Preface

This proceedings contains the full papers of keynotes and papers submitted to, peer reviewed and accepted for the CIB International Conference on Building Education and Research (BEAR 2008), held from 11th – 15th February 2008 at Heritance Kandalama, Sri Lanka. The contributions reflect the call for papers of the following CIB Working Commissions and
Task Groups:

CIB W89 (Building Education and Research)
CIB W113 (Law and Dispute Resolution)
CIB TG53 (Postgraduate Research Training in Building and Construction)
CIB TG63 (Disasters and the Built Environment)
CIB TG67 (Statutory Adjudication in Construction)
CIB TG68 (Construction Mediation)
CIB TG69 (Green Buildings and the Law)

BEAR 2008 was collaboration by a number of CIB commissions: CIB W89, W113, TG53, TG63, TG67, TG68 and TG69, CIB International Student Chapters, and EURASIA, a three year EU Asia-Link programme funded project that aims to improve capacity in training, teaching and research activities associated with the creation and long-term management of public and commercial facilities and infrastructure in selected Higher Educational Institutes in Asia and Europe. All EURASIA partners - University of Moratuwa and University of Ruhuna in Sri Lanka, Tallinn University of Technology in Estonia, and Vilnius Gediminas Technical University in Lithuania – were able to join the University of Salford for this event.

In line with the Asia Link EURASIA concept, a major theme for the 2008 BEAR Conference was to promote built environment related education and research towards a more expansive view of the life cycle of infrastructure projects, one that extends beyond the traditional cycle of feasibility analysis, planning, design, construction, operation, maintenance and divestiture. This revised life cycle should encompass the building and construction professional's ability to anticipate and respond to unexpected events that damage or destroy an infrastructure project – from earthquakes and climate change to terrorist attacks – and reflect construction's ongoing responsibility toward an infrastructure's users. The role of building and construction industry professionals and local communities in developing resilience to these types of disasters can be viewed as two separate yet interrelated aspects: To create a built environment that is not vulnerable to a disaster or disruptive challenge. This relates to the resilience of the physical state of infrastructure, buildings and cities as well as developing policies, legal and regulatory controls, and practices that govern the building industry to build safe structures. Essentially this means building cities or infrastructure that will not be affected by a disaster, and to develop organisational structures, capacities through education and training, and construction systems, that can react in the event a disruptive challenge does occur. This means responding to the immediate after effects of a disaster to restore operational conditions of infrastructure or the built environment as quickly as possible. This means also to aid in the speedy recovery of the region through sustainable reconstruction, post-disaster building or other related projects.

It is evident that the CIB network of experts and member organisations active in the research community, in industry and in education, has a wide range of expertise to offer in addressing disaster related challenges. The BEAR Conference was an intriguing opportunity to bring together the interests and expertise of these wide-ranging Working Commissions and Task Groups to discuss and attempt to address the complex and global problems associated with anticipating and responding to unexpected events that damage or destroy an infrastructure project. The Conference provided an ideal backdrop for CIB members to identify challenges and opportunities, develop synergy, and collaborate on future work. It is hoped that a series of cross-commission and task group initiatives and workings may ensue.

The conference was held in Sri Lanka, an island situated in the Indian Ocean, at the base of the Indian Sub-Continent. It is a multi-ethnic, multi-religious country with a diverse and rich culture. Sri Lanka was severely affected by the tsunami on 26 December 2004, which killed some 40,000 people and displaced 400 – 500 thousand people along two thirds of the northeast, south and south-west coastline. Half the fishing fleet was destroyed, and a quarter of hotels in the affected areas sustained serious damage. It is our hope that Sri Lanka will benefit greatly from the research and activities of W89 and commissions and task groups, and that the country provided an appropriate backdrop for tackling challenging questions on built environment education and research.

The Conference provided a forum for researchers worldwide to debate and exchange ideas and experiences on a broad range of issues related to built and human environment research. All of the papers were selected on the basis of strict review by the Scientific Committee members to ensure a good quality standard. The conference had a broad scope and covered wide ranging topics which were organised around the following themes:

Capacity Building
Construction Management
Cost Planning and Control
Curriculum Development
Design
Developing the Law Curriculum in Built
Environment Education
Disaster Mitigation
Education
E-learning
Environmental Management
Facilities Management
Information and Communication Technology
International and Comparative Law in the Built Environment
Legal Scholarship and Research within the Built Environment Discipline
Post-Disaster Reconstruction
Post-Disaster Relief
Procurement
Skill Development
Sustainability

The conference program and the structure of this proceedings all reflect these themes. The papers on this proceedings were developed by authors which includes background issues, literature reviews, problem-solving processes, decisions and conclusions. All papers appearing in the proceedings were reviewed in their entirety, prior to publication, by the International Scientific Committee comprising independent, qualified experts. Editors would like to extend their sincere gratitude to all the authors of the published contributions for their excellent work and participants at BEAR 2008. Executive summaries of the papers included within this proceedings can be fund as a bound book, produced separately.

