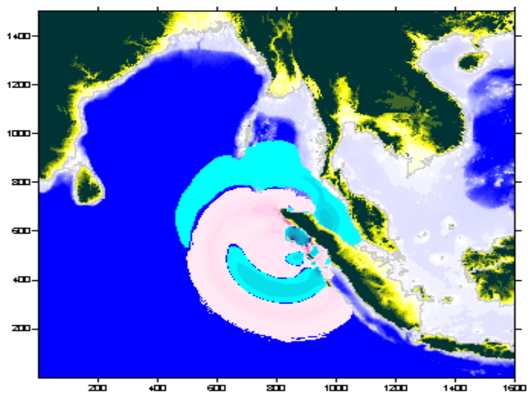

Figure 14: 1 hour after the earthquake

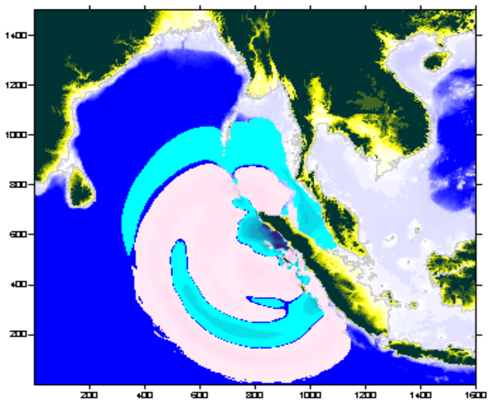

Figure 15: 1.5 hours after the earthquake

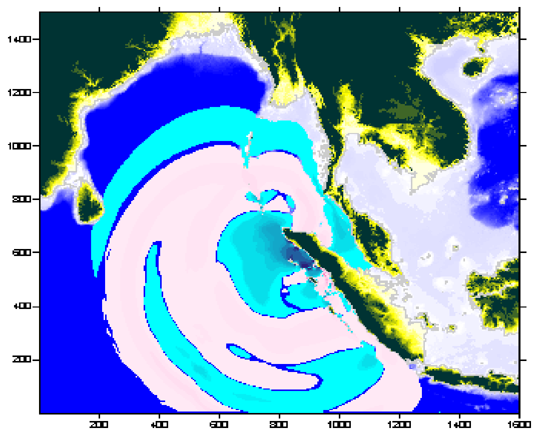

Figure 16: 2.0 hours after the earthquake

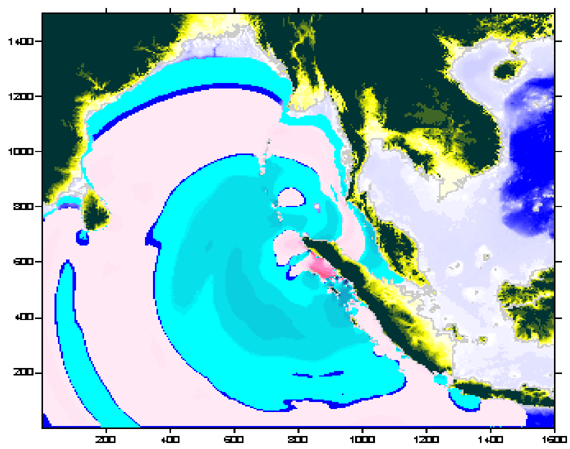

Figure 17: 3.0 hours after the earthquake

5. Conclusions

The model successfully simulates the propagation of the tsunami wave due to an earthquake. By replacing the high resolution near shore bathymetry data for Galle area inundation levels in the area could also be obtained. As the large number of bathymetry data was used for the model the nested grid system was used so that the program runs faster.

The model correctly shows the propagation patterns of the wave. As given in above Table 2 the highest wave arrival times were nearly same as those simulated by the model.

Other than that, the water surface elevation in the Colombo was obtained for 6 hours period due to the tsunami from the model. Those values were compared with the measured values in Colombo area. The shape of the graph and the values are nearly correct as shown in Figure 11.

As the grid size was larger the exact values could not be obtained. Further, because the reflected waves from India and Maldives were not taken into account as that area is not in the selected area.

Although a very coarse grid size was adopted for the numerical simulations, numerical results match with the field survey data as the arrival of highest waves, different characteristics of waves fairly well along the southern coastlines of Sri Lanka.

By replacing high resolution near shore bathymetry data in grid D inundation levels also could be obtained. Since the more detailed high resolution topography data is not available for Galle city area inundation patterns is unable to present in the paper. However the facility is there in the model and by replacing the high resolution near shore bathymetry data inundation heights also can be obtained. With that certain precautions can be taken in order to safeguard the lives from tsunami in Galle city area.

The Ecological Restoration of Coastal Terrestrial Ecosystems in Southern Sri Lanka

Cher N. Peterson,
Institute for the Environment, Brunel University, Uxbridge, UB8-3PH (UK)
(Email: cherpeterson@hotmail.com)

Abstract

This paper examines six different post tsunami ecological restoration projects conducted along the southern coast of Sri Lanka in 2006 by various Sri Lankan organisations. Eighteen months after the devastating 2004 tsunami, Sri Lanka's southern coastal zone has seen the replanting of an array of coastal vegetation ranging from *Rhizophora apiculata*, to *Borassus flabellifer* to *Cocos nucifera*. Local, national and inter-agency partnerships have been established as well as the formulation of local driven collaborative environmental restoration projects involving local communities Centred on the principles of ecological restoration, projects ranged from small and large scale mangrove replanting and sand dune stabilisation, to the re-establishment of home gardens. In addition to re-establishing nature's protective defences and acting as a natural barrier against possible future natural hazards, efforts are being made to realign the balance of damaged ecosystems by planting a selection of plants, which if utilised and managed sustainably can provide a wealth of socio- economic opportunities to coastal communities.

Keywords: Community, Restoration, Sri Lanka, Sustainable, Tsunami

1. Introduction

The past 250 years have seen in excess of 60 tsunamis in the Indian Ocean with nine of these tsunamis affecting Sri Lanka (excluding the 26th December 2004 tsunami) [4], [11]. Four of these tsunamis occurred in 1762, 1847, 1882 and 1946 in the Bay of Bengal impacting the eastern coast of Sri Lanka, three were related to earthquakes near the Nicobar Islands, India and two were triggered off the coast of Pakistan in 1819 and 1945 [11]. On the 26th of December 2004 at 00:59 GMT a 9.0 magnitude earthquake struck off the coast of Sumatra, Indonesia triggering a series of tsunami waves directly impacting coastal areas of Indonesia, Sri Lanka, Bangladesh, India, Thailand, the Maldives, Kenya, Malaysia and Mauritius resulting in the deaths of over 200,000. The worst natural disaster to have befallen Sri Lanka since historical times, the tsunami claimed over 35,000 lives, displacing over a million people and destroying homes, hospitals, roads and railways and other infrastructure [24].

As a result of the tsunami waves, the Sri Lankan coast suffered devastating ecological damage to more than two thirds of its coastline, with damage varying greatly and inconsistently from place to place [18]. Reasons for this included the differences in on-shore and off-shore coastal geomorphology, the presence/absence of off-shore coral reefs, the presence, maturity and width of mangrove belts and the location of human settlements [12], [26]. Depending on local land forms, the physical area of the tsunami impact varied from high-tide level to 1km inland [10]. The disaster was unusual in the sense that the total destruction of some areas was found metres from unharmed areas [23], [24]. Areas with estuaries and natural and artificial lagoons acted as channels for the entry of seawater, facilitating damage and leading to the intrusion of saltwater far inland; in numerous cases, several kilometres inland, leaving the land salinated damaging home gardens, agricultural crops and coastal vegetation such as *Cocos nucifera* and *Borassus flabellifer* in the process [13], [22], [23]. The tsunami struck ecosystems, previously strained by unsustainable practices including habitat destruction, over fishing, and the detrimental destruction of coastal wetlands and mangroves for prawn culture. Together these activities have threatened the state of biological diversity and the livelihoods of local communities [17], [12]. Other affected ecosystems include coastal sand dunes, lagoons, maritime grasslands, as well as environmentally sensitive areas including national parks, and special area management sites (table 1).

Coastal ecosystems have evolved over hundreds, and even thousands of years, adapting and evolving with natural catastrophes and disasters. The sheer magnitude of the 2004 tsunami had the potential to disrupt the natural stability of these ecosystems, yet the impact of the tsunami lasted less than thirty minutes, and initial environmental assessments concluded that the damage to Sri Lanka’s coastal ecosystems was disproportionately less despite the severity of impact on human life and infrastructure, with no irreparable damage occurring to terrestrial ecosystems [9], [18], [24].

Table 1: “Ecological impacts of the tsunami on coastal terrestrial ecosystems in Southern Sri Lanka” (Sources- Atapattu & Tharme 2005, Fernando et al.2006, IUCN 2005, MENR 2005, UNEP-MENR 2005)

Vegetation	Impacts
Mangroves	Various degrees of degradation and loss. Frontline and mangrove strips less than 10m devastated, broader stretches less affected. Sponge effect of mangrove swamps lessened damage. Large healthy mangroves seen toppled as far inland as 700m metres from the beach. Deeper mangroves left intact. Dense mangroves converted tsunami waves into a flood.
Sand dunes	Large, vegetated dunes absorbed wave energy and acted as a barrier stopping tsunami intrusion. Where dunes were disturbed, impact of waves was disastrous e.g. - a hotel resort, for the purpose of better scenic views, removed some of the dunes seaward of its hotel, the hotel was destroyed.
Pandanus tectorius and *Borassus flabellifer*	Seashore *Pandanus* cover reduced by up to 75%. Inland *Borassus flabellifer* less affected. Difficult to establish protective function as many settlements with interspersed palms suffered severe damage to houses.
Lagoons and Estuaries	Absorbed tsunami energy, but in doing so lost banks were scoured and lost seasonal sand barriers. However have recovered quickly. Various shifts in salinity concentration, Kalametiya lagoon transformed from a closed system separated from sea by sand bar to

	an open system- part of sand bar breached and now removed. Tsunami waters plugged estuaries.
Coastal waters	Sedimentation/turbidity of costal waters leading to algal blooms.
Casuarina plantations	Acted as an effective barrier in buffering destructive tsunami waves, although vulnerable to damage. Had little protection value on their own, although in places helped to stabilise sand dunes.
Beaches	Ecological impacts were severe where the beach was narrow and low in height. Scoured and eroded losing width and height from tsunami back-wash. Large amount of debris deposited on beaches.
Home gardens	Salt water intrusion destroyed production capacity due to high saline conditions. Up to 10 cm of topsoil was lost Approximately 27,710 home garden units were washed away or affected.
Other vegetation	Intrusion of seawater affected coconut plantations and agricultural crops (especially paddy). Salt water intrusion affected function and biodiversity in broader soil ecosystems. Sand casting occurred on productive lands.

The southern Sri Lankan coastline is characterised by sand dune systems vegetated with indigenous and alien trees (for example Casuarina), shrubs, creepers, occasional mangrove swamps and forests, *Cocos nucifera*, *Borassus flabellifer* and cashew plantations [1], [7]. Together, all these ecosystems provide coastal communities with a host of valuable services and goods including a resource of food and livelihoods, erosion control and sediment trapping, climate modification (micro and macro), habitats for wildlife and endangered species, biogeochemical cycling (nutrients, carbon sequestration), fuels and water (quality and quantity) and pollination [8], [19]. When the tsunami waves struck these services and goods were severely disrupted and in some cases, totally destroyed (Shanmugaratnam 2005).The geomorphological effects and physical characteristics relating to the impacts of the tsunami and the destruction caused to the built environment and society have been well documented [10], [12], [22], [23], yet few studies have analysed the effect of the tsunami on natural terrestrial ecosystems [10]. Post tsunami environmental issues chiefly consisted of waste management issues such as the clearing and removal of solid waste, focusing primarily on the immediate relief effort that was required, biodiversity and coastal ecosystem issues were not given due consideration [6], [18], [22]. Although at the time this was seen as an understandable focus and urgent priority, the most pressing issue to be addressed, eighteen months after the tsunami relates to the post tsunami restoration and rehabilitation of coastal ecosystems [1]. This paper reports research which evaluates this with regard to one key research question: What post tsunami activities are being conducted in southern Sri Lanka to restore coastal terrestrial ecosystems?

2. Methods

Research was conducted from April to June 2006 with the southern coast of Sri Lanka chosen as the focus of the research. Due to the physical impact of the tsunami waves being greatest on the East coast of Sri Lanka, numerous projects involving the rehabilitation of coastal greenbelts were established there in the aftermath of the tsunami. However due to increased violence and rising tensions between the Liberation Tigers of Tamil Eelam and the Sri Lankan government, it was deemed too risky to travels to these areas and so firsthand evaluation of these schemes was not possible. Therefore the southern coast was chosen as the basis for the fieldwork, with six projects being identified along the South and South-Western coast (table 2).

It was contented that by analysing six projects, a reasonable cross section of environmental restoration projects in Southern Sri Lanka would be reflected.

HUMAN RESOURCE ENVIRONMENT PROTECTION ORGANISATION

Sand dune stabilisation and vegetation planting

Research was conducted using qualitative methods, namely in-depth, face-to-face semi structured interviews and visual observation. Interviews were used to ascertain participants' role and views regarding the ecosystem projects. Participants ranged from local residents and business owners to government officials and NGO representatives. In total twenty people were interviewed- one representative each from the IUCN and the CCD, twelve local residents (two residents; one female and one male from each project), and one representative from each of the six organisations in charge of implementing the environmental restoration projects. Guided by project representatives and local residents, visual field observations were undertaken to assess firsthand the state of the restoration process. Observations were supported by photographical documentation of fieldwork sites and hand written notes with secondary data incorporated into the research in the form of maps, journal papers, environmental assessments and policy documents.

3. Results

The Sri Lankan government together with the assistance and support of the local and international community has launched a major restoration and rehabilitation programme in a bid to bring the country to a point of recovery from the devastating effects of the tsunami. As a result, broader strategic efforts are being made by government departments, NGOs, INGOs, and Community Based Organisations (CBOs) in restoring and rehabilitating the vegetation along coastal areas affected by the tsunami [20].

3.1 The Coastal Reservation Green Belt (CRGB) Project

The Coastal Reservation Green Belt (CRGB) project was founded as a direct result of the tsunami and centres around the establishment of a 100m green belt around the island. The project's overall objective is to rehabilitate ecosystems damaged in the tsunami by greening and restoring the coastal reservation [21], [25]. The CRGB strategy has been adopted in the hope that it will protect the shoreline from coastal erosion, curtail the impacts of natural hazards including cyclones, hurricanes, and tsunami to the environment, development, infrastructure and coastal communities and support and sustain coastal community livelihoods by planting commercially viable plant species. The Coast Conservation Department (CCD) is overseeing the CRGB helping to initiate many short and long term projects designed to rehabilitate, protect and conserve Sri Lanka's coastal belt [21]. All post tsunami coastal rehabilitation projects/schemes in the country are part of the CRBG project and require the permission of the CCD. This island wide initiative, estimated to cost approximately £6.7 million pounds is implemented by the Central Environment Authority (CEA), Urban Development Authority (UDA), Coconut Development Board (CDB), Forest Department (FD) and Horticultural Department (HD) [16]. This figure covers plant materials, maintenance of nurseries, awareness and educational programmes, staff training, site selection and surveys and project administration costs. As of July 2006, under the scheme, more than 25,000 plants have been planted along the Southern coast. Details of the six projects analysed in 2006 are summarised below;

Project 1: Kosgoda lagoon and beach, Turtle Conservation Project: *Mangrove and shoreline ecosystem project*

Location: GPS- N° 06 20’41.8, E° 080 01’20.4

Project partners and funding: Implemented and funded by the Turtle Conservation Project (TCP). The exact cost of project is not known but has been estimated at Rs.500, 000 rupees (£2186). After the tsunami, the organisation took an active interest in coast conservation for the sake of the turtles and the turtle breeding grounds.

Impact of tsunami: The beach was hit by six metre waves which surged 1.5km inland. 63 turtle eggs and three TCP workers were lost to the tsunami. Waves reached a height of 6 metres and penetrated 1km inland. The total destruction of *Pandanus tectorius*, *Cocos nucifera* and various species of mangroves were reported.

Project and details and objectives:

- Well rooted plants and trees including mangroves have been planted in damaged areas on the barrier beach to prevent coastal erosion in the future and to act as a protective barrier. The TCP has also established several coastal plant nurseries which maintain over 1,000 mangrove plant species.
- The project aims to re-establish the ecological destruction caused by the tsunami, leading to the preservation of the turtle breeding grounds.

Vegetation planted: *Terminalia catappa, Pandanus tectorius, Cocos nucifera, Calophyllum calaba, Barringtonia asiatica, Rhizophora apiculata, Rhizophora mucronata, Bruguiera sexangula, Bruguiera cylindrica*

Project 2: Pathamulla**:** ***Nagenahiru foundation*****:** *Mangrove Restoration and Educational Programme*

Location: GPS- N° 06 10’53.8, E° 080 05’52.8

Project partners and funding: Implemented by the Nageniharu Foundation and funded under the “EU Post Tsunami Project” by the European Commission and the Global Nature Fund, Germany.

Impact of tsunami: The project area is situated 500m from the coast beside the Maduganga River, Pathamulla. Approximately 1200 people reside in the area. Extensive damage was caused to houses as tsunami water travelled along the river to the village damaging land and buildings. 20 deaths were reported in the area.

Project details and objectives:

A nursery was established to house 5000 seedlings. 3000 mangrove seedlings have been distributed for planting in selected areas with the remaining 2000 seedlings still present at the nursery.

- As of July 2006, a mangrove educational centre is being constructed for demonstrational workshops and training sessions.
- Project organisers anticipate that the planting of mangroves will provide natural protection against the flooding of the Maduganga River and natural hazard events.

Vegetation planted: *Rhizophora apiculata, Bruguiera gymmorhiza and Excoecaria agallocha mangroves.*

Project 3: Telwatta: Rainforest Rescue International: *Establishment of home gardens*

Location: N 06 10’14.4, E 080 05’31.3

Project partners and funding: Implemented by Rainforest Rescue International (RRI) and Funded by Swiss Solidarity, the project is estimated to cost in the region of Rs 2 million rupees (£8746).

Impact of tsunami: Waves reached a height of 1.3m, penetrating 500m inland. The majority of trees in the vicinity died with only *Cocos nucifera* remaining intact. 150 people perished. An increase of salinity in the soil as a result of seawater destroyed people’s home gardens. Located 300m from the coast, home gardens in the village were left devastated and suddenly people had no way to sustain themselves or earn an income.

Project details and objectives:

- To re-establish and introduce home garden production in affected areas. Various fruits and vegetables were cultivated, and used to satisfy nutritional needs, with surplus stock later sold at local markets or roadside stalls.
- The RRI have established seven nurseries producing 100,000 plants. Plants are stockpiled to supplement subsequent requirements of the affected communities. As of July 2006, 2500 home garden plants of 10 different species have been distributed to local communities (table 4).
- To preserve Sri Lankan agricultural traditions, provide supplemental nutrition and assist communities in enhancing the availability of food improving income security.

Vegetation planted: *Moringa olifera, Carica papaya, Mangofera indica, Artocarpus heterophyllus, capsicum annum, Murraya koengii, Artocarpus altilis, Bassela alba, Abelmoschus esculentus, and Cinnamomum verum*

Project 4: Galle: UN Office for Project Services: *Tree plantation*

Location: N 06°02’58.5, E 080°11’04.2

Project partners and Funding: Funded by the UN Office for the Co-ordination of Humanitarian Affairs (UNOCHA), implemented by the UN Office for Project Services (UNOPS) and supported by the CCD. The cost of the project is Rs.750, 000 rupees (£3280).

Impact of tsunami: A 10km stretch of coastline took the full force of the tsunami waves. Pre-tsunami vegetation consisted of 150-200 *Cocos Nucifera* trees. Initially the soil was made infertile by the intrusion of salt water and therefore the CEA supplied organic manure to help with the tree planting process. 1500 persons perished.

Project details and objectives:

- 10km of coastline has been earmarked for vegetation planting. *Pandanus tectorius* and *Cocos nucifera* sapling have been planted 1m apart along a 10km stretch.

The project aims to form a protective vegetation barrier against future natural hazards as well as preventing sea breeze and wind problems to landward dwellers.

Vegetation planted: *Pandanus Tectorius, Cocos Nucifera*

Project 5: Tangalle: Mangrove conservation project: Mangrove planting

Location: N° 06 03’47.3, E° 080 52’53.1

Project partners and funding: Implemented by the Mangrove Conservation Project, Bandaramulla. Funded by German Technical Co-operation and supported by GITEC. Rs.2 million rupees (£8746) were allocated for the entire project. Rs. 1.2 million rupees (£5248) have already been spent on the establishment of a mangrove nursery, and maintenance of plants.

Impact of tsunami: 37 families were living in the area when the tsunami struck. A few *Rhizophora* mangroves were destroyed, with 7 perishing in areas where no mangroves were present with homes and hotels destroyed.

Project details and objectives:

- A mangrove nursery was first established with planting of seedlings along a 50m stretch, 100m from the coast situated next to an inland lake.
- A baseline survey of mangrove species in the area was conducted before the tsunami leading to the identification of existing mangroves native to the area. 6500 *Rhizophora apiculata, Rhizophora mucronata, Bruguiera gymmorhiza* and *Excoecaria agallocha* mangrove species have been planted. The project is expected to last 5-10 years.

Vegetation planted: *Rhizophora Apiculata and Mucronata, Bruguiera Gymmorhiza, Excoecaria Agallocha*

Project 6: Kirinda: Human Resource Environment Protection Organisation: *Sand dune stabilisation and vegetation planting*

Location: N° 06 12’06.6, E° 081 19’06.0

Project partners and funding: Implemented by the Human Resource Environment Protection Organisation (HREPO) and funded by the UNDP at a cost of Rs.600, 000 rupees £2624). World Food Organisation also provided Rs.600 rupees (£2.62) worth of dried food products for distribution amongst the local community.

Impact of tsunami: Before the tsunami the sand dunes were intact and not degraded. *Borassus flabellifer* were planted in the area to act as a buffer to the coastal winds, and it was reported that the presence of the trees had a slight effect dissipating the tsunami waves. Waves reached a height of 8m penetrating 1km inland. Approximately 150 families were affected, with 14 persons perishing. Over 46 houses were destroyed. The presence of the dunes (roughly 6m high) obstructed tsunami waves protecting the village from serious damage. Consequently the dunes were damaged and in need of restoration. It was reported that neighbouring villages which did not have sand dunes, rather coastline buildings, suffered a far worse fate.

Project details and objectives:

- Destroyed, damaged dunes left communities vulnerable to future hazards. The project aims to stabilise and restore the dunes by planting gentle, sea-shore vegetation in order to encourage the rehabilitation process along a 10km stretch of coastline.
- It is hoped that the services provided by the dunes (e.g. wind erosion control, regeneration of interior agro biodiversity, aesthetically pleasing for eco-tourism opportunities) will be restored leading to the introduction of eco-friendly employment opportunities in the southern coastal region

Vegetation planted: *Spinifex littoreus and Ipomoea pescaprea*

Project objectives

The main objectives of the six projects evaluated are fourfold: to re-establish the ecological destruction caused by tsunami waves to affected flora and fauna, to realign the balance of damaged ecosystems and to restore the services provided by affected ecosystems, to help communities build a sustainable future by introducing eco-friendly employment opportunities by planting a selection of plants which can be harvested for local handicraft and lastly to form a protective barrier against coastal erosion, wind storms, and future natural hazard events.

Vegetation planted

In total, twenty seven different varieties of plant and tree species were planted (table 3 and 4).

Table 3: Review of the plant/trees species planted

Coastal Vegetation			
Scientific name	English	Sinhala	Tamil
Cocos nucifera	Coconut palm	Pal	Tennai
Rhizophora apiculata Rhizophora mucronata	Red mangrove	Kadol	Kandal
Excoecaria agallocha	--	Talakiriya	--
Bruguiera sexangula Bruguiera cylindrica	--	--	--
Pandanus tectorius	Pandanus	Mudukeyiya	
Ipomoea pescaprea	Bermuda grass		Muhubu bim thamburu
Casuarina equisetifolia	Casuarina	Kassa	
Borassus flabellifer	Palmyrah palm	Tal	Panai
Spinifex littoreus			Maha ravana revula
Barringtonia asiatica Barringtonia racemosa		Diya Mudilla	
Terminalia catappa	Indian Almond	Kottamba	
Calophyllum calaba		Guru Kina	
Thespesia populnea		Suriya	
Sonneratia caseolaris	--	Kirala	Kinnai

Table 4: Review of tree and plant species planted for the home garden project

Scientific name	Sinhalese name	English name	Tamil name
Tree species			
Moringa olifera	Murunga	Drumstick	
Carica papaya	Papol/Gas labu	Papaya	
Mangofera indica	Amba	Mango	Manga
Artocarpus heterophyllus	Kos	Jackfruit	
Plant species			
Capsicum annum		Capsicum	
Murraya koengii	Karapincha	Curry leaves	
Artocarpus altilis	Del	Bread fruit	
Bassela alba	Nivithi	Spinach	
Abelmoschus esculentus		Okra	
Cinnamomum verum		Cinnamon/Ceylon cinnamon	

Establishment of Plant Nurseries

For all three mangrove projects, temporary mangrove nurseries were established prior to the commencement of plantation in order to produce native seed stock and propagation materials. This was due to the general lack of sufficient numbers of suitable plant species, to the sheer amount of mangrove saplings required for the restoration effort and for growing the plants until they reached a suitable size for planting. New, good quality plant genetic material such as mangrove propagules were supplied (in some cases) voluntary by the CEA, the Palmyrah Development Board, and two NGOs- *"The Green Movement"* and *"Ruk Rakaganno"*. The propagules were planted in small, black plastic bags containing soil and kept in the nursery until they reached four-leaf stages. Propagation was necessary to ensure that newly planted vegetation acclimatised to the maximum effort. The time taken to reach this stage varied from three to nine months dependent on conditions of growth. Seedlings, grown from the seed were approximately 11 months old when distributed to local communities. A temporary plant nursery was also established for the home garden project. Vegetation is a critical factor in the formation and stabilisation of sand dunes and so *Spinifex littoreus* and *Ipomoea pescaprea* seedlings were planted in bare areas on the sand dunes to stabilise the dunes [5]. The area was then cordon off to protect the vegetation from being disturbed or destroyed by local inhabitants or animals. Naturally 3 of the 6 projects analysed were concerned solely with the planting and restoration of mangroves; this was to be expected when taking into consideration the highly publicised view of the role mangroves play in dissipating the energy of the tsunami waves [8], [15], and [16]. Mangroves were planted to replace those destroyed in the tsunami as well as to boost the existing mangrove population with the intention of providing a greater range of protection to human settlements from future natural hazards. Young [27] highlights the danger of unnecessary mangrove planting in unsuitable areas in Sri Lanka's coastal zone. This concern was put forward to project officers who made assurances that the mangrove restoration areas in each of the three projects were suitable, as mangroves species planted were native to the area; *"we analysed the remaining mangrove in the area, and so planted the same species"* (Nageniharu Foundation representative).

Environmental assessments and traditional ecological knowledge

In all six projects, local communities were fully involved in initial environmental assessments, surveys and site selections including the planning and planting stages**.** Basic post tsunami environmental assessments were conducted by project co-ordinators and staff members of the named charities/organisations in conjunction with local residents. Accurate data including satellite imagery and aerial before and after photos were either not kept, available, or were disparate for the six projects concerned. Consequently identifying the impacts of the tsunami on the natural environment became a tedious task. To compensate for the lack of scientific data available, traditional ecological knowledge possessed by the local population was identified and utilised in environmental assessments of the project sites. The use of indigenous environmental knowledge by scientists and researchers has been well documented [2], [3]. Berkes [2] highlights, "*traditional ecological knowledge is as old as ancient hunter-gatherer cultures*". That statement is especially true in Sri Lanka, where local ecological and environmental knowledge of the ecosystems which the community inhabits are built upon and passed down from generation to generation. Arguably the local community, especially the indigenous population possessed firsthand knowledge of the natural environment which in turn acted as a useful and practical guide as to what steps should be taken regarding the restoration of the ecosystems found there. Discussions with project co-ordinators and participants indicated that this local knowledge and information has been valued and utilised well; "*we had some guidance* *from several government departments but we also used the knowledge of local people, if anything they know more about the area than anyone else*" (RRI representative).

Although there are several environmental restoration projects in the East and South East of the country, there is not an abundance of environmental restoration projects as originally hoped for in the South and South-Western coasts, and it is only fair to say that the process of environmental rehabilitation is slow. It seems that it is only now, some 18 months after the tsunami that the environment is being given due consideration. When questioned why environmental restoration projects have taken so long to initiate, representatives replied that it simply a case of funding for projects being delayed. Projects co-ordinators also stated the need to be certain when planting or replacing new and damaged species; *"basically it was a case of receiving the funds, but we needed to be certain of how we were to approach the restoration of the mangroves, we needed to be certain of the species of the area before we proceeded otherwise it would have been a disaster to the nature of the area"* (Mangrove Conservation Project representative). One project co-ordinator shared Katz [14] view that damaged/destroyed vegetation should be left to recover naturally without human intervention. However it was evident that this view was not shared by other representatives: *"some things can take decades to recover, however I believe that we, humans should start the restoration process ourselves"* (TCP representative). Three of the six organisations did not initially deal with the natural environment but after the tsunami, they included environmental projects in their manifesto recognising the urgent need for post tsunami environmental restoration work.

Economic benefits

Communities were subsequently assured of financial benefits, through employment on cash for work basis as plant nursery entrepreneurs, landscape contractors and green belt managers (including long-term maintenance). A system of regular maintenance and management of the vegetation planted was established. This involved local residents monitoring the plantations, removing dead vegetation, weeds etc, ensuring that the vegetation was not being trampled upon or removed and keeping the plants and vegetation free from pests and diseases. There was a noticeable discrepancy in the incentives and rewards awarded in each project ranging from Rs100 to Rs1250 rupees (approximately £0.50p-£6.00) a week for maintenance. The home garden scheme has encouraged communities to be more self reliant by introducing low cost organic farming to the project area. In turn, communities have enhanced their availability of food as well as providing communities with an economic, sustainable livelihood. In addition to all the home garden crops which provide a regular, accessible and vital source of food and nutrition, *Pandanus tectorius* and *Cocos nucifera* vegetation, featured most prominently for both its protection factor against various natural hazards and its intrinsic economic value. For example the woven leaves of the *Pandanus tectorius* can be used to make indigenous local handicrafts such as handbags which appeal to foreign tourists. Project co-ordinators envision that the restoration of these ecosystems, the very resource base that provides these opportunities, will benefit local communities through the generation of economic opportunities.

4. Discussion and conclusion

It is evident that considerable efforts are being made to restore coastal terrestrial ecosystems in southern Sri Lanka. Although half of the projects evaluated were solely concerned with the replanting of mangroves, this is just one small step of many that the country is taking towards restoring the coast to its former state, providing moderate protection against any possible future natural disasters and rehabilitating ecosystems which provide a life support for coastal communities. Capacity building at local levels is seen as a key factor for securing the sustainability of Sri Lanka's coastal ecosystems. Local, national and inter-agency partnerships involving all stakeholders have been established and the formulation of local driven, collaborative environmental restoration projects have boded well for the progression of restoration projects. Nevertheless there needs to be a greater emphasis placed on the importance of restoring affected ecosystems to the pre-tsunami state of production activity including restoring the ecosystems to a functioning state where they could provide services and goods again to local residents. Efforts are being made to realign the balance of damaged ecosystems by planting a selection of plants, which if utilised and managed sustainably can provide a wealth of economic benefits to coastal communities. Good management practices have ensured that the maintenance of vegetation planted is both meticulous and consistent and it is imperative that these efforts are continually monitored and sustained for the restoration process to achieve its desired effect.

Abstract

Government plays different roles in promoting Building Energy Efficiency (BEE), among which the role in providing incentives is commonly acknowledged as significant by both professionals and researchers. In this study, two categories of incentive instruments, economic incentives and advocatory incentives, have been classified and defined, with related items described according to this classification. Based on this classification, investigation and comparative analysis on BEE incentive instruments have been carried out through literature review in four different countries: the UK, Canada, the US and mainland China. Finally, from comparative study of literatures, a list of factors, which are supposed to affect on the BEE incentive policy design, have been identified for future study.

Keywords: Building Energy Efficiency (BEE), Partnership, Incentive Instruments, Policy Design Factors, Comparative Study

1. Introduction

Construction industry has a great influence on the use of resources and the environment. Taking China as an example, the energy consumption of building accounts for 27.6% of the whole society and takes the lead among all industries regarding its proportion in the total energy consumption of the whole society [1]. Improving the efficiency of energy use in construction industry has become a well-recognized means to meet national objectives, such as increasing energy efficient investments, improving the security of energy supply, enhancing productivity and competitiveness, reducing release of greenhouse gases as well as local environmental costs associated with energy supply and use. At an international level, energy efficiency promotion is required to mitigate climate change, decrease global warming and improve the situation of air pollution [2].

Government’s involvement is regarded as one of the essential and effective ways to promote BEE. The four main roles of government on BEE promotion well recognized in literature are: (1) Policy-maker (2) Incentive motivator (3) Financing hub (4) Advocator [3], [4], [5]. Energy analysts consider that the deficiency in promoting energy efficiency from governments, such as insufficient information for the consumers and retailers, financial disincentives for the landlords, fragmentation of on-line production, leads to market failure. Thus the public intervention is essential to rectify the situation [3]. Due to the market failure, Dennis [4] believes that achieving optimal investment in energy efficiency necessitates innovative policy intervention from governments. Free market economists also agree to use minimal public action to overcome these obstacles [6], [7]. A common consensus is formed among energy analysts and economists that governments should play a certain role in the promotion of BEE [3].

Regarding the government’s roles on BEE promotion, market-based incentive schemes are thought to be significantly effective and cost-efficient instruments. A series of policy instruments has been suggested to address the BEE problems arising from the market failure [8]. Nowadays, researchers regard market-based incentives as well as forward-looking energy policies as addressing this market failure, together with the “non-market” problems to improve the situation for building energy consumption and environmental protection [4]. Economic literature has also formed a general consensus that market-based instruments (as opposed to command and control regulations) are the optimal choice of policy instrument for reaching an environment-friendly goal [9]. Furthermore, much research notes that voluntary-based environmental policies are more effective than regulatory control [10], [11]. These types of policy help to project better public image for government because the policies offer greater flexibility for building owners to reach targets and promote dialogues between government and private sectors and raise public awareness of environmental issues [12], [13], [14]. Building up a win-win partnership between government and private sectors through incentive policy design is one of the best incentive ways for the government to improve BEE. Although it is important, it is still leaving plenty of room for future study [15], [8], [16], [17].

This paper aims at contributing to the concept of collaboration between government and private sectors, by describing incentive instruments through comparative studies and a literature review. The structure of this paper is firstly, two incentive roles played by government on BEE promotion have been briefly reviewed and the operation of these incentive instruments between government-private sectors has been explored. Secondly, according to the two categories drawn above, the authors compare the incentive instruments in different countries (the UK, Canada, the US, and mainland China), and understand the different policy instruments used in different governments and their effects. Thirdly, from comparison as well as a literature review, a list of factors are identified which will affect the BEE incentive policy design that help to build up partnership between government and private sectors. Finally, we discuss what mainland China and some other developing countries can learn from each other on incentive instruments design for improvement. The road map of paper is shown as below (Figure 1):

Road map of this paper

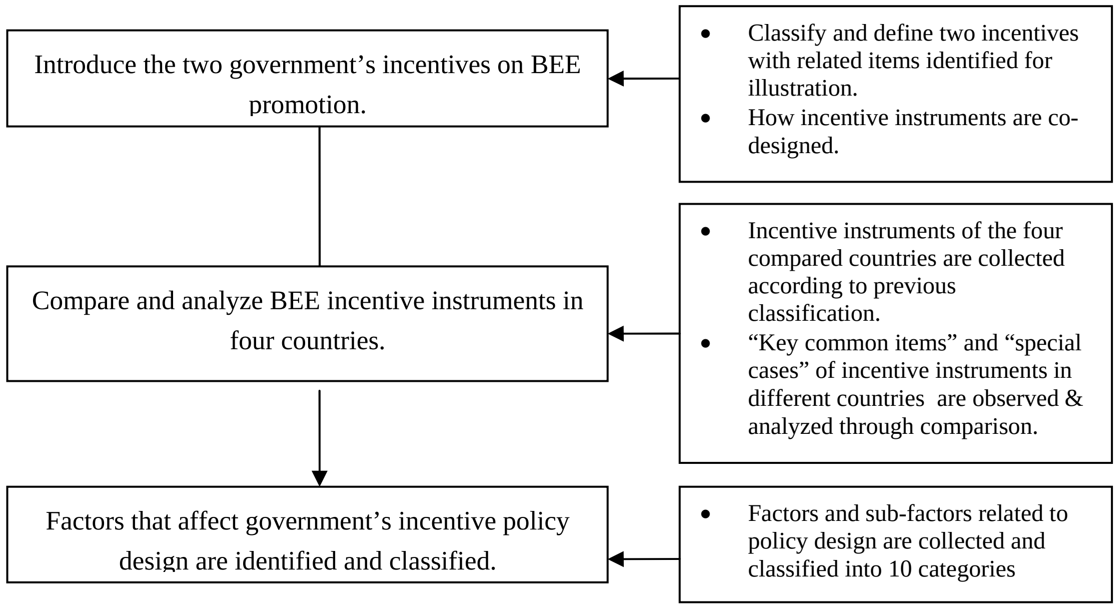

Figure 1: Road map of this paper

2. Government's incentive roles on BEE: promoting collaborations among government and private sectors

Literature review leads us to classify the government's incentive roles on BEE promotion into two categories, ***economic incentives*** and ***advocatory incentives*** [4], [18]. The items relating to each category are identified and the review result is summarised in the pattern as shown in Table 1.

Economic Incentives — Government's role is to set incentive policies to enhance the private sectors' interests in order to reduce the cost and increase the demand in the energy efficient building market, e.g., setting an feasible price for energy, tax deduction programs for energy efficient products, subsidy and rebate programs. It can also offer financial support to socially and environmentally preferred energy options through investment incentives and low-cost loans, and special funding for BEE programs [2], [4], [8], [17].

Advocatory incentives — Government's role is to advocate sustainable energy development and consumption through education, training, information publication and through activities such as product rating and labelling, energy audit and government procurement programs [18].

Table 1 Items relating to each incentive role

Economic Incentives	Advocatory incentives
• Implementation of further market-based incentives • Ensure prices reflect energy goals • Voluntary commitment and recognition • Taxation incentives • Subsidy and rebate programs • Investment incentives	• Marketing and consumer education • Information systems and databases • Decision support tools • Best practices guideline • Common user specifications • Demonstrations

• Low-cost loans • Leasing • Performance contracting • Special-purposed funds • Government procurement programs • Performance contracting • Vendor financing • Special-purpose funds • Utility financing programs • Setting an optimal price for energy	• Energy audit • Product rating and labelling • R&D and decision support tools • Government procurement programs • Advertisements and training
Reference: [2], [4], [8].	**Reference:** [2], [18].

Successful experiences from developed industries show that the BEE incentive instruments are co-designed by government and representatives from private sectors to avoid BEE market barriers[2], [19]. After these incentive policies are brought into effect, private sectors, namely market parties, would send out market signals and these feedbacks received by the government help to adjust their incentive policies on BEE promotion. With the full cycle of re-negotiation and re-design of the policy instruments, the collaboration between government and private sectors is built up and it helps the government promote BEE in a cost-effectiveness way. The diagram below shows the process of Incentive Instruments co-designed and re-negotiated by government-private sectors.

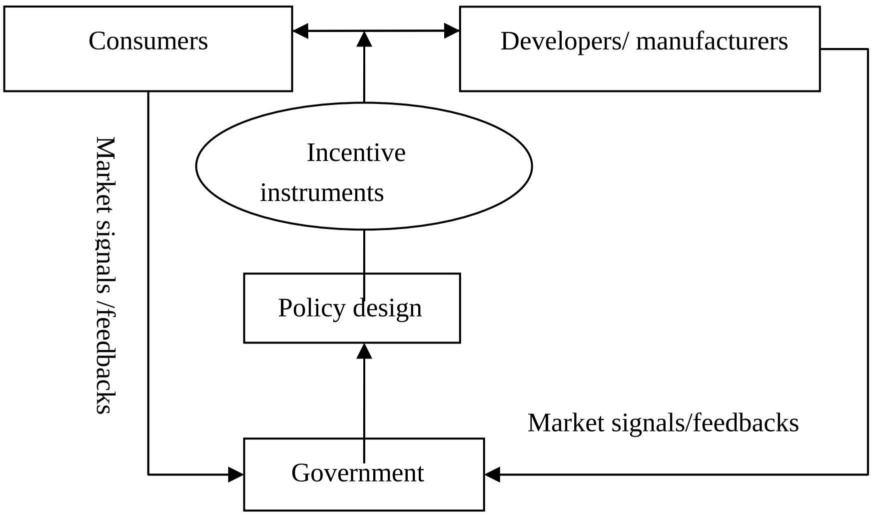

Figure 2 Process of Incentive Instruments co-designed by government-private sectors

3. Comparative study on BEE incentive instruments between China and developed countries

After clarifying the two incentive instruments that governments adopt to promote on the BEE market, we are able to make a systematic comparison between China and some developed countries through a critical evaluation of the items under the two categories: economic incentives and advocatory incentives. Table 2 shows a comparison of different incentive measures and policy instruments related to BEE in four different countries, the US, Canada, the

UK and mainland China. From the literature review, important items of incentive instruments from different countries are selected and compared under the two categories classified previously and the effect of these incentive instruments are discussed accordingly.

In table 2, it is observed that, although the incentive instruments adopted by different countries varied in some ways in practical terms at a certain period or according to their national situations, these governments' incentive involvements on BEE more or less converges to a certain pattern, especially among developed countries. Comparing to developed countries, China has a high potential to improve her current BEE situation by adopting incentive instruments. Moreover, successful experiences from developed countries also show that more incentive instruments are called for to enhance the effect and efficiency of BEE promotion in China.

Table 2 Comparative study on BEE incentive instruments

Country	Economic incentives	Advocatory incentives
The US *Ref.:[2],[20],[21],[22],[23],[24]*	Subsidy plan and turn-in programs Tax incentive schemes Green Building Tax Credit Program Market-based DSM programs Weatherization Assistance Program Discount loan and Mortgage loan for BEE Low-Income Home Energy Assistance Program R&D funding for new BEE technology Rebate System benefits charge	Voluntary assessment schemes: LEED, CHEERS and Green Building Programs Energy Star Program Home Energy Rating System; Builder Option Packages Voluntary products labelling
Canada *Ref.:[3], [17], [23]*	Commercial Buildings Incentive Program Subsidy and rebate program Tax incentive schemes Energy innovators initiative(EII) Industrial building incentive program(IBIP) Canadian Home Insulation Program (CHIP) Mortgage loan for BEE R&D funding for new BEE technology	New Home Warranty Program Building rehabilitation program EnerGuide for appliance, equipment and houses R&D, market-based research and demonstration projects to provide information Voluntary products labelling Canadian industry program for energy conservation (CIPEC Assessment)
The UK *Ref.:[24], [25]*	Subsidy and rebate program Tax incentive schemes R&D funding for new BEE technology low-cost loans	Voluntary assessment scheme: BREEAM Energy Efficiency Accreditation Scheme,1993 Energy Matters Program Voluntary products labelling
China China *Ref.:[2],[18],[20],[26]*	Provide low interest subsidies to enterprises to undertake "technical renovation" for the purpose of energy conservation, which is practically inefficient Tax benefits for energy conservation projects, which was eliminated in the late 1990's. Special funding for new wall material Low interest loans to state firms on energy efficiency projects by China conservation Investment Corporation in early 1980s, which was eliminated by 1994.	Energy-Conserving Products Certification

4. Observation of the comparative study

- ***Economic Incentives***

Analysis shows that subsidy and rebate programmes, tax incentive schemes, and low interest/ mortgage loans are all welcomed in the four countries compared, though these schemes were phased out in China in 1990s. In addition, all four governments believe that R&D funding for new BEE technology is one of the most significant ways to promote energy efficiency. Detailed remarks on the incentive instruments of the four countries are grouped under the heading of 'Key common items' of economic incentives as shown below:

Key common items:

- All the four compared countries believe incentive motivator to be an important role for government involvement.
- Tax incentive schemes, subsidies and rebate programs are the common policy tools.
- The US, Canada and the UK governments have all reported satisfactory and cost-effective results through the implementation of incentive tools.
- Government provides loans and funding for BEE promotion.
- Governments in the four countries all prefer to set a R&D funding for new technology.
- The US, Canada and the UK governments have established mature and well-functioning financing systems for BEE promotion. The financing system, with a high credit and influence, penetrates well in the BEE market.

- ***Advocatory Incentives***

Analysis illustrates that the enforcement of advocatory incentives varies according to technology development, BEE education, and particular national situations, etc. However, there are more overlaps among the developed countries. For instance, LEED, CHEERS and Green Building Programs in the US, CIPEC in Canada and BREEAM in the UK are all assessment schemes, which are adopted by different countries with some variations in terms of implementing period of time or according to their national situations. In addition, voluntary product labelling is all popular in developed countries. Up to now, however, there are no well-established voluntary assessment schemes and information publication systems for BEE in mainland China [20].

Key common items:

- All compared governments serve as an advocator to deal with market barriers.
- Voluntary assessment schemes, voluntary products labelling, education and information publication are the main functions for government's involvement in developed countries.
- The impact of these government involvements is cost-effective.
- The US, Canada and the UK governments have their own schemes to serve as advocators to promote BEE, though the purpose of each tool is similar.

5. Highlights of the Special Cases in different countries

The US

US utilities launched the first rebate-based DSM[1] program in the early 1990s, which has yielded encouraging result for savings [27], [28], [29]. Though DSM spending has fluctuated and encountered a downward trend during last decade in the US due to its own national situation, a number of utilities in various countries have introduced similar programs and gained significant savings [20].

Another incentive program in the US which undoubtedly deserves mentioning is the Energy Star Program. It is a government-backed voluntary scheme, which is well-accepted by industry. The Energy Star program was first launched in the US in 1992 and was designed to identify and promote energy efficient products. According to published data, around 30 different categories and more than 600 buildings have already earned Energy Star labels and the administrator of the Energy Star program had been working with organizations that represent approximately 17% of building square footage in the US [30]. In the recent years, EPA has licensed the Energy Star trademark to several countries, including Japan, New Zealand, Australia and Taiwan, and to the EU, but the use has been limited to office equipment only [29].

Canada

In Canada, ‘EnerGuide for House’ and ‘EnerGuide for Appliances and Equipment’ are two integrated incentive measures, both of which include information, education, motivation and labelling. ‘EnerGuide for House’ is a strategy measure, which persuades and assists housekeepers to enhance energy efficient capability of their houses. It also induces residential consumers to consider energy efficiency in their purchasing plan. The government of Canada partly subsidizes the cost of the evaluation, which helps to offset certain amount of the costs used for the energy-efficiency improvements. The amount of the grant depends on the degree of its energy-efficiency retrofits. ‘EnerGuide for Appliances and Equipment’ is a mandatory measure for new products. It gives a comparative assessment of energy efficiency and energy consumption for a range of appliances on the market, which complements the efficiency standards, and seeks to stimulate consumer awareness to influence purchasing decisions [17].

The UK

In the UK, the first building environmental assessment method, BREEAM, was launched and operated by the Building Research Establishment and came into prominence in the early 1990s.

[1] DSM (demand-side management) offers solutions to problems such as load management, energy efficiency, strategic conservation and related activities. The IEA Demand-Side Management Programme is an international collaboration of 18 countries working together to develop and promote opportunities for demand-side management (DSM).

It is the best-known scheme and has embraced 15-20% of the new office building market in the UK. In addition, BREEAM has motivated a superstore to incorporate all the current best practice in the environmental design of their operations, with the aim to half the carbon dioxide emissions that conventional supermarket designs incur. As the abovementioned worldwide acknowledged incentive programs, BREEAM has also been taken as a reference model when similar schemes were developed in Canada, New Zealand, Norway, Singapore and Hong Kong [29].

China

In China, locally made equipment and appliances are generally less efficient than those produced in developed countries are. In addition, direct financial support for energy efficiency is still weak. Up to now, there has been little government spending in support of BEE at a national level and there is almost no energy efficiency program sponsored by utility companies at present ([17], [20]). Though there are a few provincial government incentive programs for energy efficiency, they are fairly modest and are exceptions rather than a norm. So far, assessment schemes that developed and adopted in other countries, such as BREEAM in the UK, LEED, CHEERS and GREEN Building Program in the US, do not exist currently in China [29].