There were five keynote addresses from leading academics: Professor Peter Barrett, President of the CIB; Professor Malik Ranasinghe, Vice Chancellor, The University of Moratuwa, Sri Lanka; Professor John Ratcliffe, Director of the Faculty of the Built Environment, Dublin Institute of Technology, The Republic of Ireland; Conrad de Tissera UN HABITAT Programme Manager for Sri Lanka, United Nations Human Settlements Programme Colombo, Sri Lanka; and, Associate Professor Vasantha Abeysekera, Programme Leader Construction Management Programmes, AUT University, Auckland, New Zealand. These keynote addresses provide a global perspective and vision for built environment research, as the, "development of research and other skills" has permeated the whole higher education sector.

Editors

About the Editors

Dr Richard Haigh is a lecturer at the School of the Built Environment, University of Salford, UK and an active researcher in disaster management with a particular interest in capacity building and corporate social responsibility. Richard is also the Programme Director for a new Disaster Mitigation and Reconstruction Masters programme that the School is launching in autumn 2008, and joint-coordinator of CIB Task Group 63: Disasters and the Built Environment, a network of 58 Higher Education Institutes across 27 countries. Richard is joint principal investigator of EURASIA, an EU Asia-Link funded network project that aims to enhance the capacity of the partner institutions for training, teaching and research activities required for the creation and long-term management of public and commercial facilities and infrastructure.

(E-mail: r.p.haigh@salford.ac.uk)

Professor Dilanthi Amaratunga holds a chair at the School of the Built Environment at the University of Salford, UK. She is an active researcher in the field of capability and capacity building in the built environment, with a particular interest in disaster management. She has nearly 200 published papers, and has successfully managed several research projects. She is the Coordinator of CIB TG53, which aims to improve the availability of skilled researchers in building education and research through the development of researchers' capacity to produce, transfer and utilise knowledge. She is also the Co-chair of World Bank/UN HABITAT supported working group on Disaster Management in Developing CountriesHer other research interests are: gender, disasters and construction; research informed teaching.

Conference Organisers

The Conference was organised by:

School of the Built Environment, University of Salford, UK
CIB, International Council for Research and Innovation in Building and Construction

Local Organisers and Hosts

Department of Building Economics, University of Moratuwa, Sri Lanka
Department of Civil and Environmental Engineering, University of Ruhuna, Sri Lanka

In association with

Department of Building Production, Tallinn University of Technology, Estonia
Department of Construction Economics and Property Management, Vilnius Gediminas Technical University, Lithuania

Organising Committee

Chairs

Dr Richard Haigh, University of Salford, UK
Professor Dilanthi Amaratunga, University of Salford, UK

Technical Director

Kaushal Keraminiyage, University of Salford, UK

Members

Dr Nayana Alagiyawanna, University of Ruhuna, Sri Lanka
Professor Martin Betts, Queensland University of Technology, Australia
Nayanathara De Silva, University of Moratuwa, Sri Lanka
Gayani Elvitigala, University of Salford, UK
Rasansara Gunasekera, University of Salford, UK
Suranga Jayasena, University of Moratuwa, Sri Lanka
Professor Arturas Kaklauskas, Vilnius Gediminas Technical University, Lithuania
Professor Mel Lees, University of Salford, UK
Professor Irene Lill, Tallinn University of Technology, Estonia
Kanchana Perera, University of Moratuwa, Sri Lanka
Dr R. Rameezdeen, University of Moratuwa, Sri Lanka
Dr Sepani Senaratne, University of Moratuwa, Sri Lanka
Indunil Seneviratne, University of Moratuwa, Sri Lanka
Menaha Shanmugam, University of Salford, UK
Professor Chitra Weddikkara, University of Moratuwa, Sri Lanka

Scientific Committee

Chairs

Dr Richard Haigh, University of Salford, UK
Professor Dilanthi Amaratunga, University of Salford, UK

Members

Associate Professor Vasantha Abeysekara, AUT University, New Zealand
Dr Nayana Alagiyawanna, University of Ruhuna, Sri Lanka
Professor Chimay Anumba, Pennsylvania State University, USA
Professor Allan Ashworth, University of Salford, UK
David Baldry, University of Salford, UK
Professor Peter Barrett, University of Salford, UK
Adrian Bennett, Building Research, New Zealand
Professor Martin Betts, Queensland University of Technology, Australia
Dr Penny Brooker, University of Wolverhampton, UK
Professor Albert Chan, Hong Kong Polytechnic University, HK, PR China
Professor Edwin Chan, Hong Kong Polytechnic University, HK, PR China
Dr Sai On Cheung, City University of Hong Kong, HK, PR China
Dr Alice Christudason, National University of Singapore, Singapore
Paul Chynoweth, University of Salford, UK
Jeremy Coggins, University of South Australia, Australia
Professor Andrew Dainty, Loughborough University, UK
Nayanthara De Silva, University of Moratuwa, Sri Lanka
David Dowdle, University of Salford, UK
Professor Charles Egbu, University of Salford, UK
Gayani Elvitigalage, University of Salford, UK
Professor Chris Fortune, University of Salford, UK
Kanchana Ginige, University of Salford, UK
Professor Mike Hoxley, Nottingham Trent University, UK
Dr Bingu Ingirige, University of Salford, UK
Suranga Jayasena, University of Moratuwa, Sri Lanka
Dr Cassidy Johnson, University College London, UK
Professor Arturas Kaklauskas, Vilnius Gediminas Technical University, Lithuania
Kaushal Keraminiyage, University of Salford, UK
Kushan Kulatunga, University of Salford, UK
Udayangani Kulatunga, University of Salford, UK
Professor Mohan Kumaraswamy, University of Hong Kong, HK, PR China
Professor Anthony Lavers, White and Case, UK
Professor Mel Lees, University of Salford, UK
Professor Irene Lill, Tallinn University of Technology, Estonia
Dr Champika Liyanage, University of Manchester, UK
Jim Mason, University of the West of England, UK
Dr Issaka Ndekugri, University of Wolverhampton, UK
Rita Newton, University of Salford, UK
Professor George Ofori, National University of Singapore, Singapore
Professor Marcus Ormerod, University of Salford, UK
Roshani Palliyaguru, University of Salford, UK
Dr Chaminda Pathirage, University of Salford, UK
Dr Srinath Perera, University of Ulster, Northern Ireland
Kanchana Perera, University of Moratuwa, Sri Lanka
Keith Potts, University of Wolverhampton, UK
Professor John Ratcliffe, Dublin Institute of Technology, Republic of Ireland
Professor Les Ruddock, University of Salford, UK
Dr Sepani Senaratne, University of Moratuwa, Sri Lanka
Professor Martin Sexton, University of Salford, UK
Menaha Shanmugam, University of Salford, UK