In the past, there used to be two incentive programs initiated by Chinese government for energy efficiency promotion in the 1980s. One was a low-interest loan program, which was phased out during government restructuring. Another one was a “technical renovation” subsidy program, which has been substituted by a larger program by 1998. The new program has failed to achieve the incentive effect due to a lack of clear rules on program qualification and application process ([20], [31]).

6. Factors that affect government’s Incentive Policy Design

In the above comparative study, important aspects of incentive instruments from different countries were selected and compared according to the abovementioned two categories. The common items of these incentive instruments as well as effect of special case study in each country have been discussed accordingly. In order to develop these incentive instruments, governments have to go through careful design of policy for implementing the incentives. The design of a public policy involves two major elements. First, policymaker must decide on the goal, which may take the form of a long-term or near-term policy goal. Second, with the goal established, policymakers must decide on how to implement their goal, through a variety of policy implementation tools (instruments) available at their disposal. The choice of instruments and implementation strategies can substantially affect the total effectiveness of any policy, and costs and benefits consideration is one major criterion for the effectiveness of any policy. Hence, the implementation policy instruments can influence cost effectiveness in the longer term, for example through investing in R&D and innovation incentive schemes [32]. For BEE policy study, it makes sense to question what lead to the various incentive policy designs in different countries; why a government choose this incentive one scheme rather than the others;

and what affect their decision-making in the process of incentive policy design. All these bring up the need for follow-up studies on factors that affect government's Incentive Policy Design (IPD).

Through literature reviews ([4], [17], [31], [33], [34], [35], [36], [37], [38], [39]), IPD factors are collected and classified into 10 categories and their sub-factors are identified and listed according to each category as shown in Table 3. These factors and sub-factors need to be critically reviewed and re-grouped and attributed with appropriate importance weighting through research methods such as Factor Analysis and AHP etc, in future study. It is hoped that with a list of well-structured IPD factors and sub-factors, government would have a better understanding of the process of developing BEE incentive policies.

Table 3 Preliminary set of factors that affect government's Incentive Policy Design (IPD)

IPD Factors	**IPD sub-factors**
Economic	• Combination of incentive policies / instruments • Inadequate / excessive fiscal constraints • Insufficient consideration of the potential trade-offs associated with the benefits of a proposed project • The constellation of economic actors within each particular sector • Land use planning reform (absence of commensurate planning and planning reform) • Institutional design • Cost effectiveness • Diversity and flexibility of instruments
Market	• Targeting (concerned groups) • Consumer needs and consumption patterns VS. Consumer habits and behaviour • Third party financing • Information / education / motivation • Accessibility • Bounded rationality of the average consumer • Competition within construction industry • Policy uncertainties VS. market stabilities
Political acceptability	• Policy regime & degree of coercion • Political risk VS. Political stability • Inherent national policies
Environmental	• Energy market reform and access • Strategic environmental assessment • CO_2 emission level • Embodied energy of building materials
Technology	• Technological evolution • R&D / Technology procurement to an international level • Technology mix • Technical based evaluation
Democratic and accountability	• Adequacy, transparency and clarity • Public participation / involvement • Effects of certain aspects of privatization • Public consultation • Recognition as a new political majority on governmental agenda or administrative capacities

Social & Culture	• Equalizing the community risk and cost-benefit distribution • Social-economic dynamic • Poverty • Efficiency extent / degree of resource use, BEE production, distribution and services • Shortages in supply of infrastructure services
Ethical principles	• Aversion to concerned policy-maker • Optimality, fairness and justice • Stewardship • Participatory decision-making • Prudence and control
Administrative easy or not	• Resource intensiveness • Manoeuvrability on its own territory • Lack of co-ordination between/within regulatory agencies • Contextual frameworks • Process-driven reviews • Assessment / monitoring VS. auditing / benchmarking • Well-defined objectives, resources and technologies • Appropriately applied incentives • Administrative operating cost • Implementation / operational performance
Globalization	• Degree of market globalization / integration • International cooperation / negotiation • Technology procurement to an international level • Costs of international negotiations, • Costs of the decision-making process in the individual countries

7. Conclusion and Recommendations

Policy study on BEE has already aroused worldwide concern and academic debates, as policy is recognised as a bottleneck to ameliorate problems of climate change, air pollution, and energy security, etc. Among all public interventions, incentive instrument with public-private sectors partnership through appropriate policy design are the most essential and significant shortcuts to win this BEE promotion campaign. This paper highlights the incentive roles that government plays on BEE promotion by classifying incentives into two categories: economic incentives and advocatory incentives. Through comparative study of four different countries, incentive instruments are identified and collected according to the abovementioned categories. “Key common items” and “special cases” of incentive instruments in these four countries are analyzed, which helps enlighten China and other developing countries to learn from each other. Finally, the importance of careful policy design is brought up and a list of factors and sub-factors, which could affect Incentive Policy Design (IPD), is collected. Further studies are recommended to study the criteria, which could quantify the IPD factors and the way to weigh out different factors that affect government’s choice.

Abstract

Windstorm Gudrun (January 7–9th 2005, also known as Erwin in some countries) was one of the strongest storms in the Nordic Region of Europe during the last decades. It caused widespread property damage, exceptionally high storm surge levels, and the loss of 18 lives. The storm surge in the Estonian city of Pärnu at the eastern coast of the Baltic Sea reached 275 cm above mean sea level, which is the highest flood ever recorded since regular measurements started in 1824. Extremely rough seas occurred in the north-eastern region of the Baltic Sea. The overall maximum significant wave height was estimated to be about 9.5 m off the coasts of Saaremaa and Latvia. Such wave conditions are extremely rare in this water body. Despite several atypical features of this storm, the reaction of water masses was reasonably forecast 48–54 hours ahead and accurately reproduced in 24–36 hour forecasts in the leading operational oceanographic centres. The lessons learned from this event led to re-launching of routine operational oceanographic services in Estonia and were used in regular courses for students specialising in port and coastal engineering in Tallinn University of Technology, and for students in hydrography at the Estonian Marine Academy a few weeks after the events.

Keywords: Coastal hazards, extreme wave conditions, storm surge, coastal engineering teaching

1. Introduction

Windstorm Gudrun, an extratropical cyclone, also known as Erwin in Ireland, the United Kingdom and Central Europe, attacked northern Europe on 7–9 January 2005 [1]. It reached the power of a hurricane in the North Sea region. Although in the Baltic Sea it remained slightly below the hurricane level, it was one of the strongest storms in Denmark, Scandinavia and Estonia for at least 40 years. It caused widespread property damage and exceptionally high storm surge flooding levels. According to the official statistics, 18 lives were lost. The storm caused extremely widespread forest damage in Sweden, perhaps the worst recorded in recent history. It caused power supply cuts in large areas of Sweden, Norway and the Baltic states, and excited the highest storm surge in the known history (275 cm above the mean sea level (MSL)) in Pärnu [2]. New records of water level were established in many locations along the Western Estonian coast as well in the Gulf of Finland. The storm flushed totally smaller shallow areas such as the Moonsund (Väinameri, an area between Saaremaa, Hiiumaa and the Estonian mainland) with the water from the Baltic Proper. Particularly intense transport of bottom sediments occurred in certain coastal areas [2]. Many smaller harbours suffered from massive damage, and substantial beach destruction occurred on exposed coasts [3]. The meteorological conditions, details of accompanying flooding, and the reaction of water masses to this storm in Estonian coastal waters are analysed in detail in [1] and [2].

A major feature of this storm were the very rough wave conditions. The main reason for the extensive property damage in affected coastal areas was evidently the combination of rough seas and extremely high storm surges. While sea level in the affected areas was correctly filed at about 20 sites, the network of wave measurements at the downwind side of the northern Baltic Sea (Fig. 1) consisted only of two directional waveriders operated by the Finnish Institute of Marine Research, and one temporary pressure-based recorder.

Figure 1: Wave measurement sites, marked by ⊗, in the Northern Baltic proper (buoy 1), near Helsinki and at the island of Naissaar.

Thus it is intuitively clear that the measured wave data only partially reflected the wave fields during this storm. The position of the waverider is such that it adequately reflects wave conditions occurring in the case of SW winds that have the longest fetch among strong winds in this basin. The strongest winds (W-WSW) in Gudrun, however, were oblique to the Baltic proper. The area of strongest winds crossed the basin between Gotland and Saaremaa where the fetch is relatively short. The wave sensors were located much further northwards from the maximum of the wave storm. Even with these non-ideal conditions for wave generation and detection of the roughest seas, very high and long waves were recorded.

The purpose of this paper is twofold. Firstly, we bring evidence about the extension of the highest storm surges and construct an estimate of the roughest wave conditions during this storm based upon available data. The analysis involves a comparison of wave measurements with the output of operational wave models from the leading operational centres in the Baltic Sea area, *viz.* the German Weather Forecast Service (DWD, Deutscher Wetterdienst), the Danish Meteorological Institute (DMI), and the Finnish Institute of Marine Research (FIMR). A second focus of the paper illustrates how the instructive features of this storm were used in courses in the Department of Hydrography of the Estonian Maritime Academy and in the Faculty of Civil Engineering at the Tallinn University of Technology. To give an impression of extreme wave conditions and related features of the local wave climate in the Baltic Sea (which is a relatively small water body in which hurricane-strength winds occur extremely seldom), we also present an overview of the existing wave data and numerical wave studies in this area.

2. Extremes of storm surge water level

The basic driving factors of synoptic Baltic Sea sea level are the wind and air pressure patterns [4]. Sea level variation due to the tidal forces does not exceed a few cm. Long-term statistics reveal that the annual maximum values of water level have significantly increased on the Finnish coasts during the last 70 years [5]. The trend is essentially asymmetric: the annual minimum values do not show any significant changes. The increase is the most pronounced in the Baltic Sea nodal area where the maxima have increased by about 10 cm in a half century. This feature indicates that the overall variability of the water level in the Baltic Sea has increased even more than its local variations and, generally, large-scale meteorological and hydrological phenomena rather than local storms have caused these changes.

Yet local storms cause the largest sea level variations and at times extremely hazardous storm surges. A common feature along the Finnish coast is that the higher sea levels are more probable than the low levels. The enclosed eastern end of the Gulf of Finland generally hosts the largest variation of sea water level in the whole Baltic Sea. The total range of historical extremes exceeds 5 m and the highest storm surge reached 4.21 m above mean water level in Saint Petersburg. During the January 2005 storm, the sea level reached a relatively modest value of 230 cm above MSL in St Petersburg.

While typically the Baltic Sea storms establish new water level maxima in quite limited sections of the coast, usually at the bayhead measurement sites, the January storm of 2005 set new sea level maxima at many observation sites of the eastern Baltic coasts (Table 1). New sea level records were established and in all four stations in Finland, and at Tallinn and Toila, while at other sites of the southern coast the water level was close to the historical maxima [2]. The reason is an unfavourable combination of a sequence of events. As a result of strong cyclonic activity preceding the storm, the Baltic Sea level was already very high (+70 cm above MSL) [2]. The storm itself had a very wide area of strong winds (a few hundreds of km) comparable with the extension of the whole Baltic proper.

Table 1: Water level during windstorm Gudrun (8-9 Jan 2005) and historical sea level maxima along the coast of the Gulf of Finland based on [2], [5] and data from the FIMR, www.fimr.fi. The sites where new records were established in 2005 are indicated in bold.

Location	Maximum storm surge level (cm) on 09.01.2005	Highest recorded level prior to 2005		Observations date from:

3. Basic features of the wave climate of the Baltic Sea

The wave climate of the Baltic Sea is relatively mild. A reliable picture of the typical and extreme wave conditions may be derived from the longest instrumental wave measurements in the northern Baltic proper that were carried out between 1978–2003 by the Swedish Meteorological and Hydrological Institute near a caisson lighthouse of Almagrundet (Fig. 1). The procedure of establishing wave properties at this site is based on the classical zero-downcrossing method. An estimate $H_{1/3}$ of the significant wave height H_S is calculated from the 10th highest wave once an hour [6]. The overall average of the significant mean wave height at Almagrundet between 1978 and 1995 is 0.87 m. The median wave height is 0.7 m and the most frequent wave conditions correspond to the wave height ranging from 0.25–0.38 m [6]. Wave data from 1993–2003 show somewhat more intense wave activity with an average significant wave height of 1.04 m and a wave height median of 0.73 m.

Seas with $H_{1/3} \geq 4$ m have occurred about 400 times during the data observation period, that is, such wave conditions occur with a probability of about 0.42 % or, on average, during about 20 hours each year. The storms causing such high waves, however, usually occur several times a year, each lasting a few hours. The highest $H_{1/3} = 7.83$ occurred at this site in January 1984 [6], in the only storm that excited $H_{1/3} \geq 7$ m at this site between 1978–2003.

Long waves are infrequent in this area. The typical mean wave periods are 4–5 s for wave heights below 1 m, about 6 s for wave heights around 2 m, and exceed 7 s only when wave heights are 3 m or higher. Note that the data set in question contains the mean period. The corresponding values of the peak period are about 20 % larger than the mean period. Mean periods over 10 s usually dominate in remote low swell conditions when the wave height $H_{1/3}$ is well below 1 m. Large periods may also occur during extremely rough seas. For example, the mean period reached 11 s in one case of rough seas with $H_{1/3}$ around 4 m, and also in the final stage of the January 1984 storm, when waves with periods 11 s dominated the wave field with $H_{1/3}$ about 7 m.

Wave properties in the central part of the sea (buoy 1 in Fig. 1, 59°15’ N, 21°00’ E, water depth about 100 m) have been measured by the FIMR since 1996 [7]. A significant wave height exceeding 7 m has been recorded only 4 times at this location: twice in December 1999 and twice within three weeks from 22 December 2004 to 9 January 2005 during windstorm Gudrun.

The typical and maximum wave heights are much smaller in the sub-basins of the Baltic Sea. For example, data from a directional waverider deployed off Helsinki in the Gulf of Finland (GoF, Fig. 1, 59°57.9’ N, 25°14.1’ E, water depth about 60 m, buoy 2) in 1990–91, 1994 and from November 2001 indicate that the significant wave heights exceeding 4 m seldom occur. The highest $H_S = 5.2$ m in the GoF was measured at this site in November 2001 [8]. Practically no data are available from the coastal areas of Estonia and Latvia except for visual observations from the coast and for a few measurements with the use of pressure sensors [9].

The third generation wave models such as WAM [10] adequately represent the sea state in the northern Baltic Sea (e.g. [11]). Wave statistics for the Baltic proper has been estimated with the use of the second-generation spectral wave model HYPAS and wind data from 1999–2000 [12]. The spatial distribution of wave heights follows the well-known anisotropy of the wind and wave regime in the Baltic proper [13], [14]. Statistically, the regions of the largest wave activity are found along the eastern coasts of the Baltic. These areas are characterised by long fetches for the dominant winds. However, no comprehensive description of the wave climate or statistical estimates of extreme wave conditions exists in the whole Baltic proper.

4. Wave properties in the Baltic proper during Gudrun

4.1 Modelled wind data

We use in the analysis the output of operational wave models from the leading operational centres in the Baltic Sea area: the German Weather Forecast Service (DWD, Deutscher Wetterdienst), the Danish Meteorological Institute (DMI), and the Finnish Institute of Marine Research (FIMR). The models are driven by forecast winds at the standard height of 10 m above the surface level. Wind fields are provided by the atmospheric models (optionally nested into larger-scale models) with a horizontal resolution ranging from 1/16°×1/16° (DWD) of 0.08°×0.08° for the Finnish Meteorological Institute's model HIRLAM version 6.2.1.

The LSM wave model of the DWD provided operational forecasts for 48 hours twice a day in January 2005. The DMI and FIMR models were run four times a day with a 54 hours forecast length. The forecast wave and wind properties until the time of the subsequent release (that is, for the closest 6 hours for each release of the DMI and the FIMR models, and for the closest 12 h for the LSM model) are called modelled wave or wind data below. The results of the rest of each operational run are called wind and wave forecasts. Since the FIMR and the LSM models only save the wave properties three-hourly at 00:00, 03:00 GMT etc., for comparisons we use the average values of measured wave parameters (and of the DMI model output) during ±1.5 hours around the mentioned time instants. Several features of modelled wind patterns are interesting from the viewpoint of wave generation. Since the coastal data suffered from failures of equipment [2], we rely on the modelled wind properties.

The maximum wind speeds on the open sea, according to the DWD and the DMI, were 28–29 m/s between Gotland and Saaremaa (Fig. 2, cf. coastal data in [2]). All forecasts suggested that strong winds would blow for a duration of many hours. The early forecasts of the storm released on 06–07 January predicted the highest wind speeds to occur along the Norrköping–Hiiumaa/Saaremaa line. The significant wave height was forecast to exceed 10 m at buoy 1, to reach 11–12 m at the entrance of the GoF, and to be over 6 m in the central part of this gulf [15]. Such wave conditions were considerably rougher than during any other storm in this area in the history of contemporary shipping.

The area with the largest modelled wind speeds crossed the Baltic Sea somewhat more southwards than originally forecasted. They hit Gotland, the northern part of Latvia and the Gulf of Riga, southwards from the location of buoy 1 [1]. The highest waves were excited off Saaremaa and Latvia and the measured wave heights did not establish any new records. The significant wave height at buoy 1 reached $H_S = 7.2$ m at 03:00 and 07:00 GMT on 9 January [16]. The wave height was about 7 m during about 12 hours (00:00-11:00 GMT).

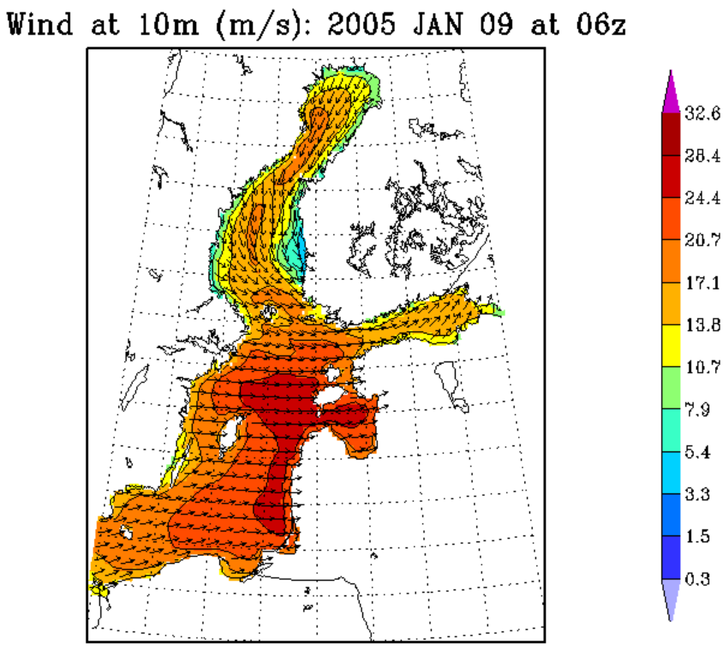

Figure 2: Modelled wind speed (m/s) and direction (arrows) 10 m above water surface at 06:00 GMT on 9 January in the DMI 6-hour forecast valid at 00:00 GMT on 9 January[16]. Courtesy of the Danish Meteorological Institute.

4.2 Wave models

All the above-mentioned centres run the third generation spectral wave model WAM cycle 4 [10] on a regular rectangular grid in shallow water mode without data assimilation. The models use different sources of wind information and their land-sea masks, bathymetry, computational grid, spatial and temporal resolution, and spectral range are different [16]. The mesh size varies from 1/10° along latitudes and 1/6° along longitudes for the LM model of the DWD down to 0.08°×0.08° of the FIMR model.

The WAM model calculates the two-dimensional wave energy density spectrum at each sea point for a set of equally spaced directions and logarithmically spaced frequencies. The LSM and FIMR models use 24 directions whereas the DMI model uses 12 directions (resolution 30°). The LSM and DMI models employ 25 frequency bands from 0.04177 to 0.41145 Hz (from about 2 to 20 s) in 10% steps. The FIMR model uses an extended range of 35 bands up to 1.073 Hz. The depth information and the land-sea mask of the LSM model are optimised for concurrent use with a circulation model. In some northern parts of the Baltic Sea they do not exactly follow the factual coastline. The FIMR model accounts for special features of the northern Baltic Sea such as the archipelago area between Åland and the Finnish mainland that is only partially passable for waves. The depth map of the DMI model is sampled from the ETOPO5 bathymetry map of the National Geophysical Data Centre with an imposed minimum depth of 5 m [16].

The available information about the validation of the models' results against measured data in the northern Baltic Sea suggests that, at least in typical wave conditions, all the listed models show reasonable performance. For example, the overall bias and standard deviation of the modelled significant wave height in the North Atlantic and the Baltic Sea from that of measured wave heights from satellites was 0.13 m (the model tended to slightly overestimate the wave heights) and 0.56 m, respectively during July 2004–March 2005 [16]. The mean relative error of the forecast of the maximum wave height in the 5 strongest storms is about 15 % for 13 buoys operated by the DMI in the Baltic Sea and in the North Atlantic [16].

The models showed good performance during windstorm Gudrun as well. The FIMR model well matched the roughest wave conditions in the early morning of 9 January: the overall maximum of H_S was overestimated by 0.44 m (about 6 %). The models of the DWD and the DMI to some extent overestimated the wave heights during the whole stormy week. The largest error (1.29 m and 1.91 m, or 16 % and 21 %, respectively) of the instantaneous wave height occurred during a short time interval when the modelled wave height reached its maximum but the observed wave heights dropped by about 0.6 m. The relative error of the forecast of the overall maximum wave height was 12 % and 20 %, respectively [16].

4.3 Maximum waves of the storm

It is of considerable interest to estimate the roughest wave conditions that occurred during this windstorm. Maximum wave heights of the storm evidently occurred much further southwards from buoy 1, off the coast of Saaremaa (Fig. 2) about 57ºN, 20.4ºE, that is, about 200 km south-eastwards from the location of buoy 1.

The overall maximum H_S during this storm can be roughly estimated from a comparison of the modelled spatial distributions of wave properties with the modelled and observed wave heights.

A sensible estimate can be constructed based on two assumptions. First, we suppose that the wave models adequately represent the spatial patterns of wave properties. Second, we assume that the relative error of the modelled wave properties is roughly the same over the entire area of intense waves. The estimate can then be obtained by correcting the overall maximum of the modelled H_S with the use of the relative error of the model at the measurement site. The results of doing so should be interpreted as indicative, because only one observation point is used as the ground truth. Yet this is a feasible way to estimate the maximum wave heights during the storm given the limited data set.

The FIMR wave model suggested that H_S up to 10.2 m occurred near Saaremaa at 00:00–06:00 GMT on 09 January [16]. Since it overestimated the maximum of H_S at buoy 1 by 6 %, the probable maximum of H_S was 9.6 m. The DMI model suggested that $H_S = 11.7$ m occurred in the same area; accounting for its overestimation at buoy 1 by 20 % leads to the probable maximum of $H_S \approx 9.4$ m. The DWD model predicted the maximum of H_S about 10.9 m at 00:00-03:00 GMT on 9 January. At buoy 1 this model gave maximum $H_S = 8.17$ m, and the overestimation of 12.4 %. The estimate for the overall maximum of H_S therefore is 9.6 m. The relatively small scatter of the results suggests that the overall maximum of H_S in the Baltic proper during windstorm Gudrun most probably was about 9.5 m. The threshold of 10 m apparently was not exceeded, however, the existing wave conditions were much rougher than expected to happen according to classical statistics, even once in a millennium.

5. The reflection of the windstorm in teaching

Although Estonia is a marine country, for historical reasons the teaching of marine matters at the university level has been fragmentary after World War II. Courses of marine physics and physical oceanography given in the Tallinn Pedagogical University (University of Tallinn since 2006), University of Tartu and in Estonian Marine Academy, were designed to offer a basic overview of the topic and did not contain questions of wave or storm surge forecast, or means of reducing the impact from coastal hazards in general. In addition, in the 1990s the department of marine forecasting in the Estonian Meteorological and Hydrological Institute, the main provider of operational forecasts, was closed. The forecasts of storm surge and wave conditions were since then constructed based on the simplest empirical relationships. Fortunately, the system of marine measurement sites was maintained.

Since September 2005, the Faculty of Civil Engineering of the Tallinn University of Technology launched teaching of port and coastal engineering as a specialization within the curriculum of civil engineering. This initiative is frequently related to the above-described extreme event. In fact, it was scheduled as early as in 2003 and was not affected by Gudrun. Yet the content of several new courses was considerably modified to reflect this event. Elements of the underlying theory and practice of wave and storm surge forecast were included into the course of wave dynamics. A thorough description of passive and active measures towards reducing the extent and costs arising from wave-induced coastal processes and of coastal floods as well as problems connected with the effectiveness of disaster management are presented in the course on coastal processes.

As a test case, a combined course containing key material from the listed courses was given jointly to students of the Tallinn University of Technology and the Estonian Marine Academy in February-March 2005. The teaching was performed a few weeks after the storm in the framework of the course of coastal hydrodynamics. Originally, the course was designed to cover generic questions of shallow-water dynamics, linear wave theory and coastal management issues. The Indian Ocean Tsunami in December 2004 and windstorm Gudrun, although not comparable in their scale of devastation, raised many questions in Estonian society about their driving factors, potential of devastation, return period, and physics of related phenomena. The series of lectures dedicated to these questions was most successful. The Indian Ocean tsunami was used to explain the role of long wave motion and related hazards. The impact of its specific geometry motivated students to learn more about dynamically similar shallow-water phenomena such as meteorological tsunamis, waves from fast ferries, and general questions of highly nonlinear wave propagation. The unexpectedly high storm surge raised a series of questions about the relative role of its driving factors and about statistical and dynamical methods of forecasting future events. The description of extremely rough wave conditions on the background of existing information about the local wave climate motivated several students to focus on attempts to reconstruct the wave climate in the Baltic Sea based on historical visually observed wave data. The series of lectures was later published in a cycle of articles in the popular science journal “Horisont.”

Analysis of more specific features of hydrodynamical processes in the coastal zone and their potential impact on local storm surge, and on the accuracy of forecasts has been included into the course of wave dynamics starting from fall semester 2006. The new key topics were wave-induced set-up and set-down, and their potential influence. Given a large number of low-lying areas potentially attacked by a combination of high water level and intense waves, such exercises are of considerable importance in the future life of students and training of their solving based on existing data is an important part of teaching.

6. Conclusions

The strong reaction of the water surface to windstorm Gudrun both in terms of sea level and high and long waves is the most interesting feature of this event that created substantial hazards both onshore and offshore. The maximum sustained wind speed (about 29 m/s in the Baltic Proper) was large but not exceptional. Also, the modelled strongest wind direction (from the West) was not particularly favourable for wave generation: the effective fetch was about a half of that for SW winds. Yet Gudrun excited very high and long waves. The central outcome of the above analysis is that that the overall maximum of H_S evidently exceeded 9 m off coasts of Saaremaa and Latvia and most probably was about 9.5 m in some areas. Such wave heights were unexpected based on the existing wave statistics from the northern Baltic proper. Another interesting feature of windstorm Gudrun is that very long and high waves also appeared in the interior the GoF, an area which generally is sheltered from long waves. The combination of such waves with uncommonly high water level is a probable reason for extensive damage to certain beaches, smaller harbours and jetties in sea areas where such long waves are uncommon [3].

It might be speculated that a future storm of the same strength and duration, but corresponding to more favourable wave generation conditions, may create even higher waves. A qualitative answer to this question follows from the analysis of the different reaction of the sea surface to wind patterns travelling in different directions. Very high waves may occur in the NBP when a strong and large cyclone travels in a NNE direction. Since only a few cyclones do so [2], such a 'perfect storm' is not likely to occur. However, if it did happen, it probably would excite even rougher wave conditions.

The comparison of modelled and observed wave data shows that the basic features of wave fields during windstorm Gudrun as well as during the following stormy period were mostly well captured by operational wave models [16]. The observed properties of the roughest windseas were generally found between the values predicted by different models. Consequently, a sort of consensus forecast based on the comparison of predictions of different models and analysis of their performance in extreme conditions might give a reasonable forecast for the future storms. This forecast method is well known in meteorology where it is used for more exact determining of sensitive parameters such as the position or trajectory of tropical cyclones or potential location of floods [17]. The performed analysis suggests that this method is also applicable in predictions of hazardous wave conditions.

(Email: sjjeyamathan2004@yahoo.co.in)

Abstract

Cement is an extensively used material in Srilanka. In Srilanka, the demand for cement is high both in building and infrastructure development. However, the environmental impact of cement production process starting from preproduction stages is significant. This study scrutinizes the environmental impact due to cement production process in Srilanka. A case study of Puttalam Cement Company Ltd, (the only cement production facility that encompasses the entire production process) revealed that the production adopted the dry process, which includes supply of raw materials, clinker burning and grinding process. Further the study showed that, 4-5% dust emission is due to the kiln feed, while the other sources of dust emissions include the crushers, grinding clinker coolers and material handling equipments. The case study suggests that the major sources of CO_2 emissions are from the fuel burning and during the clinker production in kiln, which forms a part of the cement production process itself. The study found that 0.613 ton of CO_2 is emitted when one ton of clinker's produced.

Keywords: Cement, Srilanka, sustainability

1. Introduction

In Sri Lanka, cement industry was introduced four decades ago by the state and managed by the state until very recently. Sri Lanka is perhaps the only country in this region, which uses 100% dry process for manufacturing cement (Mohanty, 1997). Puttalam Cement Company Ltd is the only factory that involves cement production from raw material excavation to cement packing in Sri Lanka.

The use of cement has long been the basis for development of society and for the welfare of the people for generations. Concrete, which is made from cement, has been the ultimate material for construction. Cement manufacturing process is technology intensive. Raw material extraction causes serious environmental problems by damaging the landscape and most of these raw materials become scarce. The cement industry recognizes its responsibility to manage the environmental impact, associated with the manufacturing of its product. Mainly, there are two types of cement production process; such as wet process and dry process. The preparation of cement includes mining, crushing, and grinding of raw materials, calcining the materials in rotary kiln, cooling, resultant clinker, mixing the clinker with gypsum and milling and bagging the finished cement. The cement production technologies in use cause extensive power consumption, gas emissions, noise pollution environmental heating and emissions of fuel (CO_2, NO_X SO_2 and CO) from the kiln and precalciner. These are the major sources of environmental pollution in the cement industry to the best possible extent.

1.1 Research aim and methodology

This paper reports the findings of a research study conducted in Srilanka to investigate the cement production process and its effect on environment. The aim of the research study is to identify the cement production process and its impact to the environment. A case study research approach has been adopted, since this better facilitates to study real life context in depth. The case study was conducted at the Puttalam Cement Company Ltd. Unstructured interviews were conducted in order to have comprehensive reasoning behind the identified environmental impacts. Comparison analysis was carried out to analyze the data gathered from case study with standard and guide lines.

2. Cement production Process

A cement production plant consists of the following three processes: Raw material process, clinker burning process and finish grinding process. The raw material process and the clinker burning process are each classified into the wet process and the dry process. The major processes involved in production are excavation of limestone crushing of limestone, preparation of other raw materials, grinding of raw materials in the raw mill, storage of raw meal in a raw mill silo, blending of limestone powder to control CaCO3 percentage, burning of raw meal to form clinker, grinding the clinker with gypsum in cement mill and storage of cement in silo packing and distribution of cement.

The specifications of raw materials used for cement productions are limestone 2470 ***(ton/day),*** laterite 130 (ton/day), raw meal (ground raw materials) of approximately 2600 ton/day that are passed through the kiln towards the firing end where heat is applied with heavy furnace oil. Temperature generated from burning oil is raised in the raw meal up to about 1450 °c in order to form the clinker at the rate of 1500 *ton/* day. The kiln feed is prepared by proportioning, grinding and blending the raw material into a consistent and homogeneous composition so that, after mild heating CO_2 and water could be taken away. The raw materials are processed at very high temperature so that they can react by solid-solid reactions to form clinker. These final products determine the cement characteristics such as hardening time, the early strength and the final strength. The largest volume of raw material needed is CaCO3 or comparable materials such as oyster shells (in locations where appropriate). The CaCO3 is often mined in chunks up to a diameter of 750mm. These must be crushed to about 10mm, and then mixed with sand, shale, and other ingredients for further grinding. Grinding and reactions of raw materials such as limestone (97%-96%) and laterite (3%- 4%) takes place under controlled conditions in order to produce clinker. After grinding, depending upon the exact process, water may be added. The mixture is then taken to some high – temperature processing unit, known as rotary kiln for conversion to cement clinker. The clinker must be cooled before further processing. Then it is ground in the plant with gypsum and other possible additives to a fine powder of finished cement.

2.1 Raw material for cement

Minerals of natural origin as well as industrial products can be used for the production of cement. Starting materials for this purpose are mineral compounds, containing the main components of cement, lime, silica, alumina, and iron oxide. The two main components are generally limestone and clay. In cement raw materials. The lime component is generally represented by an amount of 76-80%. Limestone is of a predominantly fine-grained crystalline structure which influences its colour. The main component of clays is formed by hydrous aluminium silicates. Clays are divided into the following mineral groups; Kaolin group (Kaolinite Dickite Nacrite Halloysite) and Montmorillonite group (Montmorillonite, Deidellite, Nontronite, Saponite) (Watter 1977). Chalk is sedimentary rock, which is formed during the cretaceous period in geological time. Blasting is not required for quarrying chalk and the crushing process can also be omitted. This kind of raw material considerably lowers the cement production costs. Calcium carbonate ($CaCO_3$) which is wide spread in nature of all geological formations qualifies for the production of cement. The most common forms of Calcium carbonate is very similar to marble, limestone and chalk.

2.2 Production process

There are four basic types of cement kiln processes currently in use. They are wet process, semi wet process, semi dry process and dry process. The kiln can be considered as the heart of the plant as it constitutes clearly the most important step in the process of cement manufacturing. Out of these, the dry process is the most energy efficient and most commonly used technology nowadays. But these process are selected with due consideration given to the properties of raw materials, cost of fuel, condition of location and others. For the wet process, plant construction cost is rather low and high quality products are manufactured easily. On the other hand, dry process consumes less energy and its running cost is lower. The progress of technology is, however, eliminating the differences in quality between products from the above processes.

Cement is produced by heating calcium (usually limestone) silica, alumina (typically clay or shale) and iron (steel mill scale or iron ore) in cement kilns. The cement burning process (preheater) is rapidly changed and accordingly the heat consumption rate is remarkably improved. Preheater tower is the heat exchanger where the heat of kiln exit gas is transferred to the incoming material (Kiln feed). Regardless of the type, the clinker cooler is installed to improve the product quality by quenching the clinker. For drying and grinding of coal and feeding to the kiln systems such as direct firing, semi-direct firing and indirect firing are used. Generally, cement's initial strength is enhanced by improving the fineness of the product but the long-term strength is not enhanced. Therefore, excessive fine grinding should be avoided even to prevent waste of power. In cement production technologies, the recently spread roller mill makes a great contribution to the reduction of power consumption in this process.

3. Case study of puttalm cement company ltd

3.1 Introduction of Puttalam Cement Company Ltd

At present, there are two clinker grinding factories; puttalam and Kankasanturai cement factories. But Kankasanturai cement factory is not functioning for the last two decades due to the war in the north. Puttalam Cement Company Ltd is the only remaining clinker production company in Sri Lanka. Here, the clinkers are mainly obtained from Mitsui Cement and Mahaweli Marine. From the time of commissioning, for about three decades this plant was managed by a government corporation and was transferred to the pvt sector. Holcim (Lanka) with its Swiss parent company Holcim Ltd, brought worldwide experience to the Sri Lankan market, through technical and manufacturing excellence, plus a long-term commitment to Sri Lanka. Holcim Ltd focuses on long-term benefit and wishes to facilitate and be a part of the development process of SriLanka. Holcim (Lanka) Ltd operates its only fully integrated cement plant in Sri Lanka in Puttalam. It also operates a cement grinding station in Galle. The company's premium brand manufactured at Puttalam remains the only cement available in Sri Lanka that is made from local raw materials with technological know-how from one of the world's leading cement manufacturers. Its mission is to assist the growth of Sri Lanka's building and construction industry, through a long-term commitment to product quality and service excellence. These products conform to SLS 107 certification and ISO 9002 quality system.

Holcim (Lanka) Ltd continues to promote various environmental performance initiatives in its own facilities viz; reduce dust emission, create a healthy natural environment plantation, and also reduced electricity consumption. It also recognizes the importance of social responsibility as a part of its overall commitment to sustainable development. Therein, perform the following activities: maintain a community mini-hospital to provide medical services, receive proposals from premium dealers and local communities, shortlist and finalize awards to recipients, donations, press releases, workers' provident fund, community training, promote education and development.

The Putalum plant consists of several units from limestone crushers to packing plants. There are two lines of process called stage 1 & 2 each having separate processing facilities. The main processing units are crushers unit, raw mill, homogenizing plant, kiln system, cement mill and packing plant. Here, dry production process is used because energy consumption is less and running cost is also lower compared to other process. The raw materials used are in the following compositions; limestone 95-97% and laterite 3-5%.

3.2 Environmental effect due to cement manufacturing process

Emissions to air is the main environmental challenge faced by the cement industry. Main pollutions of cement productions include; cement dust, air pollution, water pollution, solid waste pollution noise pollution, ground vibration and resources depletion due to raw material extraction. Gases from the kiln and preheat are combined and used to dry and preheat the raw materials. Fuel gases consist of the components such as CO_2, N2, 02, S02, water vapor and micro components i.e. CO and NOx formation. Gases are emitted in two stages; (a) Calcinations: In high temperature, CO_2 will be released with water vapor during the CaO formation. (b) Fuel combustion: Successful operation of a rotary kiln requires an adequate source of heat that will first rise to the desired operating temperature, and then will maintain this temperature. The requirement of heat is obtained by the combustion of fuel, with a chemical reaction in which carbon, hydrogen, sulfur and nitrogen in the fuel mixes with Oxygen in the air. Dust emission is a significant source of environmental pollution during cement production.

Sources of diffused emission of particulate matters are identified in PCCL Cement. Blasting takes place at low frequency in the Arruwakkadu quarry site. The suction system of the crusher is unable to control this emission. Due to the influence of the wind, dust formation occurs at raw material storage (open yard) because of the low moisture content of the raw materials. Lots of dust is generated during the transport, loading and unloading of clinker for storage outside the silo.

3.3 Other Environments Impacts

In order to overcome deforestation, the PCCL Plant Company has a re-forestation scheme. Aruwakkadu site consists of large open space with forest. Destruction of forests depends on the quarry located. In quarry site, noise pollution is a problem due to the high noise level caused by blasting.

3.4 Gases emissions calculation

Table 1 shows, CO_2 emission per annum in PCCL plant over the period of 1990-2001 due to calcination. The below table was based on the calculation done based on the Puttalam Cement Company Limited plant report, 2001.

Table 1 CO_2 emission per annum

Year	Clinker production (tons)	Emission Factor	CO2 Production (tons)
1990	382370	0.613	234392.81
1991	398875	0.613	244510.38
1992	408925	0.613	250671.03
1993	423455	0.613	259577.92
1994	415380	0.613	254627.94
1995	403210	0.613	247167.73
1996	439190	0.613	269223.4 7
1997	453335	0.613	277894.36
1998	448505	0.613	274933.57
1999	378358	0.613	231933.45
2000	378286	0.613	231889.32
2001	379200	0.613	232449.60

The following emissions takes place in the cement production process; CO_2 emission, water vapour, SO_2 emission and NOx emission: NOx is formed from the reactions between nitrogen and oxygen in the air during combustion. According to the PCCl plant report the amount of NOx emission from cement kiln is around 200ppm (part per million), carbon monoxide (CO) is emitted in a very small quantity (approximately 0.05%) and carbon monoxide (CO) is emitted during the fuel combustion.

3.5 Particulate Pollution Abatement

One major pollution abatement method is through the use of dust collection system in various sections of cement process in PCCL plant such as cyclone separators, electrostatic precipitators (ESP), bag filters for removal and recycling arrangements for dust, except the crushers sections. During the maintenance of this equipment dust is discharged into the atmosphere without any control. However no stand-by units are available.

Dust collecting devices with the physical characteristics such as total dust load, particle size distribution, bulk density, electrical resistivity and gas volume determines the selection of suitable and efficient collection system. Some of these characteristics limit power input and collection efficiency. Dedusting equipment is in the form of bag filtering and cyclone separators. Cyclone separators (mechanical precipitation) utilize a centrifugal force generated by a spinning gas stream to separate the particulate matter from the carrier gas. It can be used at high temperatures and is suitable where coarse particles are present. Particles are removed from kiln gases by electrostatic precipitators or fabric bag collectors, either of which may be installed after the cyclone collectors. Scrubbers have had very little applications because of the problems in handling particles, which react with water. The bag filter system is one of the efficient dedusting units used in the cement industry. The filter medium is in the form of a woven textile fabric, which is arranged as tube on a suitable framework. In the course of operation, filtration efficiency will be low until a loose "floc" builds up on the fabric surface and it is this, which provides the effective filter for the removal of the fine particles. The cloth will require cleaning from time to time, to avoid excessive build up of solids, which gives room for high pressure drop. By giving knocks in regular intervals the cloth is cleaned. The Electro static precipitator has number of passages through which the gases pass. The passages are formed by two parallel rows of vertically mounted collecting plates and a number of discharges electrodes vertically suspended between the collecting plates. The high negative voltage applied discharges electrodes which creates a strong electric field between the discharge electrodes and the dust collecting plates. This produces large amount of gas ions and the positive ions being immediately attracted to the discharge electrodes, while the negative ions go towards the collecting plates. Due to these ions, dust particles are also charged. Through the influence of the electrical field, charged particles migrate towards the collecting plates. The temperature of the incoming gas stream and the voltage fluctuations greatly affect the efficiency of the extinguishers in E.S.P.

3.6 Comparisons with standards guidelines:

A comparison of the cement industries in Sri Lanka and WorId Bank group emission guidelines has been done to point out the major gaseous pollution and to improve potential application of energy efficient and environmentally sound technologies. Cement production technology based on the dry process compared to wet process is more energy efficient while it keeps running cost to a minimum. Gas emissions through kiln stack are nitrogen oxide, carbon dioxide, sulfur dioxide and carbon monoxide. Sulfur dioxide emissions are best controlled by the use of fuels. Findings show that 300mg/Nm^3 of SO_2 are stacked through due to fuel combustion. 90% of sulfur dioxide is absorbed in high alkaline condition. PCCL especially uses furnace oil which consists of low sulfur. NOx emission should be controlled by the use of proper kiln design, low NOx burners and use of optimum level of excess air. In this case, NOx emissions are 287mg/Nm^3 from the kiln stack. However the, World Bank allows maximum of NOx emissions to 600mg/ Nm3. In PCCL, the introduction of new technology of the suspension preheater kiln maintains the optimum level of excess air.

In this case, CO emission is 720mg/Nm3 from the stack kiln. However, the amount of CO emissions depends on the burner. Because, CO becomes as CO2 in high temperature. The study also found that 0.613 *t/ton* of CO_2 is emitted from the cement production process which is higher than the amount given by the standards *(0.507t1ton).* However CO_2 emission depends on the quality of raw materials and the quantity of fuel combustion. He study found that, 14-15% of green house gases are emitted into the atmosphere out of the total gases emitted from the fuel consumption in PCCL plant.

Particulate emissions are major pollution in cement industry. Here, the dust emission in a cement plant is due to improper maintenance and operation. But, all mills are provided with electro static precipitators (ESP) and bag house filters to remove and recycle dust except crusher in PCCL plant. The study revealed that, the dust emissions are approximately 52g/Nm^3 in kiln stack. World Bank standards allows maximum of 50mg/Nm3 for particulates in stack gases under full load conditions. However, the use of electro static precipitators on kilns has not been very successful in controlling pollution. Discharge of large quantities of dust into surrounding has caused drop in crop yield in nearby coconut plants and cause damage to other trees by settlement on the leaves.

3.7 Suggestions for production improvement

In this case, dust emissions can be reduced by proper maintenance of bag house filter. A schedule for maintenance should be prepared. In house dust emission measurement i.e. intensive monitoring of bag house filters should be carried out to gain more information about its effectiveness. Properly designed and operated ESP can reduce dust emission to as low as 25g/Nm3.The efficiency of ESP can be improved by decreasing the actual gas flow through ESP. It will have a positive effect on the dust collection. The reduction of the intake air leakage and a motor control system of fans will allow a better control of the flue gas flow. When the installed CO analyzer is taken out for maintenance, ESP is switched off to prevent explosion, which can occur due to high concentration of CO. CO measuring equipment should be installed in the stack of ESP, which can be connected to the sampling point of the CO analyzer after the preheater.

4. Conclusions

The cement production process consists of three processes; raw material process, clinker burning process and finish grinding process. The raw material process and clinker burning process are classified into wet process and the dry process consumes les energy while keeping running cost to its minimum. The processes are selected with consideration given to the properties of raw materials, costs of fuel, conditions of location and other factors.

Cement production is one of the main pollution contributors due to its extensive energy consumption and gas emission. Dust emission from kiln feed is 4-5%. Other sources of dust emissions include the crushers, grinding clinker coolers and material handling equipment. The priority in the cement industry is to minimize the mass load emitted from the stacks. According to the observation of study, PCCL dust collection system such as cyclone separators, electro static precipitators and bag house filters for removed and recycling arrangement is made for dust. But no standby units are available. So, during the maintenance of this equipment, dust is discharged into the atmosphere without any control. In this case, two significant types of control problems can encounter; automatic shut-off of systems related to plant, power failures leading to the emission of particulates to a higher level for shorter period of time and gradual decrease in the removed efficiency of the system over time because of poor maintenance or improper operation. Green house gases are produced directly from fuel consumption and additional cement production process itself releases carbon dioxide when the calcium carbonate in lime stone is converted to calcium oxide during the production of clinker in kiln. Also, 0.613 ton of CO_2 emission from one ton of clinker is produced.

In this case, NOx produced due to combustion of fuel. Based on calculation, the NOx emission is 287mg/Nm3. NOx should be controlled by adjustment of the kiln burner and use of an optimum level of excess air. Sulfur- dioxide emissions are best controlled by use of low sulfur fuels. In PCCL, the use of fuel consists of low sulfur concentrations. $S0_2$ emissions are 300mg/Nm^3, where 90% of $S0_2$ is absorbed by clinker in highly alkaline condition. In PCCL, the use of water is limited because the process is based on dry process. Through observation it was found that the water is used at its minimum, because the use of water for cooling purposes and water spray for dust is controlled.

The PCCL plant is situated in large area. In the surrounding there is no public living therefore, noise emission has not caused a big problem to people. With blasting at quarry site, the intensity of the vibration emission can, to some extent be controlled by the technique employed (number and spacing of blast holes, amount of explosive fired, depth of holes). Considering the energy consumption, the process of cement manufacturing process consumes two types of energy. According to observation, earlier the factory used large amount heavy furnace oil as a thermal energy. But, by changing to furnace oil, the cost of production could be reduced slightly and the gradual reduction of specific energy consumption is due to the introduction of 4- stages of suspension preheaer at factory. According to Holcim progress report June 2002 consumption of heavy furnace oil rate is 3.095t/h.

The industry can take range of steps to reduce its green house gases emissions. Introduction of Greenhouse Energy Management System (GEMS), which is based on the green gas monitoring and evaluation has streamed- lined identification of options for reducing greenhouse gas emissions, reduce thermal energy consumption, minimize dust by proper maintenance of bag house filters and ESP, optimizing of electro static precipitators and water sprayer at site to installation of complex pollution control equipment. The industry can take measures to reduce its green house gases through some kind of plantation in surrounding.

Abstract

Adverse impacts of uncontrolled Greenhouse Gas (GHG) emissions have been identified by the global community and ratified by the Kyoto Protocol (KP). Clean Development Mechanism (CDM) under the KP is a flexible mechanism by which developing countries could harness benefits by way of offering GHG arrays through various GHG reduction measures. This study aims at investigating the "Contribution of Commercial Buildings towards GHG emissions", as an initial step towards offering GHG arrays through Commercial Buildings. The focus of the study is placed on 20 high rise buildings in the Colombo Metropolitan area as it attracts more investment than other parts of the country and also is the main financial centre of the country. According to statistics, more than 60% of financial transactions take place in financial institutions located in Colombo. The selected sample is a collection of ten office buildings, five hotels and five mixed developments. Monthly energy consumption details of the selected buildings were collected by analyzing electricity bills of Ceylon Electricity Board (CEB) and self generated electricity units consumed. In order to come up with the derived contribution of commercial buildings towards GHG emissions by the demand placed on the grid; existing thermal power plant data and their share of electricity supply on to the national electricity grid was examined. Based on the above data Derived Contribution of Commercial Buildings towards GHG emissions was quantified.

Key Words: GHG Emissions, Energy Consumption, Commercial Buildings

1. Background

1.1 Significance of Addressing GHG Issues

The complex global atmosphere which affects the climatic change is linked to the oceans, the biosphere and the world's water cycles. The industrial revolution and the human activities since then have fundamentally affected not only the atmosphere but also each of these systems. The resultant Global Warming trend that was inevitable has captured worldwide concern, especially in the developed regions. These regions mainly focus in mitigating the source of problem, namely the emission of GHGs. 80% of the anthropogenic emissions of GHGs are said to be directly related to energy consumption activities [1], and these GHGs are considered as stock pollutants and unlike many local air pollutants have an accumulating effect over time. These heat-trapping gases are generally well mixed in the atmosphere and as a consequence their impact is mostly independent of where it was emitted. The Kyoto Protocol (KP) ratified in 2005 which was initially negotiated by more than 160 nations in December 1997, at the third Conference of Parties to the United Nations Framework Convention on Climatic Change (UNFCCC), addressed the reduction in net emissions of certain GHGs, primarily CO_2. It has been estimated that over 70% of today's atmospheric anthropogenic GHG emissions are generated by the industrialized world. At the same time researches have predicted by the year 2015 China will be the largest overall emitter of GHG, and by the year 2025, the developing world will emit more GHG in total than the developed world [2]. The main complaint on this issue by developing countries is that they are being asked to limit their capacity to industrialize, reduce poverty and raise their standards of living. They are demanding the freedom of developing first and then taking actions to create an environmentally sound atmosphere, as been done by the countries that industrialized at an earlier time. Laboratory in Berkeley, California has found in an Asian study [2], that developing countries are already doing a lot to reduce their emissions, but these activities does not arise from climatic change concerns according to him. Stuart [2] further said, "They are improving their energy efficiencies and removing energy subsidies". But the studies show that they can do a lot more without jeopardizing their economic growth with any where from 5%-15% reduction in emissions possibly without negative cost". But he added that these countries need new capital and technology to achieve these reductions.

As a developing Asian country, Sri Lanka is only responsible for a relatively low content of GHG emissions, both in relation to the absolute as well as per capita terms.

Table 1: A comparison of CO_2 Emissions in Several Asian Countries

Country	Kg CO2/1990 US$ of GDP
Sri Lanka	0.63
Pakistan	1.62
India	2.17
Indonesia	1.37

Source: Ranasinghe, 2000 [3]

Nevertheless there is a high probability of increased GHG emissions from the country, in consequence of various development processes which are inevitable in upgrading the countries performance as a whole. Even then the anthropogenic GHG emissions from Sri Lanka will be negligible in comparison with the global scenario. However we must not forget the fact that as evident in the Global GHG scenario, little by little concentrations over years have grater impacts, and that prevention is always better than cure. Being a developing country Sri Lanka is equipped with the capacity to participate in the CDM, with respect to the Kyoto Protocol. The implementation of the CDM would result in competition among developed countries by offering arrays of GHG mitigating projects. Therefore it is high time to identify the prospective GHG mitigating projects in the country in various sectors. Commercial buildings sector plays a major role in the Sri Lankan economy, due to their contribution to the GDP via, various hotels, shops, offices, restaurants, etc. In addition the CEB statistics show that being responsible for a considerable number of consumer accounts as well as unit consumption and revenue generation; commercial sector represents the most viable means, where the demand on the national grid can be controlled.

The aim of the study reported in this paper is to derive the contribution of commercial buildings towards GHG emissions based on energy consumption trends.

1.2 Data Collection

The research is focused on a selected group of high-rise commercial buildings in the Colombo metropolitan region for a quantitative analysis. Because Colombo Metropolitan area is considered as the Heart of the commercial sector housing a large proportion of such facilities like Offices, Shops, Hotels, Mixed Developments, etc. Also the energy consumption of this sector peaks in this area due to the more sophisticated services supplied in these building to cater the target consumer groups. Even from these high rise buildings are significant energy consumers in this sector.

In order to select a sample a preliminary survey was carried out mainly by way of interviews with the personnel responsible for overall maintenance of a selected group of high rise buildings. This was made easy as a result of the comparatively low concentration of high rise commercial buildings in the area. This survey extended towards just above thirty buildings and due to various inconsistencies and problems a sample of 20 buildings were selected for the final survey. Table 2 shows the composition of building types chosen for the study. The selection was mainly based on; type of building, cooperation of the officials, availability of data, consistency and reliability of data, continuity of data, and ease of collection of data.

Table 2: Composition of Building Types

Type of Building	No of Projects
Office	10
Hotels	5
Mixed Developments	5

The final data collection concentrated on the energy consumption of these buildings from the national grid as well as by way of self generation. The data collection was on a monthly basis up to a minimum of two years in the case of demand on the national grid. However the data collection on the self generation was mainly restricted to the periods of continuous power cuts imposed by the CEB. Due to the lack of attention on record keeping of data, the main emphasis in the analysis was placed on the self generation during year 2001 in most cases. Based on the collected data possible contribution towards GHG emissions of these commercial buildings were derived based on several scenarios.

2. Generation of Energy Vs GHG emissions

2.1 Electricity Generation

The energy demand of Sri Lanka is supplied by the combination of the indigenous primary sources of energy, imported primary sources of energy and imported secondary sources of energy. Indigenous primary sources of energy are biomass, hydro potential energy, solar power and wind. Imported primary sources of energy are crude oil and small quantities of coal. Refined petroleum products are the imported secondary energy sources [4]. The aggregate supply of primary energy was estimated as 9.1 million Tons of Oil Equivalents (TOE) in 2003 [4]. As a developing country, Sri Lanka's per capita energy use is annually increasing. In year 2003, the total energy demand was supplied by the combination of biomass (48%), petroleum (43%) and hydro potential (9%). Meanwhile during the year 2003, industrial sector and transport sector respectively contributed 24% and 25% of the total energy demand in the country, and the rest of the demand was from household, commercial and other sectors [4].

Sri Lanka is one of the countries where electricity consumption has been increasing rapidly over the last few years. This is evident from both the trend of electricity generation and consumption by various sectors. Until 1996, Electricity demand of the country was completely met by the CEB owned hydro and thermal generating plants. The existing generating system in the country is still predominantly owned by CEB, which is about 93% of the total existing capacity where the balance is owned by Independent Power Producers (IPPs).

It has been projected the fossil fuel based electricity production will rise from 7.7% in 1991 and 48% at present to 74% in 2016 [5]. This will lead to consequent increase in the emissions of atmospheric pollutants. Further statistics indicate that the share of thermal electricity generation has risen drastically with a six year average growth of 66.9% and a ten year average growth of 33.4% opposite to -0.6% and 0.28% respective growths shown in Hydropower generation. When considering the electricity generation in the country it has been constantly increasing. However when considering hydro and thermal power generations separately it is evident that their cyclical nature in generation have been resultant from the thermal generation increases in order to meet any deficit in generation by hydro plants in drought periods.

The CEB owned thermal electricity generation share has visibly grown over the recent past. All these plant operations are based on three types of fossil fuels, namely Auto Diesel (AD), Fuel Oil (FO) and Residual Fuel Oil (RFO). The impact of thermal electricity generation on environment could be primarily due particulate or gaseous emissions. These gaseous emissions could take the form of CO_2, SO_x, NO_x, etc., where CO_2 and NO_x are identified as primary GHGs by the International Panel for Climate Change (IPCC).

2.2 GHG Emissions from Thermal Power Plants

80% of the anthropogenic GHG emissions are directly linked to energy consumption activities [6]. Thus fuel combustion, which constitutes a major process in both energy industries and energy consumption activities, invariably outshines others with regard to their contribution to GHG emissions in a country context. Figure 1 represents the totals of main GHG emissions from thermal power plants (TPPs). These figures were derived from calculations which were based on fuel consumption data of TPPs obtained from the statistical Unit [7], and emission factor for different fuel types from the generation planning branch [5].

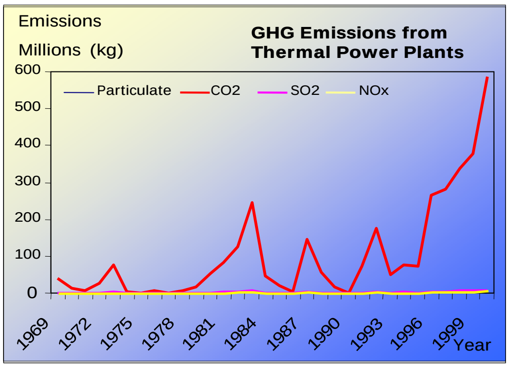

Figure 1: Emissions from Thermal Power

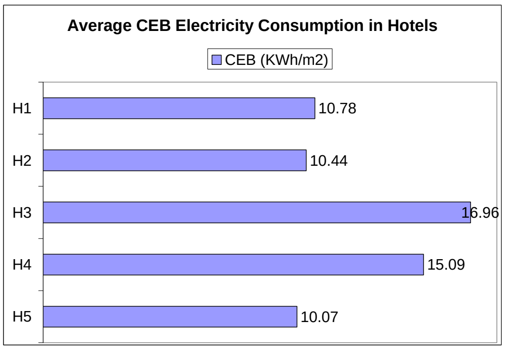
When taken as a whole as evident from above Figure 1, CO_2 emissions from TPPs dominates the others amounting to about 96.5% of the total emissions. Therefore the study is limited to derived CO_2 emissions as a result of energy consumption in commercial buildings.

3. Energy Consumption of Commercial Buildings

3.1 Hotels

In order to facilitate comparisons among the hotels themselves, the collected data on the monthly electricity consumption was summarized based on the monthly average consumptions and presented in Figure 2 below;



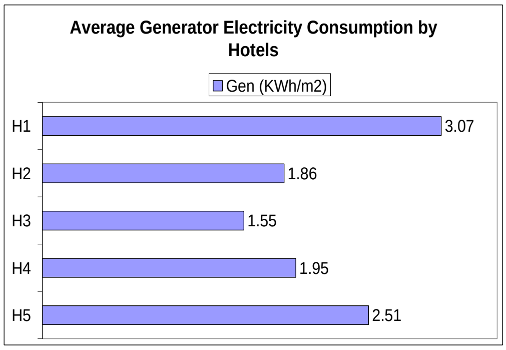


Figure 2: Average Monthly CEB and Generator Unit Consumption by Hotels

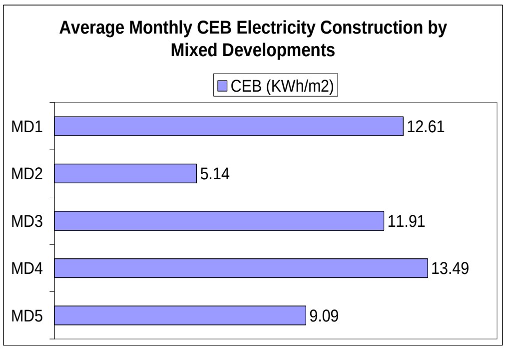
The above charts indicate that in considering the CEB unit consumption alone except for H4 and H3 whose energy consumption averages around 16.0 KW/m^2, the others shows a lower average of around 10.5 KW/m^2. However in considering the self generated unit consumption it can be said that the H3 while being the highest CEB unit consumer per GFA, have managed to become the lowest in this category with an average of 1.55 KW/m^2. All in all H2 show the lowest unit consumption of the Hotel sector amounting to 12.3 KW/m$^{2.}$ Further it was revealed that they were implemented various programmers, contests and discussions to increase the employee awareness on energy saving.

3.2 Mixed Developments

The collected data on the monthly electricity consumption of mixed developments were summarized based on the monthly average consumptions and presented in Figure 3 below;



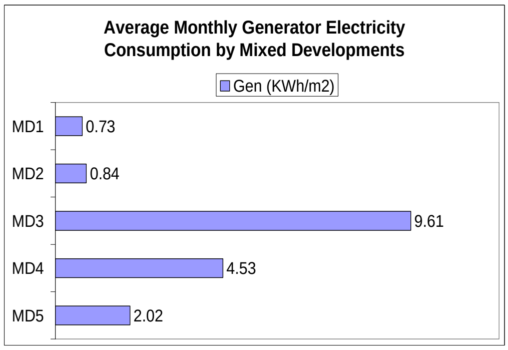


Figure 3: Average Monthly CEB and Generator Unit Consumption by Mixed Developments

On considering the actual unit and cost consumed by this sector a considerable deviation could be seen. This is could be mainly owing to the different levels of occupancy rates in these different developments. So in case of correcting the above figures, taking into account occupancy rates the data could be presented as follows

Table 3: Average Monthly CEB and Generator Unit Consumption by Mixed Developments- Corrected for Occupancy Rates

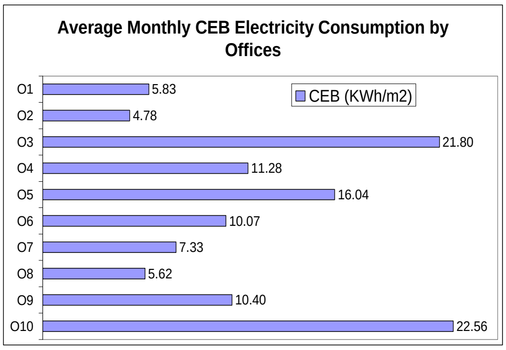
Mixed Developments	Occupancy %	CEB (KWh/m^2)	Gen (KWh/m^2)	Total (KWh/m^2)
MD5	75	12.12	2.69	14.81
MD4	100	13.49	4.53	18.02
MD3	90	13.23	10.67	23.90
MD2	55	9.34	1.52	10.86
MD1	70	18.01	1.04	19.05

The above table indicates that even with regard to adjusted electricity consumption levels MD2 still leads the others with a comparably low consumption rate of 10.86 KW/m^2. The buildings occupancy rate of 55% may have influenced this even after adjusting, which was done on a linear basis, where this may not be the case. Also the stringent control measures that are being implemented may have some effect on the above. MD3 building is recorded as the most inefficient building with regard to their generator unit consumption, which may be a result of inefficient generators and losses in transmission, etc. On considering the CEB unit consumption per m^2, MD1 seems to be the most inefficient building with a consumption rate of 18.02KWh/m^2. This may be owing to magnitude of the building which houses a range of services and the comparably high volume of common areas. The low level of generator consumption in this building is due to the inadequate generator capacity for supplying energy to the whole building.

However between the two extremes of 11KWh/m^2, around 17KWh/m^2 could be taken as an appropriate electrical energy consumption rate for these types of buildings, where the MD5 has been able to achieve with comparable margin with their energy conservation efforts. On considering the magnitude of the building MD4 tower can also be concluded to be somewhat energy efficient.

3.3 Offices

To facilitate comparisons between different office buildings the average monthly consumptions could be graphically represented as follows in Figure 4.



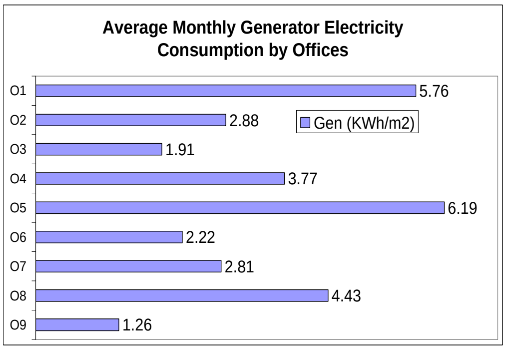


Figure 4: Average Monthly CEB and Generator Unit Consumption by Offices

The above figures contain two extremely high values with regard to CEB energy consumption per m^2. A major reason behind this could be that the existence of two telecommunication offices within the buildings which are believed to be equipped with heavy energy consuming transmitting equipment. In O10 almost half of the building energy consumption is being utilized by them, who only house around 20% of the GFA. On the other extreme the reason behind the lower CEB unit consumption per GFA in the O8 is a result of it being not totally air conditioned. With regard to the same in O2 it may be due to the building being still at the finishing stage of its construction, resulting in non utilization of it up to its potential, even though it's almost fully rented out. The recent commissioning of the building may have caused this low figure in case of the O1. With regard to generator unit consumption the O9 shows a very low figure of 1.26 KW/m^2. Here again even though they are equipped with the full capacity, they might be exercising the freedom of not providing the whole range of services during the power cut periods. The higher values retained by the O5 and O1 with regard to these may arise from one of the facts of trying to participate in the rebate scheme provided by the CEB or else inefficiencies during the generator power generation or distribution.

When taken as an average these types of buildings seem to consume around 15, 14, and 13 KWh/m^2 with regard to CEB and self total energy.

Table 4: A Comparison of Unit Consumptions of Building Types

Building Type	**KWh/m²**		
	CEB	**Generator**	**Total**
Hotels	13	2	15
Mixed Developments	10	4	14
Offices	9	4	13

On considering an overall picture of these 3 types of buildings it is evident that Hotels are the major consumers of electricity per building area with regard to CEB units consumed. The above may be owing to the higher electricity demand of these buildings to cater the required comfort levels through out the day. When considering the CEB electricity consumption of the mixed developments and Offices, the latter leads with regards to energy use.

4. Possible Contribution of Commercial Buildings towards GHG Emissions

4.1 Emissions from Thermal Power Plants

Derived emissions arise from the demand placed on these types of buildings on the national electricity grid. In order to come up with the emissions, the shares of CEB hydro and thermal supply proportions were considered. Based on the following data, possible shares of thermal power consumption of these buildings were calculated.

Table 5: CEB Hydro and Thermal Shares Used for Calculations

Year	Hydro %	Thermal %
1999	0.75	0.25
2000	0.59	0.41
2001/2002	0.62	0.38

Then based on the results the possible derived emissions from the buildings were quantified. On quantifying the emissions a CO_2 emission factor of 75.13kg/GJ was used. The factor was derived from considering the average of these factors of CO_2 emissions from 3 fuel types used in thermal power plants namely fuel oil, auto diesel and residual fuel oil [7],[8]. From the figures derived from above calculations, the following graphs were plotted to indicate the trends in total CO_2 emissions of the 3 types of chosen buildings based on yearly average. The charts represent somewhat a similar trend with regard to total CO_2 emissions for all three types of buildings. In all types an increment of emissions were visible in the year 2000. While a sharp decrease is shown in 2001 by Hotels while these are more gradual in case of the other two types. Then again all three show an in increasing trend.

Table 6: Derived CO_2 Emissions in kg

Building Type	CO_2 Emissions kg				
	1999	2000	2001	2002	Average
Mixed Developments	1,354,779	2,908,006	2,615,849	3,177,743	2,514,094
Hotels	2,920,915	4,126,402	3,270,434	3,881,414	3,549,791
Offices	801,353	1,974,481	1,638,066	1,788,536	1,550,609

As explained earlier the trend in emissions seems similar despite the deviations in their quantities. Here hotels seem to be the largest contributor when taking the total emissions in to account, amounting to 705,958 kg per year per building, followed by Mixed Developments and Offices respectively.

Here the contribution of offices per building is seen as very low where it is accountable for only around one fifth of emissions from Hotels and one Third of emissions in the case of Mixed Developments. In order to come up with a better consumption of CO_2 emissions from different types of buildings the above figures were divided from the associated Gross Floor Areas (GFAs), to come up with the CO_2 emission kg/m^2 per year, as shown in the following charts.

Table 7:CO_2 Emissions in kg/m2

Building Type	CO^2 Emissions kg/m2				
	1999	2000	2001	2002	Average
Mixed Development	6.75	14.48	13.03	15.82	12.52
Hotels	12.25	17.3	13.71	16.28	14.89
Offices	5.25	12.94	10.74	11.72	10.16

The trend seems to continue with regard to emissions per GFA of the selected types of buildings with Hotels leading and Offices being the lowest. However, in terms of the pattern of duration of occupation (on a daily or weekly basis), it can be claimed that offices are not so environmentally friendly compared to mixed developments and hotels.

Also from above figures it could be concluded that accountability of these three types of developments are almost same with regard to their contribution towards CO_2 emissions on the basis of per m^2.

4.2 Emissions from self Generation

Emissions from self generation were derived from the data collected of the units generated by these buildings together with the fuel efficiencies of the generators by way of KWh/I, which were collected during the survey. Then the derived quantity of diesel used was used to come up with the amount ofCO_2 emissions by the use of a factor of 2.7kg of CO_2 per diesel liter utilized [7],[8].

As mentioned several times earlier the power cuts imposed by the CEB have a great influence on the self generation patterns, thus on the emission levels by self generation .

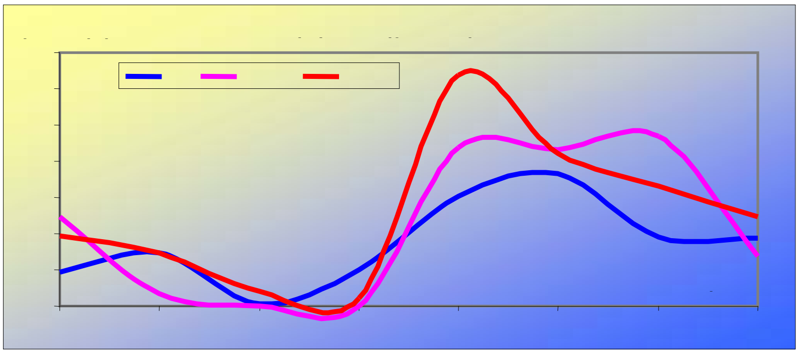

Figure 5: Actual CO_2 Emissions from Self Generation-A Comparison

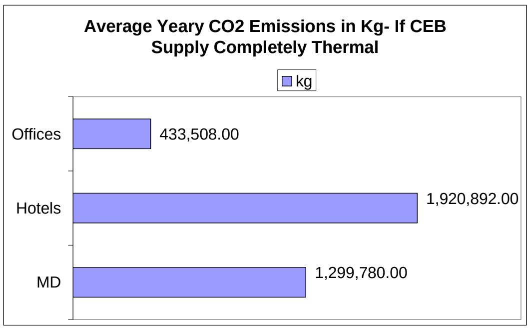
4.3 Possible Emissions If Fully Based On Thermal Power Generation

The trend of power supply by the CEB is via the expansion of its thermal share as been discussed in the previous sector. Also the prolong droughts that may come about in the future may lead to the power supply being almost wholly based on thermal power. Taking the above extreme situation in to account in this sector a hypothetical case is examined, where the whole CEB supply would be based on thermal power. Based on this hypothetical scenario possible emissions of CO_2 by the electricity demand placed on the grid by commercial buildings was examined. The calculations were again based on the CO_2 emission factor of 75.13 kg/GJ as in the previous case. Yearly total emissions were calculated for the three types of buildings. Then based on these calculated figures yearly emissions of CO_2 per unit area were derived. In case of Hotels and Mixed developments it seems the possible emissions levels will increase drastically in the above scenario, due to the larger floor of the latter. Even though this is unlikely to fully realize in the near future expansion generation plans indicate a considerable increase in the thermal share (74% in the year 2016), which may in time to come have the potential of growing further. On considering the average yearly CO_2 emissions based on this hypothetical scenario, per building and per unit area of building, based on the three types of facilities the following graphs could be derived.

It could be observed that based on the above scenario, the trend in actual emissions has increased in a similar to the actual scenario but amounting to higher emission levels. In this kind of a scenario it could be concluded that the average emission level per m^2 of building could be taken as 34kg.



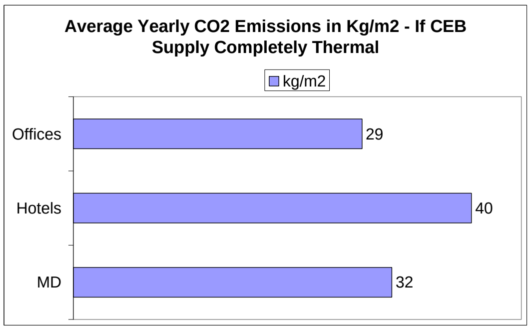


Figure 6: Possible CO Emissions in case of CEB Share fully Thermal-A Comparison

5. Conclusions

The significance of impacts on the natural environment resulting from the increased concentrations of GHGs and the importance placed on addressing these issues by the global community is well known. Despite the set backs placed by several economic giants, global community is ready to enter in to a carbon constrained world with or without their support. Ratification of the KP with binding GHG emission reductions is a mile stone achieved in this respect by the global community. In terms of the Sri Lankan context, the trend in fossil fuel based electricity production of the country has risen from 7.7% in 1991 and 48% at present, and is expected to increase further up to 74% in 2016. In addition to the above as a result of the candidate coal based power plants with higher GHG emission factors the countries contribution towards these emissions shows a drastic increasing trend. The commercial building sector is accountable for a considerable share of the demand placed on the national electricity grid and thereby become accountable for a considerable quantity of derived GHG emissions. A summary of findings with regard to this accountability can be presented as follows.

Table 8: Summary of Total Emissions by Different Types of Buildings

CO_2 Emissions by CEB & Self Generated Unit Consumption (kg) per year						
Building Type	Actual			Hypothetical		
	Per m^2	Per Building	Aggregate	Per m^2	Per Building	Aggregate
Hotels (5 Nrs)	16.58	791,042.75	3,955,213.76	41.70	2,001,976.54	10,009,883.71
MD (5 Nrs)	14.14	568,288.13	2,841,440.68	34.63	1,365,249.27	6,826,246.38
Offices (10 Nrs)	13.66	208,450.25	2,084,502.50	32.50	486,897.35	4,868,973.50

Even though the above indicate that the Hotels as the largest contributor towards GHG emissions, in reality they are already conscious of and are implementing a considerable amount of energy efficient measures. by which to become more energy efficient These are through various programmers, contests, discussions etc., aimed at mainly increasing employee awareness and exploring means. However the above concerns are mainly based on financial benefits derived. In this sector further increase of operational energy efficiency is questionable and may present low potential, as substantial measures are already in implementation for energy conservation. In case of office buildings, despite their low contribution towards the emission of GHGs, they present further potential for emission reduction, by adhering to various energy saving measures. Adhering to standard comfort cooling condition, switching off of unnecessary lighting fittings and efficient use of office equipment could be considered as some initial candidate options for above. In case of Mixed Developments the energy efficiency mainly depend on the tenants of the apartments. Here an option for operational energy efficiency increment would be awareness programmes, where by an environmentally friendly attitude could be planted on these users.

Apart from the above measures various energy efficient technologies could be used in all three instances to make them more energy efficient. The higher costs of adopting these technologies, lack of access or awareness, together with the associated risks were identified as major barriers for their popularity.

SECTION XV

POST DISASTER RELIEF

Sanitation during disaster relief and reconstruction; the experiences of Asian Tsunami 2004

Missaka Hettiarachchi
Department of Chemical and Process Engineering,
University of Moratuwa,
Sri Lanka
(email: missaka@cheng.mrt.ac.lk, nandalochan@yahoo.co.uk)

Abstract

Sanitation is an issue often neglected in development decision making. This situation becomes more evident under the extreme conditions of a disaster aftermath, where lack of sanitation can expand from a mere inconvenience to a full-scale secondary disaster causing epidemic out-breaks, permanent degradation of water resources and social unrest. Furthermore neglecting the importance of sanitation during disaster rehabilitation may jeopardize the sustainability of entire rebuilding projects.

This paper is an attempt to delineate and suggest solutions to the critical problems encountered in providing proper and adequate sanitation during refugee situations and post-disaster rehabilitation projects in underdeveloped tropical countries. The author records the experiences gained in several projects carried out as a partnership of Government and NGO sector organizations during the aftermath of the 2004 Tsunami incident in Sri Lanka. The paper also discuss how "proper and adequate sanitation" can be ensured through a proper disaster management framework. The paper would critically review the institutional drawbacks and failures which lead to the above mentioned unfortunate situations.

Keywords: Disaster Sanitation, Post-disaster rehabilitation, Social Acceptance, Sustainability, Institutional frameworks, Governance

1. Background

1.1 Disasters and Sanitation

Sanitation was officially identified as a "Basic Human Need" under the Mellenium Development Goals declared by the UN prior to year 2000. Further efforts are currently underway to recognize Sanitation as a "Basic Human Right". The available technology and know-how in the sanitation sector is sufficient to provide "Proper Sanitation" in any major geographical/climatic region of the world. Despite all these technical and policy advancements, sanitation still remains a second priority in development decision making in many developing countries. This fact becomes woefully evident during disaster relief and rehabilitation.

Access to “Proper and Adequate Sanitation” is a factor that determines the stability of a community under extreme situations. This makes it an important concern in all the phases of disaster management. But during many recent disaster situations which occurred in the South / Southeast Asia, such as the Asian Tsunami of 2004, Great Earth Quake of Pakistan (2005) etc many failures were recorded in providing access to sanitation. This paper gives a Birdseye View of how the sanitation issues were handled during the Asian Tsunami aftermath in Sri Lanka reviewing technology, management systems and institutional aspects.

Any disaster management program can be divided into three phases, which are namely: a) Immediate relief b) Intermediate rehabilitation and c) Permanent rehabilitation. Provision of “Access to Proper and Adequate Sanitation” is an important aspect in all three phases, but the methods, technology and tools applicable may vary significantly from phase to phase. A proper and adequate sanitation scheme ensures hygiene, minimal environmental impacts, social acceptability, durability, comfort and safety of the users [7]. The adequacy of a sanitation scheme may be easily judged by the existing standards on sanitation(disaster guidelines, regulations etc.), but assessing the appropriateness (“proper”) is not that straightforward and may differ significantly according to the geography, social setup etc. During the immediate relief and intermediate rehabilitation phases the adequacy may be defined by disaster guidelines such as “Sphere Handbook” developed by UNHCR. In the Permanent Rehabilitation Phase the existing standards and regulations on sanitation in the country would ultimately define the adequacy.

An appropriate technology, proper awareness on sanitation among all the stakeholders and an effective framework for implementation should essentially be brought together for success of any disaster sanitation scheme. Failure to fulfil any of the above requirements would inevitably lead to an abrupt or gradual failure of the entire scheme (see figure 01).

Figure 01: Three Components of Disaster Sanitation

Again the nature of technology, strategies for awareness building and the structure of the management framework may change significantly among different stages of disaster relief and reconstruction. The paper will discuss the experience gained by the author during each phase of Tsunami relief and rehabilitation in Sri Lanka with regard to sanitation. It separately takes into account the aspects of Technology, Awareness and Implementation Framework for each phase.

2. Immediate Relief and Intermediate Rehabilitation

2.1 Situation Analysis of 2004 Tsunami

Tsunami wave of December 26th 2004 rendered nearly a million people homeless in the immediate aftermath. Food & Shelter, Medical attention and Sanitation were the three main aspects which had to be given focus by the organizations looking after the Internally Displaced People (IDPs). Although the first two issues were successfully coped with, there is evidence to believe that post tsunami relief operations failed to ensure access to proper sanitation facilities for the IDPs in some places. Table 01 gives a list of such typical failures and their causes along with some actual examples.

Table 01: Reasons and examples for lack of sanitation during the immediate aftermath [5]

Reason	**Example**	**Location**
Large number of IDPs concentrated in certain camps	1000 inmates with only one toilet at a transit camp near Colombo	Transit camp at Koralawella –Moratuwa managed by SERV Sri Lanka
Constraint of space	162 IDP families cramped in a 3-4 acre compound in a IDP camp in Negambo	Government IDP camp at Fisheries Training Centre - Negambo
Lack of funds	Allocated funds to provide sanitation facilities are inadequate or diverted to other needs	DO
Unhygienic habits of some groups of inmates	Fisher communities in Negambo had poor sanitation habits this lead to a difficulty in maintaining hygiene in the camps	DO
Lack of expertise & Lack of labor	Skilled workers were also among the affected people in many areas and could not render their services	IDP Camp Malharus Maha Vidyala, Sainthamarathu, Eastern Province
Unsuitable physical conditions	High groundwater level and none-soaking soils frequently found in the coastal areas of Sri Lanka made the conventional disaster latrine techniques inapplicable	DO

Lack of awareness about the importance of sanitation among the institutions involved in disaster management could also be observed generally in all the effected areas. The institutional capacity (i.e. Skills or Resources) to handle the issue of sanitation were either inadequate or non-existent. Therefore many weaknesses were observed during the immediate aftermath of the 2004 Tsunami in Sri Lanka in all the three components of Disaster Sanitation (Technology, Awareness and Implementation Framework).

2.2 Technology and Practice

The disaster sanitation techniques that were in practice prior to the 2004 Tsunami were confined mainly to open pit or trench latrine systems. Portable chemical latrines were available in the country, but were mainly hired by private companies for public events [5]. Provision of detergents and sanitation chemicals were not taken as an aspect of sanitation, it was looked after under provision of medical and health supplies. Therefore only the latrine construction techniques will be reviewed here. Some of the weaknesses of conventional disaster latrine techniques are given in Table 02.

Table 02: Weaknesses in conventional emergency latrine techniques [5]

Technique	Main draw-backs
Temporary pit latrines	In most areas the soil was not good for unlined pit latrines. Soil type found in most of tsunami affected coastal areas (Sandy Regasols) would easily collapse under self weight due to the low cohesion factor. The conventional slab and pit configuration can be very dangerous, if the slab is not constructed under proper supervision.
Shallow Open-trench latrines	Due to the fact that sewage or faeces remain exposed to atmosphere and insects/vectors (only covered by a thin layer of soil), open trench latrines may release bad odour and become a threat to public health. This situation will be aggravated under excessive-use conditions in tsunami IDP camps. Many elderly inmates as well as small children will find it difficult and psychologically unfit to use trench latrines.
Portable latrines or “Portaloos”	Both construction and maintenance of Portaloos are expensive in several folds than other emergency latrine types. Portaloos were not readily available with any government institution in Sri Lanka. Portaloos are heavy and bulky structures. The destruction of roads and railways due to tsunami would have hindered the transport of Portaloos to affected areas even if they were available.

Due to the scale and complexity of the Tsunami disaster, the weaknesses of the disaster sanitation techniques practiced until then became more evident. It was clear that these techniques should be replaced with a set of scientifically proven and systematic techniques which are applicable to different site-specific conditions. The author was involved in an intensive program to develop and implement a set of appropriate sanitation techniques for IDP camps in the immediate aftermath of the 2004 Tsunami. This was carried-out as a joint project of Department of Chemical and Process Engineering University of Moratuwa (Sri Lanka), Department of Civil Engineering University of Peradeniya (Sri Lanka) and Network for Women

Water Professionals, Sri Lanka. The project identified the points given in BOX 1 as the essential characteristics of an appropriate disaster latrine technique;

During the problem identification phase of the project it was observed that construction of lined pits, construction of sanitary toilet floors and discharge of effluent under un-soaking conditions were the main problem areas. Taking these into consideration and based on the above guidelines a series of disaster latrine techniques called the Sri Lankan Disaster Latrine (SDL) Series was developed. There were four versions in the series (SDL 1 – SDL Plat).

1. Technically sound and suitable for site conditions.
2. Hygienic and safe for any category of users.
3. Minimum environmental impacts
4. Low cost of construction and maintenance.
5. Simple technology (both construction and maintenance) & Minimum requirement of technical expertise.
6. Local availability of required construction materials.
7. Quick installation.
8. Social acceptance

BOX 1

SDL 1: Main objective of SDL 1 was to provide a successful fast-construction and low-cost alternative for brick or concrete lined pits. SDL 1 uses a steel or HDPE barrel in place of a brick or concrete lined pit. It was calculated that with proper perforation and providing adequate soakage area a simple 250l steel barrel could be used as a pit for 3- 5 moths by 20 people. Price of a used barrel is only a fraction of the original fabrication cost but the strength of the material remains intact.

SDL 2: With the delays in constructing intermediate camps and difficulties in providing permanent toilets in them, SDL 1 had to be modified to last longer. To extend the usable life SDL 2 was designed with a provision to for de-sludging and finished with anti-corrosive treatment so that it could remain underground without corroding for at least one year.

Bother SDL 1 & 2 were successfully constructed and used in two IDP camps in Negambo.

SDL 3: Both SDL 2 and SDL 1 could only deal with site conditions which permit soil soaking. In places where soils were water logged or none-soaking the effluent after solids retention had to be released to a surface drain. Therefore a new version had to be developed where the discharge from the barrel is further treated (secondary treatment) before released into the environment. After considering several methods available for low-cost insitu treatment of night-soil, it was decided that attached growth upward anaerobic filter (anaerobic filter) is the best method for secondary treatment in this case. Therefore SDL 3 was designed as a twin barrel system where one acts as the septic tank and other as the Upward Anaerobic Filter.

SDL 3 was constructed in a small IDP camp in Moratuwa (20km South of Colombo) only as a pilot project and was tested for performance.

SDL – Plat: A prefabricated ferro-cement sanitary platform for toiled floors. SDL plat was designed in a way that it can be installed within a site in less than 3 hours. But it is a prefabricated item which should be kept manufactured as disaster preparedness measure.

Figure 04: Sectional view of SDL 3

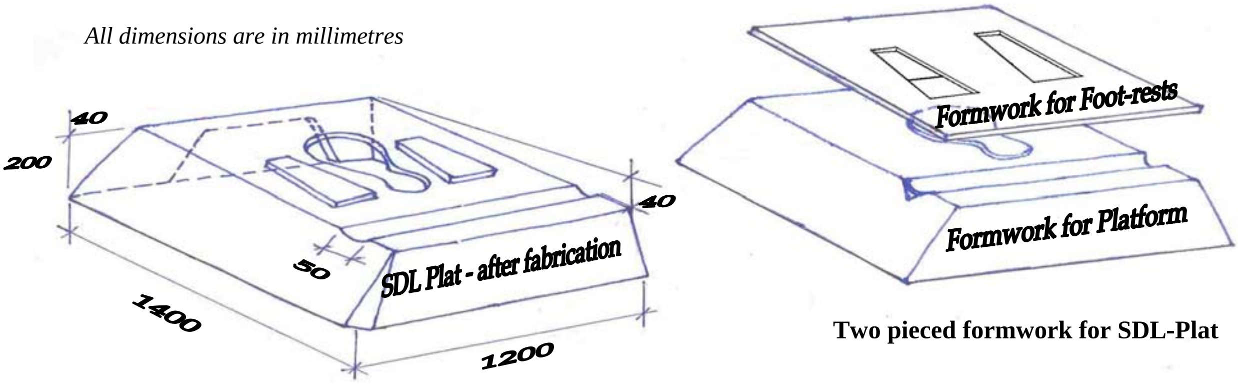

Figure 05: SDL – Plat and formwork

Table 03: Costs and comparison of different SDL units

Unit	**Cost (SLR)**	**Merits**	**Demerits**
SDL 1	800.00	Simple, Low-cost, No need to prefabricate	Short life time, not applicable to waterlogged conditions
SDL 2	1100.00	Simple, No need to prefabricate, Durable	not applicable to waterlogged conditions
SDL 3	3800.00	Applied to water logged conditions, Durable	Cost is higher than SDL 1& SDL 3, Pre-fabricated unit, Needs storage space
SDL-Plat	1200.00	Simple, Low-cost, Fast installation	Pre-fabricated unit, Needs storage space

2.3 Awareness

A general lack of awareness about the importance of sanitation was observed in the disaster management hierarchy of most organizations during the Tsunami Aftermath. A National Disaster Management Centre (NDMC) established in 1994 was already in operation at the time, there were disaster handbooks prepared by this centre for several disaster prone district of the country (Hambanthota, Rathnapura etc.). The sanitation aspects were mentioned in these handbooks but the emphasis given to the importance of it was inadequate [2]. Most of the NGOs involved in disaster management were using the “Sphere handbook” as their guideline, although the “Sphere Handbook” gives sufficient emphasis to the importance of sanitation most of the organisations failed to incorporate the provision of “proper and adequate sanitation” into their “Immediate Relief” check lists. In certain IDP camps some level of access to sanitation was provided but no attempts were made to assess the appropriateness or adequacy of these facilities.

2.4 Implementation Framework

A disaster management act was passed by the parliament of Sri Lanka in October 2005, mainly to cater for the grave concerns which emerged in the aftermath of the 2004 Tsunami. With this act a new Disaster Management Centre (DMC) was established under the Ministry of Disaster Management with a clear and nationwide mandate than its predecessor NDMC which was under the Ministry of Social Welfare. It is commendable that the organizational structure of DMC integrates the government institutions relevant to all aspects of disaster management. Figure 07 gives the Institutional Frame work for Disaster Response and Mitigation under the Disaster Management Act. Not taking into account the role of NGOs and CBOs whose contribution is immense at ground level implementation of disaster relief, is a notable drawback of this proposed institutional framework. Furthermore the arrangement is based mainly on vertical integration; lack of cross sectional consultation and delegation might lead into failures in practice.

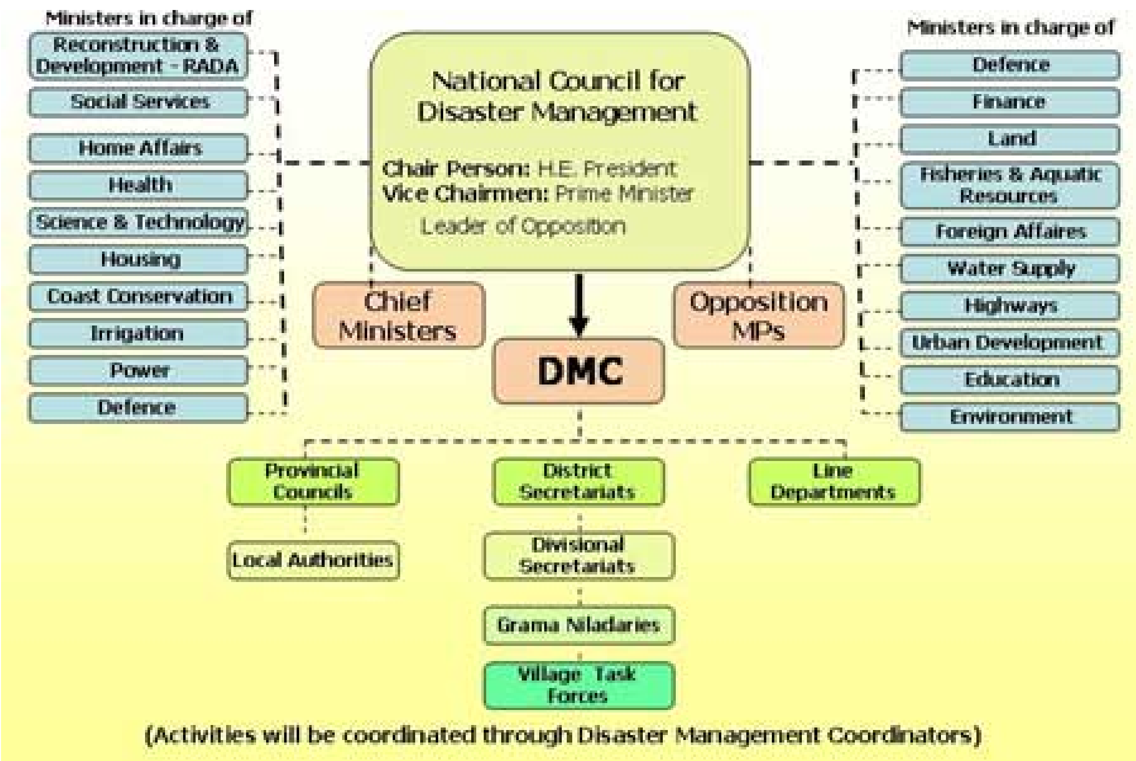

Figure 07: Institutional Framework for Disaster Response and Mitigation Proposed by the Disaster Management Act of Sri Lanka

From the experience of the 2004 Tsunami the author contends that a DRM program should have a mechanism embedded in its framework for providing access to proper sanitation to affected people. The main features of such a mechanism should be,

1. Preparedness ahead of the disaster
2. Training of volunteer foremen/technicians
3. Awareness material and Training kits

4. One subject agency to look after the implementation of work
5. Locations to store equipment and supplies during the pre-disaster period
6. Networking for Technical Support
7. Monitoring and Evaluation
8. Research and Development

Figure 08 gives a generic structure for such a framework. This was suggested as a sub-layer for the main DRM framework given by fig 07. The agency in charge of sanitation (subject agency) should preferably be a central government organization like the National Water Supply and

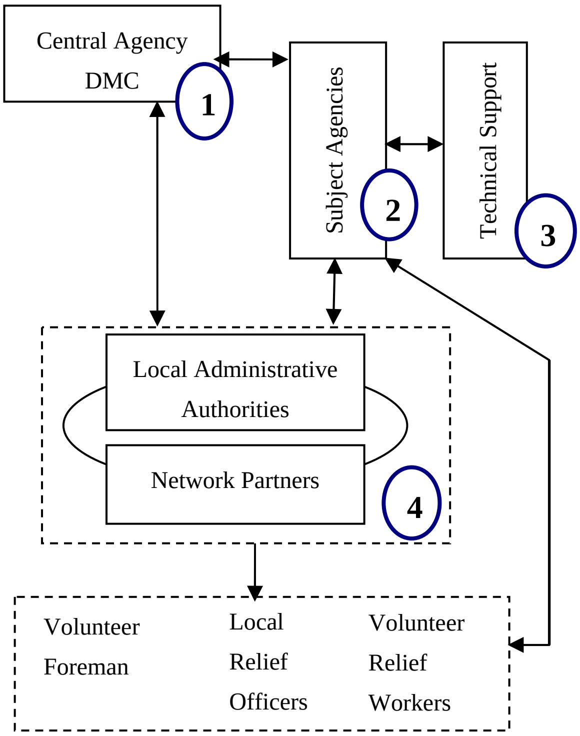

Figure 08: Implementation Framework for Diasaster Sanitation

Drainage Board (NWS&DB) which has the expertise and resources at local levels. The partnerships of local administrative authorities and CBOs, NGOs or Cooperatives are essential at community level to operate during a disaster. These partnerships can be assisted and overlooked by the Subject Agency. There should be some pre-identified organizations to provide technical support and R & D, learning from each disaster faced. The agency responsible for sanitation may have its own technical expertise, but it's always better to have relationships with other organizations such as State Universities for research and development work.

3. Permanent Rehabilitation

3.1 Situation Analysis of 2004 Tsunami

With the constrains encountered in allocating land for Tsunami permanent reconstruction projects, the "Environmental Suitability" naturally became a secondary concern. Once the construction of some of these projects started the environmental problems began to get highlighted. The author was involved in a study to investigate the potential environmental impacts of proposed permanent housing schemes for Tsunami Affected People. One of the major causes of pollution highlighted in this study was the possibility of ground & surface water contamination due to improper sanitation methods/ techniques used. Out of total number of housing projects investigated under this study approximately about 55% had sanitation related problems. The percentage was as high as 90% in Trincomalee district whereas it was less than 10% in the Gampaha district. Most of these problems were related to;

Improper disposal system: Soils soaking systems introduced in low permeability, water logged soils or excessively drained soils

Incorrect design: Incorrect sizing of tanks and soakage pits. Incompatibility with national standards. Inadequate setback distances.

Durability of Structures: Poor material selection, poor workmanship.

It should be noted that these weaknesses were not only encountered in the projects where design or construction was generally poor, but also in some sites where other aspects of design were quite satisfactory. Most of the problems were related to the back-end (disposal system) of latrines. In many cases where attached toilets were provided the front-end (superstructure) of latrine was considerably well designed and constructed.

3.2 Technology and Practice

The most established form of permanent sanitation in Sri Lanka is the onsite soil soaking system. Most of these latrines are single pit systems where solid accumulation and soaking happens in the same pit. Simple pit latrines are still in use but gradually disappearing due to their proven hazards and lack of hygiene. Apart from this Septic tank and Soakage pit systems are also widely used. Septic tanks followed by secondary and tertiary treatment systems such as Anaerobic Filters, Horizontal Flow Wetlands, Vertical Flow Wetlands and Percolation Beds are being introduced at different levels but are yet to enter the wide practice. Ecological sanitation methods are also being experimented with various communities of the country mainly in areas where conventional water borne sanitation systems are not applicable [3].

There are several guidelines and regulations governing the design and construction of septic systems and soak ways in Sri Lanka. The most comprehensive one out of these is the National Standard SLS 745 of 2003. *The Wastewater Manual of National Water Supply and Drainage Board* and the *Manual for the Sri Lanka Public Health Inspector published by the Ministry of Health* are the other guidelines available. Apart from this the National Housing Development Authority (Sri Lanka) published a guideline (CFRR Manual) on housing reconstruction for Tsunami Rehabilitation Projects, this also included a section on sanitation [6].