Dr Amarjit Singh, University of Hawaii, USA
Nuwani Siriwardena, University of Salford, UK
Professor Ming Sun, University of West of England, UK
Niraj Thurairajah, University of Salford, UK
Dr Linda Thomas-Mobley, Georgia Institute of Technology, USA
Dr Sunil Vather, Building Research, New Zealand
Dr K.S. Wanniarachchi, University of Ruhuna, Sri Lanka
Professor Chris Webster, Cardiff University, UK
Professor Chitra Weddikkara, University of Moratuwa, Sri Lanka
Associate Professor Suzanne Wilkinson, University of Auckland, New Zealand
Aled Williams, University of Salford, UK
Professor Francis Wong, Hong Kong Polytechnic University, HK, PR China
Gerard Wood, University of Salford, UK
Dr Jay Yang, Queensland University of Technology, Australia

EURASIA (European and Asian Infrastructure Advantage)

The 2008 Building Education and Research Conference was held in association with EURASIA (European and Asian Infrastructure Advantage).The EURASIA project is an International research collaboration between Asia and Europe. The partnership includes: University of Salford, UK; University of Moratuwa, Sri Lanka; University of Ruhuna, Sri Lanka; Tallinn University of Technology, Estonia; and, Vilnius Gediminas Technical University, Lithuania.

There is growing recognition of a need to enhance the capacities of Higher Education Institutions (HEIs) worldwide to cater for the challenges facing the world today. In particular, the increasing numbers of disasters that impact communities across the world make it an imperative that knowledge on facilities and infrastructure management is developed to meet the demands of disaster mitigation and reconstruction challenges. In response, the EURASIA project aims to improve capacity in training, teaching and research activities associated with the creation and long-term management of public and commercial facilities and infrastructure in selected HEIs in Asia and Europe. In response, the programme specifically aims to enhance the capacity of the partner institutions for training, teaching and research activities required for the creation and long term management of public and commercial facilities and infrastructure. In doing so, the project will support the ongoing recovery programmes set up in Sri Lanka following the Indian Ocean Tsunami of December 2004. Overall, the Tsunami affected 2/3rds of the coastline of Sri Lanka. It resulted in the destruction of more than 100,000 houses and the discontinuance of several livelihoods such as fishing, farming, tourism and handicrafts-related activities. The post-Tsunami rehabilitation operation has been affected due to unprepared local government institutions with poor response capacities to address the needs of such a magnitude. This is mainly because, before the Tsunami, Sri Lanka was known to be a safe haven where outrages of nature scarcely occurred except for occasional floods and landslides during the rainy seasons. Thus, by enhancing the capacities of partner institutions, specifically in Sri Lanka, it is anticipated that Sri Lanka will be able to take up the challenge of post tsunami recovery more strongly and successfully. The major activities of this research programme include:

- Development of a professionally accredited postgraduate curriculum on the creation and long term management of public and commercial facilities and elements of infrastructure, to be used in all the partner institutions
- A split-site PhD programme for nominated staff of Sri Lankan partner Universities to enhance their capacity for teaching and research in the field of Disaster management
- A major International Conference in Sri Lanka with a theme of creation and long-term management of public and commercial facilities and infrastructure
- Developing and improving the professional and research skills of partner Institutions' staff and postgraduate students
- Improving and consolidating academic networks through systematic exchanges so as to establish a sustainable link between EU and Sri Lankan partner Universities
- Disseminating knowledge and interpreting information through joint publications, lectures, seminars and conferences

EURASIA is funded through the EU's Asia Link Programme, dedicated to fostering regional and multilateral networking between Higher Education institutions in the EU and Asia. As part of the project, a Virtual Environment for Built Environment Researchers (VEBER) has been set up which provides a broad range of functionality that will facilitate research activities among the partner institutions. The Salford team, in collaboration with its Sri Lankan partners, is now working towards setting up a web portal to share information on the post-tsunami response, with specific reference to case material in Sri Lanka. This work will be linked with other disaster management initiatives undertaken by the Salford team, such as activities associated with the recently established CIB Task Group 63: Disaster Management and the Built Environment.