Although it's difficult to give an exact percentage, no soil permeability tests had been carried out before the design of soak-ways in most Tsunami Reconstruction Projects. Spacing of the soakage pits were insufficient in some projects especially in Galle, Kaluthara and Trincomalee districts because the land allocated for a single plot was small. The typical shortcomings related to design and construction of sanitation facilities were mainly caused by the following reasons;

1. Lack of knowledge about the sanitation techniques and methods available
2. Lack of awareness about the existing standards and regulations on sanitation in the country
3. Inadequate professional input in design and construction supervision
4. Ineffective monitoring by the relevant authorities (i.e. Environmental Officers/PHI of Local Authorities, Central Environmental Authority etc.)
5. Absence of a proper mechanism to evaluate the appropriateness of the sanitation facilities by the approving agency of the project.

It should also be noted that although the Sri Lankan regulations take the micro level pollution of groundwater by a single toilet into account, none of them cover the macro-level impact of large scale onsite disposal of sewage into a given aquifer. Therefore even the housing schemes which comply with the national regulations can contribute towards a long term degradation of the aquifer especially because most of the lowland aquifers near the coastal areas of Sri Lanka are discontinuous and highly sensitive to local impacts. The situation will be critical in the Jaffna Peninsula where a confined sedimentary limestone domain aquifer is present [1].

3.3 Awareness

The average sanitation coverage (Improved Access to Sanitation) of Sri Lanka is as high as 72.6%, but some areas affected by the 2004 Tsunami were fishing villages where sanitation coverage were particularly poor. Some of these areas (e.g Some parts of Duwa area Negambo) had zero coverage and open defecation was the standard practice in the sanitation culture of these communities. Therefore it was important to improve the sanitation awareness of the IDPs while they are in the Intermediate relief camps. There were some efforts made by the IDP camp mangers to accomplish this objective. Different strategies used by them for this purpose ranged from direct lectures to street dramas and film shows.

But unlike in the case of immediate relief & intermediate rehabilitation the institutions involved in Permanent Rehabilitation work had a basic understanding about the importance of providing access to sanitation. The shortcomings in awareness for them were as follows;

1. Inability to assess the appropriateness of sanitation techniques
2. Lack of awareness about the different technical options available in Sri Lanka for providing sanitation
3. Poor understanding about the environmental problems related to inadequate & improper sanitation

Therefore it is important to ensure a substantial improvement of sanitation literacy among the building industry professionals in coming years to avoid the repetition of mistakes and blunders made in the 2004 Tsunami rehabilitation work.

3.4 Implementation Framework

Developing an implementation framework for long term disaster rehabilitation is not as straightforward as in the case of Immediate and Intermediate Disaster Relief. It is difficult to coordinate the entire process through a central agency like a Disaster Management Centre. Usually long term rehabilitation work takes place in the form of any other development program and a Central Agency such as the DMC in Sri Lanka will bear only a monitoring responsibility.

Therefore ensuring access to Proper and Adequate Sanitation in the Permanent Rehabilitation Phase of Disaster Management has more to do with awareness building and improving the Skill levels and Capacities of the Institutions (Government or Non-governmental) with regard to sanitation aspects.

4. Conclusions

Many weaknesses and drawbacks were observed with regard to ensuring access to Proper and Adequate Sanitation during all three phases of the 2004 Tsunami disaster management process. The resulting failures extended from inconveniences for IDPs in the immediate response stage to considerable waste of resources in the permanent rehabilitation stage. From the observations made by the author it is clear that the technical resources available for providing disaster and permanent sanitation in Sri Lanka is satisfactory, the weaknesses exist mainly in the awareness and the implementation frame work of the institutions involved in disaster management. Improvement of Sanitation Literacy among general public is also an important requirement. Furthermore it was observed that a direct intervention and implementation approach will be affective in providing access to sanitation during the Immediate Response and Intermediate rehabilitation stages whereas a more indirect approach which involves awareness & capacity building, development of proper documents on sanitation standards and regulations etc. should be followed in the permanent rehabilitation stage. Mainstreaming the aspect of sanitation in Disaster Management decision making in the country should be the ultimate objective of this whole process.

Abstract

A shell formed architecture can be quickly obtained by a light steel bearing structure holding insulated polyurethane sandwich panels, shaped in shell form or straight. Lightweight façades could be shaded, in hot climates, with textile extentions and double roofs. Methodology follows very strict design phases which have brought to different systems with different, but a very simple, final shapes. Some prototypes have been realized in order to optimize the system and to verify all the theoretical calculations about wind loads and earthquake loads (above all the collaboration of the outside curved shell and the bearing structure). Many tests have been carried out to check natural lighting, optimization of spaces, static loads, dynamic loads, thermal behaviour, daylight factors analysis, logistic optimization, acoustic analysis.

One of these concepts has been named **L'Armadillo®** and measures 6,60mx8,00m (3,30 m is the radius of sandwich panel, frontal span of the arch is therefore 6.60 m and each arch span to next one is 4.00 m). The volume optimizes thermal behaviours and gives a high efficiency energy buildings which can be equipped with thermal or photovoltaic cells. Sandwich lightweight steel-polyurethane houses are a clear alternative to a normal house and can be quickly built with a goal to allow affordable spaces with good qualiy even in extreme situations. **L'Armadillo®** is a new system conceived from the Italian Company Brianza Plastica to find new options for its existing product Elycop® (curved sandwich panel). Therefore with a transfer of technology from an industrial product: Atelier 2 who designed it, link this project with previous experiences in design of **Hospitals for Emergency** (Italian NGO) with dry technology, **Casa Parasol** and **Casa Paraiso** with Dubosc and Landowski (Paris). Shell houses give multiple flexibility, are transportable as a kit in a container and easily assembled (and eventually disassembled) on site for different purposes: housing, hospitals, churches, schools, restaurants, etc. That is all those things which may disappear in a disaster contest.

Keywords: Post disaster quick built, Energy saving, Flexibility, Dismountability, Technology transfer.

1. Background

1.1 Structure Envelope (STREN) Technologies for quick construction

Simple construction principles and housing systems normally require complex processes of analysis that lead to the synthesis of their final form and technology. Industrialized systems of construction, based on sandwich panels or stratified layers supported by a frame structure, seem to offer several advantages in a quick reconstruction situation.

Jean Prouvè was the master in this area during the Modern Movement. His ability to interact with industry, opened a new era to the paradigm of the mechanical assembly of buildings. This allows to application of the the paradigm of mechanical assembly and connections to very ordinary buildings, with medium/low budgets, using a light structural skeleton and internal and external light weight envelopes. The use of steel sandwich panels with polyurethane (normally applied in industrial buildings or roofs) is an example of how existing technology can be used to make low cost homes, resistant to strong winds or hurricane, naturally ventilated and shaded, used in both normal conditions (thanks to the speed of construction) for temporary/emergency accomodation. The field of application of the stratified layer construction derives directly from vernacular buildings. Hybrid systems at low cost and low processing are possible and suitable in many emergency or post disaster situations, where is necessary a quick response to a often large amount of houses. The durability/quality of the solution is also very important considering that the temporary solution tends in most cases to become the permanent one [1]. As a consequence temporary accomodation have to fulfil higher performances than simple tents, caravans or containers. The light weight stratified layer building system is a Structure-Envelope system where the lightweight steel structure, supports the outside envelope [2]. The latter is made of sandwich steel and polyurethane panels (the inner envelope could be realized later on its own secondary structure). In the vacuum between the two main envelopes, further insulation could be added for winter and summer time. This would provide the necessary delay time of heat transfer from the outside to the inside in warm climates. Services can be applied both to the structure and/or to the sandwich panels. Close to the Tropics and to the Equator the hyper-insulation is less important because the envelope must mainly face overheating, which means shadowing the building and introducing natural ventilation are essential. A practical, technical and functional result can be obtained through aesthetical expression by using materials (such as simple wood panels or thin corrugated metal sheets or sandwich panels) used in a different way, from their normal purpose, with simple rules of stratified assembled and resistance. This shows that the value of each architecture is not contained just in the costs of the materials but also in the investment in intelligence, using very simple materials in a clever way [3].

1.2 Technology: "Shell-House", ready made industrialized home

A "Shell-House" is based on a simple concept but it is the result of integrated design among architects, engineers and building industry. This helped to achieve different goals: the use of products already available on the market, the weight optimisation and the logistic, transport optimisation, simplicity and speed of assembly, and last but not least important, pleasant architecture. The design approach has similarities to the one used in the automobile industry, where options can be added to the basic version. Self supporting corrugated steel shells have also been used by the military for many decades but a "Shell-House" is a different thing for many reasons. It is a "mechano kit" and this allows transport in rather small parts. On the contrary self supporting shells needed big spaces to be transported, therefore only using military trucks and never stored in a container like the "Shell-House" is. That is why there is no need for making the arches self supporting but using them only as envelope and using the steel "skeleton" structure as the bearing frame. This solution also allows the reduction as much as possible of the foundations to few points instead of being obliged to design a foundation platform (therefore using much water which can be a problem in some regions). Anyway, in case of need, also a concrete plattform could be realized as foundation.

The first "Shell-House"prototype, using curved and linear sandwich steel-polyurethane panels, was designed by Atelier 2 (Gallotti and Imperadori - Milano) with the Company Metecno. In that first case the unit was designed, free of charge, for the Italian NGO Emergency, organization which supports civilian war victims. It was meant to be a FAP (first aid post, or a small hospital unit in severe climates and dangerous war sites) and it has been erected and disassembled twice time (without any damage) before beeing given as a gift to another NGO who have built the unit for the third time (therefore showing its power of flexibility) as a site Hospital in the Rumanian countryside. This NGO is also italian, "Gruppo 29 Maggio", and they are building a orphanage village. The "shell-house" Emergency unit will function as small hospital for this new community. This unit was designed using a trapezoidal, self bracing, hollow tube steel structure which bears a secondary hollow structure and then the curved sandwich panel. This is the panel "Oyster" (thickness 80 mm, radius 3.50 m) produced from Metecno and normally used for industrial roofs. All façades and floors (formed by a steel beam optimized grid) are in structural sandwich steel-polyurethane panels (named "Glamet" – thickness 80 mm). Interior finishing is in wood but all the shelves and partitions are also made in sandwich panels. Each structural frame has an inter axis of 3.50 m, therefore with a frontal diameter of 7.00 m ("Oyster radius is also 3.50 m) the final units measure in ground around 100 sqm. The building is equipped as a small hospital unit [4][5].

Figures1,2,3 Delivery and construction of Emergency unit in Rumania as small hospital in 2007.

1.3 "L'Armadillo", ready made industrialized home

Figure 4 – L'Armadillo housing unit in Carate Brianza (Milano) integrating photovoltaic cells on the roof.

"L'Armadillo" is a clever evolution of the "Emergency" unit into a house or other living space. In this case it has been designed by Atelier2 (Gallotti e Imperadori – Milano) with the Company Brianzaplastica using their existing roof panel "Elycop" (sandwich with 40 – 80 mm thickness, radius 3.30 m). Bearing structure has been optimized into a 3 hinged arch (each frame is at 4.00 m span to the next one) supporting a secondary hollow section steel structure and then the sandwich “Elycop” panels. This solution, compared to the previous one used for the Emergency unit, allows a totally free space on the ground floor to be divided for any cutomized purpose. The building system is made of a light weight dry assembled kit. Foundations are in concrete on single elements (or platform/raft, depending on wind loads). Due to the light weight of the module the wind load becomes the critical factor to the foundation design. The principal bearing structure is made of galvanized steel profiles, shaped in a semi circular frame (linked at the base with a main beam to hold the secondary beams and the floor) which holds 2 secondary square tubes. Structural elements are connected with simple bolted connections. The curved Elycop sandwich panels are fixed to the secondary structure with steel screws. Sandwich steel panels are fixed to the ground floor secondary beams with steel screws. Façades panels are fixed to the sandwich floors and to the sandwich shell. The floor is totally above ground where only 3 steel supports for each main frame descend to concrete foundations and are fixed to them with simple bolted connections. Façades are completed with 2 sunshading made of textile that protect the building from sun radiation, which is much more intense on the vertical surfaces than on the curved shell, except from the top third where it is necessary to fix also a further metal sheet to ventilate the upper part of the sandwich arch. The main steel structure is made of three hinged arches that support square steel sections that act as purlins. The main arches are connected with a floor beam that distributes weight to three fitted stabilisers. Over the master beams there are secondary beams supporting the sandwich panel floor, suspended above ground and therefore ventilated, made of 80 mm-thick sandwich panels in pre-painted steel filled industrially with polyurethane hardened foam. Outer covering consists of end window walls made of aluminium pre-painted windows and doors inserted in the 80 mm-thick sandwich panels. Elycop panels are modular. Normally they are used for industrial roofs and their commercial dimension is 40 mm. For the “Armadillo” a new evolution of Elycop’s use has increased the panel thickness to 80 mm in order to give better thermal, acoustic and static performances. This product improvement has been introduced to guarantee the same performances are achieved by both the vertical façades and horizontal bearing floor (which are also made by 80 mm sandwich panels). To increase the thickness to 80 mm accurate studies in the fluidity of polyurethane foam and time of expansion have been undertaken. This permitted the adaptation of the same machines used to produce the 40 mm panel without the requirement of expensive technology. This has given very good results in terms of economy of the solution and the distribution of polyurethane in the curved sandwich has been successful without air voids.

Figures 5,6,7,8 The 3 hinged main arches are in ordinary steel profiles HEA 120 mm and they carry the secondary rectangular beam section profiles on which is fixed the curved Elycop panel. On the floor a sandwich panel of 80 mm which acts as bearing structure fixed on main steel beams. The final shape allows energy equipment to be integrated.

The Outer shell consists of three modules (a middle unit and two side units) which are shaped to fit at the joints after they have been made water tight; the conjunction of the curved panels is located always at one third of the arch. The internal space can be partitioned with gypsum board dividers or wooden panels. The underflooring is made with plywood planking, which allows for gluing the floor finish. In general aesthetic and functional characteristics of Armadillo make it available for a wide range of uses. It can be used as a single unit or assembled with other units in both of the main axis of expansion to create larger, living spaces, emergency hospitals, first aid, temporary houses, schools, emergency food storage areas or restaurants. The living unit, realized as a prototype and tested, is a small curved shell measuring 6.60 x 8.00 m, which can be divided into sub-units of 6.60 x 4.00 m, or enlarged into units measuring 6.60 x 12.00 or 16.00 m, by adding one or two spans to the basic module. Since the interior of the shell is completely empty, and can therefore be fitted according to the client’s needs, many different configurations, both for residential uses and other functions, are possible. Also different modules can be joined together along the transversal axis to obtain open spaces for different purposes. “Armadillo” is surprisingly spacious inside, and so any arrangement is possible. Internal dimensions clearly show the difference between this and other industrialised homes (especially containers or caravans), and also demonstrate its adaptability to different requirements. It can be assembled like a “mechano” construction system, in just a few days, on a simple loadbearing foundation. Elycop panels are fastened over the light, durable metallic frame, also to increase the whole structure’s level of rigidity. The system can be supplied in separate kits, depending on the project requirements. They can also be autonomously devised by the client who has the option of buying only the building frame and order separately the other components. Reliable insulation and the correct position of openings results in high savings on fuel for heating/cooling needs and also on electricity. “Armadillo” can also easily be equipped with photovoltaic systems or solar panels, and therefore be totally independent of fuels. The majority of the building components are made from recyclable, environmentally friendly materials [6].

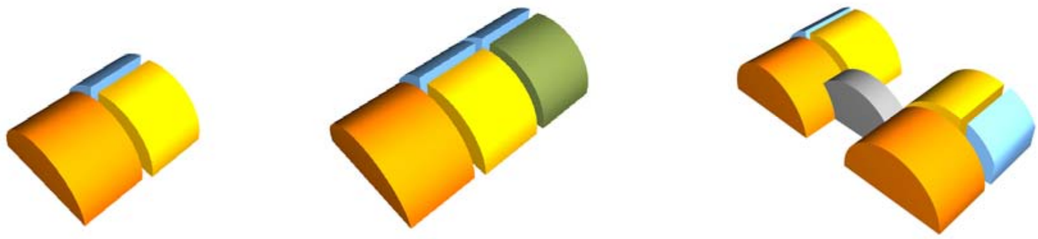

Figure 9 The multiple flexibility and evolutive design of L’Armadillo.

1.3 Prototype and site tests

A prototype has been constructed and was tested in 2005 in Carate Brianza (Milano). Dimensions are 6,60 m x 8,00 m (more than 50 sqm), which is the surface corresponding to the base unit. Interiors have been conceived as kitchen/living room, bed room, bath room and a terrace, 2 sun shading screens have been integrated with the front and rear facades. The 3 hinged main frames (spaced 4,00 m) are in ordinary steel profiles HEA 120 mm. The arches carry the secondary box beam section profiles. Main arches are linked with a base beam ILS 200 mm, connected to the foundation with 3 short steel legs, bolted in concrete. Secondary floor-beams ILS 140 sit on the main beams and carry the sandwich panel of 80 mm as a bearing floor. Thermal resistance of the 80 mm polyurethane panel has been shown to perform very well in winter-cold conditions and in summer-hot condition the system can rely on natural ventilation and the presence of a further ventilation layer on the shell improves the overall condition. The curved panel overlapping guarantees water and wind tightness and all the connections with vertical façades or floors are carefully protected for the same reason (in some cases also with additional polyurethane foam). In the prototype the internal space has been partitioned with gypsum board panels. The finished floor is a rubber layer glued on a wood layer which is fixed with screws to the floor bearing sandwich panel. The structural system has been calculated firstly with Straus automatic finite elements program both for stress and strains and the prototype has been tested to verify the structural calculations. Design and testing on site have been undertaken following the Italian Building regulations[1].

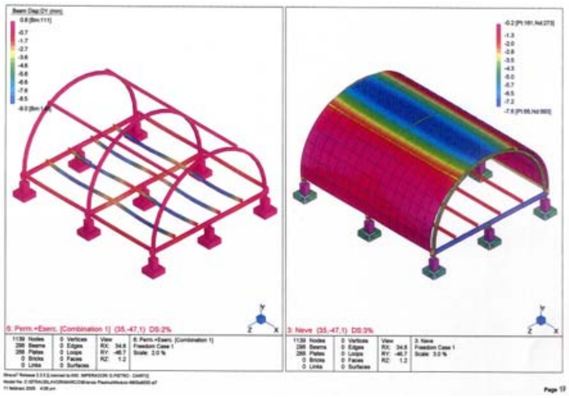

Figure 10,11 The structural system has been calculated with Straus automatic finite elements program both for stress and strains. A test programme has been carried out to verify the theoretical calculations.

Horizontal load tests have been carried out on the prototype by applying hydraulic jacks to the main frames and to the secondary structure in order to verify the theoretical model and also to prove that the presence of the sandwich permitted the structure in the direction of the load not to be braced. The introduced stiffness without additional bracing maximises the usable space and reduces costs. Different scheme tests have been carried out by adding curved panels to the bearing structure in order to prove the enhancement of stiffness thanks to the contribution of the sandwich shell. The 2 hydraulic jacks applied were driven by a oleodynamic system controllable and measurable with pressure manometer. Structural deformations have been evaluated with a tolerance of 0,5 mm and the results show a substantial elastic behaviour with some plastic corrections very probably due to a small plastic behaviour of the connectors and joints (bolted or screwed). Static analysis on the simple automatic model has given very good results compared with the real behaviour of the prototype. After analysing a partial model and testing the prototype on site, under horizontal loads to verify the increasing rigidity of the system due to shell panels, a full complex model automatic has been completed. This model has been finally checked under single or combined load actions (permanent loads, variable loads, snow, lateral winds, frontal winds, earthquake). All stress and strain outputs have been within the limits of safety and functionality, for this typology and for the applied materials.

2. . Temporary Pub “Pian Cafè”

Figure 13 “Pian Cafè” has been quickly constructed in an exhisting square in Piancamuno – Italy.

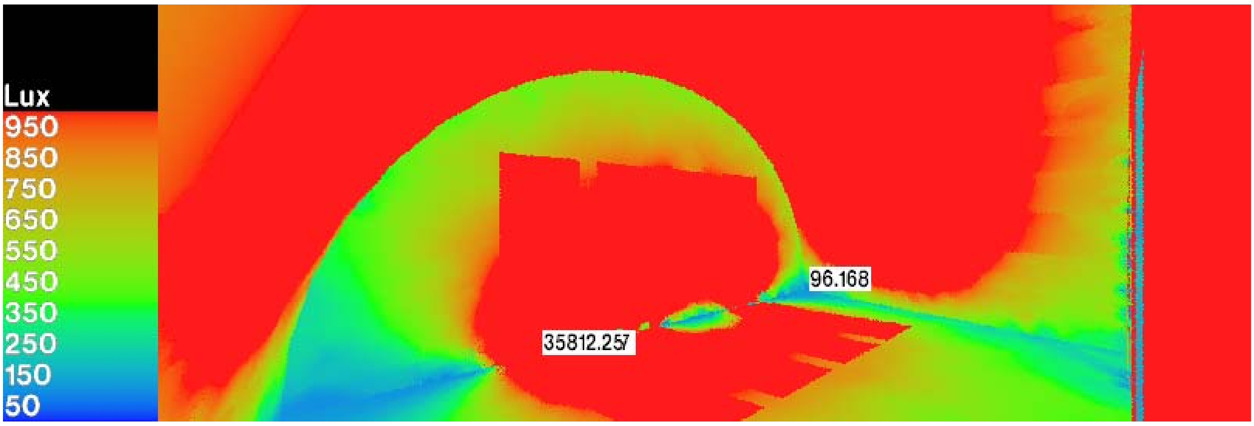
“Pian Cafè” is the direct application of “L’Armadillo” for a different purpose of temporary and dismountable unit. It has been conceived to be a Pub in a small town in northern Italy (Piancamuno) where Atelier 2 (Gallotti and Imperadori – Milano) also designed a new contemporary square for the town’s open air market.

Figure14,15 Construction assembly of external sandwich façade and internal gypsum board walls

A Pub with public toilets (also for disabled people) was then needed and the low budget of the community led to the application of a “Shell-House” concept. A corten steel skin applied with rivets on the Elycop panels was added to L’Armadillo. This was for an aesthetic reason (all the square walls has corten steel as a final layer) but also because it creates a ventilation layer between it and the corrugated Elycop panel. Façades have been conceived to be protected from summer sun by 2 huge exhisting trees and to be able to save energy in winter .

Figure16 South Façade and corten steel high durability outer shell

Foundations are on concrete plattform to resist winds prevailing in the Valley where it is placed. In winter the building profits of passive sun energy, through south façade, and also from all internal thermal loads (coffee machine, fridge, washing maschine) therefore doesn't use any extra heating source during the cold season.



Figures 17,18,19 Daylight factors and sun gain studies for the South façade.

3. Conclusions

Figure 20 Politecnico di Milano students visiting the prototype "L'Armadillo". A real vertical load test which shows the huge space of the single unit.

This building system shell-shaped, is a house composed by exhisting industrial products, the result of a commitment to specialization, research and product innovation between the company policy and a pool of designer and consultants always led by Atelier 2 (Gallotti and Imperadori, Milano).

The Shell House realized are modular units designed and built with quality products, present on the market and often used for non-residential purposes. "L'Armadillo" is designed to be shipped in a container, erected and dismantled, if necessary, through simple, quick procedures. It's streamlined conformation optimises the heat loss and win ratios between the internal volume and the outer surfaces. Application of solar and photovoltaic panels can transform the unit and make it independent from other energy sources in case of need.

This extremely durable living unit was even designed to be used in areas where seismic activity and high winds are actiing, according to Italian regulations, and therefore can be used in areas with extreme climate conditions. The use in other specific areas will request to verify the specific wind loads in order to verify the bearing and bracing structure (which is the shell itself) for the area selected to the application, as well as the dimension of foundations or concrete platform.

Figures 21,22 The modular nature of L'Armadillo allows a wide range of project solutions. Basic unit can be enhanced with a vast selection of complements and accessories, that make various applications possible in relation to the different needs and conditions.

Abstract

Many basic yet effective building environment tools are not used and moreover not included in courses on design and construction. This is evident in the gaps in the literature and more importantly by their non use in the field [12] [13]. Basic tools such as bio-climatic charts, the Griggs Putnam Defomity index for wind, house spacing to ensure natural ventilation and simple techniques for solar shading together with data and research applicable to emergency shelter are not accessed. Nonetheless, the need for such tools is recognised by the United Nations Inter Agency Standing Committee (IASC) Working Group whose "Report of Emergency Shelter Cluster November 2005" sought to improve the overall effective response of humanitarian assistance by the: "*… develop (and building on existing) guidelines and tools for rapid participatory shelter assessments and interventions in different climatic and geographical conditions and different contexts, including ways of supporting communities for clearing and restoration of damaged shelter immediately after the crisis*".

This paper gathers those existing thermal comfort tools presently available to site planners/civil engineers for the design of emergency shelter as a first step to filling the above gap.

Keywords: Thermal comfort, emergency shelter, tools, guidelines, climatic design, education

1. Background

Emergency shelter in a major disaster can be sought in various ways that includes one or more of the following:

- Shelter inside the damaged house.
- Shelter along side or as close as practicable to their damaged house in tents or temporary constructions.
- Shelter with relatives or friends that are nearby.
- Shelter with relatives or friends that are distant.
- Shelter inside requisitioned buildings (formal situation).

- Shelter inside vacant or public buildings (informal situation).
- Shelter in emergency centres provide by outside national or international agencies
- Shelter in emergency camp sites that are located in the area or region
- Shelter in emergency camp sites that are located outside the area or region (evacuation).

A major disaster (man made or natural) is defined by Lambert and Davis as being one where the death rate is greater than 1 per 10,000 people affected/day and 2 per 10,000/day is a major disaster out of control [12]. And such high death tolls are usually associated with developing nations. The approach in this paper is that emergency shelter, regardless of its geographical location and which of these shelter options above is selected will largely be tents in such a disaster with the basic objective of modifying the outside climate to achieve thermal comfort.

2. Climate Data

Climate data is the starting point for the tools and approaches listed below. Documents such as the "Climates of the World" published by the Dept of Commerce USA give minimum and maximum temperatures for many cities through the world. It can be down loaded from www.ncdc.noaa.gov/climate/climatedata.html#clim . This site also has the facility to format and down load recent monthly averaged climate data for 1,600 stations outside of the USA. This is a good starting point. Such data is usually not available for the precise site and when data is available from a nearby weather station (such as an airport or city) it usually requires mathematical modified for differences in terrain and topology. The required modification factors can be readily obtained from any structural loading code. Where the topology blocks the climate (rather than modifying it) such an approach of mathematical modified is not appropriate and other methods are required.

Once on the ground data can also be sought from both the Public Works Departments and Government Meteorological offices. And failing that, data can be measured on site and also inferred from prevailing topographical conditions. Simple recording devices such as the digital temperature and humidity measuring device as shown in figure 1 below can be used. These give immediate readings and "validates" in an informal sense data collected earlier. Temperature data are the easiest to obtain and can be extrapolate from "broad brush" temperature maps to obtain usable data. However, wind speeds (and particular wind direction data) remain problematic.

One approach is to estimate the extreme wind speeds in the area by count the stones holding down roofs. This load of stones can be taken as equivalent to the wind loading generated by a 5 year return period gust and by using standard wind coefficients design wind speeds (with a return period of 100 years) can be quickly derived. In addition, natural ventilation studies by Aynsley et al [1] have shown that such extreme wind speeds are 1.5 to 2 standard deviations above the average wind speeds (useful for natural ventilation analysis) and that such an analysis based on standard deviation data for the wider area provides useful results.

Figure 1: Simple Temperature and Humidity Measuring Device.

One approach is to estimate the extreme wind speeds in the area by count the stones holding down roofs. This load of stones can be taken as equivalent to the wind loading generated by a 5 year return period gust and by using standard wind coefficients design wind speeds (with a return period of 100 years) can be quickly derived. In addition, natural ventilation studies by Aynsley et al [1] have shown that such extreme wind speeds are 1.5 to 2 standard deviations above the average wind speeds (useful for natural ventilation analysis) and that such an analysis based on standard deviation data for the wider area provides useful results.

Wind direction (always the difficult factor) can be inferred from both the local geography and from the local landscape [2]. For example, consider the camp site in the bottom of the valley in figure 1 below. Provided,

$h_1 > L/5$

h_1 = the heights of the lower hills above the respective shelter site and
L= distance between the hill tops forming the valley

the wind direction will be predominantly along the valley. Similarly, if the emergency shelter is located on the side of the hills h_2 below the top of the hill then provided that $h_2 > L/5$ still holds then the wind direction will again be predominantly along the valley. When h_1 or $h_2 < L/5$ other tools such as the Griggs Putnam Index of Deformity (refer to Appendix A) can be used. The index gives the average wind speed (and direction) for the area based on the relationship between the trunk and canopy of trees.

Another option is to observe the typical buildings used locally and by referencing bio-climatic charts get a sense of what type of local climate one is dealing with in terms of emergency shelter requirements. A typical chart is included in Appendix B.

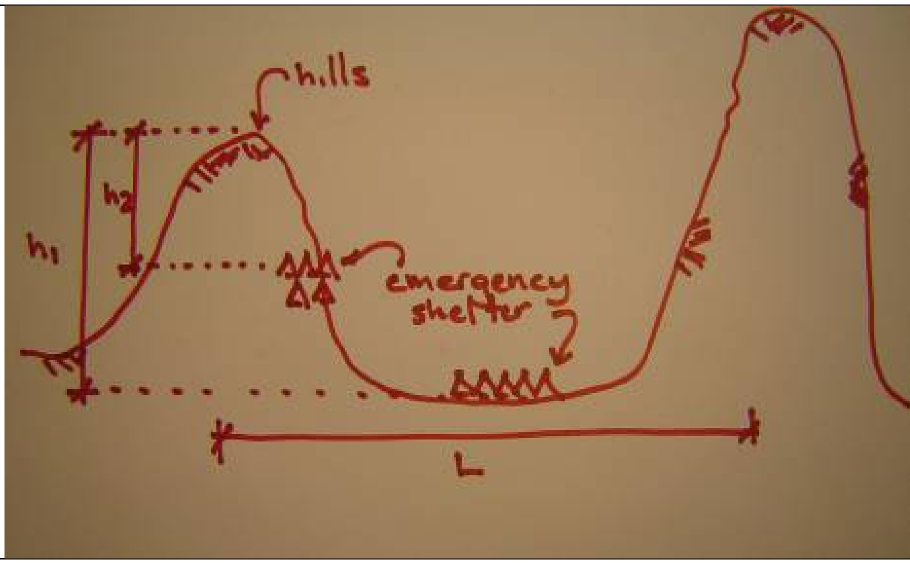

Figure 2: The Impact of Topology on Wind Climate.

And finally, local people can be surveyed as to what are the dominant climatic features for the area though usually as a check on earlier data collection. But by this point the site planner/engineer/ architect should have a good sense of the climate that they are dealing with and the driving requirements for the emergency shelter.

3. Geographical Areas and Building Typologies

Geographical areas (and there associated climatic zones) have been used to classify different building topologies and the example in Appendix C tabulates building topologies for different geographical zones that are characterised not only by their latitude/ longitude but also their vegetation and cultivation practices [3].

While interesting (and also stated in the IASC November 2005 report), such tables are not effective in the field. Differences within zones allowing several different climate typologies to exist concurrently makes there application problematic. Nonetheless, such tables can be useful for “checking and validating” other data and assumptions used to develop a workable emergency shelter strategy. Such checks are essential in an emergency situation where hard data is often lacking.

4. Thermal Comfort Models

Thermal comfort is a complex and contentious issue. The relationship between the objective measurement and the subjective response is not clear and remains at the centre of an ongoing thermal comfort debate. Field studies of free running or naturally ventilated buildings supported an “adaptive” rather than the “static” approach for essentially “sealed” buildings [4]. People were “adapting” to their environment and for example MacFarlane [5] had found as early as 1958 that Europeans in Singapore preferred temperatures that were some 2^{O}C warmer than those in Sydney.

This has led various researchers to develop algorithms for adaptive comfort models, the most recent by Brager and deDear [6] that appears to have brought some agreement on what algorithm should be used with their model which is as follows:

$$\text{Optimum Temperature} = 17.8 + 0.31\text{x } T_{a(out)}$$

Where $T_{a(out)}$ = the average temperature of the daily maximum and minimums for the previous month.

Such a thermal comfort model can be used in various applications. It can be used in either a warm/ humid climate or in cold climates. In cold climates it can be used to calculate the optimum temperature (and hence heating requirements) inside emergency shelter/tents. In warm/ humid climates it can be used in conjunction with other models to ensure that there is adequate natural ventilation potential in emergency camps and shelters. The importance of natural ventilation in achieving thermal comfort in such shelter is not readily documented nor understood in the field. Thus, thermal comfort modelling is central to providing not only durable solutions but also shelter with "dignity".

For warm/ humid climates, the MacFarlane [5] criteria can be incorporated into such thermal comfort models to adjust for the positive cooling effects of the wind and the detrimental impacts of higher humidity. MacFarlane's criteria are as follows:

- For each 10% increase in relative humidity above 60% the Optimum Temperature should be decreased by 0.8^{O}K.
- For each 0.15 m/s increase of air speed the Optimum Temperature should be increased by 0.55^{O}K for air temperatures up to 37^{O}C

Thermal comfort is then achieved for 80% of the population when the actual temperature is within $\pm 2.5^{O}$C of the Optimum Temperature modified as required by MacFarlane's criteria above.

5. The Cooling of Tents: Natural Ventilation

So how can the beneficial cooling effects of natural ventilation for emergency shelter be exploited in warm/ humid climates? Natural ventilation is caused by either wind induced pressures or by solar induced temperature differentials with wind usually being the dominant source. It is one of the few (and often only) options open to shelter occupants to achieve thermal comfort and hence the goal is to maximize the airflow through the tent or shelter. Consequently, the first requirement is to review the wind data gathered earlier. Tents should be within $\pm 60^{O}$ (and preferably $\pm 45^{O}$) of the dominant wind direction. Tents are typical placed "along" the dominant wind direction to achieve maximum airflow (and consequently the best thermal comfort conditions for shelter occupants). Screens and fences should be away from tents by at least 5 x the height of the screen or fence to ensure that wind flows initially disturbed by the screen "re-attaches" to the ground thus re-establishing their cooling potential. Where this is not spatially feasible wind catchers such as shades can be used to collect and channel wind down into the tent or shelter. And when the tent can not be placed along the wind small end walls can again be used to channel wind through the tent.

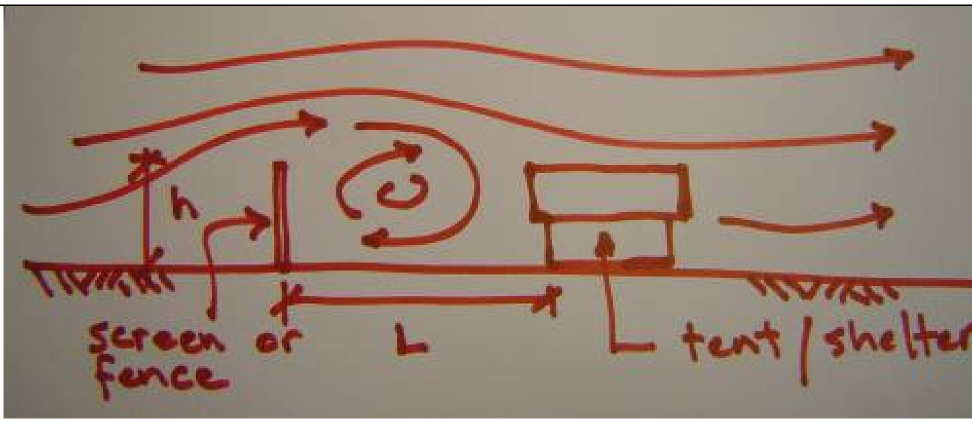

Figure 3: The Impact of Fences and Screens on natural Ventilation of Shelters.

The airflow around dispersed tents or buildings is quite different to the "infinite" or "semi-infinite" (in terms of their length to height ratio) screens or walls. Research by Lee and Soliman [7] has shown that there are three flow patterns for separation gap between adjacent buildings. These are as follows:

- Isolated roughness: The two buildings are sufficiently far apart that the air flow reattaches to the ground between the two buildings.
- Wake Interference: As the separation between the buildings is reduced a "horse shoe vortex forms. The air flow pattern is maintains circulation in the building separation.
- Skimming mode: Finally the separation distance is sufficiently reduced that the air flow "skims" over the separation between the two buildings.

A sketch of the first and last flow patterns are shown in figure 4 below.

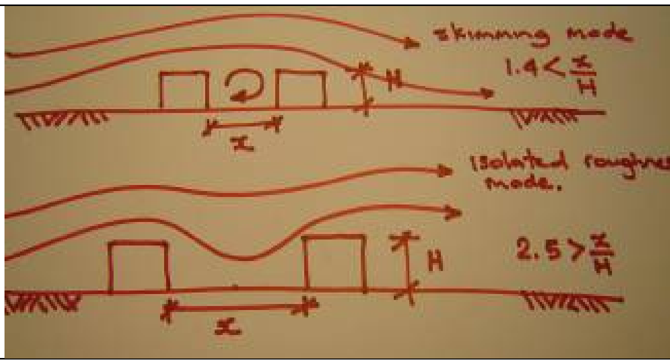

Figure 4: Airflow Patterns Around Numerous Equally Spaced Shelters.

Their research showed that this skimming pattern occurs when the ratio of the building separation distance "x", and the building height "H" is less than or equal to 1.4. In this instance the wind flow simply went over the top of the shelters and did not touch the ground in between. Between 1.4 and 2.5 they found a wake interference flow pattern and here the wind flow increasingly started to reach down into the gap between the shelters. At 2.5 an isolated roughness flow pattern developed and the wind flow finally re-attached to the ground between shelters producing similar wind conditions as up stream of the shelters. Mathematically this is represented below as:

$$1.4 < x/H < 2.5$$

x = the building separation distance
H = the building height

Consequently, the separation distance between tents or shelter should be at least 2.5x tent height or around 5 metres. Thus, for a 1 metre high fence there is not difference in the suggested separation distance. However, this difference between fences and discrete structures becomes important where each individual plot could be fenced or where large groups or families are assign blocks and the block is fenced instead. These two options are commonly used in emergency shelter situations.

Having achieved the best wind flow characteristics how is this realised at the tent? As mentioned earlier, the tent orientation is critical but within a wide angular range to the prevailing wind direction. Having achieved that orientation the need is to ensure a "cross ventilation mechanism" with openings on the windward and leeward ends of the tent or shelter. The leeward opening is often forgotten. The flow rate can be then calculated based on the British Standard for Natural Ventilation [8]:

$$q = C_D \times A_W \times U_r \times \sqrt{(\Delta C_P)}$$

q = flow rate
C_D = discharge coefficient usually taken as 0.61
A_W = ratio of area of inlet to outlet openings
U_r = reference velocity usually to the top or eaves of the building.
ΔC_P = pressure differential.

It should be noted that large increases in ΔC_P values (which are generated by the prevailing wind direction and the shape of the tent) produce relatively small increases in flow rate. For example, an increase in ΔC_P from 0.1 to 1.0 results in only 3 times more wind through the tent. However, it is more important to keep wind ward and leeward openings of similar area.

Natural ventilation is the only cooling strategy employed in emergency shelter programs. Yet it remains essentially unknown. More research is required to develop specific design guidelines for commonly used planning typologies such as the ("U" shaped layout advocated by UNHCR) and to develop guidelines as emergency shelter moves away from sole tent structures into more "permanent" materials.

6. The Heating of Tents

Recent aid following the earthquake in Pakistan have also highlighted that there are issues on the heating side for tents as well as the more usual cooling requirements discussed above. In Pakistan, aid agencies (initially) issued non winterised tents and there were significant issues in the field to resolve this problem before the onset of winter. This came to be known and publicised in the media as “the winter race”[9] and required a significant effort from the technical support teams in devising practical upgrade options. This section draws on the technical lessons learnt from that experience.

The heating requirements for tents are based around the Heat Loss Equation which is as follows:

$$Q = UA(T_{in}-T_{out}),$$

Q= rate of heat loss
U= “U value” or thermal transmittance or the inverse of the thermal resistance
A= surface area of tent
T_{in}= Temperature inside the tent
T_{out}= temperature outside the tent.

Thus to reduce heat loss requires one or more of the following:

- Lowering of the U value (or conversely increasing the thermal resistance of the sides, roof and ends of the tent). This is achieved by better insulation.
- Minimizing the surface area of the tent. This not a real option given the practical constraints on tent dimensions other than digging down into the ground.
- Rationalizing (and hence increasing) the outside design temperature T_{out}. If tents are in frost areas then an outside temperature of -2^{O}C would be appropriate. Moreover, if the presence of a nearby river means that temperatures would only reach say 0^{O}C and this is used instead than a lower heating loss would be achieved.
- Lowering the inside temperature T_{in}. This should be set by the thermal comfort model discussed earlier.

(It should be noted that there are many “home truths” about how people survive cold that should be analysed careful against the framework as outlined above).

These strategies above are now discussed in more detail.

6.1 Infiltration Losses from Tents

The heat loss equation above assumes that the tent is air tight. This is not the case and the canvas material used for many tents is “porous” allowing hot air to leak out. This process is referred to as infiltration.

This loss increases when there is wind on the tent which creates areas of “suction” on the leeward side of the tent and positive inward pressures on the wind ward side. This results in air inside the tent being “sucked” out by these pressures in addition to the natural movement of hot air upwards (and outwards) from inside the tent. The actual extent of this increase depends on the orientation of the tent and the spacing between tents (the opposite to what was suggested for natural ventilation). The fly only marginally mitigates this loss and in many cases increases it by creating higher negative suction pressures between the fly and the inner tent. Plastic is significantly less permeable and the installation of “plastic sheeting” over the inner tent (as opposed to the fly) significantly reduces loss by infiltration.

In the field it is common for the fly to be covered with plastic sheeting firstly because it is easier to install but primarily because it is also perceived as reducing dampness inside the tent. However, covering the fly only increases the wind pressure differential between the plastic and the tent with the fly caught flapping between the two. Consequently, any rain that makes it way into this gap between the plastic and the tent will quickly migrate inside the tent because of this increased flapping and contact between the plastic, the fly and the tent [10]. And hence any plastic cover sheets must be placed under the fly to be effective. From an operational perspective, this installation will not require tent occupants to move out nor require any access (and hence disruption) inside the tent.

Typical figures for infiltration (using a pressurized approach intended to simulate wind effects) are shown in table 1 below and are taken from a study by Spence et al [11]. Their liner was apparently on the inside of the tent and not on the outside as suggested in this paper. This difference should not be significant but could result in condensation if the thermal gradient through the tent is not adequately controlled. Nonetheless, table 1 below shows that the inclusion of the plastic sheet potentially reduces permeability by 50% in still conditions and by 25% in windy conditions. Looked at another way the figures also show that in still conditions most if not all the heated air in a typical tent will have dissipated within 30 minutes in still conditions and 10 minutes when there is a breeze. After that (short) time period, the temperature inside the tent would then be the same as the ambient (outside) temperature. In addition, if someone opens the flap of the tent to enter than these times will be shorter. These leakage times underline the permeability of canvas and the cooling speed of a tent. Later tent designs are minimizing infiltration losses by adopting impermeable and water proof polyester fabrics.

Table 1: Comparative Infiltration Rates.

	Air permeability at 50Pa ($m^3/hr/m^2$)	Air permeability at 5Pa ($m^3/hr/m^2$)
Damp canvas	45.6	9.56
Dry canvas	41.4	13.4
Liner, dry canvas	32.6	7.01

6.2 Insulation of Tents

Canvass, as well as being permeable, is also not a good insulating material. This means that heat inside the tent is quickly dissipated by conduction through the fabric to the outside. And its thermal conductivity is so high (or conversely its insulation resistance value (R) is so low) that heat inside the tent is quickly dissipated to the outside colder temperatures. Table 2 below gives typical thermal conductivity values for different materials. A higher value indicates that the material conducts heat away faster and hence canvas at 27 is only half that of steel at 50 and thus is conductive. On the other hand plastic with a value of 0.04 to 0.05 is more than 50 times less conductive than canvas. However, canvas is typically thicker than plastic sheeting but a 250 thick micron plastic (which is thin) would be equivalent to12 mm thick canvas. Interestingly, diamonds are one of the most conductive materials available.

But perhaps the most significant value from table 2 is that for air which (in the form of an air gap) has one of the lowest thermal conductivity values. And when combined with plastic sheeting provides a cost effective, logistically light solution to tent insulation.

Table 2: Conductance Values for the Tent Roof in w/m^{O}C

Diamonds	1,000-2,600	**Plastic sheeting**	0.04-0.05
Steel	50	**Fibre glass insulation**	0.04
Canvas	27	**Polystyrene**	0.03
Ice	1.6	**Air**	0.026
Wood	0.4-1.2	**Styrofoam**	0.01

6.3 Heating

Using the above "U" values in combination for the complete system (rather than just one material) then allows the calculation of the heating requirements for the tent. Upgrading options considered for the winterisation of the tents provided in Pakistan included the following:

- The addition of a plastic outside fly sheet and inner lining
- The addition of a plastic outside fly sheet and sewing the roof edge of the tent
- The addition of a plastic outside sheet over all the tent

and are tabulated in table 3 below. What was interesting was how close the in field solution came to the usual winterised tent version suggesting perhaps that instead of a winterised and non winterised version that there should be a non winterised version with a winterising kit supplied where required.

Table 3: Heating Requirements Inside the Different "Tent" Options.

Material	Calculated Heating(watts)	Heating Provided by People(watts)	Required Supplementary Heating.(watts)
Standard non winterized UNHCR tent (consisting of a canvas fly and inner tent)	4,178	500	3,678
Canvas fly and inner tent + plastic sheet + inner cloth type liner.	2,826	500	2,326
Canvas fly and inner tent + plastic sheet + sewing edge for air gap.	2,430	500	1,930
"Tent within a tent" approach	1,724	500	1,224
UNHCR Winterised tent	1,581	500	1,081

7. Solar Models

Much has been written about the importance of building orientation and controlled solar access. And when solving problems of orientation, sun control and predicting sun penetration and shading of buildings the use of models have proved extremely useful. Such models include:

Sun path Diagrams
Computer models and software packages
Refer Olgyay: 1992 for a full list of Solar Models.[14]

The most appropriate "in the field models" would be Sun-Path Diagrams and Computer software packages.

7.1 Sun Path Diagrams

The utilization of sun path diagrams aids the development of healthy living spaces by taking into account the hourly, monthly and seasonal changes in solar access to buildings. They also allow the designer to allow for shadowing from adjacent buildings or obstructions. Sun path Diagrams for locations around the world are available from local government publications, Texts dealing with solar control, international Web sites, and computer draughting software packages. An example is the University of Oregon Solar Radiation monitoring Laboratory Web site http:// solardat.uoregon.edu/SunChartProgram.html [15] Charts are available as Polar and Cartesian, selection of chart type is commonly a personal preference choice.

Issues of local clock time and solar time may need to be addressed, where solar noon does not match noon clock time due to local time variances eg. daylight saving time. Note: Sun path diagrams show Solar or true north, allowances must be made for magnetic north variances at specific locations where north is derived from a compass. Magnetic declination for world locations can be obtained via the World Magnetic Model: WMM-2005 Main Field Declination, from the National Geophysical Data Centre (NGDC) USA Web site http:// www.ngdc.noaa.govt/seg/wmm/data/wmm-D05.pdf

The essential concept is to take advantage of solar radiation through control. Control of the radiation transmitted into the spaces interior, and control of the interior space through ventilation. The important considerations are therefore, climatic zone, latitude, time zone, building orientation, solar access, shading, window or fenestration sizes, projections, solar obstructions, strategies for the effective control of ventilation of spaces. The optimal word here is **control,** control of solar access, control of radiation and the control of ventilation.

8. Conclusion

Much of what has been presented in this paper will seem straightforward and certainly has been known for some time (as can be seen from the reference list below). But it is not used in the field nor is it readily known operationally. And this is because the “Tools of Trade” have never been collected in one place and hence this paper. But the reason for such tools not previous being gathered together is because of the wide range of disciplines involved. Therefore, any training needs to reflect this wide ranging cross discipline approach required to adequately prepare site planners/ engineers and architects involved in emergency shelter.

Bioclimatic Chart with Design Strategies

Appendix 3: Occurrence and Characteristics of Main Climatic Zones in the Tropics.