Further information on EURASIA can be obtained from: www.eurasia.buhu.salford.ac.uk.

The Asia Link Programme

The Asia-Link Programme was launched at the beginning of 2002 as an initiative by the European Union (EU) to foster regional and multilateral networking between higher education institutions in European Union Member States and South Asia, Southeast Asia and China. This five-year programme, which has a total budget of £40 million, aims to provide support to European and Asian higher education institutions in the areas of human resource development, curriculum development and institutional and systems development.

The document has been produced with the financial assistance of the European Union. The contents of this document are the sole responsibility of the Editors
and can under no circumstances be regarded as reflecting the position of the European Union.

Keynote Speakers

Professor Peter Barrett

CIB President & Pro-Vice-Chancellor Research, University of Salford

Professor Barrett is Pro-Vice Chancellor for Research and Graduate Studies at the University of Salford where he is also a long-time member and ex-director of Salford's 6* (top) rated Research Institute for the Built and Human Environment. He is also Chairman of SCRI, a £5M programme of research funded by the UK research council. He has been active in the CIB for many years, including as coordinator of W65 (organisation and management of construction). More recently he was Chair of the CIB Programme Committee and has now been elected President of the CIB for 2007 - 2010. Peter has led numerous construction management research projects over the last 15 years and has published over one hundred and sixty single volume reports and refereed papers. After becoming the first Chartered Building Surveyor to gain a PhD, Peter established the postgraduate programme of research at Salford which now supports around 160 research students. He is currently championing the CIB's proactive theme of Revaluing Construction, an important element of which is the "Awareness of the Systemic Contribution" of the built environment.

Professor Malik Ranasinghe

Vice Chancellor, The University of Moratuwa, Sri Lanka

Professor Ranasinghe is the Vice Chancellor and a Professor in Civil Engineering at the University of Moratuwa (UoM). He is the immediate past Dean, Faculty of Engineering and a former Chairman, Centre of Excellence in Project Management at UoM. Prof. Ranasinghe is a Professional and Chartered Engineer, a Fellow of the Institution of Engineers, Sri Lanka and the National Academy of Science, Sri Lanka. He is also a Director on the Board of Directors of The Colombo Stock Exchange, Sri Lanka. In March 2000, Prof. Ranasinghe was appointed as the Head of the Department of Civil Engineering at the UoM, where he lead and managed the largest academic Department with over 40 senior academic staff. As a result of his unobtrusive leadership as Head of the Department of Civil Engineering, the Faculty of Engineering elected him unanimously to be their Dean in March 2001. The Faculty of Engineering at UoM is the largest Engineering Faculty in Sri Lanka with over 3500 undergraduate and postgraduate students. Prof. Ranasinghe's vision as the Vice Chancellor is to produce world class graduates at the UoM, in an environment that provides a rewarding experience for its students and staff.

Professor John Ratcliffe

Director of the Faculty of the Built Environment, Dublin Institute of Technology, The Republic of Ireland

John Ratcliffe is a chartered planning and development surveyor with almost forty years experience as a consultant and academic in the fields of urban planning and real estate development. Currently he is Director and Dean of the Faculty of the Built Environment at the Dublin Institute of Technology, which is the largest university level institution in the Republic of Ireland, and Founder and Chairman of The Futures Academy there. He is also an Honorary Visiting Professor at the University of Salford and the University of Lincoln as well as an Associate of the futures consultancy Outsights in the UK. Over the past decade he has acquired a particular expertise in the futures field, with special reference to the sustainable development of city regions. A special interest of Professor Ratcliffe at the moment is the nature and development of responsible business practice.

Conrad de Tissera

UN HABITAT Programme Manager for Sri Lanka, United Nations Human Settlements Programme Colombo, Sri Lanka

UN–HABITAT has a long history of cooperation in Sri Lanka and has pioneered innovative approaches in community rebuilding of housing and basic urban services and infrastructure delivery. As the UNHABITAT Programme Manager, Conrad de Tissera currently leads several post tsunami rebuilding community infrastructure & shelter projects, enabling the target communities to rebuild essential physical facilities, including shelter, so that they can restart functioning as normal communities, helping to create wage employment from the investment of the rebuilding process as a way of contributing to the recovery of the local economy and rebuilding self-confidence and restoring human dignity. Conrad has a B Sc. Engineering and a M Sc. in Soil Mechanics and Foundation Engineering, and has served as the head of the National Building Research Organisation in Sri Lanka. He further has over 40 years of construction industry experience and has been the Director General of the Institute of Construction Training and Development of Sri Lanka and Secretary of the Ministry of Housing and Construction during his long standing career. In his role as a visiting lecturer, he has also shared his practical experience with university graduates whenever he has had the opportunity.

Associate Professor Vasantha Abeysekera

Programme Leader, Construction Management Programmes, AUT University, Auckland, New Zealand

Dr Vasantha Abeysekera is a Sri Lankan New Zealander. He is the Associate Professor of Construction Management at AUT University in Auckland in New Zealand and heads the construction management programmes. He graduated with a first class in civil engineer from the University of Moratuwa and obtained his master's and doctorate in construction management from the Loughborough University, UK. He maintains professional memberships with engineering and quantity surveying associations in addition to various other professional bodies. In a career spanning over 25 years, with almost half in industry and the rest in academia, Dr Abeysekera has been involved in diverse roles in Asia, Africa and Oceania, He currently focusses on teaching and research with RD&D interests in, security of payment and contract retentions, health and safety, and time management.

(email: p.s.barrett@salford.ac.uk)

Complexity, Connections and Consciousness

Professor Peter Barrett,
President of the CIB

Abstract

This presentation will seek to link thematically the areas of disaster management (DM), education in the built environment and the activities and aspirations of the CIB.

In recent years DM has rightly come into focus for many construction researchers. It has, however, become apparent that, although the disaster itself is the most evident aspect that demands attention, it is important not to overlook the periods before and after the disaster. It is in these times that there is the opportunity to mitigate or at least prepare before a disaster and afterwards there is the long haul back to a new normality. Both of these periods deserve attention and broaden considerably the scope of DM research.

Implicit in this view is the need to educate people so that there is the technical and organisational capacity to respond. This involves being able to:

- analyse potentially hazardous situations
- engineer technical solutions
- organise the delivery of these solutions
- handle the associated social and economic issues
- sustain the effort through very different phases, that will last several years

The scope of the last two of this list in particular highlight the complexity of the skills required. Technical issues must be addressed in fractured social contexts, which are both shifting through radically different phases, once the initial basic demands have been met. So the education of construction professionals must fit these people to be able to deal with this *complexity*, both individually and collectively. Interestingly, the characteristics evident for DM are quite generally needed amongst construction professionals. The need to deal coherently with complexity links to the necessity of making *connections*, both in terms of connecting specialists in multi-disciplinary working and strongly connecting the processes into and out of the construction phase.

These dimensions of connection lead to consideration of the mind-set those involved have towards the scope of the issues involved. Everyone involved needs to have strong specialist knowledge and skills to contribute, but they equally need a broad *consciousness* of the purposes of construction as a contributor to and part of society more generally. This is most easily evident around understanding and responding to the role of clients and users of buildings and built

infrastructure, but extends to wider social, environmental and economic issues. This has challenging implications for the education of built environment professionals.

The CIB brings together over 2000 experts in 60 countries and has for over 50 years covered a wide range of hard, technical and soft, social topics, through around 50 working groups. Central to the CIB is an acceptance of the *complexity* of construction related issues and to work to address this by making *connections* between relevant experts. Over recent years there has been a deepening understanding that this connectivity has to run powerfully through the whole life cycle of a building / facility strongly addressing the contribution made to clients, users and society. This trend involves a shift in *consciousness* that sees construction as a key means to creating value, but not an end in itself. Thus, the four CIB priority themes that cross-cut the work of the working groups, address both the demand side, with emphases on sustainable development and clients' needs, and the supply side, with pushes in the areas of "revaluing" the capacity of construction industries and achieving integrated design solutions at the project level.

And of course, the CIB also has working groups specialising in education and disaster management!

Stakeholder Consultation in the Decision Making for Development Projects using Educated Trade-offs

Professor Malik Ranasinghe
Vice-Chancellor, University of Moratuwa, Sri Lanka
(email: vc@mrt.ac.lk)

Abstract

The recovery from the Tsunami that struck Sri Lanka in 2004 was hampered by a decision taken by the Government of Sri Lanka (GOSL) not to permit reconstruction of any building 100 meters from the coastline, even if the property right was privately owned and the reconstruction/rehabilitation was carried out without any support from the GOSL. This decision taken without any consultation with those who were affected, the stakeholders, severely delayed the recovery from the Tsunami.

When resources are scares, stakeholders' judgments on trade-offs between different resource uses tend to be emotional than rational. As such, stakeholders need to be well informed on all aspects of conflicting issues, to make rational decisions on trade-offs between limited natural resources. A five-step framework to formulate 'educated trade-offs' is proposed which can be used as a tool for effective stakeholder consultation in the decision making of development projects. This paper focuses on the application of the framework to the conflicting issues related to clay mining in Sri Lanka.

The term 'educated trade-off' means that stakeholders are able to engage in technically, economically and environmentally (including socially) informed (educated) decision-making between the critical resource uses (trade-offs) in development projects. The conflicting uses/issues of the development project are identified through the consultation of key stakeholders. The critical bounds of the technical requirements of the conflicting resource uses/issues identified are first estimated. The economic value and the environmental value of the respective critical bound of the technical requirements are then estimated. Combining the economic and the environmental value of critical bounds, "educated trade-offs" for stakeholder consultations are established.

Keywords: educated trade-offs, stakeholder consultation, economic values, environmental values, clay mining

1. Introduction

The recovery from the devastating Tsunami that struck Sri Lanka on 26 December 2004 was severely hampered by a decision taken by the Government of Sri Lanka (GOSL) not to permit reconstruction of any building 100 meters from the coastline, even if the property right was privately owned and the reconstruction/rehabilitation was carried out without any support from the GOSL. This decision taken without any consultation with those who were affected, the stakeholders, delayed the recovery from the Tsunami. Even though this decision was subsequently revoked by the GOSL, it caused numerous hardship and anxiety to those stakeholders who were in a position to return and reconstruct their damaged property themselves.

Stakeholder involvement (consultation and participation) is an essential but an often-ignored aspect of decision making for development projects in all sectors. In the past, most development activities were planned and implemented independently, where the decisions were based on sectoral interests (e.g. hydropower, irrigation, mining of clay on river banks) and were primarily for economic or political benefit.