Zone	Approx. Lat. Range	Natural Vegetation	Typical Cultivation	Climate	Problems	Requirements
Warm Humid Equatorial	7.5^{O}N-7.5^{O}S	Tropical Rain Forest	Banana, Palm Oil	Warm with high humidity and rainfall	Humidity prevents sweat evaporation, hot nights makes sleep difficult, high rainfall and glare from other cast sky, sun on east and west facades	Air movement from the fans or cross ventilation, low thermal capacity construction, sloping roofs and large overhangs, windows facing north and south.
Tropical Island	5-30^{O}N 5-30^{O}S	Rain Forest	Sugar Cane	Warm, humid but less cloud than warm humid zone	Similar to warm humid equatorial, but clear skies and bright sun more frequently	Similar to warm humid but with additional care in the design of shading the south facing windows (vice versa in the southern)
Hot dry Tropical	15-32^{O}N 15-32^{O}S	Desert, Steppe	Palms, Grazing (nomadic)	Hot and dry with high annual and daily variation of temperature	High diurnal range, very hot days in summer, cool winter days, low rainfall, very strong solar radiation and ground glare, sandy and dusty environment	High heat capacity construction, shading devices which allow solar heating in winter, small windows, flat roofs (often used for sleeping), small courtyards to give shade and protection.
Maritime Desert	15-30^{O}N 15-30^{O}S	Desert	Palms, Grazing	Hot, humid with low rainfall	Similar to hot dry climates but with higher humidity causing discomfort by preventing sweat evaporation	Similar to hot dry but air movement is desirable at times.
Intermediate composite or Monsoon	5-20^{O}N 5-20^{O}S	Monsoon Forest, Dry Tropical Forest	Paddy Rice, cane, Millet	Warm humid and hot dry seasons	Combines the problems of warm humid and hot dry climates	Compromise between the requirements of warm humid and hot dry climates or ideally (but more expensively) two buildings or parts of buildings for use at different times of the year
Equatorial	10^{O}N-	Broadleaf	Millet	Temperate to	Combines the problems of the warm	Designed to take advantage of solar

Upland	10^{O}S	Forest, Mountain Vegetation		cool depending on the altitude	humid and hot dry climates with those of a temperate or cold climate for all or part of the year	radiation when cool or cold. Heating and additional installation maybe required
Tropical Upland	10-30^{O}N 10-30^{O}S	Steppe, Cedars	Wheat	Hot summers, cold winters	As above	As above
Mediterranean	32-45^{O}N 5^{O}S	Mediterran ean Scrub	Vines, Olives, Citrus Fruits	Hot dry summers, cool wet winters.	Summers have some of the problems of a hot dry climate while winters are cold and humid with moderate rainfall.	Design with high thermal capacity, medium to small openings, and courtyards to give shade and protection.

Identifying Value Adding in Humanitarian Programs

Unitec Auckland New Zealand
(email: lkestle@unitec.ac.nz)

Abstract

Earlier work by Kestle had established a management model for design management in remote areas [1]. That model was subsequently tested in the humanitarian aid context of West Darfur in June 2004 and found to be very effective in modeling and understanding the issues related to the provision of humanitarian aid in remote locations [4]. And in this paper, the authors extend the application of that model into identifying where value was added (both perceived and actual) by the Jesuit Refugee Services (JRS), as part of it's Tsunami Relief Program in Aceh, Indonesia. It then suggests ways that this value could be enhanced. This need came about as part of an end of program evaluation of the TRP.

The mission statement of JRS is to "accompany, serve and defend" and it was interesting to see how this worked out in the field. Many/most of the JRS field team felt that their added value was linked to it's flat organisational structure and it's bottom up management structure that meant that JRS could respond rapidly to changing circumstances and beneficiary requests. The Kestle Model provided a framework to compare what was seen in the field against what was planned by management. And from that comparison and analysis demonstrate where value was being added.

Keywords: Added value, humanitarian, aid, management, framework

1. Background

How do different humanitarian aid organisations add value?

As part of an evaluation of their 2 year tsunami program in Aceh, it became clear that JRS believed that they did have their own particular way of doing things and moreover this was identified by those in the field as being the main way that JRS added value [7]. What was interesting for the evaluation team was that none of this "JRS way" was actually written down and this also appeared to be at difference to the organisation's mission statement. The mission statement of JRS is to "accompany, serve and defend" and it had been doing that in Aceh since July 2001 with a focus on relief, emergency support and accompaniment for refugees (those returning from countries outside

Indonesia) and internally displaced persons IDPs (those returning from other parts of Indonesia) to Aceh in North Sumatra [6].

The imposition of Martial Law in Aceh in 2003 severely restricted the work of all humanitarian agencies and in particular the work of JRS. By 2004, JRS's role in Aceh was to strengthen traditional coping mechanisms as a response to the impact of conflict and peace building. The earlier monitoring of human right abuses was still needed, and advocacy remained an important aspect with local authorities [2].

There was no change in the situation in Aceh when Martial Law ended in May 2004 and was replaced by a Civil Emergency period. And it was only the Indian Ocean Tsunami on December 26th, 2004 with it's massive death toll and extent of destruction that the Government of Indonesia (GoI) re-opened the area for humanitarian aid. JRS returned to Aceh just days after the tsunami and rapidly set up their Tsunami Response Program (TRP) [3].

The assessment (that formed the basis of the TRP) determined specific areas of assistance that included the following:

- The replacement of boats and the construction of new houses for the Pulo Aceh people that lived on an island just out from Banda Aceh, the provincial capital of Aceh.
- In Banda Aceh, JRS set up a medical program for the IDP's in various camps throughout the city, built permanent shelters and educational hostels.
- In Krueng Raya (a fishing port near to Banda Aceh) JRS set up a livelihoods program replacing lost fishing boats.
- In Lamno (usually an hours drive south along the West coast of Aceh) JRS supported logistics, education, livelihoods and health care.
- And in Meulaboh (the most southern city on the West Coast of Aceh affected by the tsunami) JRS built homes gave books and various basic needs for IDP children.

These programs were up and running well before those of the major International NGOs and UN Agencies. And it is the resulting program from this that is studied in this paper.

2. Methodology

The study used a conceptual design management model developed by Kestle [1][4][5]. The model was originally developed in terms of "reviewing and synthesizing theoretical published 'production principles' and 'sociological factors' associated with design management, and lean design management." And has it's theoretical basis in Just in Time (JIT), Total Quality Management (TQM) and Lean Production theories.

The model uncovers value generation within the design management process and the four areas of the model reflect the many stake holders participating in this value adding process. For example, developing a shared understanding of what is valued on the project and identifying, and then agreeing the objectives for a project with the stakeholders. How this was achieved was critical to the original evaluation but was particular interesting in terms of the usefulness of the model. Much of the lean thinking research falls into the tactical category rather than strategic and theoretical, that is, until the work of researchers Koskela and then Seymour [8][9]. Seymour suggested a proposal for implementing lean construction at an organisational rather than just at the operational level. This work was then followed up two years later by Seymour and Rooke using an ethnomethodological approach in terms of setting up an organisational culture that established how people may perform their site work activities in a visibly orderly manner, by changing their mindset, for instance. Similar findings were published by Howell and Ballard stating that changes of the mental model needed to be made [both are reported in 5]. They further suggested that lean thinking (applied at the beginning, or alternatively applied midway on well run projects) revealed the weaknesses of the current systems by mapping the project value stream. The lean design principle of 'flow' is relevant from a sociological and environmental viewpoint, as it tends to be focussed on a more holistic approach for theoretical and project development work. The thinking and principles associated with lean design management, made a significant contribution in terms of informing the development of the Process Integration factor for the conceptual design management model (for remote sites) [5]. The key factors of design management for remote sites were therefore established as being - 'value generation', 'knowledge integration', 'process integration' and 'timely decision making'. These are discussed in more detail below.

2.1 Value Generation

Value generation - refers to the value that the client and stakeholders place on the project and will vary according to the differing clients' and stakeholders' expectations of the projects. And for example in the West Darfur Humanitarian Aid Project in Sudan, value was concerned with making a difference to the lives of the aid beneficiaries through the provision of basic shelter and the necessaries of life [4]. The impression gained from the field as part of the evaluation was that flexibility and speed of response to beneficiaries needs was the main value added service that JRS provided and it was this view that needed to be reviewed as part of the evaluation. JRS's organisational structure consisted of only 3 levels from their National office in Yogjakarta to the field staff. And consequently there was some basis for what field staff were working to.

2.2 Knowledge Integration

Knowledge integration – is a complex process concerned with endeavouring to capture, and then integrate, the specialist knowledge of all those personnel involved on a particular project, prior to and during the project phases. To be successful, this requires that key personnel be involved with the pre-design briefing, pre-planning, and in the regular monitoring and review of the design and construction processes, as the project progresses. Specialist knowledge is required to ensure the best design solutions and end results despite frequently working with non-negotiable timelines.

The sense from the field was that this was not happening.

2.3 Process Integration

Process integration – involves the timely and cost-effective co-ordination and planning of a range of processes across the total project, such as construction planning methodology, logistics, information management, and design/ production interface management. In certain instances this may require alternative procurement strategies. Logistical planning and implementation is complex, as well as critical, for remote sites. The timing, costs and restrictions associated with shipping, or air freighting building components, add to the complexities of the logistical aspects of a design management model for these remote sites.

2.4 Timely Decision Making

Timely decision making - refers in the main to financial and design decisions, which are critical to the successful management of the design and construction of remote site projects. These decisions are made within the context of frequently non-negotiable windows of buildability, fixed budgetary constraints, and the need for "durable solutions" [10].

3. Interviews

Structured interviews were held with the 7 members of the management team and their responses for each of the 4 areas of the Kestle model summarised and then tabulated into a contextual spreadsheet. Such a spreadsheet (despite being a summary of the full interview) made comparisons and patterns more evident by being able to look across all the interviews at once and is included in Appendix A below.

4. Results

What did the spreadsheet show and how did that compare to what was happening in the field?

Value Generation for JRS was directed linked to outcomes for beneficiaries but these appeared to vary and fell into three areas namely:

- Direction and alignment (this appears to be intuitive and non personal)
- Team welfare (personal and intuitive)
- Reports (non personal and un-intuitive)

All managers were concerned about money flows, corruption and the accountability for both in their respective programs. Nonetheless, feedback from the beneficiaries through the management levels appeared to be driving programs. However, that feed back was not critically analysed and appeared to be accepted at face value. So that if beneficiaries requested boats they were supplied with boats if they were able to show they had a boat pre-tsunami. The pre-tsunami situation was not analysed as to whether the aid provided could not simply replace what was lost but better the village or community overall.

The team relied heavily on the reporting of transactional narratives with beneficiaries for it's knowledge integration. Again, this was not analysed as part of the various meetings in the field, at the Aceh sub office and at the National office in Yogjakarta. All managers saw the need for a better system but also admitted that it would be difficult to implement such changes. And finally managers conceded that there were issues in attracting staff let alone specialist staff on to their programs. This reliance on almost "word of mouth" may have come from the sensitivity of the work that JRS is usually involved with, often in conflict situations [1][2]. It was clear from the interviews and the evaluation that there was a significant amount of trust between managers (mostly Jesuit priests) and that work orders and programme changes were often based on an email. Emails were heavily relied on for knowledge integration.

Process Integration appeared to be "rule based" with a strong "go and see" approach. Improvement of the system centred on staff capacity building with the main responsibility of HR being solely to provide staff. And not the training or capacity building of staff.

Timely decision- making was centralised and depended on the "distance" from the field. Those based in the National office felt that the process was decentralised while those in the field felt it was centralised. Staffing and financial were centralised in the National office with other decisions made at sub office and field level. Both staffing and financial were strictly controlled by process and rule.

5. Conclusion

So where was the value that JRS added? And to what extent was the sense (as mentioned earlier in this paper) that flexibility and speed of response to beneficiaries needs was the main value added service that JRS provided, was this confirmed by the model?

The TRP had a strong and singular beneficiary focus. That clearly came through in the Value Generation and Knowledge Integration factors. But the flexibility and speed of response were not recognised as value adding. While it could be that both were treated as "givens" being evident in the reliance on feed back, field reports and the informal nature of the knowledge integration identified better value would have been realised by promoting flexibility and response in any future programs.

It is also evident from this analysis that there is the potential for further value adding to beneficiaries by the following:

- Value Generation- More emphasis on flexibility, response and the development of a stronger community of practice (COP) approach.
- Knowledge Integration- Analysis of the responses of beneficiaries
- Process Integration- Development of COP approaches.
- Timely Decision Making- Further decentralisation

This aside, the interesting (and surprising outcome) was the usefulness of the Kestle's framework in analyzing such a situation suggesting that the model was more robust and portable than perhaps originally thought?

Appendix A: Contextual Spreadsheet Summarising Management Responses for the Four Key Factors of the Kestle Model.

QUESTION	Person 1	Person 2	Person 3	Person 4	Person 5	Person 6	Person 7
VALUE GENERATION:							
How do you know or measure the effectiveness of your role as it relates to Aceh?	Direction, alignment with JRS Regional and beyond. Staff resources	Direction and clarity	Difficult to get outputs without assessments	On time and finance report checked	Administration only	Difficult, probably how well the team is working esp. With staff changes	Based on reports and feed back from team.
Are there any rules of thumb that you intuitively apply?	Yes	Watch out for unbalanced verbal reports	Follow ups	None, but system is self checking	Not sure	Go where the need is, ensure beneficiaries talk to us?	Community pride with JRS
What and how do you get feed back from "clients"?	Feedback from regional, national and field staff	Oral and notes and reports from national office	Little and relies on stories	Feed back from Field	Mostly email and reports	Meetings discussions and field visits.	Meetings with beneficiaries
In what ways do you feel that you are accountable?	Money, no corruption and cash flow for projects.	Progress and openness	Not accountable no decision making power.	Responsible for money tracking	For system set up	Use of money for beneficiaries and helping beneficiaries	For project related matters.
KNOWLEDGE INTEGRATION:							
How is what you have learnt on Aceh recorded and passed on to others?	Calling teams together for planning and future. Tacit knowledge.	Discussions informal, information transfer.	Narratives, write ups posted on web and international newsletters.	Not clear	Visits to field office	Difficult to ans. Emails and documents	Reports
How are you or would you like to improve your	Character and spirit of JRS. Small and non	Structured without being too formal.	Set up info reqd. and lists	Quality of reporting	Better management system and	Info officer and media	Capacity building of field staff.

situation?	bureaucratic.				policy		
And are such changes easy to implement?	Potentially difficult because they are obscure. Unique.	Hard to move towards written	Difficult to get outputs without assessments	Can be difficult	Not clear		Some are hard, no writing culture in Indonesia.

Abstract

During the summer of 2007 the United Kingdom experienced some of the worst flooding in its history, with the city of Hull amongst the worst affected. An examination of the government handling of mitigation measures and disaster response in this instance raises comparisons to the 2005 Hurricane Katrina related flooding in New Orleans, USA. These events are especially appropriate for comparison given the vulnerability of each city and general feeling of dissatisfaction among residents. This paper examines each event individually and presents a comparison of the actions and inactions of each government. The result is a call for stronger and more decisive measures to combat climate change and protect vulnerable populations more efficiently against natural disasters.

Keywords: Flooding, Hurricane Katrina, Disaster Management, Disaster Response, Mitigation, Climate Change

1. Background

1.1 Parallels of two cities

In these times of escalating concern over global warming and its effects on weather patterns, as well as the size and frequency of natural disasters, it seems fitting to analyse and discuss how effectively governments are planning for disasters and whether they are responding to them appropriately. This paper will compare two recent natural disasters; Hurricane Katrina which devastated the US Gulf Coast in 2005 and the major flooding which wreaked havoc in the UK during the summer of 2007.

Both events brought extensive damage and material loss, as well as human casualties. Although hardly comparable in scale with regards to death toll or economic loss, these events have raised many parallel issues in government mitigation and response protocol and initiative.

Firstly, each disaster will be examined individually as will the government's role in putting mitigation measures in place prior to the event and responding to the crisis once in motion. The facts and figures of each emergency will then be compared and discussed. This paper will focus on two cities with many similar issues and which were two of the worst affected; New Orleans and Hull City. Each is topographically vulnerable and guarded by a pump system unable to cope with the most severe floods. The residents of each city ultimately felt that they were neglected and let down by the government in terms of the provision of mitigation against flooding and the disaster response effort which took place.

The overall efforts made by the UK and US governments to plan for and respond to these events will be examined and discussed, as will the feelings of affected residents. General public feeling towards governments and agencies responsible for their protection and aid will then be gauged and analysed.

Following a discussion of all these factors, conclusions will be drawn as to the extent of protection afforded each country and in particular each of the cities under scrutiny in the face of these events and the level and efficiency of aid given to affected residents once each disaster was in motion, as well as the ability of the affected population to recover post-disaster in light of assistance received from the government.

2. Flood Events

2.1 Hurricane Katrina related flooding

On August 29th 2005, Hurricane Katrina made landfall on U.S soil with the eye of the storm hitting about 55 km east of New Orleans. The storm at the outset brought most damage as it swept along the Louisiana and Mississippi coast but when several levees protecting New Orleans failed a day later, about 80% of the city filled with water.

This natural disaster crippled a city, left lives in chaos and caused colossal economic loss in the region to the tune of an estimated $81 billion [1]. The vast impact on the Gulf Coast made Hurricane Katrina the largest natural disaster in U.S. history [2] while triggering a massive relief and evacuation effort.

In the two years since Katrina struck questions over the adequacy of disaster mitigation measures prior to the storm and the speed and efficiency of response efforts to the crisis have been widely criticised in the world's media. From an early stage, multidisciplinary experts have advised on appropriate measures to be taken to ensure long term recovery in the region [3]. Even now the rebuilding process seems laboured and funding continues to pose a problem. Considering the facts and figures on the table, it is little wonder that many residents of New Orleans and the US Gulf Coast harbour ill-feelings in Katrina's aftermath towards the government and agencies which they feel have failed them in their time of need.

A combined failure of federal, state and local government to put in place mitigation measures against a storm of Katrina's magnitude has clearly occurred. In 1965, the government took responsibility for the long-term safety of New Orleans by passing the Flood Control Act of 1965 in Congress [4]. This authorized a flood protection system to be built by the U.S. Army Corps of Engineers and was projected to be complete in 13 years. This system was supposed to mitigate against the strongest storms characteristic of the region.

When Katrina passed east of New Orleans, this system failed in over 50 places. Nearly every levee in the city breached and caused 80% of the city to flood, along with many areas of neighbouring parishes [5]. 40 years after the Flood Control Act was passed in Congress, the protection system was still only 60-90% intact with an estimated completion date of 2015 [4]. This constitutes an extreme failure by the parties responsible for protecting the historic city of New Orleans and its population.

Over 1.2 million residents in the Gulf Coast were covered under a voluntary or a mandatory evacuation order as Katrina approached [1]. Based on Louisiana's guidelines for state evacuations, residents in the forewarned areas were supposed to be moved out in phases commencing 2 days before landfall. Even in this respect, there was an element of bureaucratic bungling as FEMA claimed Louisiana governor Blanco did not request aid for coastal parishes and therefore they were omitted from President Bush's declaration of emergency for Louisiana [6]. By the time Katrina made landfall, around 80% of the residents of New Orleans had been evacuated, with those still in the city either refusing to leave or without the means to leave [7].

There has been a drive following Katrina to implement better practices in construction and stricter building codes in the region. The Louisiana State University Hurricane Centre study found that had state wide building codes been in place, it would have saved Louisiana $7.9 billion and Mississippi $3.1 billion in economic damage and spared a total of nearly 40,000 buildings from destruction during Katrina [8,9]. However, the devastation that occurred in New Orleans has more to do with why so many houses were built in such a vulnerable position than it does with design and code failures.

We can see that even now the government is encouraging and funding rebuilding efforts in the same areas and using the same construction methods as before. At the same time protection measures in the Louisiana basin are not complete and will not be able to cope with a direct hit until at least 2010 and even then $4 billion must be spent to achieve this [10]. Surely questions must be asked when rebuilding is allowed to commence at such a large scale where a pump system cannot cope with catastrophic flooding coupled with levee failure that may indeed reoccur before protective measures are complete.

Comparisons have been drawn to the comparative ease with which the US government and agencies prepared and responded to Hurricane Rita which occurred on September 24th 2005, in the wake of Katrina. Aid was stockpiled on the ground two days before Rita made landfall while 10,000 national guardsmen were called to Texas in order to make the emergency response immediate [6]. Four weeks earlier, only 5,000 were summoned to Louisiana in preparation for Katrina. After Katrina, some people in New Orleans were left without basic aid for days afterwards while poor communication and allocation of resources meant that at one stage 5 helicopters arrived to rescue the same individual [6].

Thousands of people were crammed into 'relief centres' such as the Louisiana Superdome for as long as 6 days, without adequate food, water and medical supplies while what they really needed was to escape New Orleans. Some of these people even died while waiting for help [11]. Meanwhile 200 school buses were left unused and underwater following Katrina because of bureaucratic red-tape. These buses could have evacuated around 13,000 people [6]. The immediate federal response for relief was so incredibly inept it left many to wonder if the lack of support was deliberate and had any political, racial or social motivation. Experts had warned for years that New Orleans was a disaster waiting to happen [12], yet an effective emergency plan that would include all co-operating levels of government was still not in place.

The overall death toll associated with Katrina stands at 1,836, mostly from Louisiana (1,577) and Mississippi (238) [13]. Many people are still missing and many of the confirmed deaths are indirect; as such a total definitive figure is impossible. The storm displaced over 400,000 people from the region, primarily from New Orleans, and left many of these people living in poverty elsewhere [14]. The aftermath of Hurricane Katrina, the storm coupled with the failure of New Orleans' levees, presented arguably the worst set of catastrophes in the history of the United States.

2.2 UK flooding summer 2007

In the summer of 2007, the United Kingdom sustained widespread flooding caused mainly by unseasonably low pressure systems during June and July which dumped record amounts of water on certain areas that were simply not equipped to deal with such a volume of water [15]. This created a crisis for the government and hundreds of thousands of affected residents who even now are in the process of recovering and rebuilding their lives.

As the flooding involved many towns, cities, regions and as such many facets of local as well as central government, this report will concentrate on the mitigation measures put in place and the level and effectiveness of the disaster response in one city particularly hard hit by the floods, Kingston upon Hull.

Many of the issues faced in the crisis situation in Hull were similar to those faced across the country to a lesser extent. Hull was particularly vulnerable to begin with in its low-lying position but in recent years the pumping system had been significantly upgraded and this indeed may have averted a catastrophe [16]. Given the fact that the flooding was a 1 in 150 year event and the city was assessed as a 1 in 30 year flood risk, it is encouraging that key civil infrastructure did not fail [17]. Flooding occurred because the drainage system was full to capacity as were all waterways so effectively there was nowhere to pump to.

The build-up of water during the month of June meant that many areas were saturated to capacity by the time some of the heaviest sustained rainfall occurred on the 25th of June. This was especially true in Hull; a city built 90% below high tide level and entirely pumped. Large parts of the city are built on reclaimed marshland and some major areas are below sea level [18]. On this day in particular, emergency action needed to be immediate and decisive to minimise damage and casualties.

Although the pumping system performed well in the circumstances, there was no contingency plan in place in the event of the system being overwhelmed [17].A problem appeared during the crisis regarding co-operation between multiple agencies in charge of different areas of the drainage system; the Environment Agency, Hull City Council and Yorkshire Water. No agency accepts responsibility for any elements outside their own terms of reference and this is undoubtedly a problem nationwide [19]. During the summer floods, Prime Minister Gordon Brown announced a review of the handling of floods and the infrastructure much of which was bequeathed by the Victorians. [20] One has to wonder why it took a major disaster before the government would listen to calls for a drainage system overhaul when 3 years ago they were warned that a flood disaster was imminent with current drainage capabilities [21].

Concerns have been raised about flood warning systems in place in Hull and across the UK. Although the Environment Agency operates an automated system warning its floodline subscribers of danger from flooding, this system only deals with coastal, estuarine or river flooding. There is currently no provision to warn of flooding caused by heavy rainfall [17].This problem exists at a national level and as such must be addressed by central government. Meanwhile affected residents are left to wonder why a system like this was not in place given the inherent topographical vulnerability of Hull.

The Environment Agency issued early warnings of heavy rain beginning on June 22nd and 23rd. On Sunday 24th a flood watch alert was issued and on the 25th a major incident was declared triggering a rapid response and relief effort. Initial reviews of the response effort have shown that it was for the most part well organised. The Humberside Fire and Rescue Service went above and beyond their call of duty in order to keep casualties to a minimum although with more co-operation between agencies, the army could and should have been called in for assistance [17].

Local residents and councillors were unhappy at the lack of media coverage afforded Hull given the scale of devastation [22,23] and there has been some suggestion that if the flooding had occurred in the Home Counties (around London) the response would have been quicker and aid for recovery would be much greater. For these reasons City Council leader Carl Minns dubbed Hull "the forgotten city" [22].

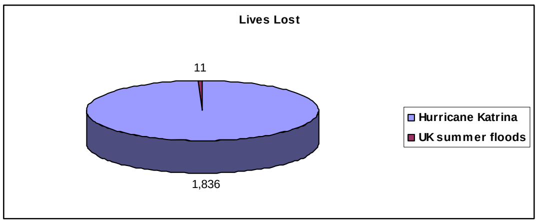
Residents were further outraged when it surfaced that the government had been warned months in advance by the Met office that summer flooding was probable because the El Niño phenomenon had weakened, but no action was taken [24]. There was time to warn local governments, agencies and indeed residents to prepare for the worst but this was not done. Liberal Democrat leader Sir Menzies Campbell accused the government of lack of preparation leading to a ‘summer of suffering’, and said, ‘With sophisticated weather forecasting as we now have, particularly in relation to what’s happened over the weekend, there are quite a few questions as to how it was that flood-prevention measures were not in place or were not more effective.’ [25]

In total, the floods are thought to have caused 11 direct deaths. The damage has affected thousands of businesses, tens of thousands of homes and further affected up to a million people [15]. Estimated damages are over £3 billion. Gordon Brown has promised to put pressure on insurance companies to pay out and also allocated recovery funds to individual councils to be distributed as they see fit [26].

3. Discussion

3.1 Comparing the figures

In terms of life and economic loss, the flooding in Hull does not come close to the catastrophe in New Orleans. Hurricane Katrina claimed an estimated 1,836 lives to the 11 killed in the UK summer floods 2007 [13,27,28]. New Orleans in particular saw mass displacement of its population some of whom still cannot return to uninhabitable conditions while in the UK, most people have now returned to their homes and started to rebuild. Katrina caused economic loss of around £40 billion ($81 billion) to the £3 billion estimated to be caused by the UK summer floods [1,26]. (see figures 1 and 2)



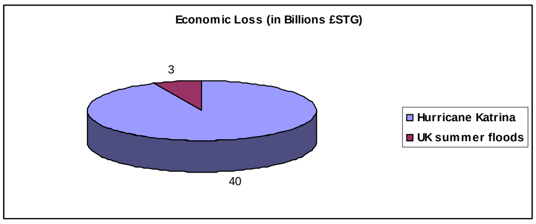


Figure 1: Comparing lives lost

Figure 2: Comparing economic loss

It is important to realise that although the scales of these disasters are quite different, we can draw many similarities between the respective disaster management strategy inadequacies.

3.2 Government mitigation measures and disaster response

Around the world when a natural disaster occurs, people generally notice the initial response and rescue effort and governments are commended or criticised accordingly. This study has revealed some lesser known facts and shows that both governments were forewarned about these disasters and should have ensured that appropriate mitigation measures were taken.

In New Orleans, the incomplete levee system should have been finished several decades previously and was not equipped to combat a hurricane of Katrina's magnitude [4]. The responsibility for this does not fall on any person or organisation, though many people in New Orleans hold the Army Corps of Engineers accountable for their design of the flood protection system while others assign blame to the federal government for lack of funding.

Meanwhile in Hull, a city in a similarly vulnerable topographical position, the pumping system is relatively up to date compared to elsewhere in the UK [16]. However the decision was made to protect Hull from a 1 in 30 year flood event when in reality the city was hit by a 1 in 150 year event. Suggestions have been made following the summer floods to provide additional areas to pump water into because in June all waterways and sewers were full to capacity [17]. The affected residents are left to wonder why additional measures were not put in place to protect against a 1 in 150 year flood before the event given the vulnerability of the city.

Before Katrina made landfall, bureaucratic mix-ups were already taking place within US government as has been outlined with regards to hurricane warnings, evacuations, the early stocking of supplies in the region likely to be affected and the positioning of enough emergency response personnel to deal with the crisis that was likely to unfold. In the UK, to a somewhat lesser extent, a similar lack of foresight meant that there was no warning system in place to account for flooding due to extreme rainfall [17].

In each case, a lack of action in the face of scientific warnings that such events were likely has cost dearly in terms of life and economic losses. Despite the knowledge that New Orleans was one of the most at risk cities in the country, funds were diverted away from the project meant to protect it [29]. In recent years scientists have repeatedly warned of the carnage that would ensue if a strong hurricane hit New Orleans [12] but people were still caught unawares when the disaster struck. In the UK, despite the fact that the Met office warned the government in the spring of likely widespread flooding in the summer no additional mitigation measures were undertaken and residents were not properly prepared for a crisis that the government knew was probably on its way [20,24].

The emergency response from both the UK and US governments to these disasters has created a mood of resentment within sections of the affected communities who felt that they were neglected in one way or another.

In New Orleans speculation has been endless as to the possible political, social and economic motives that could have delayed the disaster response effort [11]. Besides this sinister possibility, there was a plethora of mistakes made which influenced the speed and efficiency of the response. As outlined previously, not enough National Guard were positioned in the area prior to Katrina’s landfall, there was poor communication between agencies and different levels of government leading up to and during the crisis and bureaucratic mix-ups caused inevitable delays and missed opportunities to minimise the scale of casualties and losses.

Meanwhile in Hull many residents felt that the government was not as concerned for their region as it might have been had the flooding occurred in the Home Counties [22]. However, given the lack of co-ordination between agencies and the uncertainty over responsibility for overall flood response, the problem seems more likely to be rooted in a poorly specified chain of command and network of responsibility. The army were not called in when it was entirely feasible to do so and would have taken pressure off the Humberside Fire and Rescue Services who were operating outside of their remit already.

4. Conclusion

The probability of a hurricane the size of Katrina hitting the United States in any given year is relatively low, according to risk assessors [30]. However many experts warn that due to climate change the risks are growing along with the magnitude of hurricanes [31]. Recent climate model simulations show that a doubling of CO_2 may increase the frequency of the most intense cyclones [32]. Equally, the changing weather systems in the Pacific Ocean are likely to alter the magnitude and frequency of extreme events in the UK [24]. Climate researchers have suggested that the unusual weather leading to the floods may be linked to this year's appearance of La Niña in the Pacific, and the Jet stream being further south than normal [33].

In the face of scientific evidence that climate change is most likely causing an intensification of extreme weather events, governments worldwide must accept that change is necessary in both environmental policy and disaster planning and management.

It will never be a simple task to manage a natural disaster as events of nature are inherently unpredictable and unquantifiable; however the combined failures of the UK and US governments to prepare for and cope with these natural disasters exposes flaws in all levels of government.

In the UK, it would appear that the mistakes made were arguably more naïve than in New Orleans, where the total inadequacy of flood defences, evacuation measures and the relief effort makes it difficult to accept that the response was equivalent to what would have been done had a disaster crippled New York, San Francisco or Washington DC. Looking only at the figures, it is important to bear in mind that Hurricane Katrina was a much larger disaster management problem than the UK summer floods and therefore a portion of the errors made and inadequacies exposed were surely unavoidable given the scale of the disaster.

Claims have emerged by residents of Hull that they were similarly neglected by their government [23]. The failure to protect such a vulnerable city in the face of scientific advice and evidence and subsequently lend at best mediocre relief and financial support to the area [34] leads us to the conclusion that this may indeed be true to an extent. However, this could be in part because the eye of the media was drawn to Sheffield where the possibility of the Ulley reservoir dam collapsing would cause catastrophic damage but also create a major news event [35].

It is simply unacceptable that the US and UK governments have not done all that is necessary to mitigate as far as possible against such disasters, particularly when these countries are two of those responsible for much environmental damage and possessing the capability to implement change[36,37]. Perhaps there is still time to introduce extreme measures to slow down global warming but science tells us that if nothing is done, our weather will become more extreme and unpredictable and disasters will become more frequent and powerful[31,32]. Governments worldwide need to accept that the risk is now too great to leave their communities without adequate protection.

Abstract

The October 8, 2005 South Asian earthquake devastated the northern regions of Pakistan, destroying or damaging close to 600,000 homes, leaving more than 73,000 dead, and resulting in displacement of 3.5 million persons. Given the scale of devastation the government relied heavily on outside assistance, either in the form of direct aid or loan. One such grant aimed at rehabilitating livelihoods was the Livelihood Support Cash Grants which provided $50 per month for six months to 260,00 vulnerable families. We evaluate the implementation of this grant, in particular examining whether the grant was given to those families identified as vulnerable and as such focus on leakage and under-coverage of the program. We observe that one in two deserving families received the grant, and that the other family did not fulfil the criteria but was receiving funds. Through a multivariate analysis, we next built a parsimonious model to explain exclusion and false inclusion (leakage). We observe that for exclusions, families reporting a female as head were 8.1 (95% C.I. 4.1-15. 9) more likely to be excluded than families with male heads, and families with increasing number of children were 2.5 times more likely (OR=2.5, 95% C.I. 2.1-2.9) as compared with families with fewer number of children. The likelihood of exclusion was also higher with increasing age of family head (OR=1.1, 95% C.I. 1.07-1.2) and if a family resided in Azad Jammu and Kashmir (OR=2.6, 95% C.I. 1.2-5.7). With respect to leakage the model shows that families with younger ages (20-39 years) of family head (OR=4.4, 95% C.I. 1.4-14.1), increasing number of males (OR=2.9, 95% C.I. 1.8-4.6), and families living in Azad Jammu and Kashmir (OR=2.6, 95% C.I. 1.2-5.5) were more likely to be receiving the grant. In evaluating this program, we conclude that the Livelihoods Cash Grant Program was successful in only reaching half the vulnerable population as defined, and missed the most vulnerable families that is families with a female heads and increasing number of children.

1. Introduction

The October 8, 2005 South Asian earthquake with a magnitude of 7.6 on the Richter scale, covering a total area of 30,000 square kilometers of the Northwest Frontier Province and Azad Jammu and Kashmir, took an unprecedented toll on the lives and livelihoods of people living in northern parts of Pakistan. The fault line of destruction extended north to south taking a heavy toll in five districts of North West Frontier Province: Abbottabad, Mansehra, Batagram, Kohistan and Shangla, and four districts of Azad Jammu & Kashmir: Muzaffarabad, Neelum, Bagh & Poonch. An estimated 73,338 persons died [1]; an additional, 69,400 suffered from injuries and 3.5 million persons were displaced from their homes [2]. In addition, an estimated 600,000 houses were partially or completely destroyed in 4,000 villages across nine administrative districts.

Given the scale of devastation, the government relied heavily on international assistance for funding relief and rehabilitation. A humanitarian appeal was launched for $6.5 billion (U.S.), and donors contributed $370 million for immediate humanitarian needs. Of the total amount requested for assistance, international donors committed $5.75 billion of which $2.6 billion were to be given in the form of grants and 3.15 billion as loans. One of the larger loans $400 million from the World Bank through the Earthquake Emergency Recovery was provided for reconstruction of houses that were destroyed in the earthquake. Included in this loan by the World Bank was allocation by ERRA, $85 million, for a program that provided direct cash assistance of $50 per month for six months to over 260,000 vulnerable families, the Livelihoods Cash Grants Program (LSCG). Our study focuses on cash assistance provided to vulnerable families for mitigation of any adverse affects on livelihoods.

Since cash assistance has been used as a mechanism for social protection, it is necessary to determine how effective the government targeting strategies have been in including vulnerable families. Relief Information Systems Earthquake –Pakistan (RISEPAK) based at the Lahore University of Management Sciences (LUMS) was contracted by the World Bank to determine whether funds reached families that truly deserved the cash assistance according to the vulnerability criteria determined by the GoP. For this purpose RISEPAK conducted a survey to determine under-coverage (exclusions of vulnerable families) and leakage (false inclusions--awarding grants to families that are not deserving as per criteria) in the LSCG program. We selected a sample of families from seven of the nine districts, excluding Kohistan and Shangla for reasons of security, based on the enrollment figures provided by NADRA. Our team of surveyors visited 2,612 families between October and November 2006, collecting information pertaining to the cash grant including the thirteen digit number printed on the Computerized National Identity Card (CNIC) of family head and respondent. Records were then matched between our dataset and the LSCG dataset on the basis of this national identification number. A total of 2,001 records matched, and it is for this subset that we evaluate under-coverage and leakage in the LSCG program.

2. Background

2.1 RISEPAK

Relief Information Systems Earthquake Pakistan (RISEPAK), established within the first two weeks of the October 8 earthquake, is a loose network of South Asian academics. It is based at the Lahore University of Management Sciences (LUMS) in Lahore, Pakistan, and has been involved in several surveys providing village level information on damage, deaths, and humanitarian relief. In May 2006, RISEPAK was awarded the Stockholm Challenge prize for the most innovative IT project in the area of public administration. In fall 2006, RISEPAK was contracted by the World Bank to conduct an evaluation of the Livelihood Support Cash Grants (LSCG) Program, with a main focus on determining exclusions (families who were eligible and did not receive the cash grant) and false inclusions (families who were not eligible according to the vulnerability criteria but receiving the cash benefit). To achieve our objectives we designed a field survey at the household level of families living in the earthquake-affected areas. Of the nine affected districts, we included seven and could not include two (Kohistan and Shangla) for reasons of security. These districts did not have as much damage compared to the other areas, and in both instances enrollment was small.

2.2 Livelihood Support Cash Grants Program

The Livelihood Support Cash Grant (LSCG) disbursed funds ($300) to over 260,802, and was conceived as central to recovery of vulnerable families. It enrolled nuclear families that could provide a national identification card (CNIC) of the family head and a valid bank account for transfer of funds if selected. Banks have been an important part of cash assistance programs, and need further study. The LSCG program included an elaborate framework for implementation and allocated 13 percent of overhead ($11.05 million) from the total funds ($85 million) of the program. Several international and local consultants were hired to develop the methodology and supervise the work. Special Targeting and Enrollment Teams (TET) were trained and hired that established a stationary presence in a village for a few days to week to enroll families. A Verification Facilitator, part of the TET was present in the field to assure that all information being provided was accurate. The completed forms were then transferred to Pakistan’s capital city, Islamabad, where they were entered and eligibility lists created by the National Database and Registration Authority (NADRA), a quasi-government agency that was specifically contracted for this purpose. Over 750,000 families enrolled in the program from the nine affected district of northern Pakistan, and the LSCG program claims that over 30 percent of families receiving the cash grant are considered as fitting the vulnerability criteria [3].

The LSCG criteria and priority of selecting vulnerable families was based on the following: (a) family with no male members between 18-60 years of age or a male member between 18-60 years that reported a disability and (b) families with five plus children. Selected families had to have reported house damage. Civil servants enrolled in the program had to have a rank of less than Grade 17 (non-professionals). The information collected by the LSCG enumerators included the Computerized National Identification Card number and other information on the head of household, family members under 18-years, disability amongst family members, house damage, livestock losses, and bank account information. This information was then verified in the field by a Verification Facilitator, and the completed form was sent on to the National Database and Registration Authority (NADRA) responsible for data entry.

The selection of eligible beneficiaries was made by members of the GoP and the World Bank: "In light of objective analysis of data by ERRA, the list of eligible families will be finalized in agreement with the province/state governments and the World Bank, subject to resource availability" [4]. Once a beneficiary family was selected then the cash grant funds were to be transferred through the banks to the beneficiary's account, which could take from three to six weeks. In addition, any family that had not enrolled or those who wished to contest their non-eligibility status could file an appeals process through local administrative offices within seven days of public display of lists of beneficiary families. The LSCG program was extended for another six months and provided funds "for the most vulnerable female-headed households" [5]. As of December 2007, it was providing cash assistance to 7,594 families in the Northwest Frontier Province and 13,272 families in Azad Jammu & Kashmir.

3. RISEPAK Survey

3.1 Objectives

The two main objectives of RISEPAK's study were: (1) to determine exclusions of families from the LSCG program or in other words to see if deserving families were left out as beneficiaries and (2) to document false inclusions or leakage in the program such that non-deserving families were receiving the cash benefit. While we had other interests such as the effectiveness of outreach and the use of banks, we do not focus on these aspects in this paper.

3.2 Methods

Between October and November 2006, RISEPAK conducted a household survey of 2,612 families in seven of the nine earthquake affected districts—Bagh, Muzzaffarabad, Neelum and Poonch in Azad Jammu and Kashmir and Abbottabad, Batagram and Mansehra in the Northwest Frontier Province. We constructed a two-tiered sampling frame based on the enrollment distribution by LSCG Program, figures that were provided by NADRA, the institution handling data management for the program. We first selected our sample proportionate to district-wise distribution of enrolled families, which gave us an estimate of the sample for each district. Next, Union Councils and Patwar Circle (UC/PC), lower administrative units, were ranked within each district based on enrollment distribution. We then chose those UC/PCs with the highest proportion of enrollment, and within each UC/PC identified villages while in the field on the basis of ease of access. At each location we selected a cluster of houses (sometimes the whole village) that were close to roads and those that required a twenty to thirty minute walk from the road. We carried global positioning devices, and recorded the coordinates of most location including altitude. Close to one third (11 out of 36) of the locations visited were over 1200 meters. The final figure was not based on any statistical calculation of sampling but more on what was feasible in terms of given constraints on fieldwork and an acceptable figure for understanding exclusions (under-coverage of the program) and false inclusions (leakage, i.e. grant given to non-deserving beneficiaries).

In both urban and rural locations, houses were selected in clusters with a random start and surveyors fanned out in numerous directions when houses were not contiguous. This was particularly the case in rural, mountainous settings, where homes were often far apart even though part of the same neighborhood (mohalla). In urban areas, we interviewed most houses in the same neighborhood before moving on to the next cluster of homes. In certain cases we were not allowed into homes, especially true for Batagram district where male surveyors were prohibited from entering homes with female and in most instances females spoke Pashto or a local dialect so female surveyors could not conduct an interview. In such cases, we sat near a mosque or a school to enroll families. We only enrolled families that could provide us with a Computerized National Identity Card (CNIC) or an old National Identity Card (NIC) for the family head. In the event that the original CNIC or NIC were not available, photocopies of the original card were acceptable in our survey. We completed forms for nuclear families—husband and wife and their unmarried offspring. If there was a married son/daughter living with his parents we filled out a separate family form. For as many cases as possible we asked the family head to identify his or her children under 18-years of age. This identification, including confirming female-headed households, was not always possible especially in the Northwest Frontier Province district of Batagram that is religiously conservative.

The questionnaire, developed by RISEPAK, included seven sections and took an average of 20 minutes to complete. The questionnaire was translated from English into Urdu, and then translated back to English. The first section began with noting the CNIC number of the head of household and respondent, and also included basic demographic information about the family. In this section information on members of the family including gender, age, education, employment, occupation and disability, and whether the family had taken custody of any orphan children was also noted. The second section evaluated the LSCG information campaign and enrollment in the program. The third section on program beneficiaries was asked only of those families that reported as having been selected by the LSCG program and included questions on when and how many payments were received. Section four assessed the appeals process and the status of appeals in cases where a family had filed an appeal. Section five addressed issues related to accessing banks, including time and monetary expenditure to determine beneficiary status of a family within the program. This was an important component given the high percent of illiteracy and the cultural issues surrounding women's mobility. The last two sections were on housing damage and coping mechanisms, including the receipt of cash assistance to mitigate adverse affects of the earthquake. The questionnaire was field tested, and a pilot conducted prior to beginning the field survey. The survey was conducted over a period of six weeks, and the forms that were filled during the day were checked and verified by the RISEPAK team in the evening, and whenever possible any mistakes by surveyors were corrected that day. The total numbers of forms were tabulated every night (including number of female headed households).

The data was inputted in a relational database designed in MS SQL, and a user interface was developed in Visual C# to facilitate data entry. Forms from the Northwest Frontier Province were entered by a team of volunteer students and that of Azad Jammu and Kashmir was outsourced to a data entry firm. Of the 2,641 interviews, we excluded information on 29 families as they had either incomplete and/or were missing critical information or were duplicates. The final dataset had 2,612 family level surveys with unique CNIC numbers which were verified by the RISEPAK team.

The cleaned dataset was then taken to NADRA for the purposes of matching exact CNIC numbers with the LSCG dataset. In cases where CNIC number did not match exactly, we next tried an exact match with the family number and name of family head. Altogether 2001 records or 77 percent of the sample matched between RISEPAK and LSCG datasets of which 1,932 matched exactly on the 13-digit CNIC and 69 records matched on the family number and family head name. This matched subset, as well as the overall RISEPAK data, was analyzed in SPSS version 15.0. For this analysis we report on the overall RISEPAK survey as well as the 2001 matched cases. Since the NADRA records can be different for selected variables, we report on any such differences only for the 2001 cases. For each dataset, we have reported the frequencies and percentages of our variables, and included the mean and standard deviation as required. For variables with multiple responses, a percentage ranking of the most frequent responses has been presented.

Our main analysis was on under-coverage (exclusions) and leakage (false inclusions) of the LSCG Program. We examine the 2001 cases by eligibility status and subsequent beneficiary status or non-beneficiary status as given in our dataset and according to NADRA's records. We calculate the percent of under-coverage and leakage in the program, as well as determine any observable pattern particularly vis-à-vis Union Councils or Patwar Circles. Next, we determine factors affecting under-coverage (exclusion) or leakage (false inclusions) in the program. For the univariate analysis, the association of the dependent variable (under-coverage in model 1 and leakage in model 2) with each independent variable was assessed. Variables were categorized into socially meaningful categories, wherever required. Prevalence odds ratio and 95% confidence intervals were computed individually for all the potential factors associated with leakage and under-coverage.

Multivariate analysis was carried out to see the independent effect of factors associated with the dependent variable identified in the univariate analysis using logistic regression. The approach towards building the final model sought out the most parsimonious model, which was meaningful in the context of the program. Variables with a p-value of less than 0.25 in the univariate analysis, along with the variables of known importance such as male adult between 18-60 years of age, were considered for inclusion in the multivariate analysis. However, before commencing multivariate analysis, correlation among the various independent variables was also checked. The model building exercise began with the variable found most significant in the univariate analysis and continued with the subsequent addition of the next most significant variable. Once a parsimonious model was built to explain under-coverage, the model building exercise was repeated for leakage.

3.3 General Demographics

Our distribution of all families in the survey by district is similar to the matched 2,001 cases (Table 1). In Azad Jammu and Kashmir only 74 percent of cases match between the two datasets and in the Northwest Frontier Province 80 percent of cases match. The district of Poonch has lowest matching percentage, 71 percent as compared to the other districts of Azad Jammu and Kashmir. The demographic profile also matches between the two datasets with the mean age of family head at 45 years with a standard deviation of 15 years. In our dataset as compared with the matched dataset, we observe that female heads of families were slightly different (15.4 percent in the overall sample and 13.4 in the matched sample). Otherwise, most other demographic information was similarly distributed between the larger and matched datasets.

Table 1: Distribution by District of RISEPAK, Matched and Unmatched Families

District	RISEPAK Survey (N=2612)	Matched Cases with NADRA-LSCG (N=2001)*	Unmatched Cases (611)
AJ&K	56.0 (1459)	53.9 (1079)	62.5 (382)
Bagh	15.1 (394)	14.5 (291)	16.9 (103)
Muzaffarabad	21.8 (569)	21.2 (425)	23.4 (143)
Neelum	2.3 (59)	2.5 (51)	1.8 (11)
Poonch	16.7 (437)	15.6 (312)	20.5 (125)
NWFP	44.0 (1153)	46.1(922)	37.5 (229)
Abbottabad	5.9 (156)	6.1 (122)	5.4 (33)
Batagram	14.5 (378)	15.5 (310)	11.0 (67)
Mansehra	23.7 (619)	24.4 (488)	21.1 (129)

*Two cases that we matched were reported to RISEPAK from Mansehra but according to NADRA records were from Kohistan and Shangla. These two cases are included in the analysis.

In examining the distribution of eligibility criteria, we observe that there are differences in the distribution of cases between LSCG Program and RISEPAK because in the NADRA dataset it is not possible to calculate the total number of economically active males or disabled males. The LSCG form was able to capture only family heads as reported by the respondent. For example, if a married female with a husband between ages 18 and 60 years enrolled herself as family head in the LSCG questionnaire, the form could only capture her marital status and not determine the age of her husband. The LSCG form also could not also differentiate between disabled family members as compared with a disabled male over 18 and under-60 years of age.

For our analysis on under-coverage and leakage, we used the more robust 2001 matched cases rather than our complete sample. In the 2001 cases, 603 were eligible according to our samples based on the specified criteria of families with no males or a disabled male between 18 and 60 years of age and those with five or more children. Eligible cases were distributed in the following mutually exclusive manner: 257 families with no male members between 18 and 60-

years of age; 83 families reporting a disabled male member between 18 and 60-years; and 263 families with five plus children. The remaining 1,398 families were ineligible.

In the matched sample, our dataset identified 363 families as beneficiaries or receiving the cash grant at the time the survey was conducted. However, not all families that were reported as beneficiaries were eligible according to the criteria. In our case, 195 families receiving the grant fit the eligibility criteria and 168 families did not. Leakage with respect to beneficiary status was 46.3 percent (168 ineligible families divided by 363 beneficiaries). In other words, nearly one in two families receiving cash assistance was not deserving of it but was getting it anyway. Furthermore, of the 603 eligible families there were 408 families that qualified according to the vulnerability criteria but were not recipients of the cash grant, and excluded from the LSCG Program. The exclusion or under-coverage in our matched sample was 67.7 percent (408 divided by 603 families). It would appear that two out of three deserving families were not receiving the cash benefit even though they were entitled to it.

Given that our survey was conducted in October/November 2006 and the matched analysis was done in February 2007, we observed that in the NADRA reported 247 new beneficiaries, families that were now receiving the cash grant but had reported to us as not receiving it at the time of the survey (Table 2). We therefore included these cases with the assumption of the possibility that these families received the cash grant after our visit. Of these 247 new beneficiary cases, 135 families were eligible as identified by our survey and 112 families were ineligible for the cash grant but receiving it any case. In terms of recalculating leakage or false inclusions, we observed an additional 112 ineligible families that were getting the grant according to the NADRA records that had reported to us as not receiving it at the time of the survey. These 112 families plus the 168 added up to 280 non-deserving families in receipt of the grant. These 280 cases divided by total families receiving the grant (610 families) meant that 45.9 percent of beneficiaries were ineligible and not deserving of the grant but receiving cash assistance. The leakage in the program therefore did not improve much from our original observation of 46.3 percent. However, with the addition of 135 new eligible beneficiaries, the under-coverage or exclusions improved from 67 percent to 55 percent.

Table 2: Matched Cases of Eligibility and Beneficiaries between RISEPAK and NADRA Datasets

	EliGible FAMILIES (n=603)	**INeligible fAMILIES (n=1398)**	**tOTAL cASES (n=2001)**
Non Beneficiary in both datasets	273	1118	1392
Beneficiary in both datasets	195	168	363
Beneficiary in NADRA dataset only	135	112	247
Total Beneficiaries Receiving Cash Grant	330	280	610

We next disaggregated cases of exclusions and false inclusions on the basis of RISEPAK's initially matched data for beneficiaries and eligible families across the various Union Councils. As to not get skewed results, we only included Union Councils in which we had interviewed more than 49 families. In looking at exclusions or under-coverage, we counted those Union Councils that were five percentage points higher than the overall exclusion percentage of 68 percent. And similarly, for leakage or false inclusion we identified Union Councils that were five percentage points above 46 percent.

In our matched dataset, the following Union Councils appeared as having a high percentage of exclusions: Barian (90%), Kaimanja (89%), Jambeera(76%), Muzaffarabad(75%), Garlat(73%), and Batagram(73%). Union Councils with high percentage of leakage were: Pachhiot(63%), Bagh(60%), Rawalakot(59%), Garlat(54), Batagram(52%), Bakot(51%). Garlat and Batagram, urban centers located in the Northwest Frontier Province, show higher than average percentage of leakage and under-coverage. Pachiot and Rawalakot in Poonch district and Bagh in Bagh district have high percentages of leakage and similar or lower than average rates of exclusions. Jambeera, Muzaffarabad, Barian and Kaimanja have higher than average exclusion percentages but very low false inclusions rates. The problems of false inclusions and exclusions seem greater in Azad Jammu and Kashmir than in the Northwest Frontier Province. In Azad Jammu and Kashmir, union councils with major urban settlements show percentages of false inclusion and exclusion that are above average percentage being reported for Muzaffarabad, Bagh, and Rawalakot.

Having determined that exclusions and false inclusions were a problem in Azad Jammu and Kashmir, we next developed a model to assess which factors were most predictive in deserving families not receiving the grant and undeserving families getting the cash grant. For the under-coverage model, we adjusted for distance to the program enrollment location and the number of males between 18-60 years in the family. We also included disabled male members in the model because of its significance in being selected for the cash grant. In our sample, there were 54 families with a disabled male member that did not receive the cash grant. The numbers were insufficient for inclusion in the model. These 54 families were evenly distributed between Azad Jammu and Kashmir and NWFP.

The final adjusted model for under-coverage (Table 3) indicated that the chances of exclusion were eight-folds higher in a family headed by a woman as compared to a family headed by a man (adjusted POR=8.1, 95% CI: 4.1, 15.9) while controlling for the effects of distance to the program enrollment center and the number of adult male members in the household. Similarly, not receiving grant money even when eligible almost doubled with every additional child under 18 years (adjusted POR=2.5, 95% CI: 2.1, 2.9) as well as with increasing age of the family head (adjusted POR=1.1, 95% CI: 1.07,1.2). Under-coverage was also significantly associated with families residing in Azad Jammu and Kashmir (adjusted POR=2.9; 95% CI: 1.4, 3.8). Therefore, an older female head of family with a large number of kids was at greater risk of being excluded from the benefits of the LSCG program even though she was deserving of assistance. The likelihood of being excluded was greater in Azad Jammu and Kashmir.

For leakage in the program, we built a multivariate model that adjusted for distance from the enrollment location and the total number of children (Table 4). In this model, we observe that a family whose head of family was less than 40 years of age (adjusted POR=4.4, 95% CI: 1.4, 14.7) as well families where there were greater number of adult male members (adjusted POR=2.9, 95% CI: 1.8, 4.6) were more likely to receive the cash grant money even when they did not meet the eligibility criteria. In other words, young males (20-39 years) were 4.4 times more likely to be recipients of the cash grant even though they did not deserve it. Moreover, with every one additional male member in the family the likelihood of the grant increased 2.9 times. Being located in AJ&K province (adjusted POR=2.6; 95% CI: 1.2, 5.5) was also significantly associated with leakage in the LSCG program. Undeserving families living in AJ&K were two and one-half times more likely to be receiving the cash grant even though they did not fit the eligibility criteria.

4. Discussion

There has been a growing trend in giving families cash assistance instead of material aid after a disaster [6]. Targeting assistance in the best of situations can be difficult given that money is clearly much more attractive in the community and it is easier to take advantage of it in the case of a targeted group [7]. Moreover, despite the best of intentions cash can be diverted by those in power and targeting agencies can altogether miss the most vulnerable families, especially women in patriarchic structures with rigid cultural norms that govern women's mobility. However, while accepting a degree of inclusion error (leakage) may be the most realistic option but a leakage rate of nearly fifty percent is problematic and unacceptable. On the flip side, what degree of exclusion error is acceptable in such programs? Although there is not much available on this aspect, evidence suggests that targeting cash may be more difficult than commodities [8, 9].

Our analysis on the effectiveness of targeting vulnerable families in the LSCG program suggests that exclusion and leakages criteria appear to mirror each other—one in two deserving families did not receive the grant even though they fit the criteria and one in two non-deserving families received the cash assistance. The exclusion of deserving families was most significant for the most disadvantaged group which is older female-headed families with a large number of children. Access and mobility of such families may be limited given the cultural norms in the earthquake affected areas. Although we have not included education in our model, the level of literacy may also be a factor. However, we cannot fully explain the reasons for why female heads of families which were the target of this program overwhelmingly excluded them, and on the other hand families with males were favored and 4.4 times more likely to receive the cash grants. The likelihood of leaving out deserving families and including non-deserving families was twice as likely to take place in Azad Jammu and Kashmir, which is politically sensitive vis-à-vis Pakistan. Given that local district level governments were involved in selecting beneficiaries it is possible that funds were misdirected to benefit their interests. In a patriarchic society such as Pakistan, where patron-client relationship is well entrenched even in administration and the culture and social norms discriminate against women's freedom of movement, the possibility of limited access to resources is an issue. Extra care is required to ensure that purported benefits reach those that are the target of the program, and at greatest disadvantage in society as a result of the disaster. The overall evidence appears to suggest that it is in the selection of beneficiaries that prejudices may have taken place. Cash transfers in this case targeted only one in two vulnerable families and missed out a substantial number of deserving families. We conclude that the targeting of cash did not completely serve the purpose for which it was intended that is to support vulnerable families through a critical time of recovery from the adverse impact of the earthquake.

Managing Projects to Reduce Delivery Schedule Failures

Ajibade Ayodeji Aibinu
Faculty of Architecture Building and Planning, University of Melbourne, Australia
(email: aaibinu@unimelb.edu.au)

Abstract

The problem of project delivery schedule failure is an old but recurring problem in the construction industry. In this study, the significance of forty-four sources of project delivery schedule failure were examined based on a survey of 35 construction contractors, 46 quantity surveyors, and 19 designers in Nigeria. The results shows that there is agreement between the three 3 groups of respondents regarding the ranking of the 44 sources of schedule failure. Clients' cash flow problems, contractors' financial difficulties, incomplete drawings, equipment problems, late instructions, poor supervision, material shortages, variation/change orders, planning and scheduling problems and price escalations were believed to be among the top significant sources of the problem. Using cost data obtained from 43 private sector- and 17 public sector- procured projects, the impact of variations orders and price escalation on delivery schedule failure were quantified. Simple Linear Regression Analyses show that about 16% percent of project delivery schedule failure can be explained by variations ordered by clients and their consultants while another 16% can be explained by price escalation. In order to lessen project delivery schedule failure, clients and their project management team need to pay greater attention to the most significant factors. In particular, they need to give adequate time for project planning in order to adequately capture client's needs, ensure adequate scoping of project, reduce incompleteness of design, reduce design errors and thereby reduce variations during construction. Clients need to arrange for sufficient finance prior to project award; and during tendering, consultants should conduct thorough due diligence investigation to ensure that the selected contractor is financial capable and has sufficient financial and management capability. The use of management-led procurement approach could also mitigate coordination and decision-making problems. Based on anticipated inevitable changes/variations and price escalation during construction, the regression models developed could assist professionals at the pre-contract stage when estimating projects cost and time.

Keywords: Schedule, Delays, Project delivery, Procurement, Contractors, Designers, Quantity surveyors, Nigeria

1. Background

Project delivery schedule are notorious for their inability to deliver according to plan. In Nigeria the problem is severe and is a major cause of cost overrun. Projects in Nigeria overrun their contract duration by between 50 and 420% [1]. Delivery schedule slippage could have significant effect on the completion cost projects [2]. It often generates conflict between parties when they are unable to determine and allocate responsibility for the problem [3]. Conflict and dispute could lead to further delivery schedule slippage. Factors contributing to schedule slippage are many. In an earlier study, variation order and price escalation were found to be factors significantly influencing schedule failures and cost overrun in Nigeria projects. However, there are few published quantitative studies making use of real life projects on the subject. Understanding of the sources of the problem and quantifying their impact using real life data would provide a better understanding of the problems and how they can be alleviated. The objectives of this study are:

- to understand how quantity surveyors, designers and contractors perceive the significance of the various sources of project delivery schedule failures

- to explore whether there is agreement between the 3 groups regarding the identified sources of delivery schedule failures.

- to quantify the impact of variation orders and price escalation on project delivery schedule failures.

- based on the findings, offer some recommendations on ways of managing projects to reduce delivery schedule failure.

The results provide useful information on ways of managing projects to ensure timely completion.

2. Literature Review

Dlakwa and Culpin found that variation orders, design errors, deficiencies in public agency organizations and deficiencies in contractor organizations, price fluctuation and late payment to contractor were among the most cited reasons for delay in public projects in Nigeria [4]. Mansfield et al found that the problem of financing of and payment for completed works, poor contract management, change in site conditions and shortages of materials are the four most important causes of delays and cost overruns in public highway and building projects [5]. Odeyinka and Yusif classified the causes of delays in Nigeria housing projects into 4 categories namely client-, consultant-, and contractor-caused delays, and extraneous factors [6]: Their findings show that Client-caused delays arise from variation orders, slow decision making and cash flow problems while contractor-caused delays results from financial difficulties, material management problems, planning and scheduling problems, inadequate site inspection, equipment management problems, and shortage of manpower. The causes of consultant -caused delays identified include: incomplete drawing, slow response by consultant, variation orders, late issuance of instruction, and poor communications. Inclement weather, Acts of God, labor dispute and strikes were found to be extraneous factors responsible for delays.

Elinwa and Joshua surveyed construction practitioners in Northern Nigeria and found that the relative contributions of the client, contractor, and others to time overrun are 62, 32, and 6% respectively [7]. Factors responsible for project delivery schedule slippage have been studied in other countries (see Aibinu and Odeyinka [8] for a detailed review).

Bramble and Callahan classified the causes of delays by looking at the responsibility of major parties to the design and construction process [9]. According to the authors, owner-caused delays could arise from late release of site to the contractor, late approvals, financial difficulties, contract administration responsibilities, change orders and interference while designers-caused delays could arise from design defects, slow correction of design errors, tardy shop drawings review, and delays due to test and inspection. Failure to evaluate the site and design, contractor management problems, inadequate resources and construction defects were listed as potential sources of contractor-related delays while weather, act of God, strikes and labour disputes were identified extraneous factors that could cause delivery schedule slippage.

In this study, the sources of project delivery schedule failure are investigated by looking at the responsibilities of project participants as highlighted by Bramble and Callahan [9]. The level of agreements among contractors, designers, and quantity surveyors regarding the significance of the sources are also tested. Empirical relationship between variation orders and delivery schedule failure, and between price escalation and delivery schedule failure were analysed, which is lacking is previous studies.

3. Research Method

3.1 Data Collection and Sampling

Based on the literature review and a pilot survey of selected construction industry practitioners, 44 sources of delivery schedule failure were identified and developed into a questionnaire (see Table 1). The respondents were asked to rate the extent to which each of the factors contributed to delivery schedule failure on projects they have been involved. They were asked to respond by assigning weights to each factor from 1 to 5 where *'1' is not significant and '5' is extremely significant'1'.* The questionnaire was sent to 60 contracting firms, 90 quantity surveying firms, and 50 design firms (architect/engineers) in South-western Nigeria.

3.2 Response Rate and Characteristics of Sample

Of the 60 contractors surveyed, 35 responded representing a response rate of 58% while out 90 quantity surveyors 46 completed and return the questionnaire representing 51% response rate. Of the 50 questionnaire sent to designers 21 were returned representing a response rate of 42%. Overall, the respondents have 22 years of experience, and on the average, they have been involved in 32 projects. The majority are bachelor's degree holders (83%) and are professionally registered (86%). Thus it is understood that the data obtained from the respondents can be relied upon with confidence.

4. Data Analysis and Results

4.1 Sources of Project Delivery Schedule Failure

To address objective 1, the contributions of the 44 factors to delivery schedule failure were determined by transforming the five-point Likert scale into Relative Significance Index (RSI) for each factor [10] using the following expression:

$$\text{RSI} = \frac{A}{B \times C}$$

Where:

A = total Score;

B = highest response option (5 in this study);

C = total number of responses; and

$0 \leq RSI \geq 1$.

The factors are then ranked based on their RSI's. RSIs were computed for quantity surveyors, designers and contractors (Table 1).

According to quantity surveyors (Table 1), the top 15 most significant sources of delivery schedule failure include: client change orders, client slow decision making, client cash flow problem, incomplete architectural drawing, architect late issuance of instruction, incomplete structural drawing, contractor financial difficulties, contractor planning and scheduling problem, contractor shortage of manpower, material shortages, late delivery of ordered materials, equipment breakdown/ maintenance, delays in manufacturer delivery, nominated suppliers cash flow problems, and price escalation.

Table 1: Relative Significant Indices and Ranking of Sources of Delivery Schedule failure

Variable Name	Quantity Surveyors		Designers		Contractors	
	*RSI	*R	*RSI	*R	*RSI	*R
Client variation/change orders	0.66	**13**	0.64	**13**	0.70	**11**
Client slow decision making	0.65	**15**	0.63	**15**	0.68	**15**
Client cash flow problem	0.84	**1**	0.82	**1**	0.81	**3**
Late contract award	0.52	43	0.56	28	0.52	40
Late preparation of interim valuation	0.53	41	0.56	29	0.66	18
Late valuation of variation	0.56	36	0.62	17	0.67	16
Incomplete architectural Drawing	0.78	**3**	0.62	18	0.83	**2**
Architect Late issuance of instruction	0.68	**11**	0.53	37	0.71	**9**
Architect variation/change orders	0.62	19	0.65	**9**	0.70	**12**
Architect inadequate supervision	0.59	27	0.54	35	0.58	31
Poor information dissemination	0.60	26	0.57	25	0.56	34
Architect delays in work approval	0.60	24	0.56	30	0.61	25
Incomplete structural drawing	0.74	**6**	0.56	31	0.76	**4**
Structural engineer change orders	0.59	28	0.49	41	0.62	24

Inclement weather	0.61	23	0.51	40	0.68	**14**
Acts of God	0.46	44	0.37	44	0.42	44
Labour dispute and strikes	0.58	34	0.47	42	0.59	30
Civil disturbances	0.54	40	0.46	43	0.55	35
Slow permit by government agencies	0.53	42	0.57	27	0.52	41

*RSI= Relative Significance Index; R = Rank; (Top 15 sources are highlighted)

According contractors (Table 1), the following are the top 15 significant factors that are responsible for delivery schedule failure on projects: Contractor financial difficulties, incomplete architectural drawing, client cash flow problems, incomplete structural drawings, incomplete services drawing, unforeseen material damages, equipment shortage, delays in manufacturers' delivery, architect late issuance of instruction, material shortages, client change orders, architect change orders, price escalation, inclement weather, and client slow decision making.

Designers perceived the following as the top 15 significant sources of the problem: Client change orders, client slow decision making, client cash flow problem, architect change orders, services engineer inadequate supervision, contractor financial difficulties, contractor planning and scheduling problem, contractor shortage of manpower, material shortages, late delivery of ordered materials, equipment breakdown/ maintenance, equipment shortage, delays in manufacturer delivery, nominated suppliers cash flow problems, and price escalation.

It is observed that there is almost a perfect agreement between quantity surveyors, contractors and designers regarding the ranking of the following: (1) Client change orders (2) client slow decision making (3) client cash flow problem (4) material shortages (5) price escalation and (6) contractor financial difficulties.

4.2 Test for Agreement between Respondents

The following sub-hypotheses were tested to address objective 2 of the study, which is to statistically determine whether there is agreement between the 3 groups regarding the overall ranking of the 44 sources of project delivery schedule failure:

Hypothesis 1: There agreement between quantity surveyors and designers regarding the ranking of the 44 sources of project delivery schedule failure.

Hypothesis 2: There is agreement between quantity surveyors and contractors regarding the ranking of the 44 sources of project delivery schedule failure.

Hypothesis 3: There is agreement between the designers and contractors regarding the ranking of the 44 sources of project delivery schedule failure.

Spearman's rank correlation analysis was employed to test the hypotheses. Spearman's rank correlation coefficient (r_s) measures the correlation between two sets of rankings and was determined using the expression:

$$r_s = 1 - 6\sum D^2 \Big/ n(n^2 - 1)$$

Where:

D is the difference between the rank given by one group and that given by the second group

N is the numbers of items being evaluated (44 items in this study)

The rank correlation coefficients r_s is from -1 to +1. A correlation of coefficient of +1 suggests a perfect linear correlation while a value of -1 means a negative correlation implying that a high ranking by one group is associated with low ranking by the other group. A zero value indicates that no linear association exists. Since the three groups of respondents are from random samples of population, we may test for true agreement in ranks by using the values of the observed r_s. We may test at a chosen level of significance the null hypothesis that the two groups under comparison differ as regards the ranking of the factors [11] i.e. that the rankings are independent in the population and the observed value of r_s differs from zero only by chance. Table 2 summarize the results. The results support hypotheses 1 (r = 0.612, p = 0.000), hypotheses 2 (r = 0.502, p = 0.001) and hypotheses 3 (r = 0.309, p = 0.041). Thus, we may conclude that there is agreement between contractors, quantity surveyors and designers regarding the contribution of each of the 44 factors to project delivery schedule failure. However, it is observed that agreement between designers and contractors is the weakest (0.309).

Table2: Result of Spearman's Rank Correlation Coefficient

		Designer	**Quantity Surveyor**
Quantity Surveyor	Correlation Coefficient	0.612**	
	Significance probability	0.000	
	n	44	
Contractor	Correlation Coefficient	0.309*	0.502**
	Significance probability	0.041	0.001
	n	44	44

** Correlation is significant at 0.001 level

* Correlation is significant at 0.05 level

4.3 Impact of Variation Orders and Price Escalation on Project Delivery Schedule Failure

Consistent with previous studies, the results from questionnaire analysis show that change order and material price escalation are among the top 15 most significant factors contributing to project delivery schedule failure. Thus a further analysis was conducted to address objective 3, which is to quantify the impact of variation orders and price escalation on project delivery schedule failure. This was achieved by analysing data on 60 completed projects obtained from quantity surveying firms. Two linear regression models (model 1 ad 2) were set up with project delivery schedule failure (Y) as dependent variable in each of the models and variation/change order (A) and price escalation (B) as the independent variables in model 1 and model 2 respectively. The models are expressed in mathematical form follows:

Y = f(A)………………………………………………………Model 1

Y=f(B) ……………………………………………………Model 2

Where:

Y is project delivery schedule failure (measured by the amount of discrepancy between contract and actual project duration.

A is the magnitude of variations/changes ordered by clients and their consultants (measured in terms of the monetary value of variations claims paid to the contractor as reflected by the final account statement of each project); and

B is Price Escalation (measured by the amount of fluctuation claims paid to the contractor as reflected by the final account statement of each project).

The hypotheses are that: significant changes in project delivery schedule failure can be explained by variation orders; and that significant changes in project delivery schedule failure can be explained by price escalation. Prior to data analysis, the monetary values of variation/change order and fluctuation claims for all the projects were brought to same base using the Consumer Price Index Published by the Federal Office of Statistics, Nigeria. The regression results (Table 3) show that about 16% changes in project delivery schedule failure can be explained by variations ordered by clients and their consultants ($R^2 = 0.157$, F = 11.966, p = 0.001).

Table 4 *Result of Regression Analysis*

Variable	Predictor	β Coefficient	Standard Error	t value	p value
Project Delivery Schedule Failure (Y)	Constant	5.139	0.698	7.360	0.000
R^2 = 0.171	**Variation (A)**	0.423	0.122	3.459	0.001
R^2 Adjusted = 0.157					
Project Delivery Schedule Failure (Y)	Constant	5.324	0.688	7.740	0.000
R^2 = 0.168	**Price Escalation (B)**	0.410	0.178	3.424	0.001
R^2 Adjusted = 0.154					

*Variables are significant at 5% level (p <0.05)

Also, 16% of the changes in discrepancy between contract and actual project duration (projects delays) can be explained by price escalation ($R^2 = 0.154$, F = 11.724, p = 0.001). The result suggest that variations ordered by project owners and or their representatives and price escalation both accounted for a significant change (about 32%) in delivery schedule failure. The following are the regression models of the relationships:

Estimated Regression model 1 (for Variation orders): $Y = 5.139 + 0.414A$

Estimated Regression model 2 (for Price Escalation): $Y = 5.324 + 0.410B$

Where: Y is project delivery schedule failure

A is Variation or changes ordered by clients and their consultants

B is Price Escalation

5. Discussion

This study shows that variation orders, price escalation, poor planning and scheduling, client slow decision-making, client cash flow problems, contractor financial difficulties, incomplete design, design errors inadequate supervision, and late issuance of instructions are the top most significant sources of project delivery schedule failure in Nigeria building projects. Variations ordered by clients and their consultants, and price escalation accounts for 32% of the problem.

The findings are not unexpected. Variations could disrupt the progress of work and prolong the contract period. Also, when not sufficiently provided for in the contract (by way of management reserve or contingency), price escalation could to lead to financial difficulties and clients putting aside projects for months before they are continued. It may also lead to contractor's financial difficulties when domestic sub-contractor and suppliers' price upon which tender estimates are based becomes outdated. These problems could further generate tension and conflict at all levels of the supply chain hence disruption to progress on site and further delivery schedule problems.

Price escalation is a serious problem in Nigeria. Over the last 2 decades the Nigeria economy has witnessed a high and fluctuating level of inflation rising from 4.1% in March 1991 to 78.2% in August 1995 and 16.8% in September 2005 (Federal; Office of Statistics, Nigeria) and 10.5% in 2006 (CIA World Fact Book). This puts Nigeria in number 32 out of 211 countries on inflation rate ranking (CIA World Fact Book). It is likely that the impact of price escalation on project delivery schedule failure is exponential rather than arithmetical in that during the period when projects are delayed due to price escalation, there could be further price escalation leading to further delays. To exacerbate the problem, contingencies included in contract sum are often based on 5 – 10% rule of thumb and often inadequate [2]. Regarding poor planning and scheduling, a most recent survey of the impact of ICT on professional practice in Nigeria shows that less than half of the respondents use project planning software [12].

Also, client’s slow decision-making is serious problem in public sector projects. The structure of most public clients’ organization is such that independent consultants engaged on projects are cut off from client’s top executives. In the author’s experience while monitoring a major public sector project in Nigeria, sometimes decisions on matters affecting time and cost of projects are made in the absence of the responsible professionals. The inputs of independent consultant project managers and professionals in the client’s decision-making are often frustrated by lack of independence and the bureaucratic nature of public clients’ organisations. Contractors sometimes openly disregard and despise directives of the independent project manager and professionals on believe that there will be no penalty enforced by the client (government departments or authorities) for lack of performance. It would appear that political ties dictate the tune.

Further, while integrated procurement method such as design and build; and management-led procurement such as management contracting and construction management are well known among stakeholders in Nigeria, the use of traditional method procurement method is still dominant [13]. In fact, all the projects analysed in this study were completed using traditional method of procurement. This may explain the problem of late instruction and slow decision-making.

6. Conclusion and Recommendations

Based on the findings of this study, it is apparent that clients and their project management team (quantity surveyors, designers, and other consultants) need to take responsibility for timely delivery of projects by paying greater attention to how projects are managed at the conception, planning and construction stage. The following recommendations are proposed for managing projects to reduce delivery schedule failure:

Building Capability in Project Management and Promoting Project Management Climate

Clients and construction practitioners need to build capability for managing projects and to promote project management culture. This is essential as there is now an unprecedented increase in size and complexity of projects, which cannot be ignored. To build project management capabilities, professional bodies in Nigeria need to mandate project management training and competence as core aspect of continuous professional development and criteria for registration of professionals.

When procuring projects, clients and their consultants need to give sufficient time for client’s briefing to understand client’s needs and clarify project objectives at project inception in order to reduce future variations to project scope. They need to spend more time on planning and design of project to reduce design errors and incomplete drawings. Poor planning and scheduling could be reduced by the use relevant information technology tools. Promoting project management culture and coordinating with the client could reduce late instruction, poor supervision, and slow decision-making.

Further, professionals are considered to be of superior knowledge and they owe a duty of care to their clients. In their advisory role, clients' project management team need to ensure that clients obtain sufficient finance prior to project commencement, conduct due diligent investigation to ensure that capable contractor with appropriate financial and management expertise is selected at the tender stage. In this regard, following due process in project procurement (especially in the public sector) and during tendering is a way forward.

Improving Clients Project's- and In-house Organisational Structure

The problem of client's slow decision-making (especially in the public sector) could be addressed by reforming public sector procurement policy to ensure due process, transparency and reduce bureaucracy. Such reform needs to provide for-, guarantee-, and protect- the independence of construction professionals in project procurement. While the new Public Procurement Act, 2007 (developed on behalf of the Federal government of Nigeria by World Bank and in collaboration by some Nigeria private specialist) passed by senate in June 2007 is a step forward in improving the performance of public project delivery, there is still a lot to be done regarding the provisions of the Act which are beyond the scope of this study.

Using Appropriate Procurement Strategy and Project Governance

There is need to consider the use of design- and management-led procurement approach for projects procurement in order to reduce project delivery schedule failure. However, choice of procurement arrangement option for each project should be subject to other project peculiarities such as risk, complexity of project, quality requirements and cost. The advisory role of Nigeria professionals who act as clients advisers is critical in this regard. Optimum procurement arrangement option should be chosen based on consideration of relevant criteria. A mismatch of procurement method and project peculiarities will certainly lead to failed project (delivered beyond budget cost and schedule and with poor quality). Thus professionals need to build capability in procurement management and project governance.

Improving the Accuracy of Project Time and Cost Estimates

Turning to the problem of price escalation, this study discovered that price escalation could explain a significant amount of project delivery schedule failure. While the problem of price escalation is national issue, professionals such as quantity surveyors have an important role to play. The challenge is to find ways of improving the accuracy of cost and time estimates of projects. Contingency estimate based on 5 – 10% rule of thumb is certainly inadequate in Nigeria. There would be need to improve methods for quantifying risks, including price escalation, and taking them into proper account when estimating project cost and time. This may be achieved by the use of appropriate risk management and modeling tools. Also, the practice where public sector clients in-house executives and professionals reduces project budget to get their favourite project approved need to be discouraged as it could be a major source of cash flow problems resulting from unrealistic and inadequate budget and time estimates.

In this study, 2 regression models were developed representing the relationship between variation orders and project delivery schedule slippage; and between price escalation and project delivery schedule slippage. The models could be used by professionals to predict the likely time overrun on projects based on anticipated uncontrollable changes to project scope and based on anticipated price escalation during construction period. The assessment could be factored into project time and cost estimate thereby increasing price and cost certainty prior to project commencement. It is likely that certainty of project cost and time could reduce lending institutions perceived risk of construction projects financing in Nigeria. This could increase their confidence in construction business thus increase in construction industry access to capital and inadvertently may reduce contractors and clients financial difficulties which are top ranked sources of project delivery schedule failure.

7. Significance of the Findings

This study provides useful information to stakeholders and foreign architectural engineering and consultancy (AEC) firms in Nigerian construction industry and to those contemplating venturing into Nigeria construction market on some of the forces that could influence project delivery schedule failure on their projects. It provides information that could support project planning and bid preparation. It also indicates areas in which firms could add value to project execution in Nigeria and thus increase their market share. It also provides vital information to pubic policy-makers in Nigeria and those who have control over the procurement of projects. While the new Public Procurement Act, 2007 is a step forward for improving the performance of public project delivery, the understanding gained from this study would assist when implementing the Act. The findings of this study also could assist in amending the Act in the future. Other levels of government proposing to develop procurement policies may also find the results useful. Although the data for this study is from Nigeria, the findings are applicable to other developing countries as they are faced with similar situation. This study is useful to international organizations such as World Bank, who are providing aid and supporting capacity building in developing economies. It provides them with independent knowledge of some of the problems and challenges of project procurement in Nigeria and developing economies. The findings are critical for poverty reduction in that a huge amount of public sector spending in developing countries and loans provided by international organizations as loans are expended on programs with huge construction element. Thus by improving public sector procurement policies to reduce project failure will be most beneficial to the common people in developing economies.

Abstract

Subcontractors play a significant role in the Palestinian construction industry. The relationship between the general contractor and subcontractors is one of the keys to any successful construction project. Despite this importance, little information is available about the actual working relationship which exists between general contractors and subcontractors. Subcontractors are specialist agents in the execution of a specific job, supplying manpower, equipment, tools, and designs. They respond only for the executed part of the workmanship, acting as agents of the production system of the contracting company. The aim of this paper is to explore the actual working relationship between contractors and subcontractors. This study was based on a questionnaire survey of general contractors in the Gaza Strip. Information was obtained on reason, for subcontracting, communication process, selection criteria, negotiation with subcontractors, commitment, type of contract, and control tools. The results indicate that more than 90 percent of the work is performed by subcontractors. General contractors select subcontractors according to the complexity of the work and previous experience with subcontractors.

Keywords: Contractors, subcontractors, relationship, construction, development.

1. Introduction

The contribution of subcontractors to the total construction process can account for 80-90% of the total value of the project [1; 2; 3; 4]. This large involvement of subcontractors can be attributed to the shift from the traditional craft base, to a greater reliance on increasingly sophisticated technology-based products [2]. This has resulted in general contractors concentrating their effort, on managing construction site operations rather than employing direct labor to undertake construction work [3]. Arditi et al [5] has also attributed the increased use of subcontractors to the increased complexity of both the construction of buildings and the organizational relationship.

Subcontractors contribute significantly to the capital risk, resources, managerial effort, and business expertise supporting the largest industry in the country. The trend toward more subcontracted work accelerated as the technical development of building materials and methods escalated the requirement for craft skill and knowledge. Quality control and labor management problems on construction projects became less complicated for general contractors utilizing specialty trade subcontractors in lieu for furnishing all craft labor themselves [6]. Hinze and Tracy [1] have studied the working relationship between subcontractors, and contractors in the United States from the subcontractor's perspective. They put forward a series of recommendations to improve the subcontractor-main contractor relationship. The purpose of this study is to explore the actual working relationship between general contractors and subcontractors in the Gaza Strip for the main contractors' perspective.

2. Overview of the construction sector

Construction sector is one of the key economic sectors and is the main force motivating the Palestinian national economy. Upon the establishment of the Palestinian National Authority and the assumption of its powers over the Palestinian territories in 1994, the construction sector has witnessed noticeable expansion and activities. The contribution of the construction sector to the GDP is currently rising in real terms and as a percentage of the total labor force. Construction sector contributes 33% to the Palestinian GDP. This is a large proportion covered by this sector, thus positively affecting various economic, social, educational and vocational sectors in addition to other Palestinian institutions. Construction is one of the most important sectors in the assimilation of labor force throughout Palestinian cities and towns. Construction sector employs an average of 22.3% of Palestinian labor force volume. It employs about 10.8% of laborers directly, and 30% indirectly in factories related to the construction sector and other service and productive sectors. Construction sector contributes largely to different sectors of investment, such as manufacturing of construction materials. In addition, it provides materials needed for construction, such as stone, marble, brick, floor tiles, etc. Further, the sector is one of the main resources of the commercial sector in Palestine [7].

This has resulted in the recovery of the construction contracting profession and subsidiary industries, encouraged the investment of the Palestinian expatriates' capital in the local construction sector, and contributed to the creation of jobs for thousands of Palestinians. Therefore, the construction sector has occupied the foremost position among the rest of sectors, mainly in the attraction of investments and creation of new jobs. In addition to subsidiary industrial and productive sectors, construction sector is the largest and most important of all other sectors. As such, the construction sector has been crucially significant, mainly in the past two years, for the role it plays in reconstruction, road rehabilitation and construction of infrastructure.

The typical image of the construction contracting profession, whether in the Arab World or in Palestine does not match the role active contractors' play in the building of their societies. Contractors are effective entities involved in all professions subsidiary to the construction sector through a complementary relationship. Further, contractors possess the skills necessary for financial management and project administration. Taking into account that a large number of Palestinian contractors are engineers, contractors' professional experience is also consolidated by Palestinian expatriates. Such status has led to the upgrading of the construction contracting profession in Palestine as regards quality, specialty and professionalism.

Construction contracting is considered the hub for construction sector in Palestine. Hence, Palestinian contractors have proved their national role and outstanding ability in construction and reconstruction. In addition, construction sector proficiency been enhanced following the establishment of the Palestinian National Authority in 1994. According to recent figures, contractors registered as members at the PCU have amounted to (1180) throughout Palestinian cities and towns in July 2003. Contractors registered as members in the West Bank have been (800), and those registered in the Gaza Strip have reached (380).

3. Previous studies

Subcontracting has been defined as a legal-economic relationship between two agents, in which the characteristic criteria are substitution and subordination. The substitution criterion means that the subcontractor executes the operation with technical and financial risks, instead of the job assignor; the subordination criterion means the subcontractor must follow the direction given by the contractor (Pagnani, cited in [5]. Another definition was given by Hinze and Tracy [4] who stated that the subcontractors are specialty contractors who are hired to perform specific tasks on a project. Subcontracting can be classified as volume subcontracting and specialist subcontracting. Volume subcontracting can be used when an enterprise commission a subcontractor because, while technically able to carry out the operation, it is overloaded and has to obtain additional capacity from another source. Specialist subcontracting can be used, when the main contractor obtains goods or services, which he does not produce or is not able to produce himself.

Beardsworth et al [8] pointed out that subcontracting could be seen as an organizational alternative for some economic activities. Firms are decentralizing their jobs more and more, allowing subcontracting to become a basic part of the work organization. Firm does not need to have the control of all the value string, being able to externalize non-strategical activities, aiming to reduce costs. The subcontractor's typical source of work is the general contractors that assume responsibility for complete construction of the project. At any point of time, the subcontractor is providing specialty construction services to a number of general contractors with varying expertise in subcontract development, subcontractor management and relations; project management, coordination, and control; and project cash-flow reliability. Decisions on individual projects are often influenced by the objective of sustaining an on-going relationship. Both the short-term (project) and long-term relationship with the general contractors are essential to the success of all specialty contractors [6].

Bennett and Ferry [9] described building firms as organized into a consistent operating core based on their individual capabilities. Construction companies are becoming construction managers or contractor managers, transferring construction work to specialists. Subcontractors are specialists' agents in the execution of a specific job, supplying work force, besides materials, equipment, tools or designs. They respond only for the executed part of the workmanship, acting as agents of the production system of the contractor company. Specialty contractors are construction "job shops", performing construction work that requires skilled labor from one or at most a few specific trades and for which they have acquired special-purpose tools and equipment as well as process know-how [10].

Chung and Ng [11] have studied the practice of subcontractor appraisal in the construction of Hong Kong. They have developed a common standard to monitor the performance of suncontractors and to uplift the quality standard of construction works eventually. Russell and Mcgowan [12] stated that up to 95% of the total project value was entrusted to subcontractors in Canada. The trends was similar in Asia countries like Japan [13] and Singapore [14]. Adriti and Chotibhongs [1] investigated a number of issues in subcontracting practice such as: safety issues, productivity issues, construction insurance, and subcontracting bonding.

4. Method

This study was based on a questionnaire survey of general contractors in the Gaza Strip. The questionnaire design was based on previous related literature [1. 3, 5, 6, 15] and contractors' expert. The content and understanding of the questionnaire have been reviewed and tested. 100 questionnaires have been sent to general contractors randomly. 53 (53%) completed questionnaire have been returned and descriptive analysis has been used.

5. Results

The results indicated that the majority of the general contractors' respondents stated that it is a common practice to use subcontractor to execute specific operation in the project. They added that more than 90% of the works are performed by subcontractors. This result is similar to previous researches results in USA, UK, Hong Kong, and Brazil. The main reasons behind using subcontractors were found to be shortages of skilled labor, maximizing profit, reducing overhead costs, and reducing the work pressure on the main contractors. In addition, monitoring and controlling quality control, safety management, and labor management problem, on construction projects become less complicated for general contractors.

Concerning communication process between major contractors and subcontractors, 50% of respondents indicated that informal, face to face communication was the main mean for communication. The results indicated that 33% of respondents communicate with subcontractors by telephone. Only 6% of the respondents have mentioned that they have formal communication (using letters) with subcontractors. This result reflects the informal characteristics relationship between general contractors and subcontractors. This type of relationship (litte documentation) can be a source of problems which may affect the progress and the quality of the work.

The majority of respondents (60%) have stated that they select subcontractors according to the required specific activity and to the nature and complexity of the work. It has been noticed from the results that 13% of general contractors' select subcontractors according to their previous experience with them. Surprisingly, 7% of the respondents select subcontractors based on their reputation. This can be traced to the trend of the major contractors in the local industry in selecting the lowest bid regardless of the safety and quality of work.

It has been found that 70 % of the respondents gave all necessary drawings and bill of quantities to subcontractors in order to estimate their costs for the required operations. It was noticed that only 7% of subcontractors have visited the construction sites during the estimation process. This has led, in many cases, to inaccurate cost estimation which affected the quality of the work as subcontractors are interested to make profit without enough attention to the quality of the work being implemented (this has increased the probability of a conflict and claims after construction work has begin). The general contractor required from subcontractors to submit in addition to bid price, method of execution, past experience in similar works, time schedule, expected obstruction, and any other special conditions.

The majority of general contractors' respondent committed with the selected subcontractors during the tendering stage when they awarded the contract. However, most respondents (87%) practiced negotiation with the subcontractors after winning the contract in order to reduce the agreed costs in the tendering stage. This may be due to the sever competition between contractors that enforce them to reduce the tender price, and thus asked the subcontractors to reduce their previously estimated cost. Regarding contract type between general contractor and subcontractor, it was noticed that more than 60% of the respondents used contracts similar to the one between owners and contractors. The other respondents used a simplified contract.

Regarding methods of measuring the performance level of the subcontractors, it was noticed that contractors (87%) have used bar chart and s-curve in monitoring the progress of the subcontractors. This reflects the formal procedures and gives a good tool to the management body of the project to correct any defaults that may occure by the subcontractors. Concerning the safety measures of the subcontractors, the majority of general contractors (93%) stated that subcontractors are obliged to adopt the safety measures as specified in the contract between the owner and the general contractor. This is a crucial point in the local construction industry as almost all works are implemented by subcontractors and general contractors.

The majority of the respondents have agreed that there is a close cooperation and a good flow of information exchange between general contractors and subcontractors. In general, the main contractors' respondents were satisfied with the performance of subcontractors.

6. Conclusion

This study has explored the working relationship between general contractors and subcontractors from the general contractors' perspective. A decision to subcontract part of the process should be a strategic decision, and not one driven solely by resource problems. It may involve long-term strategic views related to the core skills required for the company's future, as well as consideration of the importance of design re-use and internal control of the design and manufacture of the product. The general contractors have stated that, it is a common practice to use subcontractors to execute specific operation in the project.

There are many benefits to be gained from working with subcontractors. It provides skilled labore, reducing overhead costs, and reducing the pressure on the main contractors. Monitoring and controlling, quality control, safety management, and labor management problems on construction projects become less complicated for general contractors. It is apparent from the results that informal communication is practiced between general contractors and subcontractors. General contractors have indicated that they select the subcontractors according to the complexity of the work and previous experience with subcontractors.

Some subcontractors have failed to exercise the proper diligence and care when submitting their bids; even they do not have the time to visit construction sites during the estimating process. General contractors committed to the selected subcontractors during the tendering stage; they negotiate with subcontractors after winning the contract in orders to reduce the agreed costs in the tendering stage. This is due to the sever competition between contractors which enforce them to reduce the tenders price, and thus asked the subcontractors to review and reduce their previously estimated costs. Overall, general contractors indicated that they have good relationship with subcontractors and they satisfied with their performance.

Further in-depth study concerning all aspects of the relationship between general contractors and subcontractors is recommended. It is imperative to improve and develop the subcontractors position towards the general contractor, by upgrading the understanding of all contract terms such as; wording and potential for negotiations of conditions including indemnity, payment and retention terms, warranties and call backs, schedule of work, delays and liquidated damages, lien and bond rights, and of curse scope of work. It is advisable to establish a Palestinian subcontractors union for better networking improves the quality and conditions of work, improving the terms of contracting and place subcontractors in a good position in the local market.

Abstract

The traditional construction procurement systems have come under constant scrutiny in the past decades for their numerous drawbacks, resulting in under-performance of the industry. International research in this area showed that the adaptation of approaches such as, partnering and alliances, which are based upon relational contracting (RC) principles, could lead to numerous benefits to all parties and uplift the industry performance. However, these practices still have not proliferated into the Sri Lankan construction industry, which continues to use the traditional system as the most popular procurement approach. Therefore, the need to identify the potential to develop RC cultures in the Sri Lankan construction industry was identified. Through the literature review, thirty factors facilitating RC and thirty-nine factors impeding RC was identified. A questionnaire survey was conducted among project team members of construction projects with Design-Bid-Build (DBB) and Design and Build (D&B) type arrangements, to gather the perceptions of the respondents in relation to the applicability and validity of these factors in the Sri Lankan context. The study revealed that overall, there is an environment conducive to the development of relationship-based procurement approaches in the Sri Lankan construction industry. It was identified that in general, the contractors were much more supportive towards adaptation of such practices and thereby shifting away from the traditional system than the consultants. In addition, it was revealed that as the level of integration within the project team improved, the project environment became more conducive towards RC approaches.

Keywords: Procurement, Relational Contracting, Facilitators, Impediments, Sri Lanka

1. Background

Most traditional forms of construction procurement rely upon segregated teams, fragmenting the construction process. The numerous drawbacks of this system such as, adversarial relationships, unhealthy competition, purely price-based selections, numerous change orders and improper risk-shedding tactics [1], creates a general atmosphere of poor co-operation, limited trust and ineffective communication in project teams, ultimately resulting in unsatisfactory project performance. In recent years, a number of studies and industry reports around the world have addressed these issues. Industry reports in Hong Kong [2], Singapore [3] and UK [4] have highlighted limited co-operation and fragmentation as impediments for proper consideration of issues such as, buildability, safety and life cycle costs in their respective construction industries [5]. Further, other studies, (for e.g. in Canada), have found that the cost of mistrust generated by confrontational situations inherent in the traditional contracts to amount to 8 – 20% of contract value [6]. All these have created an urgent need for new procurement approaches encouraging better relationships and team working within project teams, which has influenced a global shift towards "relational contracting (RC)" practices, such as partnering, alliancing, joint venturing, relationship contracting etc.

Recent local surveys have shown the dominance of traditional procurement systems in the Sri Lankan construction industry [7] and the stated weaknesses of these systems are quite common in the Sri Lankan context as well. Further, the future construction demands of the country are likely to call for increased efficiencies and performance from the industry. Therefore, considering all these, development of RC cultures in project delivery teams in the Sri Lankan construction industry, seems sensible and appropriate in the out set. However, RC is not a "one-size-fits-all" guaranteed fix, but rather a philosophy that must be tailored for each situation for which it is applied [8]. The successful implementation of a RC culture will undoubtedly present hard work, especially in an industry full of individuals well conditioned in working in adversarial climates.

Although, many countries around the world are quite advanced in the practice of RC approaches, it remains an unexplored area for research in the Sri Lankan context. The aim of this paper is to explore the potential for building a successful relationship-based procurement culture in the Sri Lankan construction industry. Specific objectives have been set to identify the factors (1) facilitating and (2) impeding the development of a RC culture in the Sri Lankan context and (3) to assess the capacity to adopt RC practices in the Sri Lankan construction industry.

2. Limitations of the traditional procurement system

Construction industry in any country is a complex, high-risk sector, dominated by contracts. It has strong backward and forward linkages with a large number of other industries such as, manufacturing, finance, labour etc. The construction industry has a direct impact on the national economy and is generally used as an indicator of economic well being of the country. It can influence a country's national economy in four aspects namely, production of specific and national basic needs, provision of fixed capital assets and infrastructure of a country, direct contribution to the Gross Domestic Product (GDP) and employment generation [9].

Despite its significance, the industry has and continues to suffer consistently from many weaknesses. There is a deep concern that the industry as a whole is under achieving [4]. The profitability and productivity levels in the construction industry are frequently acknowledged extremely poor in comparison to other industries. Studies have shown growing dissatisfaction among clients about the performance of the construction industry [4], indicating a rise in the demand for greater efficiencies and client focus. The industry is criticised for failing to meet the demands of the modern business environment, which require the ability to be competitive in the international market and provide best value for clients. Much of the blame has been placed on the traditional procurement systems and their limitations, which prevents the industry from performing up to its full potential.

It is the general view that the traditional Design-Bid-Build procurement approach provides a measure of protection to less informed developers and other clients, who lack faith in the professionalism of their contractors [8]. Fragmentation of the industry has been identified as one of the major disadvantages of the traditional system. A large part of the low performance of the UK construction industry has been blamed on fragmented teams over the past few decades [4]. The lack of co-operation, limited trust and ineffective communications between these fragmented parties lead to adversarial relationships, which often result in project delays, difficulties in claim resolution, cost overruns, litigation and win-lose mentality among parties. The traditional procurement environments are ineffective in managing interdependencies between design, construction and supply activities [10], thus affecting the quality and buildability of the design. Lack of communication and cooperation and fear of opening up claims exclude valuable contributions from parties. Furthermore, fragmented teams result in extra transaction costs being incurred between fragmented functions [11], which have a direct impact on the value of production. The transaction costs of competitive tendering may constitute 15-20% of the total project value [12] and includes, costs of negotiation, monitoring contractual performance, enforcing contractual promises and costs associated with breaches of contractual promises etc [13].

These limitations of the traditional procurement systems, makes such systems inappropriate in dealing with the changing market conditions, adapting new technological developments and meeting rising clients' expectations. This has lead many researchers to stress the importance of shifting away from the traditional procurement culture to improve the industry performance. Emphasis on Relational Contracting practices has been one of the most significant developments in this context.