The environmental and social impacts of such sectoral activities, especially impacts on other stakeholders are generally not known and are often neglected at the design and planning stages [1]. Most of the negative long-term impacts including adverse effects of degradation of the environment and other ecological problems of such activities/projects are realized only long after the projects have been implemented [2].

With the realization of the importance of the social and environmental impacts of development projects, stakeholder involvement has been identified as an aspect that goes hand in hand with the technical development of a project enabling adjustments needed from time to time. With attempts at 'integrated river basin management', a wider stakeholder involvement has been used increasingly in the recent past in river basin projects [3], [4], [5], [6], [7].

There are two important recent research projects on stakeholder participation in integrated river basin management, European Union HarmoniCOP (Harmonising Collaborative Planning) Project [8] consisting of nine European countries and Illinois River basin study consisting of three states in the United States of America [9].

The EU HarmoniCOP project attempts to give a comprehensive overview and analysis of the state of the art in participatory River Basin Management Planning (RBMP) in Europe, using a social-learning perspective. It also addresses scale issue in public participation and RBMP in a systematic way and uses information and information tools as a means for social learning in participatory RBMP in different national, cultural, geographical, institutional and legal contexts [8]. The Illinois River basin study attempts to advance stakeholder consensus through an interactive process of communication, analysis, education and deliberation by providing stakeholders with sufficient information, analysis and imagery to enable them to arrive at a consensus on polices that can be successfully adapted and implemented [9].

With motivation from the above two studies, [8], [9], a framework is formulated to estimate the 'educated trade-offs' which is a tool for the stakeholders of development projects to make intelligent decisions between the different uses of limited natural resources [10]. The term 'educated trade-offs' means that stakeholders are able to engage in technically, economically and environmentally (including socially) informed (educated) decision-making between the critical resource uses/issues (trade-offs). The framework attempts to identify the key impacted stakeholders, the key social and environmental impacts and then to value them.

The objective of this paper is to describe and demonstrate the versatility of the framework developed to formulate ‘educated trade-offs’, which can be used as a tool for effective stakeholder consultation in the decision making of development projects. The next section describes the framework. The conflicting issues related to clay mining on the lower reaches of the Ma Oya river basin in Sri Lanka is used to demonstrate the versatility of the framework in the third section. The conclusions on the application of the developed framework to clay mining in Sri Lanka are stated in the fourth section.

2. Educated Trade-off Framework

1. The framework consisting of the five steps to determine educated trade-offs is as follows.
2. Identify the multiple stakeholders and the resource uses/issues that need stakeholder consultation for the development project.
3. Bound technical requirements of the resource uses/issues.
4. Estimate economic value of the critical bound of the technical requirement of the resource uses/issues.
5. Estimate environmental (including social) value of the critical bound of the technical requirement of the resource uses/issues

Estimate net value of the critical bound of the technical requirement of the resource uses/issues by combining the economic and environmental (including social) values.

2.1 Step 1 - Identify the Multiple Stakeholders and the Resource Uses/ Issues that need Stakeholder Participation

This step identifies the multiple stakeholders and the resource uses/issues, which need to be addressed through stakeholder consultation. Development projects are complex and in that they involve many different stakeholders with divergent views and expectations [11]. For example in a river basin, the interest of stakeholders could be of many folds; how they are linked to the basin, use of resources, restrictions faced by them with respect to the use of resources, awareness of negative impacts of their uses, concern for environment and other uses. The stakeholders also represent a variety of sectors such as government administrative authorities, line ministries and agencies, NGO’s, other formal and informal groups, and as individuals. Besides the education level, age and gender are also important factors to be considered in selecting a representative group of stakeholders for data collection as well as for decision-making.

In any development project four main categories of stakeholders are possible [11].

- Directly affected people: those who reside and derive their living from areas where the project will have a direct impact.
- Indirectly affected people –Those who reside near project area or relies on resources in the project area and will have to change or adjust their livelihoods.
- Government and public sector agencies – Ministries, provincial, district or local government agencies such as those responsible for land, water resources, agriculture.
- Other stakeholders – project donors, NGOs with a direct interest in the project, external advisors, consultants and private sector.

In the case of a new development project, the identification should include all present resource use sectors, possible future developments and environmental concerns and to screen for the sectors, which will be significantly impacted by the development project. For existing issues, like clay mining the concerns raised by the different categories of stakeholders are the starting point to apply the framework.

For example, the critical issues in the Ma Oya river basin at the mid reaches are sand mining, discharging of pollutants by industries, extraction of water to supply urban areas. At the lower reaches the above issues are expanded to include clay mining and maintaining the ground water level to provide fertility to the lands in the basin. Decisions with regard to limitations in critical issues such as sand and clay mining and the allocations for water extraction/consumption issues will have to be made using educated trade-offs starting through stakeholder consultation.

2.2 Step 2 - Bound Technical Requirements of Natural Resource Uses/Issues

In this step, the engineering knowledge is utilized to estimate the critical bounds of the technical requirements for utilization of the different resource uses of the development project. For example in the Ma Oya river basin issues dominated by water such as requirements for human consumption, water supply and environmental needs would have the volume of required water as the technical measure with the minimum volume to satisfy the requirements being the critical bound. Other river basin uses such as sand mining, clay mining and discharging of pollutants would have the volume of clay or sand extracted and volume of pollutant discharged as the technical measure with the maximum volume not to exceed assimilative capacity of the river basin being the critical bound.