3. Relational contracting

3.1 Concepts of relational contracting

The phrase "relationship contracting or RC" is intended to describe a spectrum of project delivery methods that emphasize and focus upon the relationship between parties to a construction project [14]. Relational contracts are regarded as informal agreements and codes of conduct between parties, sustained by the value of the future relationships that powerfully affect their behaviour [15]. In contrast to the traditional forms of construction contract, relational contracts are flexible in nature and provide a flexible response to information problems. It acts as a safe guarding mechanism designed to smoothen transactional friction and make provisions for "incomplete contract" in complex scenarios [16]. Relational Contracting (RC) defines the relationship of parties, who do not always govern themselves bounded by the strict legal framework of the contracts. They provide the relationship among the project participants the same level of importance as the project itself. The prominence given to the terms of the contract is less compared to that given to the relationship between parties. Practices such as, partnering, alliancing, joint venturing etc; are based upon these RC principles. RC approaches are useful in achieving the overall project objective of reducing the total of production and transaction costs. It offers a cost effective means of encouraging mutually beneficial behaviour, overcoming most of the limitations of the traditional procurement systems.

3.2 Benefits of relational contracting

A number of studies around the world have reported on the benefits of RC practices such as, partnering, alliancing etc. According to Thompson and Sanders [17], benefits achieved through partnering are in direct proportion to the risk assumed and dramatically increase as the relationship is unified and developed through the acceptance of uncertainty and a willingness to be vulnerable.

Most of the authors [17; 18; 19] have emphasised the lowering of the risk of time and cost overruns as main benefits of RC approaches, which are achieved as a result of better time and cost control over the project. Other than that, adopting RC practices is seen to provide an opportunity for innovation, especially in the development of value engineering changes and constructability improvement [19]. Evidence from the UK construction industry indicates that practices such as partnering and value management are providing a platform to develop sustainability strategies [10]. A case study on the National Museum of Australia [20], which was the first project alliance in building construction in the world, have observed significant added value to the client and many innovations resulting from the collective work of the parties to the contract. Many government organisations in UK that have adopted partnering have documented a decrease in litigation [17] owing to the framework for conflict resolution and improved communication. Furthermore, alliances are seen by smaller contractors, as an opportunity to join forces to work on large projects and to develop on the areas of work that need improvement [21].

Other than these measurable improvements, benefits of partnering (i.e. RC) include improvements in subjective areas such as worker morale as well [17]. This is achieved through the delegation of increased levels of authority in decision-making. Such authority raises the level of accountability of individuals and leads to increased commitment. A similar view is held by Lamont [22], who states that the empowerment, which is a direct result of partnering, can encourage individuals to work together more effectively.

The case studies and surveys around the world have proven and established numerous benefits of RC practices in the construction industry. The examples of such successful partnerships/alliances have encouraged a considerable number of clients and contracting organisations around the world to adopt these strategies. Partnering and alliances, which may be considered as the most widespread adaptations of RC in construction, has been well researched in many countries. Comprehensive case studies have been done on milestone projects, such as the National Museum of Australia [20], which has successfully adapted project alliancing to achieve significant benefits to all parties. Further studies in the area [8], have identified the factors facilitating and impeding partnering in countries such as, Singapore and Hong Kong. Sri Lankan construction industry however, is still far behind in this context. According to Rameezdeen [7], the only type of practice based on RC principles adopted in Sri Lanka is joint ventures (1-3%). This has also been attributed to the involvement of international contractors. However, in future as clients' expectations continue to rise, Sri Lanka will need to follow the initiative of countries such as, UK, Australia, Singapore etc; and shift towards project delivery processes encouraging cooperation and collaboration within project teams and supply chains, such as partnering. Therefore, it is worthwhile to investigate the factors, which are facilitating and deterring the adaptation of these practices in the present Sri Lankan context.

4. Research Method and Approach

4.1 Selection of respondents

The implementation of RC practices requires a change of attitudes and culture in the project delivery teams. This research sought to gather the perceptions of project team members, with respect to the applicability of thirty facilitators and thirty-nine impediments to RC identified through the literature survey in the Sri Lankan context. The inherent adversarial relationships present in the traditional DBB procurement culture was expected to form a barrier, in gathering data on the facilitators and impediments to RC, preventing any truly significant conclusion from being drawn up. To overcome this problem, two separate samples were selected from projects with traditional Design-Bid-Build (DBB) type procurement arrangements and projects with Design and Build (D&B) type procurement arrangements. It was decided that selection of ten construction projects with each type of procurement arrangement was a suitable and manageable sample size for this research. Selection of these two samples also enabled to explore any significant improvements in the facilitators to RC with higher degrees of integration in the project teams. The convenient sampling technique was used with the main purpose of securing a good response rate. In addition, the nature of the data collected was such that no bias could be expected by selecting the convenient sampling technique over random sampling.

RC approaches are generally advocated for large projects, which are able to gain the most benefits from implementing these approaches. This was also considered in selecting projects for this research and therefore, projects with large project values were selected. The project values of the selected projects ranged from Rupees forty-two million to Rupees ten billion. Out of the twenty projects selected, six (i.e. thirty percent) had project values greater than Rupees 1.5 billion. Only fifteen percent of the projects had project values less than Rupees 100 million.

In each DBB project, a member of the consulting team and a member of the construction team were selected and questionnaires were distributed to them. In the projects with D&B arrangements, the same team (from a single organisation) acted as the design and the construction team. Therefore, in this instance, a single questionnaire was given to a member of the project team.

Table 1: Facilitators and Impediments to RC

	Facilitators to RC		Impediments to RC
1	Senior management "championing" of the partnering (i.e. RC) process	**1**	Prevailing attitude of cynicism
2	Empowering decision making process at the lowest possible level	**2**	Rigid / preconceived attitudes about specific sectors / partners
3	Support and enthusiasm of the client	**3**	Lack of belief in the effectiveness of partnering
4	Client's knowledge about the project processes	**4**	Too narrowly focused role / job
5	Vertical intra-organisational trust	**5**	Restricted internal / external authority
6	Mutual trust among parties	**6**	Lack of understanding of RC concepts
7	Efficient communication	**7**	Inadequate partnering skills
8	Effective coordination of parties	**8**	Lack of RC experience
9	Team working spirit of all parties	**9**	Conflicting priorities
10	Timely responsiveness	**10**	Competitiveness (within sector)
11	Alignment of project objectives of parties	**11**	Intolerance of other sectors
12	Alignment of commercial objectives of parties	**12**	Incompatible organisational cultures
13	Adhering to mutual goals	**13**	Lack of competency to perform
14	Mutually agreed performance appraisal mechanisms	**14**	Poor communication
15	Mutually agreed dispute resolution mechanisms	**15**	Lack of top management commitment
16	Combined responsibility of parties	**16**	Up front time required and cost for implementing RC
17	Continuous periodic evaluation	**17**	Bureaucratic client organisations
18	Long-term commitment	**18**	Poor project planning
19	Adequate resources of parties	**19**	Inappropriate procurement strategies
20	Experience in RC approaches	**20**	Inappropriate risk allocation/sharing
21	Learning culture within project teams	**21**	Price only selection methods
22	Capacity for innovation	**22**	Ambiguous contract clauses/documents
23	Positive attitude towards continuous improvement	**23**	Lack of scope for innovations
24	Flexible contracts to address uncertainties	**24**	Lack of client's initiatives
25	Encouraging and motivating risk-reward plans	**25**	Lack of team working attitude
26	Inclusion of all key parties in risk-reward plan	**26**	Lack of trust
27	Equitable risk allocation / sharing arrangements	**27**	Inappropriate issue resolution mechanisms
28	Clearly defined risk allocation / sharing arrangements	**28**	Separate coordination and monitoring plans
29	External facilitators	**29**	Being conditioned in win-lose environments

30	Conducting work shops for relationship building	**30**	Potential legal liabilities in resolving non-contractual issues
		31	Commercial pressures of contacting parties
		32	Absence of a risk-reward plan
		33	Exclusion of consultants from the risk-reward plan
		34	Exclusion of major subcontractors from the risk-reward plan
		35	Exclusion of major suppliers from the risk-reward plan
		36	Externally determined reward system for middle management or site staff
		37	Separate / unrelated risk-reward plans for different parties
		38	Local social / political / economic climate
		39	Incompatible public sector rules and regulations

4.2 Profile of Respondents

All the respondents fall into the category of 'professionals'. Some held senior or middle management positions within their respective organisations. Therefore, all the respondents were actively interacting and dealing with members from other organisations working in the project team. Thus, their views on the facilitators and impediments to the development of more collaborative working relationships were developed through hands-on experience of working with other project parties. Table 2 gives the years of experience of the respondents in the construction industry. On average, respondents have worked in the industry for 14 years. Seventy-seven percent of the respondents had over six years of experience in the industry.

Table 2: Years of Experience in the Construction Industry

Years of Experience	Number	Percentage (%)
1-5	7	23
6-10	6	20
11-15	5	16
16-20	5	16
21-25	4	13
Over 26	3	10
Total	30	100

4.3 Design of the Questionnaire

The questionnaire was divided into two main sections. The first section sought general information about the respondents, while the second section sought the respondents' perceptions on the factors facilitating /impeding collaborative working between project parties in that particular project. Facilitators and impediments to RC, which were found through the literature review were analysed and factors such as, mutual objectives, external facilitators, past experience in RC practices etc; which obviously was not applicable to the Sri Lankan context, where no RC approaches are being practiced were excluded. The remaining factors were combined and thirty-seven items were obtained. The questionnaire requested the respondents indicate their degree of agreement, on a seven-point Likert scale ranging from disagree very strongly to agree very strongly, on each of the issues considering the selected projects. Therefore, care was taken to have a roughly equal number of positively and negatively worded items, to force the respondent to consider each item carefully, thereby minimizing the effect of responses automatically set towards either agreement or disagreement. A seven-point Likert scale was chosen as appropriate for the purpose of this research as it is easy to understand and interpret by respondents and discriminates well between respondents' perceptions. Furthermore, as this questionnaire dealt with factors, which may be perceived as sensitive to the respondents, it was decided to use a neutral point on the scale to avoid forcing the respondents to one side and alienating them, thus resulting in fewer completed surveys.

As the data collected using the Likert scale were ordinal in nature, it was not possible to carry out arithmetical calculations such as, mean or standard deviation [23]. Instead, the median and the inter quartile range were used. The median was taken to represent the average response of the respondents. The Mann-Whitney *U* test, which is the nonparametric equivalent of the independent samples t-test, was used to detect any differences in the respondents' perceptions between groups. The Mann-Whitney *U* tests were designed to distinguish between the perceptions of, (1) the project team members in Design-Bid-Build and Design and Build type projects and (2) the contractors and consultants in Design-Bid-Build projects

5. Data analysis and discussion

5.1 Factors Facilitating RC in the Sri Lankan Context

Considering the median responses given by the respondents, thirty out of the thirty-seven factors considered could be regarded as factors facilitating the development of RC in the current Sri Lankan context. Out of these, nearly seventy-five percent of the respondents 'agreed', 'agreed strongly' or 'agreed very strongly' that there is vertical intra-organisational trust and top management commitment towards developing cooperative relationships between project parties. The results also indicated that none of the respondents disagreed to the statements that their organisations possessed good competency to perform and that there was good capacity for innovation within the project team. Similarly, there was strong agreement among respondents to the statement that there was a mutually agreed dispute resolution mechanism in the projects. With respect to above three items seventy-five percent of the respondents stated that they 'agree', 'agree strongly' or 'agree very strongly' with the statements, whereas the remaining 25% of the respondents were 'undecided' on the issue.

Factors such as, open and efficient communication between parties, effective coordination between parties, team working attitude of all parties and mutual trust among parties, which are essential in building a RC culture, all had a median of 5. This meant that on average respondents 'agreed' that these factors were present in the current project environments. These factors, along with top management support were found to be the most important facilitators of RC in the works of Cheng and Li [24] and Kumaraswamy et al [8]. Thus, the presence of these factors to this extent in the present project environment, where polarisation of parties is expected due to past experiences of adversarial relationships, disputes etc; is an important aspect.

5.2 Factors Impeding RC in the Sri Lankan Context

On average, the respondents agreed that commercial pressures on organisations prevented them from working co-operatively with other project parties. This was especially relevant to the contractors, as increased competition, as well as lowest price selections, had forced them to operate in increasingly tight margins. Thus, they are forced to compromise and choose between developing collaboration and better relationships with project parties having conflicting objectives to their own and their own objectives of profit maximisation. The result was consistent with the findings of the Construction Industry Institute of Australia (CIIA) study, where there was strong agreement among respondents that commercial pressures on organisations was a barrier to developing successful partnering relationships.

In addition to above, median responses of ‘undecided’ were obtained for six items, where the responses were spread in an equal manner between agreement and disagreement. For instance, the results revealed that the respondents were divided between agreement and disagreement, with respect to long-term commitment of the other project member organisations, the ability of their own organisations to work collaboratively with competitor organisations, equality between project parties, timely responsiveness to problems, joint responsibility for the project outcome and arrangements to share rewards as well as risks. Therefore, it was necessary to investigate these items further and explore if the perceptions improved with integration of teams, by comparing between DBB and D&B projects before a conclusion could be made.

5.3 Differences in Ratings by Consultants and Contractors in DBB Projects

The Mann-Whitney *U* test was carried out using SPSS (which is a computer software for statistical calculations), to assess whether there were any significant differences between the contractors and consultants of DBB projects. The results show that thirty out of the thirty-seven factors considered had a significance level greater than 0.05. Therefore, the null hypothesis, H_0 is supported for these thirty factors. The remaining seven factors had a significance level lower than 0.05. Therefore, for these factors the alternative hypothesis, H_1 is accepted. This means that with regard to these seven factors, there are different perceptions in the two groups of respondents.

There were considerable differences between the opinions of the two groups with respect to four items. Seventy-five percent of the contractors were willing to allow small losses to their own organisations in expectation of end of the project mutual gains or future projects from clients. This was indicative of the long-term commitment of the contractors, which is an important facilitator to RC. However, all of the consultants were either undecided or disagreed with the statement. All the contractors were either ‘undecided’ or ‘disagreed’ with the statement that all project parties were held jointly responsible for the outcome of the project, while none of the consultants disagreed with the statement. The contractors’ responses were indicative of their frustration that the consultants were able to escape blame for problems in design and design communication. Altogether, the responses indicate that generally contractors have a more conducive attitude towards developing collaborative relationships within the project teams.

5.4 Differences in Ratings by Respondents in DBB and D&B projects

In addition, Mann-Whitney *U* tests were carried out to assess whether there were any significant differences between DBB and D&B project cultures. Results indicated that twenty-five out of the thirty-seven items considered have a significance level greater than 0.05. Thus, for these items the decision is to accept the null hypothesis H_0 that there are no differences in opinions between the two groups of respondents. Conversely, the remaining twelve factors had a significance level lower than 0.05, leading to acceptance of the alternative hypothesis H_1.

All the items, except one, showing significant differences between the two groups indicated better facilitators to RC in D&B project cultures. There were noteworthy differences between the two groups with regard to equality between parties within the project team and timely responsiveness to problems. In DBB, projects 50% of the respondents ‘disagreed’, ‘disagreed strongly’ or ‘disagreed very strongly’ to the statement that there was equality between project parties. Whereas, less than 25% of the respondents form D&B projects ‘disagreed’ with the statement. The consultants’ dominant position in the DBB project teams, especially in approving payments to contractors was significant in affecting the equality between parties in these projects. Furthermore, more than 50% of the respondents in DBB projects disagreed that there was timely responsiveness to problems arising in projects. This was interrelated to the fact that there was poor coordination in these projects. Over 50% of the respondents in DBB were undecided or disagreed (with 25% of the respondents stating they ‘disagree strongly’ or ‘very strongly’) to the fact that there was effective coordination within the project team. On the other hand, 75% of the respondents from the D&B projects stated varying degrees of agreement to the statement. Similarly, project team members from D&B projects were more supportive towards trying to reach win-win solutions to problems. This indicated that a change of adversarial attitudes was possible through better integration in the project process.

However, a surprising result was obtained for one item, where 100% of the respondents from D&B projects agreed that commercial pressures on their organisations were preventing them from working cooperatively with other project parties. On the contrary, the respondents from DBB projects gave a median response of ‘disagree’ to the statement, with less than 50% of the respondents stating that they agree with the statement. This may be explained by the fact that the D&B projects considered in the research had rigid lump sum contracts and the statement applied especially to the relationship between the D&B team and the client. In fact, in two of the projects considered there was expressed disagreement between the client and the D&B contractors with respect to claims for price fluctuation.

Overall, the test results revealed that the D&B projects had stronger facilitating environments to RC than DBB projects. Therefore, the hypothesis, that as relationships between project parties improve through integration of project teams, the project environment seemed more conducive to RC approaches was accepted.

6. Conclusions

In general, the results showed that there is a facilitating environment to Relational Contracting in the Sri Lankan construction industry. However, the factors facilitating better relationships between parties in the traditional Design-Bid-Build procurement environments are overridden by barriers to corporative working such as, adversarial climates, conflicting objectives, commercial pressures and other inherent pressures created by the traditional procurement environments. The dominant position held by the consultants in the traditional Design-Bid-Build project teams over the contractors had added on to these pressures. Commercial pressures on organisations were found to be the most prominent impediment to developing and maintaining cooperative relationships between parties.

Further, comparison of perceptions of contractors and consultants in Design-Bid-Build projects revealed that, contractors were more supportive towards the development of collaborative project environments than the consultants. This showed the frustration of the contractors towards the inferior position they are constantly given within project teams, as well as the unwillingness on the part of consultants to give up their dominant position. Mann-Whitney *U* tests between Design-Bid-Build and Design and Build project team members revealed that the factors facilitating RC were stronger in the Design and Build environments. Significant improvements were found in Design and Build projects with respect to equality between project parties, timely responsiveness to problems and the willingness of project parties to reach win-win solutions to disputes. However, a surprising finding was made with respect to one item. All the respondents from Design and Build projects agreed that commercial pressures on their organisations were preventing them from working cooperatively with other project parties, whereas, the respondents from Design-Bid-Build projects on average, disagreed with the statement. The discrepancy was attributed to the rigid lump sum contracts used in majority of the Design and Build projects, and their effect on the relationship between the client and the Design and Build team. Nevertheless, overall it could be seen that there were more or stronger facilitators to RC with increased integration in project teams. This complimented the findings of Kumaraswamy et al [11] and their statement that approaches to building a RC culture can be reinforced through measures to promote integrated teams could be held valid to the Sri Lankan context as well.

It was revealed that the research findings concurred with the findings of similar researches done in other countries. Therefore, it could be deduced that the results obtained have a high reliability. Further, these findings make all the relevant international literature on this area applicable to the Sri Lankan context as well. RC based approaches, such as, partnering and alliances are not practiced in the Sri Lankan construction industry. Therefore, the validity of the results could not be explored in a real RC culture.

Drawing from the results of this study, it is recommended that initiatives should be taken in shifting away from the traditional project delivery strategies towards RC. Measures should be taken to promote integrated teams in project delivery process. The government and other industry related institutions could initiate this movement by promoting integrated project teams and supply chains following the initiative of Construction Industry Review Committee (CIRC) of Hong Kong and Strategic Forum for Construction in UK. At the same time, awareness should be given to clients (especially clients of large scale or repetitive construction projects) on these RC practices and the potential benefits that could be obtained through their adaptation.

A tool for strategic safety-rating of constructors

K. Imriyas
Faculty of the Built Environment, University of New South Wales, Sydney, Australia.
(imriyas@unsw.edu.au)

Abstract

The construction industry has poor safety records in globally. Improving safety has been an important goal for the WorkCover, Australia. Setting up a rating system for contractors that evaluates them on their safety records and the workplace safety programs in place would be a good strategy towards this goal. This paper proposes a model that serves this purpose. The proposed model can derive a safety index for a contractor, which may be utilised as one of the factors for tender evaluations by clients whereby better-rated contractors may be favoured. It could also be used by insurance companies so that lower insurance premiums for better-rated firms. The implementation of the model in the WorkCover can facilitate accident control in the construction industry.

Keywords: Occupational health and safety, Safety index, Tender evaluation, Insurance, WorkCover, Australia

1. Introduction

The construction industry appears to have poor safety performance records globally. It was reported that the construction industry of the Unites States accounted for only 5% of the United States' workforce but claimed a disproportionate 20% of all occupational fatalities and 9% of all disabling injuries [12]. In Great Britain, construction accounted for 31% of all work-related deaths in 2002/03 [5]. The incidence of workplace fatalities in the Australian construction industry was 9.2 fatalities per 100 000 employees in 2002–03 which was three times higher than the national average of 3.1 fatalities per 100 000 employees [4]. Raising safety standards by introducing new laws and frameworks has been a goal for safety authorities like the Health and Safety Executive (HSE) in the UK, Occupational Safety and Health Administration (OSHA) in the US and the WorkCover in Australia. It is hypothesised that setting up a new rating system for construction companies that evaluates them on their safety performances would be a good strategy towards this goal. The rating may be utilised as one of the factors for tender evaluations whereby better-rated contractors may be favoured. It could also be used by insurance companies so that lower insurance premiums for better-rated firms. A company that pays lower premium for insurance would be more competitive in bidding.

Safety rating has received broad attention in the construction literature. There are few previous efforts that introduced models for safety rating including: Experience Modification Rating (EMR), Accident Rate (AR), Incident Rate (IR), Score Card (SC), and Safety Performance

Evaluation Framework (SPE). The EMR reflects the cost a contractor has to pay for workers' compensation insurance. Workers' compensation is directly related to safety performance via claims paid due to accidents. It is calculated by taking the ratio between the dollar amount of actual workers' compensation claims filed to the dollar amount of expected claims for a particular type of construction, and is a three-year running average starting one year prior to the last full year. Thus, an EMR of 1.2 means that a contractor has to pay 20% more for workers' compensation insurance than a similar company with an EMR of 1.00 [7]. However, this method is not reflective of the present safety performance of a company since the latest EMR is based on an average of a contractor's performance four, three and two years ago [9]. The AR measures a contractor's safety performance simply by the number of reported accidents. Contractors diligently reporting and investigating accidents are disadvantaged in comparison with less scrupulous contractors who under-report accident occurrence [17]. The IR is computed based on the number of lost time cases, number of days lost for all lost time cases and number of fatalities, injuries and illness with or without lost workdays. Similar to the AR, the accuracy of the IR depends on how honest a contractor in revealing the reportable incidents [13]. In the SC system, six key aspects are rated in projects including: provision and maintenance of plant, provision and maintenance of work environment, provision of information, instruction and training, provision and implementation of safety systems of work, employment of safety officers/supervisors, and site accident records. The weighted score reflects the safety performance of the contractor. However, the key weakness of the system is that it only considers safety commitment at project level [13]. The SPE framework takes into account of safety commitment at project and organisational level. However, this model totally ignores a contractor's accident history which reflects the actual execution of implemented safety programs. Hence, the aim of this study is to develop an effective tool for safety-rating of construction companies. The specific objectives are:

- Identifying and exploring the factors that need to be assessed for safety-rating of contractors;
- Developing an effective model for safety-rating of contractors; and
- Automating the model as a fuzzy system.

However, due to word limitation this paper discusses only the proposed safety-rating model for contractors, and the subject is discussed in various sections in due order. Firstly, the hypothesis, aim and objectives of the research are outlined in the introduction. Secondly, the literature review findings on safety performance evaluation methods and variables are described. Then a new model for safety rating is proposed followed by the conclusion.

2. Evaluating contractor's safety performance

It was found in the literature that the equal assessment of three key factors is important to evaluate the safety performance of contractors.

1. Dingsdag [4] quoted that sustained improvement in safety performance on sites will not happen without an established safety culture at organisational level. Thus, evaluating the

safety culture in a contractor organisation is a key factor towards safety performance evaluation.

2. Mohamed [11] argued that the existence of safety climate on sites leads to safe work behaviours by operatives and thereby lesser accident rates. Measuring the safety temperature on site is therefore a key factor for safety performance evaluation.
3. While the previous two factors are pro-active and they are good measures of risk exposure, it is important to monitor how safe work behaviour is practised at both organisational and project levels through an obvious indicator. Every contractor is required to procure workers' compensation insurance to transfer the compensation liability for occupational injury victims as set out by Workers' compensation ACT. Thus, it is likely that contractors will report all the incidents diligently to the insurer to relieve them from financial burden of compensating. Hence, the usage of workers' compensation data to develop a passive indicator would be a reasonable step in this regard.

2.1 Measuring organisational safety culture

Organisational culture is defined as "a complex framework of national, organisational and professional attitudes and values within which groups and individuals function" [6]. Part of that culture in hazardous industries relates to safety, which is the "ability of organisations to deal with risks and hazards so as to avoid damage or losses and yet still achieve their goals" [14]. In construction, the safety culture is concerned with the ability to manage safety with a top-down organisational approach [11]. Safety climate on construction sites is a product of safety culture in the organisation. Many authors defined the components of a good safety culture as described below.

- Jaselskis [10] and Parker [14] recommended the following features to cultivate a good safety culture in a contractor organisation:
  1. The availability of a safety department of adequate size and competency with set benchmarks, aims, objectives, action plans and responsibilities.
  2. Adequate safety investments by the organisation to strengthen upper management attitude towards safety.
  3. Adequate number of safety meetings conducted between upper management and field safety representatives and between upper management and subcontractors.
  4. Adequate number of informal site inspections made by upper management. Choudhry [3] reinforced that the top management of an organisation with good safety culture would commit to conducting safety climate surveys on construction sites to ensure employees are motivated to adhere to standard work procedures.
  5. The existence of reward systems to recognise good safety performances by the upper management and the safety department members.
- Reason [15] proposed that an organisation with an effective safety culture would have a safety management information system. The desired features for a construction safety management information system were recommended by various authors as described below.
  1. Sorine & Walls [18] emphasized the need of a module to store, analyse, update and communicate necessary safety information on standard job procedures which includes: (1) sub-steps, potential hazards associated with each sub-step, and recommended

precautionary measures; (2) history of previous incidents and near misses in sub-steps with causes and effects; (3) regulatory mandates regarding a sub-step.

2. Blotzer [1] suggested having a module for accident reporting and investigation, and safety reminders.
3. Rivers [16] recommended incorporating a module to capture direct and indirect costs of accidents, analyse these data and produce various accident cost summaries for the project and for the company as a whole for disseminating to site and upper managements. This information can motivate safety professionals to set safety benchmarks and goals both at organisational and site levels. The direct costs include: workers' compensations; equipment repair and replacement costs; fines, fees and settlements; damages to works and temporary structures. The indirect cost refers to the cost of production downtime.
4. Cheung [2] quoted that the integration of such computer technologies as web, database and knowledge base is essential to produce a robust safety management information system for construction.

2.2 Measuring safety climate on site

Mohamed [11] identified ten constructs that establish a good safety climate on site, viz:

1. Commitment construct – the greater the level of management commitment towards safety, the more positive the safety climate.
2. Communications construct – the more effective the organisational communications dealing with safety issues, the more positive the safety climate.
3. Safety rules and procedures construct – the better the perception of safety rules and procedures, the more positive the safety climate.
4. Supportive environment construct – the higher the level of support given by co-workers, the more positive the safety climate.
5. Supervisory environment construct – the more safety aware and relationship oriented the supervisors, the more positive the safety climate.
6. Workers' involvement construct – the higher the level of workers' involvement in safety matters, the more positive the safety climate.
7. Personal appreciation of risk construct – the higher the level of workers' willingness to take risk, the less positive the safety climate.
8. Appraisal of physical work environment and work hazards construct – the greater safety's integration in site layout planning to identify safety hazards, the more positive the safety climate.
9. Work pressure construct – the higher the perception of valuing expediency over safety, the less positive the safety climate.
10. Competence construct – the greater one's experience and knowledge of safety issues, the more positive the safety climate.

Imriyas [8] introduced a comprehensive list of factors with their respective attributes for facilitating safety climate measurements in construction projects, and Table 1 summarises those factors. Despite the table lists most of the key elements of safety climate measurement, it could be improved by adding two more factors: (1) Incentive systems for encouraging workers' involvement in ensuring the safety of oneself and co-workers, (2) Work pressure and operational targets that conflict with safe behaviours.

Table 1: Project safety auditing roster

Safety element	Audit aspect
1. Project safety organisation	• Adequacy of the team & duties & responsibilities
2. Hazards assessment & management	• Adequacy of the in-house hazard assessment system for the project
3. Safe work practices	• Application of safe work procedures & codes of practice • Permit-to-work systems • Personal protective equipment usage
4. Safety training and competency of people	• Safety training to management team • Certification & safety training of operators • In-house safety training to workers
5. Safety inspection	• Regular inspection of hazardous activities & the work site • Housekeeping
6. Machinery & tools use & maintenance regime	• Testing & certification of machinery • Inspection systems for machinery & tools • Maintenance systems for machinery
7. Sub-contractors' safety systems	• Sub-contractors' safety management systems • Sub-contractor monitoring
8. Emergency management system	• Emergency response plan • Emergency response team • Emergency response equipment and facilities

(Source: Imriyas [8])

2.3 Measuring safety implementation through workers' compensation

Workers' compensation provides valuable protection to workers and their employers in the event of a workplace injury or disease. All Australian employers must have a workers' compensation insurance policy to insure themselves against compensation claims for workplace accidents. Depending on the nature and severity of the injury, an injured worker may be eligible for the following benefits:

- Fees for medical and related treatments - include payments made to medical specialists, hospitals and other health service providers in respect of injured workers.
- Weekly benefits – if a worker becomes unfit for work for a short period due to a workplace injury (known as partial incapacity), the worker is entitled to receive weekly benefits until he/she becomes normal or up to a maximum of 52 weeks, whichever is lesser.
- Permanent impairment benefits - if a worker has a permanent impairment as a result of a workplace injury or illness, he/she may be entitled to receive a permanent impairment benefit.
- Death benefits and funeral expenses - the benefits payable when a worker dies as a result of a workplace accident include a lump sum and weekly payments, together with payment for reasonable funeral expenses.

The total amount of workers' compensation claims that a contractor has filed in a construction projects is a passive indicator of the frequency and severity of accidents in that project, which in turn is the result of the effectiveness of safety management. The EMR, as used in the US, represents the claims history of a contractor, but it does not take into account of the recent claims until after two years from the accident outbreak. However, a modified method would be a reasonable indicator of the previous and recent safety performances on site.

3. Proposed model for safety rating of contractors

Based on the finding of the literature reviews above, a new model for safety rating of contractors was developed as depicted in Figure 1. As per the proposed model, the Contractor Safety Performance Index (CSPI) is computed by assessing three intermediate indices using a fuzzy algorithm, as shown in Eq.1, and 0≤*CSPI*≤1.00. If a contractor's safety performance is excellent, the CSPI will yield a score of 1.00. Otherwise, it would yield a score between 0 and 1.00.

$$CSPI = f\left(PSCI, OSCI, ICLR\right)$$

Eq. 1

Where:

1. *PSCI* is the project safety climate index, which is computed by analysing 10 project safety elements as per the framework shown in Table 2. The computation of the *PSCI* adopts a fuzzy algorithm as shown in Eq.2 below.

$$PSCI = f\begin{pmatrix} PSO_{score}, HAS_{score}, SWP_{score}, STC_{score}, SIS_{score}, \\ MTS_{score}, SSS_{score}, EMS_{score}, WIS_{score}, WP_{score} \end{pmatrix}$$

Eq.2

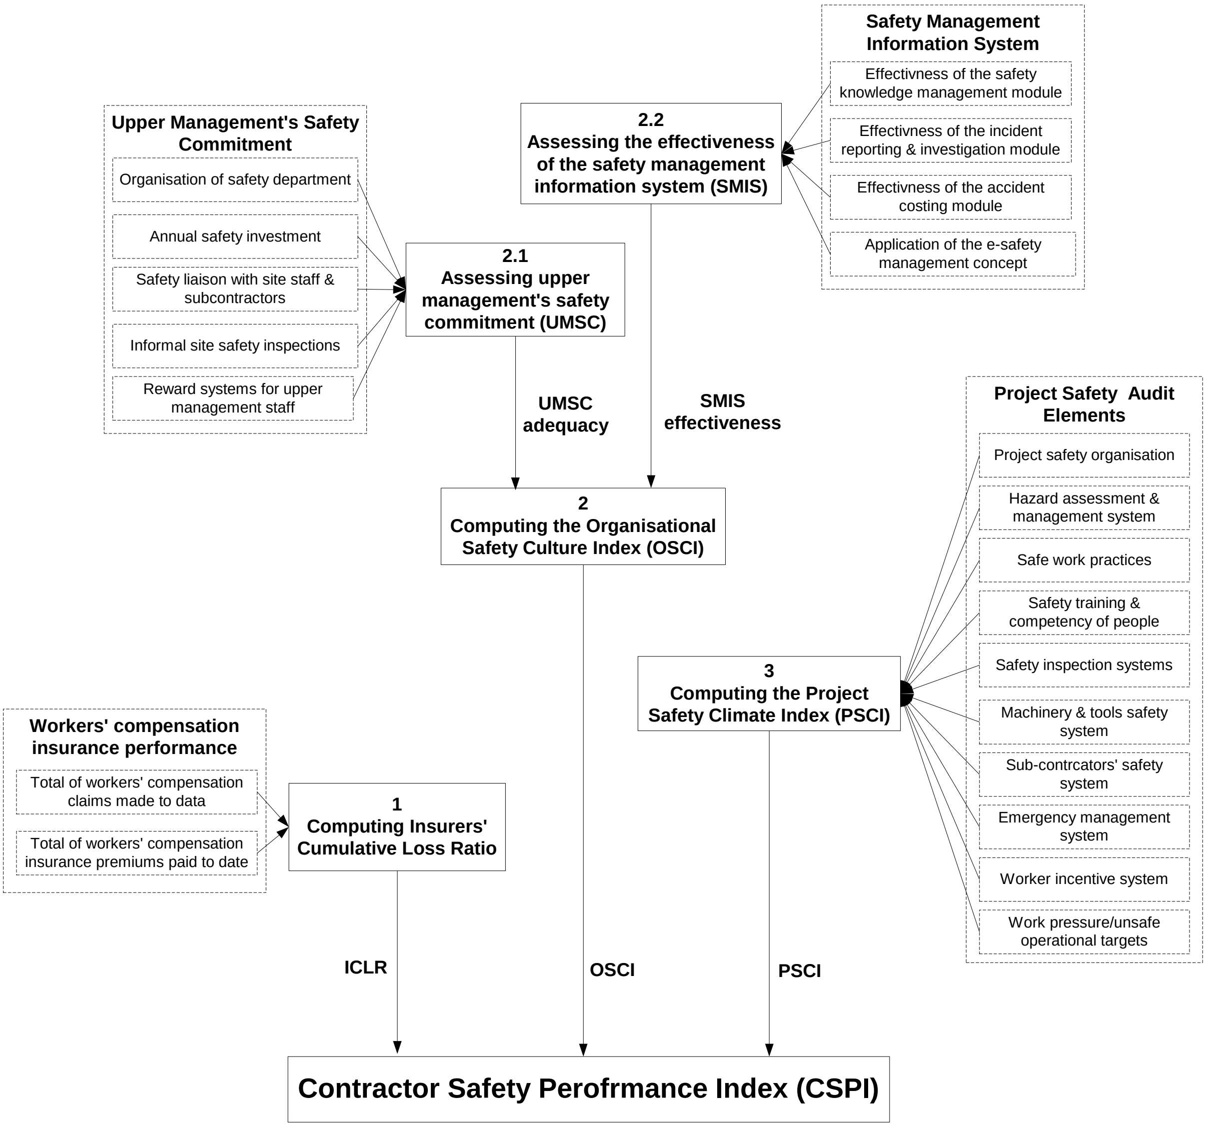

Figure 1. Proposed model for contractor safety rating

2. *OSCI* is the organisational safety culture index, which is computed by equally analysing the adequacy of upper management commitment to safety ($UMSC_{adequacy}$) and the effectiveness of the safety management information system in the organisation ($SMIS_{effectiveness}$), as shown in Eq.3.

$$OSCI = \frac{1}{2} x \left(UMSC_{adequacy} + SMIS_{effectiven\,ess} \right)$$

Eq.3

- The $UMSC_{adequacy}$ is computed by a fuzzy algorithm as in Eq.4, analysing five variables: organisation of safety department (SD_{score}), annual safety investment (ASI_{score}), safety liaison with site staff and sub contractors (SL_{score}), informal site safety inspection (SI_{score}) and reward system for upper management staff (RS_{score}).

$$UMSC_{adequacy} = f\left(SD_{score}, ASI_{score}, SL_{score}, SI_{score} RS_{score}\right)$$

Eq.4

- The $SMIS_{effectiveness}$ is computed by another fuzzy algorithm in Eq.5, analysing four variables: the safety knowledge management module (SKM_{score}), the incident reporting and investigation module (IRI_{score}), the accident costing module (AC_{score}), and the application of e-safety management concept (e-safety_{score}).

$$SMIS_{effectiven\ ess} = f\left(SKM_{score}, IRI_{score}, AC_{score}, e - Safety_{score}\right)$$

Eq.5

3. The *ICLR* is insurers' cumulative loss ratio, which is computed by analysing the total amount of workers' compensation claims filed by the contractor from the last 3 projects and the amount of workers' compensation insurance premiums paid for those projects. Eq.6 is utilised to compute the *ICLR* value.

$$ICLR = \frac{Total\ claims\ filed\ to\ date}{Total\ premiums\ paid\ to\ date}$$

Eq.6

The model was translated into a fuzzy expert system in which equations 1, 2, 3, 4, 5 and 6 were incorporated for computations. However, the development and the validation of the fuzzy system are not described here due to word limitations, and they are described in another paper by the author.

Table 2: Framework for evaluating safety climate on construction sites

Estimating the Project Safety Climate Index						
A) Project safety organisation						
Please rate the adequacy of the duties and responsibilities of the following personnel/team in the project safety organisation.	Low………………………...High					
1. Workplace safety and health coordinator	1	2	3	4	5	
2. Workplace safety and health auditor	1	2	3	4	5	
3. Workplace safety and health committee	1	2	3	4	5	
PSO $_{score}$						
B) Hazards assessment and management system						
Please rate the adequacy of the following aspects of the risk assessment and management system in the project.	Low………………………...High					
1. Risk assessment team and responsibilities	1	2	3	4	5	
2. Risk assessment procedures	1	2	3	4	5	
3. Reporting procedures to workers of identified risks	1	2	3	4	5	
4. Control measures for risks identified	1	2	3	4	5	
HAS $_{score}$						
C) Safe work practices						
C.1) Work procedures: Please rate the effectiveness of the work methods and procedures for the following trades.	Low…………………………….High					
1. Concrete works	1	2	3	4	5	NA
2. Structural steel and pre-cast assembly	1	2	3	4	5	NA
3. Erection and dismantling of scaffolds and false works	1	2	3	4	5	NA
4. Works at heights	1	2	3	4	5	NA
5. Demolition works	1	2	3	4	5	NA
6. Excavation works	1	2	3	4	5	NA

J) Work pressure: Please rate the following items in the project that contribute to work pressure in the project.	Low……………………………High				
1. Reasonableness of operational targets	1	2	3	4	5
2. Workers' perception about work pressure on site	1	2	3	4	5
3. Supervisors' perception about work pressure on site	1	2	3	4	5
WP_{score}					

4. Conclusion

Improving safety in the construction industry has been a long felt need of the WorkCover in Australia. One of the strategies towards this goal is to set up a rating system that evaluates contractors on their safety performances. This study developed a model that evaluates contractors' safety performances analysing three such factors as organisational safety culture, safety climate on site and actual implementation of documented safety management system. The model can be used by the WorkCover, Australia for deriving safety indices for contractors. These indices can give manifest pictures of contractors' safety consciousness which can be a key factor for clients in tender evaluations, and for insurance companies in premium-rating of workers' compensation insurance. Contractors with lower indices would have competitive advantages in the industry, which will motivate other contractors to improve safety. Eventually, this would pave the way to an accident-proof construction industry.

The Effect of Winner’s Curse on Post-Contract Management

Abstract

This study aims to identify whether there is an adverse effect to the client when a project is awarded to a bidder with a large winner’s curse. The contractor is likely to run in to cash flow problems when he suffers from a large winner’s curse. Therefore it is suspected that this would also have adverse effect to the client.

The study is interesting because large winner’s curses are found to exist in Sri Lankan construction industry. Hence, some winning contracts may carry numerous problems due to very low or negative profits. The contractor may try to compensate his poor cash flow by submitting numerous claims and he may try to make profit by reducing the quality and time performance. Thus, this research intends to establish the relationship between the winner’s curse and post contract management difficulties.

The research was designed as a correlation research with a survey based on 20 building projects. The winning bid range and winning margin are used to measure the winner’s curse. Post contract management difficulties are measured using the contractor’s claim attitude index.

The research finds that winning margin showed better correlation to claim attitude than the winning bid range. This indicates that the perceived winner’s curse has higher impact than the real winner’s curse on post contract management difficulties. Therefore the findings suggest that a client should be cautious when awarding the contract to a bidder with a large winning margin.

Keywords: Disaster Claim attitude index, Post contract management, Winner’s curse, Winning bid range, Winning margin

1. Introduction

This paper presents a study conducted in Sri Lanka to identify whether there is an adverse effect to the client when a project is awarded to a bidder with a large winner’s curse. The study is interesting because large winner’s curses are found to exist in Sri Lankan construction industry [8] and the knowledge about their effect is limited.

1.1 Background

Awarding the contracts to the most appropriate contractor is one of the critical decisions to be taken by a construction client. This is very important to achieve successful project outcomes [11, 14, 15]. Awarding the contract to the lowest bidder is usually practiced in the public sector particularly because of its greater accountability. Many private clients also award contracts to the lowest bidder for cost reasons [4, 5, 6]. Therefore, the lowest bidder is typically the winner.

Successful bidders (that is, those who won the competition) tend to obtain returns that (on average) lie below initial projections. This discrepancy between realized and anticipated returns, and the possibility that winning bidders end up making losses, is called the winner's curse [1].

There is evidence that high probability for large winner’s curse to exist in the Sri Lankan construction industry [7]. This means that the winning contracts shall either carry losses with below average profits or even negative profits. The contractor is likely to run in to cash flow problems when he suffers from a large winner’s curse. Under the circumstance the contractor may try to compensate his poor cash flow by submitting numerous claims. He may also try to make profit by reducing time and quality performance [3]. Either context would lead to post contract management difficulties as the client and consultants would be required to take extra effort for corrective measures.

2. Winner’s Curse

The Winner's Curse is a term originally apprehended in the oil industry and it described a phenomenon that occurred in common value auctions with incomplete information [2]. In common-value auctions, the value of the item is the same to everyone but different bidders have different estimates about the underlying value [9].

For example, an oil field had an actual intrinsic value of \$10 million, oil companies might estimate its value to be anywhere from \$5 million to \$20 million. The bidder who erroneously estimated at \$20 million would win in the auction, but will later find that it was not worth the amount he paid. Accordingly, even when a bidder's evaluations are correct on average, a bidder's evaluations on the tract he wins are not correct on average: they are biased upward [1]. If he wins, he loses money and thus he is cursed.

2.1 Winner’s curse in the construction industry

Recall that the winner in the construction industry in competitive bidding is typically, the bidder who submits the lowest bid. When each bidder estimates the project cost and bids accordingly, the winner would probably be the bidder who has most underestimated project value. Thus he wins the contract and agrees to complete the project for a price which is less than the “right price” or the “true value” of the project. The winner therefore may become disappointed in the first instance of having largely underestimated; and later will look for means of rectifying it.

2.2 Detection of the winner's curse

The difference between the lowest and second lowest bids is often referred as "winner's curse." However, the correct quantitative measure of the winner's curse should be the difference between the "right price" of the project and the winning bid [13]. However, the "right price" is literally unknown and thus the measure is not practical.

To represent the winner's curse, winning margin is a useful measure. The term "winning margin" (*W*) is the difference between the second lowest bid and lowest bid. The "percentage-winning margin" (*PW*) is the ratio of the winning margin to the lowest bid and can be used to compare across projects of differing sizes [8]. These can be mathematically represented as:

$$W = (P_1 - P_0) \quad \text{, and}$$

$$\text{PW} = \frac{(P_1 - P_0)}{P_0} \times 100$$

where, P0 is the lowest bid and P1 is the second lowest bid. Since the winning margin is the obvious foregone profit to the winner, it represents the perceived winner's curse.

A recent study has shown that the winner's curse in the Sri Lankan industry is a serious issue. The average percentage-winning margin was equal to 9.323 [7]. This means that a second lowest bid is 9% larger than the lowest in general and this is significantly a high figure. The study further found that the distribution of bid prices was symmetrical and close to the normal distribution. Most of the bids were scattered closely around the average bid. With the conjecture that the majority is correct, the right price lies in the centre. When the lowest bid that lies in tail of the distribution, is the winning bid; there is a high probability for large winner's curse to exist.

With the presumption that the majority is correct, the winner's curse measured based on the average bid price would be a better representation of real winner's curse. Therefore to measure the winner's curse "winning bid range" (*B*) can be used and it is the difference between the average bid and the winning bid. The percentage- winning bid range (*PB*) is the ratio of the winning bid range to the winning bid. These are mathematically represented as

$$B = (P_a - P_w)$$

$$PB = \frac{(P_a - P_w)}{P_w} \times 100$$

Where, P_a is the average bid and P_w is the winning bid; and P_w is equal to P_0 when the lowest is the winning bid.

3. Research Methodology

The research was design as a correlation research based on an industry survey. The sampling population was Sri Lankan building projects, which were awarded to Grade M4 or above contractors and completed during last five years. A random sample of 20 projects was used for collection of data. All data was abstracted from the project documents. Both winning margin and winning bid range were used to measure the winners curse.

The challenge was to measure the project management difficulties. Current literature did not produce an appropriate quantitative measure. Thus, it became necessary to unfold a new measure.

Claim management is one of the main issues of the post contract management activities. And also cost performance is one of the main concerns when considering the contractor's performance [12]. If the contractor runs into the cursed context and tries to rectify it at the expense of client's time and money; the key strategy he would use, is to make numerous claims [10]. This would yield additional paperwork and negotiations for client and his consultants; and also cause adversarial relationships. Therefore the contractor's Claims Attitude Index (*Y*) was identified to measure the level of post contract management difficulties. It was the ratio between the amount claimed for the contractual claims such as variations, fluctuations and cost headings under time extensions by the contractor, and the actual amount approved for payment:

$$\text{Claim attitude index } (Y) = \frac{\text{Quoted amount by contractor}}{\text{Approved amount}}$$

4. Data Analysis

The correlation between variables was tested using the Pearson Correlation Coefficient. Two independent variables: Percentage Winning Margin (*PW*) and Percentage Winning Bid Range (*PB*), were analysed for correlation with dependant variable: Claims Attitude Index (*Y*). The analysis results are presented in Table 1 below.

Table 1: Pearson correlation analysis

Independent variables / **Dependent variable**		**Claim Attitude Index (Y)**
Percentage Winning Bid Range (PB)	Pearson correlation coefficient	0.051
	Confidence level (1- tailed)	0.584
Percentage Winning Margin (PW)	Pearson correlation coefficient	**0.274**
	Confidence level (1- tailed)	**0.856**

Both independent variables (*PB* and *PW*) showed a positive correlation with the dependent variable (*Y*). However, PB showed poor level of correlation and confidence. Percentage Winning Margin (*PW*) showed a better level of correlation at 85.6% confidence level. Even though confidence level is little below the general statistical norms to conclude the correlation is significant; for a research of this nature, it is a significant figure.

5. Conclusions

The evidence of high probability for existence of large winner's curse in the Sri Lankan construction industry, urged the need to identify if a contractor with a large winner's curse is an adverse selection. The winners curse was quantitatively measured by two variables: Winning Margin and Winning Bid Range. Claims Attitude Index measured the post contract management difficulties to test whether the contractor is an adverse selection.

The Pearson Correlation Analysis results showed both the winning bid range and the winning margin are correlated positively with the claim attitude. Thus, the relationship between Winner's curse and post contract management difficulties found to be positive. Therefore, awarding a contract to a bidder with a larger winner's curse could be an adverse selection. However, the correlations are not significant enough to statistically theorise this as a fact. But, the results provide clear indication about the relationship.

The Pearson correlation coefficient was 0.051 between winning bid range and claim attitude with poor confidence level; but it was 0.274 between winning margin and claim attitude with confidence level of 85.6%.

Since the winning margin is a measure of perceived winner's curse; it can be now concluded that the perceived winner's curse has larger adverse impact to the post contract management activities than that from the real winner's curse. This is because winning bid range, which is the selected measure for the real winner's curse shows a very weak relationship to the claim attitude. This is pragmatic because, the large perceived winner's curse gives the feeling to the contractor that he losses a significant amount from the contract. He would have bid 1$ less than the second lowest and still could win the contract. Thus, the Winning Margin is obviously a foregone profit.

With the conclusions of the research it is advised that a client should not award a contract to a bidder with a large winner's curse, especially when there is a large perceived curse.

Abstract

Design and build has become a popular mode of procuring construction work. It is now, regarded by majority of clients because is offer greater confidence to clients. Even most of the researchers had found that the design and build procurement method is better than the traditional method in most of the areas, in general it does not developing as dominant or highly practicing procurement method in most of the countries except France, Greece and also Norway and Mexico in private sector. In Sri Lanka, design and build has not extended as it is expected. Therefore, it is worthwhile to find out the reasons behind the drawbacks of design and build procurement system development. Thus this research is intended to identify the most significant impediments to the development of design and build procurement method in Sri Lanka.

A two round questionnaire survey facilitated to identify the significant impediments to the development of design and build procurement system in Sri Lanka and few unstructured interviews with most experienced professionals in the area were carried out in order to study and understand the context. Twenty significant impediments were identified and ranked according to the negative impact they create on the development of design and build procurement system. It is found that very less contribution given by the government to promote design and build is the first most significant impediment. Lack of clients' knowledge related to alternative procurement systems, less contribution to the development given by research and development institutes, unfamiliar of contractors' professionals with the design and build procurement process, clients' lack of experience with design and build procurement method, less contribution to the development given by professional institutes, and reflection of consultants' own interest in procurement selection are found as other six uppermost significant impediments.

Keywords: Design and build, Procurement method, Impediments, Sri Lanka

1. Introduction

Design and build (D&B) is becoming popular due to its advantages providing over the traditional procurement system. The D&B procurement route has witnessed significant growth in many countries over the world and considered as dominant procurement system too.

However, some researches shown than in Sri Lanka the traditional procurement system is dominating the procurement market over the years and D&B procurement system use as next alternative option among alternative procurement systems but, less in practice. There this paper presents a study undertaken to identify the impediments to the development of D&B procurement system in Sri Lankan based. The significant impediments found out through the surveys and unstructured interviews are discussed and explained in the appropriate sections.

2. Background

2.1 D&B procurement system

Design and Build procurement system is defined as, 'A construction procurement method where the contractor offers to undertake the entire design and construction of a project' by Cox and Townsend 1998 (cited in [1]). According to Moore and Dainty [2], D&B emerged as a procurement system to overcome the drawbacks of the separated system by offering greater confidence to clients seeking to avoid delays, exposure to costly claims, possible litigations and to improving project performance. D&B is now regarded by majority of clients than the for the traditional system, which providing the optimum route to obtain value for money and it is easy for the clients to enter in to a single contract rather than many where, the conflicts among parties are less. Its popularity arises from its perceived ability to bring design and construction processes closer together culturally, and associated improvements in cost and time certainty. Further, the system has also been advocated as facilitating a seamless procurement process, improving team relationships and producing a more efficiently delivered product. It offers a potential route for the implementation of new concepts such as: fair and equitable relationships, continuous performance improvement and changes in management and culture. The system reduces time to a minimum by eliminating traditional tendering procedure and produces more advantages to the clients and contractors when comparing to the traditional procurement system.

2.2 Trends in procurement systems

There was a time, when traditional system was the only option on the table to clients. An architect designs a building from beginning to its end and then contractors looked over the drawings and bid on the project. But the states now have changed and there are different project delivering methods to fulfil the client's need according to project requirements.

According to the research conducted by the Royal Institute of Charted Surveyors (RICS) Construction Faculty [3] over the years for United Kingdom (UK) construction industry, D&B is a single most prevalent alternative procurement method since year 1995. Until such time the Bills of Quantities dominated the industry. This was the time of major shifts in procurement strategies come up. This survey reinforces the dominance of D&B as a procurement strategy. D&B has remained steady at just over 40% of total workload value. Not only in UK construction industry but also in many other countries such as China, Denmark, Great Britain, Japan and United States of America (USA) D&B procurement method shows an increasing trend. In Private sector countries like France, Thailand, Norway and Mexico uses D&B system more than 50%. Public sector too in countries like Greece and France uses the D&B as the procurement system [4].

According to the research conducted by Rameezdeen and Ratnasabapathy [5], the Measure and Pay method dominates the Sri Lankan construction industry, but decrease in certain periods paving way for other systems. Majority of public works in Sri Lanka found to be procured using these methods by considering accountability and transparency. D&B has recorded a usage rate of 20-35% during the year 1977 to 2003. The management contracts, lump sum, prime cost contracts procured only few projects during the study period. Table 2 indicates the survey result of trend procurement systems in Sri Lanka [5].

Table 2: Trend in methods of procurement in Sri Lanka (by value of contract)

% of Use (average) / Procurement System	1977 -81	1982 -86	1987 -91	1992 -96	1997 -00	2001 -03
Measure and Pay	55	50	58	50	64	72
Lump Sum	12	10	8	7	10	5
Prime Cost	10	8	5	4	3	1
Design and Build	22	31	28	35	21	22
Management Contracting	1	1	1	1	1	0
Joint Venture	0	0	0	3	1	0
Total	100	100	100	100	100	100

In Sri Lankan context the growth pattern of D&B was positive up to year 1996 and then it began to decline up to year 2000, but there after no significant changes shown in its growth. The growth of D&B is not up to the expected level in Sri Lanka when comparing with the countries mentioned earlier. The traditional procurement system remains widely procuring method and it's seems to be strong. Therefore, it is essential to explore why the D&B procurement is not popular in the Sri Lankan context and identify the barriers preventing the popularity, in order to develop the innovative procurement system in Sri Lanka.

3. Methodology

This research is designed as a survey study to identify the most significant impediments to the development of D&B procurement system in Sri Lanka. Therefore, the data collection is done based on two round structured questionnaire survey. The first round of the survey was used to identify the presence of the impediments in the local context by using a sample of ninety professionals. The next round used to rank the impediments according to their negative impact to the development of D&B. Screening process, considering the respondent who are mostly complying with the first round results reduces the second round sample size up to thirty in number. The sample for both survey rounds consisted similar number of clients, consultants and contractors' professionals with different professional disciplines such as: Architects, Engineers and Quantity Surveyors. Some unstructured personal interviews were setup for the purpose of study the local context parallel to the first round questionnaire survey. Based on the literature survey, questionnaires were prepared and distributed to identify the current impediments that are emerged in the local context. In the basis of first round results the second round aimed to identify the significant impediments and Relative Important Index (RII) was used to analyse the data in the second round.

4. Impediments to the development of D&B procurement system in Sri Lanka

The impediments can be created externally or internally to the development of design and build procurement system. The factors that beyond the control of the stakeholders of the construction industry were identified as external factors and factors, which can be controlled by the stakeholders, were taken as internal factor. According to Rolwinson [6], the external environment factors that affect the construction industry as well as the development and use of procurement systems, which comprise political, economical, technological, financial and social aspects. The internal factors contain: issue imposed to the development of D&B procurement by client, consultant, contractor, government, statutory and regulatory bodies, research and development instituted (R&D) and professional institutes.

Twenty most significant impediments were identified both internally and externally, that effecting the development of D&B procurement system in Sri Lanka. The factors were discussed under appropriately categorized sections and explained. Table 3 shows the identified significant impediments in the rank order.

Table 3: Twenty significant impediments identified through the survey

Rank	Impediments
1	Government contribution in promoting D&B in Sri Lanka is very less
2	Clients' lack of knowledge regarding alternative procurement systems
3	Less contribution to the development of D&B procurement system by Research and development institutes in Sri Lanka
4	Contractors' professionals are unfamiliarity with D&B procurement system
5	Clients' lack of experience with D&B projects
6	Less contribution to the development of D&B procurement system by Professional institutes in Sri Lanka
7	Reflection of consultants' own interest in procurement selection
8	Government preferences for D&B only by only considering time factor
9	Poor relationships create by client with the consultants

Rank	Impediments
10	Barriers to enter in to D&B market by the construction contractors in terms of: not familiar with D&B projects earlier and incapability of contractors
11	Negative attitudes among consultants' professionals toward D&B procurement system
12	Inadequate in-house design team in contractors’ organizations to compete in the market
13	Poor project management practices by the D&B contractors
14	Contractors' professionals inflexible to accept the changes when involving in D&B process
15	Effect of political environment in procurement selection
16	Barriers to enter in to D&B market by the construction contractors in term of political environment
17a	Inadequate cover by the 'Standard Conditions of Contract'
17b	Very less contribution is given by the Ministry of Finance to the development of D&B procurement system as a regulatory body of Sri Lanka
19	D&B contractors’ profit making interest rather than thinking of client’s requirements
20	Less market strategies used by D&B contractors in order to promote their services

4.1 Clients related factors

The study point out that the lack of clients’ knowledge related to alternative procurement systems (ranked-2) act as a major barrier to the development of D&B in Sri Lanka. It is difficult for the clients to gain knowledge regarding new procurement system, since most of the construction clients are laymen and any institutes or contractors do not conduct awareness programmes for clients in order to educate them regarding the innovative procurement systems. Therefore, the clients do not intend to use alternative procurement systems other than the traditional system.

Clients’ lack of experience with D&B projects (ranked-5) widely effects the selection of D&B system in their projects. On the other hand it consequently reduces the probability of using D&B for most of the projects and this factor give a negative impact to the growth of D&B procurement method. Most of the clients fear to take an additional risk by selecting a procurement system, which is not familiar to them. Also there are lack of examples in the industry to show the success of such system due to only few projects are carried out using D&B procurement system in the industry.

Other than the clients' lack of knowledge regarding alternative procurement systems and lack of experience with D&B projects; maintain poor relationships with consultants by clients (ranked-9) act as impediment to the development of D&B. Clients are overemphasis on fee rather than services, ultimately they get poor consultants services for their projects by consider low cost. Ultimately, they provide insufficient project brief, provide inadequate time to prepare proposals to contractor, often change their scope of work, create lot of difficulties in the construction stage especially in quality control and creates conflict with contractors. Therefore, this gives a negative effect to the development of D&B.

4.2 Contractors related factors

The unfamiliarity of contractors' professionals with D&B process is the forth major significant impediment in ranked order, which effect the development of D&B in Sri Lanka. The reason could be Sri Lankan professionals are generally practice the traditional procurement system due to the domination of the systems in the market. It is found that the public contracting organizations are widely use the Measure and Pay rewarding method for D&B system even though Lump Sum method is conventionally used for D&B system. In some instances they bid for Lump Sum method and later change to Measure and Pay method due to the difficulties faced after the commencement of the project. This evidences the unfamiliarity of Sri Lankan public contracting organizations with the system. In addition, most of the private contracting organizations have lack of experience with D&B projects due to the ascendancy of the traditional procurement system in the market. Therefore, most of the contractors' professionals are not willing to work for D&B projects and this act as a barrier to the development of D&B in Sri Lanka.

Also, there are barriers to the construction contractors to enter in to the D&B service market due to their incapability and unfamiliar with D&B projects earlier. Inadequate in-house design team in contractors' organizations act as a barrier to D&B contractors to, compete in the market. However, the responses from contractors for this factor are little varied from consultants and clients. Most of the contractors in Sri Lanka go for joint venture with design teams for D&B projects and the contractors feel that it is easy and better to outsource the design team. In addition, unstable demand for D&B type projects discourages the contractors to establish in-house design teams. This might be the reason for absents of pure D&B organizations which only undertake projects under D&B system in Sri Lanka. But, the consultants and clients experienced that joint ventures bring additional cost factor to the project, more difficulties and conflicts after the project completion. The improper project management practice by the D&B contractors in Sri Lanka ranked 13th in order. It is obvious that this factor prevent the consultants and clients to select D&B as project procurement. Also, the contractors' professionals are reluctant to accept the changes when involving in D&B process due to strong uncertainty avoidance and rigid culture of the Sri Lankan construction professionals also found as another impediment to the development of D&B in Sri Lanka.

Other than the above mentioned factors, contractors' profit making interest rather than thinking of clients' requirements (ranked-19) and less market strategy used by the contractors (ranked-

19) identified as a significant impediments. The profit making interest leads to reduction in quality of the project and the clients are not in a possession to derive the benefits of this procurement method without sacrificing quality. Marketing or sales development long ignored by many contractors who depend on word-of-mouth in a defined geographical marketing arena, also the market strategy used by D&B contractors are very less compare to countries which use D&B widely and this factor act as a barrier to increase the D&B projects in the context.

4.3 Consultants related factors

Reflection of consultants' own interest in procurement selection (ranked-7) has given a considerable effect to the development of D&B. The reason for this could be that the consultants do not use systematic procurement selection criteria for project procurement selection. Therefore, the selection could always be bias rather than a logical approach. Thus, consultants select the traditional procurement system as project procurement, which they are well familiar in most of the cases. The selections are made without taking additional risk by selecting an unfamiliar procurement system. Ultimately, this leads to reduction in probability of use D&B system for appropriate project scenarios.

It is revealed through the study that, there are negative attitudes among consultants' professionals toward D&B procurement system in Sri Lanka. This is due to the image among consultants' professionals regarding D&B such as loss of their traditional leading role, authority and job satisfaction. Further the consultants' professionals are reluctant to change from the tradition and experience new challenging role in the innovative procurement system due to their rigid culture. Ultimately this factor effects the D&B procurement selection in project procurement and reduces the usage of D&B.

4.4 Government and political environment

It is found that the very less government contribution in developing D&B is the first most significant impediment to the development of D&B procurement system in Sri Lanka. The government started to procure more projects using D&B system from year 2001, after publishing 'Standard Bidding Document' for D&B contracts. But bidding for most of those D&B public projects are not open to the private sector contractors. Generally government goes for negotiated based D&B contracts with public contracting organizations. This discourages the use of D&B in private sector. If the government open the tenders to the private sector, the contractors may be encouraged to develop further their D&B knowledge in order to stay competitive to bid for future projects. Once they are familiarized with D&B, the level of adoption will be increased. As a consequence, the use of D&B is significantly promoted across a broad spectrum of the construction industry, which the government fails to do so. Therefore, initiation of the D&B procurement system in private sector by the government as a major client in the construction industry is the lagging contribution within the context in order to develop D&B procurement system.

Also, it is found that the government goes for D&B procurement system only to gain advantages from the time factor that the system produces, but excluding other advantages it provide and without any systematic review. Therefore this factor affects the use of D&B procurement system for most of the public projects. In addition the political environment interims of policies and directions act as a barrier to the contractors to enter in to D&B market and in procurement selection. If the government's directions are toward increasing D&B projects, the market entries and D&B procurement selection will ultimately increase in the context.

4.5 Contribution given by research and development (R&D) institutes in Sri Lanka

In the Sri Lankan context the R&D practices are less in the industries when compare to the developed countries. It is around 0.15% in the total GDP. The R&D institutes are imperative to construction industry, since they bring new knowledge and develop new cultures in the construction industry. The contribution of R&D to develop alternative procurement systems makes rapid impact to the industry and pilot to change the trend of procurement systems, which has not happened in the Sri Lankan context. Therefore, poor contribution by R&D institutes (ranked-3) acts as a significant barrier to the development of D&B in the context.

4.6 Contribution given by the professional institutes in Sri Lanka

Less amount of contribution given by the professional institutes in Sri Lanka (ranked-6) indicated as sixth major impediment to the development of D&B. Few professional institutes do not prefer the D&B system, some of them are against the development for the purpose of protecting the small and medium construction contractors who can not involve in D&B projects. This factor gives an unconstructive effect to the development of D&B.

4.7 Standard conditions of contract

The standard conditions of contract used for D&B contracts are use with considerable amendments due to inadequate cover by such documents in the Sri Lankan construction industry and it creates many problems during the construction process. It is found that the 'standard conditions of contract' published by the regulatory body of the construction industry with in the country: Institute of Construction Training and Development (ICTAD) for D&B is the widely used document for D&B projects in Sri Lanka.

5. Conclusions

In Sri Lankan context, the traditional procurement system is widely used for both private and public projects up to now, since the government and regulatory bodies promoting the traditional procurement method and widely use in public project procurement. In addition the clients are not knowledgeable regarding alternative procurement systems and the construction professionals are reluctant to change themselves from the system that they are well familiar.

However, the research and development institutes, and professional institutes also do not contributing to the development of alternative procurement systems.

The Design and Build (D&B) system has recorded a usage rate of 20-35% up to year 2003 in Sri Lanka and the growth of the D&B system is not up to the expected level comparing to some other countries like UK, France, Greece and etc. Therefore, this research was intended to identify the significant impediments to the development of D&B procurement method.

It is found that in Sri Lankan context: very less contribution is given by the government to promoting D&B, clients' lack of knowledge regarding alternative procurement systems, less contribution to the development of D&B by Sri Lankan Research and Development Institutes, contractors' professionals unfamiliarity with the D&B process, clients' lack of experience with D&B projects, less contribution to the development of D&B procurement system by Sri Lankan Professional Institutes and reflection of consultants' own interest in procurement selection are the impediments to the development of D&B respectively in the significant order.

The government acts as the single largest client of the construction industry and is responsible for all the public construction needs. Failing in initiation of D&B procurement as one of the major procurement system by the government and their policies in procuring D&B such as; offering the job to public contracting organizations in negotiated base and no systematic review in procurement selection are some major facts which create such significant impediment. Lack of clients' knowledge related to alternative procurement methods creates a major problem in developing D&B procurement method and it effects the selection of a suitable procurement method for projects. Since, the contribution given by research and development institutes and professional institutes are very less, it is difficult to develop an alternative procurement method as a dominant procurement method within the context, because these institutes play the central role in introducing innovations to the industry. Unfamiliarity of contractors' professionals with D&B process creates a barrier to the development of D&B procurement method. Since, professionals do not prepare to involve in the new process and face challenges due to the rigid culture and strong uncertainty avoidance it is difficult to develop an alternative procurement method as a dominant procurement system in the context.

Neglecting the procurement selection criteria in project procurement selection by the consultants (ranked..) is an issue in the Sri Lankan context. This creates a better opportunity to the consultants to select the procurement system based on their own interest. Since, the industry is well familiar with the traditional procurement system there is a higher probability to select the traditional procurement system as project procurement. Therefore, consultants' own interest in procurement selection negatively effects the development of D&B procurement system. Ultimately, all the above factors highly restrict the development of D&B as a dominant procurement system in Sri Lanka.

Abstract

The construction industry is one of the backbones of the economy of many countries. The industry's characterization is determined by the external environment in which it operates. Therefore, the development and the use of project procurement systems are affected by such environmental factors. These environmental factors influence the industry in various ways thus determining the procurement shares and trends. Therefore, examination of such factors influencing the procurement selection in the construction industry is critical for the successful outcome of a project as well as to the development of the industry. In this context, the aim of this paper is to examine the significant factors influencing the selection of procurement systems from external environment. Four rounds of Delphi survey were conducted to investigate the most significant factors from external environment and their level of influence on various construction procurement systems in Sri Lanka. In addition, few interviews were conducted with selected industry experts in the view of interpreting the results derived from Delphi survey. It was found that the external environment significantly influence the selection of procurement system for any kind of projects. A statistically significant consensus on the weighting of the utility values for each procurement system was obtained from 25 experts from the industry. Based on the Delphi survey results, a set of exclusive selection criteria for five factor categories was established. The five factor categories formulated from this study include 'Market condition', 'Economic condition & Fiscal policy', 'Technology', 'Socio cultural suitability' and Regulatory environment'. Further, it was also found that Market conditions have significant influence on procurement selection compared to others factors. Therefore, it can be concluded that beside the commonly considered factors in terms of key selection criteria like client's requirements and project profile, clients should take into account other factors from the operating external environment that influence the procurement selection.

Keywords: Construction Procurement, External Environment, Procurement selection, Selection Criteria.

1. Background

The construction industry of any country is recognized as an economic regulator which contributes to the national economy in large scale. Thus, the well being of the national construction industry is of paramount importance for the economic development of the country. The construction industry's uniqueness throughout the world is determined by the external environment in which it operates. The external environment consists of several sub-systems such as economical, political, financial, legal and technological [11]. Further, the construction industry is an open system therefore, it is sensitive to change. This changing nature has resulted in the industry to be in a challenging position in addressing the changes forced by the subsystems of the environment in an efficient and effective manner. Consequently, construction project procurement systems practiced in the industry have also been subjected to changes resulting in many newly innovated procurement systems that could be used to meet the clients' contemporary requirements in a dynamic construction environment. Thus, the development & the use of procurement systems are also affected by the factors from external environment. These environmental factors influence the industry in various ways thus determining the procurement shares and trends.

Client's requirements and project characteristics are two major criteria to be considered in selecting a suitable procurement system for any kind of construction projects. The selection process is an open system, which receives information from its environment, transforms and returns as an output to the environment [9]. According to Sheath et al. [12] and Chen [4], client's requirements will ultimately be influenced by the context in which they operate; and this implies that the choice of procurement selection criteria may also be influenced by the predominant environment. On the other hand, Kumaraswamy and Dissanayake [6] have concluded that the most appropriate procurement system must necessarily depend on the project scenario or project profile that can be derived from contextual conditions such as external factors related to projects. As a result, client's requirements and characteristics of the project that dominate the procurement selection are influenced by the factors from external environment. These factors may have direct or indirect influence on the formulation of selection criteria and thus on the selection of suitable project procurement system.

There is no single procurement system which is suitable for all type of clients and all projects. Each project has its own characteristics and requirements and therefore, it is crucial to match the client's needs, project characteristics and influence of external environment with the most appropriate procurement system to achieve the correct balance between priorities and risks and ensure a successful outcome. Therefore, it is crucial to examine that what factors from external environment drive the procurement system and how these factors might influence the selection of procurement systems. In this viewpoint, the aim of this paper is to identify and analyze such environmental factors which influence the selection of procurement system and their level of influence. It presents a set of exclusive selection criteria formulated based on the influence of external environment in Sri Lankan context.

2. Literature Review

Researchers have argued that identification of relevant selection factors is the first step to formalize the selection process in a systematic manner. Previous studies in construction procurement selection have identified several coherent procurement selection parameters, such as time certainty, cost certainty, speed, flexibility, responsibility, complexity, price competition, risk allocation, and quality. While these parameters are crucial to procurement selection, doubts have been cast over the accuracy of decisions generated from a limited number of parameters [3]. Most of these identified factors are related to Clients' requirements and Project characteristics. Review of past studies on procurement selection factors reveals that the number of studies associated with the factors influencing from external environment is limited compared to internal environment. Table 1 summarises the review of past studies on factors governing the procurement selection in the frame work of external environment.

Findings from literature reveals that factors such as Market competitiveness, Technical feasibility, Regulatory feasibility, Availability of experienced Contractor and Labour productivity have been identified by several studies compared to others. Walker [13] and Hughes [5] identified a series of construction-related environmental influences pertinent to the project level, and these include political, financial, economical, sociological, legal, institutional, competitive, cultural, technological, environmental, physical and aesthetical aspects. They further signify that for instance, ''market's competitiveness and contractor's availability'', ‘‘labour productivity’’ and ‘‘material availability’’ may be associated with the competitive and economical aspects; while the ‘‘regulatory feasibility’’ and ‘‘technology feasibility’’ synchronises the legal, technological, environmental and physical aspects. In this regard, all the external environmental factors are inter-related and have direct or indirect relationship with the factors from project’s internal environment.

3. Methodology

Delphi technique was adopted as the main research method in this study. Delphi method is a highly formalized method of communication that is designed to extract the maximum amount of unbiased information from a panel of experts. It is conducted by rounds interspersed with group opinion and information feed back in the form of relevant statistical data [2]. Therefore, it was considered that it would be appropriate to adopt the Delphi technique for formulating a set of exclusive criteria in terms of external environment. Delphi method adopted in this study consisted of four rounds which targeted to derive the expert opinion on factors which affect the procurement selection. At the completion of the fourth round, utility values for significant factors were derived against various types of procurement systems which are commonly used in construction industry. The following Table 2 summarizes the formats of Delphi survey conducted for this study. In addition to the Delphi survey, few interviews were conducted with selected industry experts in view of interpreting the results derived from Delphi survey.

Table 2: Format of Delphi survey

	Round 1	**Round 2**	**Round 3**	**Round 4**
Instrument	Questionnaire 1	Questionnaire 2	Questionnaire 3	Questionnaire 4
Data base for Questionnaire	Literature review	Results from round one	Results of factor analysis carried out for round two results	Results from round three
Purpose	To gather a set of specific selection criteria for construction procurement	To identify the level of importance of each selection criteria	To assess the suitability of each factor against various procurement system	To reconsider and reassess the suitability of each factor against various procurement system
Duration	Two weeks	Eight weeks	Four weeks	Five weeks
Number of experts responded	35	35	30	25

4. Results and Analysis

The factors suggested by the panel of experts in the round one were carefully analyzed and a list of factors was formed for the Sri Lankan context. The list includes the factors suggested by the experts and the factors identified from comprehensive literature survey. Factors which conveyed similar meanings were combined and rephrased. Altogether 21 factors were consolidated to form a list of factors for the second round of Delphi.

4.1 Results of Delphi round two

The results from round two were subjected to several analysis which are included under main two steps as follows;

Step 01 – Identification of Significant Factors

- A mean weighted rating for each factor was computed to derive an indication of the importance of each factor.
- The Severity Index was calculated to rank the factors based on their significance on procurement selection.
- Coefficient of Variation (COV) was computed which expresses the standard deviation as a percentage of the mean to compare the relative variability of different responses.

Table 3 presents the results of the data analysis which is the indication of relative importance of each factor. Out of 21 factors, 14 factors were assigned by mean ratings of higher than the neutral point 2, and each of them maintained a Severity Index of more than 65%. This indicates that these 14 factors significantly affect the selection of procurement system. Remaining 7 factors which gained mean rating of less than 2 and Severity Index of less than 65% were removed for the third round of Delphi.

Step 02 – Factor Analysis

Unimportant factors identified from step one analysis were disregarded and only the significant factors were considered as eligible factors for factor analysis. Factor analysis was performed to elicit the underlying relationships among the eligible factors affecting the procurement selection and to reduce the factors into a small number of components [8]. The factor analysis was carried out using SPSS package. The first stage of factor analysis was to determine the strength of relationship amongst the factors affecting the procurement selection based on their Correlation Coefficients.

Table 3: Results of round two (Indication of the level of importance)

Factors	SI	M	SD	COV
Market competitiveness	76.67	2.30	0.868	0.3775
Technological feasibility	73.33	2.20	0.876	0.3983
Regulatory feasibility	66.67	2.00	1.095	0.5477
Availability of experienced Contractor	78.89	2.37	0.930	0.3929
Education of Contractors	72.22	2.17	0.785	0.3622
Availability of materials	66.67	2.00	1.033	0.5164
Cultural differences	66.67	2.00	1.155	0.5774
Government as a policy maker	66.67	2.00	0.966	0.4830
Government as a major Client	70.00	2.10	0.928	0.4419
Finance for the project : Donors	77.78	2.33	0.974	0.4173
Finance for the project : Aids	75.56	2.27	0.962	0.4245
Economic condition of the country	72.22	2.17	1.030	0.4752
Information Technology	66.67	2.00	1.033	0.5164
Environmental issues	66.67	2.00	0.966	0.4830
SI- Severity Index, M- Mean, SD - Standard Deviation, COV – Coefficient of Variation				

Based on the principle component method, the factor solutions with eigenvalues greater than 1 were produced. Varimax orthogonal rotation was employed to transform the factor matrix produced by un-rotated principle component matrix into one that is easier to interpret. The extracted five factor categories were grouped using Varimax orthogonal rotation. The Table 4 shows the key factor categories and associated variables based on varimax orthogonal rotation.

Table 4: Factor Analysis grouping using Varimax Orthogonal Rotation

No	Factors	Associated Variables
1	Market condition	• Market competitiveness • Availability of experienced Contractors • Availability of material
2	Economic condition and the fiscal policy	• Economic condition of the country • Source of finance: Donor/Aid • Government as a policy maker • Government as a major client
3	Technology	• Technological feasibility • Information Technology
4	Socio cultural suitability	• Cultural differences • Education of Contractors • Environmental issues
5	Regulatory environment	• Regulatory feasibility

4.2 Results of Delphi round three

In the third round of Delphi, experts were asked to provide the utility values for each factor against various procurement systems. A wide range of variants under each main categories of procurement system were adopted. The utility values were defined using a score starting from 10 to 110, in which 10 represents 'low suitability' and 110 represents 'high suitability' . The analysis was based on the utility values provided by the experts. The means of the utility values were computed for the responses. To obtain a measure of consistency, Coefficient of Concordance (w) of utility values were calculated using SPSS package in order to measure the rate of agreement. Coefficient of Concordance (w) ranges between 0-1 where, 0 represents 'No agreement' and 1 represents 'Complete agreement'. In this study, a concordance coefficient of 1 indicates that all experts ranked the procurement options identically (Chan *et al.*, 2001, p. 704).

Further, significance rate was calculated to gain the significance level of each factor. The significance level (α) is based on the asymptotic distribution of a test statistic. Typically, a value which is less than 0.05 is considered as significant. The asymptotic significance is based on the assumption that the data set is large. If the data set is small or poorly distributed, this may not be a good indication of significance.

The results revealed that the mean utility values provided for the five factors were sufficiently consistent at significance level of 0.05 or smaller. Compared to other related factors, market competition is having a considerable level of correlation among the participants. There is a considerable level of significance for the factors other than the socio cultural suitability, which scored 0.258 (> 0.05). This shows the less significance of the socio cultural suitability. Even though, significance level for the Socio cultural suitability is low, based on its influence on industry practice, it was considered to be appropriate selection criteria particularly for Sri Lankan industry.

4.3 Results of Delphi round four

The consistency of the experts' utility values was again tested by calculating the Kendall coefficient of concordance using SPSS package. Table 5 portrays the average utility values of five main factor categories against various procurement systems. Summary of the comparison of results obtained from round 3 and 4 are given in the following Table 6.

The re-assessment of utility values at fourth round made considerable improvement in the significance level. The socio cultural suitability was changed in to the significant level of 0.021(<0.05) which shows the higher level of significance. Economic condition and the fiscal policy were changed from 0.041 to the 0.012; this also indicates the increased level of significance. The significance level of Technology, Regulatory environment and Market condition for the project were increased to the maximum from the 0.011 and 0.001 respectively.

Table 5: Average utility values of factor categories against various procurement systems – Results of round four

Selection Factors	**Construction Procurement Systems**											
	Separated			**Integrated**					**Management Oriented**		**Collaborative**	
	Measure & Pay	Lump Sum	Prime Cost	Design & Build	Package Deal	Turnkey	Develop & Construct	PFI	Const. Mgt.	Mgt. Cont.	Partnering	Joint Venture
Market competition for the project	73.61	68.87	59.13	77.00	68.39	70.78	67.20	65.64	59.78	58.83	54.57	57.61
Economic condition and the fiscal policy	55.57	69.13	55.78	69.09	53.88	55.57	56.87	66.51	64.57	63.92	71.56	73.04
Technology	53.91	53.48	47.83	78.04	63.17	71.87	64.43	65.75	62.83	61.39	73.04	74.78
Socio cultural suitability	54.65	53.70	61.87	50.22	49.13	49.04	45.00	58.61	59.57	60.04	59.30	61.43
Regulatory environment	54.35	52.91	51.39	59.57	59.35	62.35	64.57	69.91	66.74	63.70	65.66	68.04
PFI - Private Finance Initiatives, Const.Mgt. - Construction Management, Mgt. Cont. – Management Contract												

Table 6: Comparison of Concordance Coefficient in Delphi round 3 & round 4

Factors	Concordance of Coefficient (W)			Significance Level	
	R-3	R-4	I (%)	R-3	R-4
Market condition	0.105	0.160	52.38	0.001	0.000
Economic condition & the fiscal policy	0.074	0.096	29.73	0.041	0.012
Technology	0.089	0.172	93.26	0.011	0.000
Socio cultural suitability	0.049	0.135	175.51	0.258	0.021
Regulatory environment	0.089	0.147	65.17	0.011	0.000
R- Round, I - Improvement					

On the other hand, the correlation between the respondents' view with regards to the external environmental factors was also increased. This indicates that the respondents possess closer opinion on the factors influencing the procurement selection. Significant change occurred for the socio cultural suitability, which changed from 0.049 to 0.135. Further, changes have been occurred to other factors such as Technology, Regulatory environment, Market condition and Economic condition & fiscal policy.

5. Conclusions

This study has formulated a list of 14 selection factors through four rounds of comprehensive Delphi survey, and these factors cover various aspects of the external environment. As some factors are interrelated, attempts were made to consolidate related factors using factor analysis. A five-factor solution for the formulation of procurement selection criteria was derived. These five factor categories include "Market condition" (Factor 1); "Economic condition and the fiscal policy" (Factor 2); "Technology" (Factor 3); "Socio cultural suitability" (Factor 4) and "Regulatory environment" (Factor 5). Further, it was also found that Market conditions have significant influence on procurement selection compared to others factors. Except the factor 5, all other factors include related variables which reflect the influence of various aspects of the external environment. Therefore, it can be concluded that beside the commonly considered factors in terms of key selection criteria like client's requirements and project profile, clients should take into account other factors from the operating external environment that influence procurement selection.

Pautz *et al*. [10] stated that the lack of structured procedures, based on good information, for the selection of construction procurement system sometimes inhibits the opportunity for clients to choose a procurement option in a fully informed manner. Therefore, in order to establish procurement selection procedures, clients should formalize a set of suitable procurement selection parameters based on their needs, objectives, project requirements and influence of external environments. The selection criteria established and the utility values derived by this study provides a solid base for clients in initial decision making on the selection of appropriate procurement system for any kind of building projects in the construction industry.

Abstract

Partnering and the related forms of collaboration have been seen as a way of tackling fragmentation and lack of integration that has bedevilled attempts to improve project performance over the years. This represents perhaps the most significant development to date as a means of improving project performance, while offering direct benefits to the whole supply chain. Partnering can have a substantial positive impact on project performance with regards to time, cost, quality and also more general outcomes such as greater innovation and improved user satisfaction. Despite the amount of interest shown in partnering, actual empirical research is rather thin on the ground and much of the work is notable for its prescriptive tendencies and heavy reliance on anecdotal data with the focus on the experience of the exemplar organisations. Conflict and failure could occur by a fundamental deviation in goals, especially in relation to accountability, thus hindering all cooperation that may have been attained by the partnering process. There is case evidence of the failure of partnering to meet performance expectations in construction. Thus it is important to adequately address and evaluate the challenges and potential problems in construction partnering. This paper looks into construction partnering challenges especially cultural and behavioural challenges in the UK. Empirical data is collected from expert opinion to find out the major partnering challenges and their root causes. Also, this paper stages arguments and discussions regarding the importance of the leadership role, in transforming culture, towards a cooperative and caring environment.

Keywords: Partnering, Cultural and behavioural challenges, Expert opinion, Leadership.

1. Background

In recent years there has been a growing interest in the use of partnering in construction [1-5]. This represents perhaps the most significant development to date as a means of improving project performance, while offering direct benefits to the whole supply chain [4, 6]. This needs a powerful change initiative to generate an appropriate project culture by reshaping the approaches and realigning attitudes of different contracting parties [7]. Literature synthesis on partnering shows the significance of cultural and behavioural challenges inhibiting the adoption of partnering arrangements. This paper looks deep into the empirical evidence of cultural and behavioural challenges to arrive at categorised/grouped root causes of these challenges. Furthermore, common to all partnering relationships is the formulation of mutual objectives, trust and an understanding of each other's commitments. It is, however, less than clear about the way in which these essential cultural and behavioural characteristics are tackled in construction partnering projects [2]. It is essential to bring about cultural change, encouraging project participants to go beyond the conflicting interests and to build a shared culture. It is certainly not easy to bring about cultural change to adopt a new set of behaviours as a consistent way of working among the people. To get a deeper level of understanding or to predict the future behaviour correctly one must attempt to get at its shared basic assumptions and taken for granted perceptions [8, 9]. As such, management has the most significant role to play in the transformation of attitudes. The discussion in this paper revolves around the root causes of cultural and behavioural challenges in construction partnering and proposes the necessity of leadership for cultural transformation.

2. Construction partnering

The UK construction industry is one of the strongest in the world, with output ranked top amongst top global construction industries [10]. The industry produces, maintains and adapts around 60% of all fixed capital investment [11]. Thus construction in the UK is considered as one of the pillars of the domestic economy, with its capability to deliver the most difficult and innovative projects, matches that of any other construction industry in the world [12]. Nonetheless there is a deep concern that the industry as a whole is underachieving. Successive independent reviews of construction have emphasised the need to improve the culture, attitude and working practices of the industry.

Change in major projects is driven by major clients and by government, as a means to champion better performance [12-17]. Perhaps the Latham report [15] has proved to be the most significant milestone as it indicated the construction industry especially the public sector should change procedures and methods to incorporate the concept of 'partnering'. Latham's proposals were undoubtedly the influence of the NEDC [18] and CII [19] reports. This initiative was further reinforced by Egan [12] by pointing-out that the UK construction industry languishes in the same unfavourable condition of that of the UK automobile industry in the 1960s. Partnering has been endorsed as one technique that could be easily adopted from 'design to manufacture' industries such as the car industry and retailing, and adapted, it has been argued, to give considerable benefits to all partners involved [20].

In the last decade there has been an enormous amount of interest in the use of partnering and to understand the factors leading to an inhibiting successful collaboration amongst construction firms [1, 4, 21, 22]. Partnering and the related forms of collaboration have been seen as a way of tackling fragmentation and lack of integration that have bedevilled attempts to improve project performance over the years [2]. It seeks to re-design relations between actors in projects by promoting the use of collaborative, more open, less managerial and less hierarchical relationships [13]. Many commentators argue that partnering can have a substantial positive impact on project performance, not only with regard to time, cost and quality objectives. It can also impact more general outcomes such as greater innovation, improved user satisfaction and reduced confrontations between parties, thus enabling an open and non-adversarial contracting environment [15, 23-26].

2.1 Concepts of partnering

According to Moore [27], contracting relationships can be seen in a continuum with 'spot buy' where transactions are purely incidental at one end, whilst 'partnering' at the other end under which the contracting organisations function cooperatively as a team to accomplish the transaction objective. Partnership appears to be a form to encourage integration of the project team and create competitive advantages to all that participate in the project by building stronger personal relationships and trust based on goodwill and cooperation. According to Naoum [16], this concept originated in Japan and the USA in the early 1980s where team building, cooperation and equality, rather than the single-sided relationship of adversaries to a project, were encouraged. A consistent theme discerned through the early construction industry commissioned reports was of fragmentation, short-termism, a lack of trust and a lack of collaboration within the client/design/construction team [11, 12, 15, 17, 20, 28]. These shortfalls were leading to consistently low levels of performance in areas such as cost, time, quality, running costs and fitness for the end user and as a result, when partnership/partnering was first debated in the US [19, 29] it was received with a level of enthusiasm in the UK [20].

As such, partnering has steadily gained popularity from the early 1990s in the UK. Radical changes in the way that the construction industry performs and provides services to customers, particularly those in the public sector has been supported by the British Government and as previously stated, both the private and public sectors in the UK contributed towards the 'client driven' change [12, 15, 16]. Since then, research into construction partnering has become widespread and has been seen as a primary management strategy for improving organisational relations and project performance. However, one thing that became clear from the literature synthesis is that there are many definitions of partnering in construction.

2.2 Partnering – the definitions dilemma

An early definition of partnering came from The US Construction Industry Institute [29] where it was defined as *'A long-term commitment between two or more organisations, for the purpose of achieving specific business objectives, by maximising the effectiveness of each participant's resources'*. It also emphasised the requirement of changing traditional relationships to a shared culture without regard to organisational boundaries, while the relationship is based on trust, dedication to common goals and the understanding of each other's individual expectations and values. Expected benefits included improved efficiency and cost effectiveness, increased opportunity for innovations and the continuous improvement of quality products and services.

This primary concern with maximising effectiveness and efficiency opened the gateway towards new management improvement techniques [20].

However, notwithstanding these definitions, different types of partnering relationships developed in the last decade. According to Matthews et al [30], there are no fixed definitions used when defining partnering in construction although common themes/elements prevail. He also noted that goals and objectives, trust, problem resolution, commitment, continues evaluation, group working and teams, equity, shared risk, win-win philosophy, and collaboration as common elements raised in partnering literature. While there is an agreement about these elements of partnering, there are varying views on its features. This includes a wide range of concepts capturing culture, behaviour, attitudes, values, practices, tools and techniques. According to Crowley and Karim [31], partnering also can be looked at as a process/means that leads to the intended results. In that regard partnering can be defined in one of two ways:

- *by its attributes - such as trust, shared vision, and long-term commitment; and*
- *by its process - whereby partnering is seen as a verb and includes developing mission statements, agreeing goals and conducting partnering workshops.*

Perhaps the most widely accepted definition is that offered by Bennett and Jayes [24] in the seminal work 'the seven pillars of partnering: a guide to second generation partnering'. Here, the idea of partnering revolves around three key principles applies by project teams, identified as:

- *agreeing mutual objectives to take into account the interests of all the firms involved*
- *making decisions openly and resolving problems in a way that was jointly agreed at the start of a project, and*
- *aiming at targets that provide continuous measurable improvement in performance from project to project.*

According to Naoum [16] partnering is a concept which provides a framework for the establishment of mutual objectives among the building team with an attempt to reach an agreed dispute resolution procedure as well as encouraging the principle of continuous improvement. Thus partnering is intended to reduce the adversarialism which is said to be typical in the industry and which has confounded previous attempts to encourage better integration and cooperation between contractual partners [12, 15, 32]. According to Li et al, [33] partnering is an establishment of an informal group among construction partners and creates non-legitimate but permanent relationships and is used to resolve disruptive inter-organisational conflicts.

Furthermore, mutual trust and understanding of each others commitments appears to be the prerequisites of changing traditional relationships to a shared culture in partnering [16, 25]. Ultimately partnering is about management of the relationship that must be trust-based [27]. Bresnen and Marshall [2] reinforce the requirement for the change in attitudinal and behavioural characteristics to achieve mutual trust. Barlow et al. [34] succinctly argues that, to achieve mutual trust, organisations must ensure that individual goals are not placed ahead of the team alliance. He also supports the idea of "gain-sharing" which effectively relates improvements back to all the participants. All these point out that partnering is built upon the attitudinal and behavioural characteristics of participants which lead towards mutual trust in order to move away from the traditional adversarial culture of the construction industry.

2.3 Benefits attributable to partnering

Several studies indicate that there is little doubt about the positive aspects of partnering arrangements [4]. Bennett and Jayes [24] suggest that performance, in terms of cost, time, quality, build-ability, fitness-for-purpose and a whole range of other criteria, can be dramatically improved if participants adopt more collaborative ways of working. Furthermore they illustrate ways to create undefined win-win relationships that involve a sophisticated strategy and require a willingness to improve the joint performance. Their research cites a remarkable potential savings of 40–50% in both cost and time [4]. However, the benefits were often cited in terms of cost and time [16] ignoring the other benefits to the team players which are more difficult to assess. This section briefly identifies and illustrates the common benefits of partnering cited in various partnering related literature.

Most of the research lists cost savings as the main advantage in employing partnering in construction. Chan et al. [35] suggests that partnering has great potential to improve cost performance and reduce the risk of budget overruns. There are many reasons quoted for better cost performance, such as: alleviating rework; reduction in variation; lower change order rates; maximised value engineering; reduction in costs of developing and supporting productive relationships; lower administrative and paper work; reducing scheduled time; reduction in scope definition problems, effective problem solving, and shared project risk [35-37]. As mentioned, better time control and reduced dispute and litigation contribute towards improved cost performance. Furthermore, Black et al. [38] believe that medium to long-term relationships compress the normal learning curve and thereby reduce the normal costs of developing and supporting productive relationships between the parties.

According to Chan et al. [35], an effective partnering agreement improves project quality by replacing the potentially adversarial traditional relationship and case building with an atmosphere that fosters a team approach to achieve a set of common goals. Partnering also provides a way for all parties to develop continuous improvement. With this joint effort and long-term focus barriers to improvement are eliminated. Hellard [37] suggests that partnering can increase the potential for innovation by encouraging partners to evaluate advanced technology for its applicability. These in turn produce high quality construction and service and reduce engineering rework [33, 38]. As one of the other quality benefits, the safety performance can be enhanced as partners better understand each other, taking joint responsibility to ensure a safe working environment for all parties [35].

Working with suppliers can improve the capacity of the organisation to meet the client's programme, quality, flexibility and cost requirements. According to Black et al. [38], one of the key benefits of partnering is the resultant synergy between project participants, enabling constant improvement in the key variables. In particular, the early involvement of contractors in the design stage can assist in constructability input and maximising value engineering, thus improving both cost and schedule [2]. Also, a fair and equitable attitude from project participants jointly resolves many disputes, discrepancies and changed conditions that arise during construction. Gransberg and Dillon [39] found that fewer numbers of liquidated damages were imposed on the partnered projects than the non-partnered ones.

As the partnering literature points out, a mechanism for problem solving is an inherent part of the concept [35]. Thus partnering aims to reduce adversarial relationship that will allow focus on mutual goals to the benefit of both parties [16, 38]. This encourages mutual trust and gain sharing which results in closer relationship, providing a better environment for the project [35, 40]. Improved culture enhances open communication between the project participants resulting in the elimination of blame shifting. Improved customer focus, augmented involvement of team members and joint satisfaction of stakeholders are achieved through this. Since partnering is seen as a recipe for potential benefits, its success factors are worthy of in-depth investigation. There is a lack of attention to these critical factors that needs to be addressed if partnering is to be successfully implemented as a strategy for performance improvement [41].

2.4 Critical success factors of partnering

Critical success factors are the key areas that are essential for management success. Cheng et al. [41] suggested that partnering can become successful by using pertinent management skills and developing a favourable context. It is essential to create an appropriate environment in which inter-organisational relationship can flourish. Management skills are vital for effective control of the relationships. They form the basis for initiating and facilitating the partnering process. Similarly some partnering characteristics can affect the partnering relationships. In consequence, it is important to identify these critical characteristics that form the favourable context conducive to partnering success.

Partnering requires timely communication of information and it encourages open, direct lines of communication among project participants [37]. Effective communication skills can help organisations to facilitate the exchange of ideas and visions, which can result in fewer misunderstandings and stimulate mutual trust. Similarly, effective coordination can result in achievement of stability in an uncertain environment by the creation of additional contact points between parties to share project information [41]. The other critical management skill is ‘productive conflict resolution’ which can be achieved by joint problem solving in order to seek alternatives for problematic issues. Conflict resolution techniques such as coercion and confrontation are counterproductive and fail to reach a win-win situation [41]. Furthermore, regular monitoring and early implementation of partnering process are essential to ensure partnering success [42].

Similarly, some of the critical characteristics form the favourable context conducive to partnering by establishing interdependence and self-willingness to work for the long-lasting cohesive relationship. Most of these contextual characteristics are soft critical success factors such as, top management support, long term commitment, mutual trust, willingness to share resources and commitment to win-win attitude [33, 41, 42]. Support from top management is always a prerequisite to initiate and lead a successful partnering arrangement. Commitment to win-win attitude represents the open airing of problems among parties and encourages risk sharing, rewards and willingness to exchange ideas [42]. This leads towards sharing of resources that can be used to strengthen the competitiveness and construction capability of a partnering relationship. However, there is a tendency within the partnering literature to concentrate on success stories [4]. Conflict and failure could occur by a fundamental deviation in goals, especially in relation to accountability, thus hindering all cooperation that may have been attained by the partnering process [43]. There is case evidence of the failure of partnering to meet performance expectations in construction [25]. Thus it is important to adequately address and evaluate the challenges and potential problems in construction partnering.

3. Partnering challenges and problematic issues

The concept of partnering, overhauls the ethics of traditional contracting with the paradigm shift towards cooperative and caring environments. According to Naoum [16] successful partnering could attain a win-win solution and gain sharing. In general, with a cultural shift in attitudes project partnering can be successful and bring benefits to the stakeholders involved in the process [43]. However, changing traditional relationships to a shared culture requires mutual trust and dedication to common goals [3, 4, 44]. An absence of mutual trust and scepticism within participants may result in various problematic issues.

According to Lendrum [1998 cited 43] a lack of open and honest communication may lead to degradation in the stakeholders' ability to efficiently resolve any problems. Thomas et al. [43] identified a lack of empowerment and technical knowledge from the client's side and usage of competitive tendering, failure to include key suppliers and subcontractors together, with lack of training as some of the main problematic issues in partnering projects. They argued that the role of client as the head facilitator of the partnering arrangement should take a leadership role, and ensure full commitment and correct facilitation throughout the entire duration of the projects. It was identified that the majority of problematic issues experienced in project partnering arrangements were related to the commitment provided to the attitudinal change and procedural implementation required in efficient project partnering [43].