The estimates for critical bounds could then be used to educate the stakeholders technically, on minimum/maximum requirements of resources (upper/lower bounds) for different use sectors.

2.3 Step 3 - Estimate Economic Value of the Critical Bound of the Technical Requirement of Resource Uses/ Issues

The upper/lower bounds of the economic values of different resource uses are estimated in this step of the framework. The starting point of the economic analysis of a resource use is the financial analysis of that resource use.

The financial analysis measures the receipts (benefits) and payments (costs) relevant to the investors or owners of the resource/project. It is a tool that provides investors with the information required to decide whether to undertake an investment. Hence, the objectives of the financial analysis are to determine, analyse and interpret all financial consequences that may be relevant to and significant for investment and financing decisions.

The economic analysis is of exactly the same nature as a financial analysis, except the benefits and costs are measured from the viewpoint of the economy. Instead of relying solely on cash flow techniques to measure benefits and costs as in the case of the financial analysis, economic valuation requires the use of economic techniques of measurement. The economic net present value (*ENPV*) of a resource use can be expressed as [12];

$$ENPV = \sum_{i=0}^{n} \frac{B_i - C_i}{(1+r)^i} \qquad (1)$$

where B_i and C_i are the benefits and costs of the resource uses in the i^{th} year, 'n' is the duration of the project period and r is the discount rate.

For example in the Ma Oya river basin uses/issues dominated by water such as requirements for human consumption, water supply and environmental needs, the economic value would be the value of the volume required to satisfy the minimum water requirements of that use/issue. For other river basin uses such as sand mining, clay mining and discharging of pollution the economic value would be estimated at the critical bound which is the maximum volume of the damage not to exceed the assimilative capacity of the river basin (or the replacement value to restore the damaged resource).

2.4 Step 4 - Estimate Environmental Value of the Critical Bound of the Technical Requirement of Resource Uses/ Issues

Implementing a new development project or prioritizing a resource allocation could cause imbalance in the existing system and create social and environmental impacts on other users. Valuations of such impacts as environmental and social costs or benefits are carried out at this step.

Then all of the environmental benefits and costs of impacts valued in constant value terms become line items in the economic analysis. The present value of the environmental costs (*PVofEC*) can then be obtained as;

$$PVofEC = \sum_{i=0}^{n} \frac{E_i}{(1+r)^i} \qquad (2)$$

where Ei is the net environmental costs of the resource uses in the ith year, 'n' is the duration of the project period and r is the discount rate [2].

The economic costs and net environmental costs are separated in order to focus on environmental costs and benefits. As suggested by Pearce and Warford [2], present value of the EnvioPV is construed to be a cost, but in a number of cases EnvioPV may well be a benefit. The present value of environmental costs of the next best alternative (i.e. externalities of the alternative that is not adopted) is considered to be environmental benefits of the preferred alternative due to the avoided environmental costs [13].

The net environmental costs referred to here are those, which are either not quantified or underestimated in the economic analysis as part of normal engineering practice. Economists use a range of primary and secondary valuation methods to assign values to environmental impacts and the methodologies to evaluate environmental values are based on them [14].

2.5 Step 5 - Estimate Net Value of the Critical Bound of the Technical Requirement of Resource Uses/Issues by combining the Economic and Environmental Values.

The combined value of the technical bound can be estimated from the extended net present value (*ExNPV*), process by which indirect costs are included into the economic analysis, as [13],

$$ExNPV = \sum_{i=0}^{n} \frac{B_i - C_i}{(1+r)^i} - \sum_{i=0}^{n} \frac{E_i}{(1+r)^i} \qquad (3)$$

Knowing the combined net economic value at the critical bound of the technical requirements (*ExNPV*), helps stakeholders to make decisions based on educated trade-offs on the issues/uses that need to be prioritized.

3. Application of the Framework to Clay Mining in Sri Lanka

Until the 1980s, the mining of clay for the production of bricks and roof tiles in Sri Lanka was done manually during the dry months. With the increase in the demand for building materials during the eighties and nineties, the mining process for clay was mechanised. This resulted in large clay pits, some over fifty feet deep, which fill with water during the wet season. Since pumping water after the wet season for further mining becomes expensive, the miner attempts to remove as much clay as possible during a single dry season. Hence, the environment is changed drastically within a short period. The impacts of this change identified by stakeholders can be seen in [15]:

- large areas of abandoned clay pits along the Ma Oya River banks;
- loss of productivity of adjoining agricultural lands - abandoned rice fields are visible where clay mining has been carried out;
- an increase in the incidence of health problems such as malaria and respiratory diseases.
- lowering of water levels in the dug wells used by villagers.

The people in the affected areas feel that social costs of clay mining are so great that the only solution is to ban clay mining. While clay miners acknowledge that there is an impact on the environment due to clay mining, they argue that they are carrying out a necessary economic activity after paying the required fee [15].

The developed framework for educated trade-offs is applied to the conflicting issues related to clay mining in the Ma Oya river basin. The next section analyses the viewpoint of the miner by developing a condition for private (financial) profitability (feasibility) of clay mining. The third section analyses clay mining from the viewpoint of the economy by developing a condition for economic feasibility. This analysis excludes social (environmental and non-environmental) costs of clay mining. In the fourth section damage to roads as non-environmental costs; and health costs and costs of productivity loss as environmental costs are estimated. This provides the lower bound for cost of clay mining. The condition to analyse the social profitability (feasibility) of clay mining is developed in the fifth section by including the social costs to the economic feasibility for the extended benefit cost analysis.

3.1 Private Profitability of Clay Mining

Study Area

The focus area of the study was the Dankotuwa Divisional Secretariat which is located in the Puttlam District in the North Western Province of Sri Lanka. It is the area where the largest volume of clay on the Ma Oya river basin has been and is being mined. The study area consists mostly of privately owned coconut and rice lands. In the areas of clay mining there are no forests and no endangered wildlife. See Ranasinghe [15], [16], [17] for details of the study.

The average depth of clay pits in different local administrative areas in the study area ranged between 8 to 24 feet with an overall average depth of 17.5 feet. Since the depths of individual clay pits were elicited from clay pit owners and village officers, the estimates were generally believed to be lower than the actual depths. A sample clay pit, 1 acre in area and 20 feet in depth, was used throughout the study for estimation purposes [15]. That allowed all estimations to be compared for the same volume of clay and/or pit size. The in-situ volume of the sample pit is 8,712 cubes (1 cube = 100 cubic feet). All estimations used British Imperial units because the market prices for clay and transport are per cubes in the study area.

Condition for Private Profitability

The condition that will ensure clay mining to continue as a private economic activity is,

$$- MCL + PB_c - PC_c > 0 \qquad (4)$$

where MCL is the market cost of the clay land to the miner, PB_c and PC_c are the private benefits and the private costs of clay mining at time zero, respectively.

Private Benefit

The market price of a cube of clay at the time of the study was US$ 4.80 (today it is approximately US$ 23). The insitu volume of the sample clay pit is 8712 cubes. However, during excavation there is bulking of clay. The value for bulking that is generally used in Sri Lanka is 40%. For all estimations in this case study, 40% of bulking on excavation is assumed. Then, the volume of clay sold from the sample pit is 12,190 cubes and private benefit to the miner is US$ 58,512 [15].

Market Cost of Clay Land

According to Harischandra [18], the market value of an acre of clay in the sample study areas where mining is not prohibited was approximately US$ 16,000 [15] (today it is approximately US$ 27,200).

Direct Production Costs of Clay Mining

The mechanized operation to mine clay requires in general, an hydraulic excavating machine, a skilled machine operator for the hydraulic excavating machine, an unskilled labourer to assist the machine operator, and a supervisor to be in charge in general and to keep count of the volume of clay that is sold from the clay pit. The machine cost was estimated at US$ 17,066 and labour cost at US$ 1740 per sample clay pit [15]. Therefore, the direct production cost to mine the sample clay pit of 20 acre feet was estimated at US$ 18,806 [15].

Analysis

The market rate for capital is used as the discount rate. The average market rate for capital available to the private sector was assumed at 24% for the study [15]. As shown earlier, this analysis assumes that the mining operations and the sale of clay in the sample pit are completed within six months. Hence, there is no impact of inflation on the discount rate. For discounting, it is assumed that benefits and costs of clay mining will occur at the mid point (three months) of the six month mining operation. Then, the net present value equation for private profitability can be written as,

$$NPV = - MCL + \frac{PB_c}{(1+i)^{0.25}} - \frac{PC_c}{(1+i)^{0.25}} \qquad (5)$$

The estimated benefits and costs of the sample clay pit for the private profitability condition are depicted in Figure 1. The net present value from equation (5) when the discount rate is 24% is US$ 21, 627. The benefit cost ratio is 1.64 [15].

3.2 Economic Feasibility Of Clay Mining

The objective of an economic feasibility analysis is to ascertain whether an activity can be expected to create more net benefits to the economy than any other mutually exclusive alternatives, including the option of not doing it. In principle, the economic analysis should take into account all benefits and costs to the economy, and it is generally confined to inputs and outputs incurred or produced directly by the activity or the project [12].

This analysis required shadow priced clay sold from the pit, shadow priced labour and equipment cost, opportunity cost of clay land and economic discount rate. The economic discount rate of 6%, recommended to the National Planning Department, Sri Lanka by Curry and Lucking [19], was used for the economic analysis.

Condition for Economic Feasibility

The condition for economic feasibility of clay mining is,

$$- OCL + PEB_c - PEC_c > 0 \quad (6)$$

where OCL is the opportunity cost of the clay land, PEB_c and PEC_c are the economic benefits and the economic costs of clay mining, at time zero, respectively. Similar to the previous analysis, it is assumed that mining and sale of clay in the sample pit will be completed within six months of commencing mining operations.

Economic Benefit

Since there is no taxation on sale of clay and sale of clay is carried out by private individuals, the market price was assumed as the economic price. Thus, the economic benefit from the sale of clay in the sample clay pit of 20 acre feet was US$ 58,512 [15].

Opportunity Cost of Clay Land

The opportunity cost of a clay land is defined as the cost of the next best use of that land [20]. The opportunity cost of clay land, cost for using it for housing, was assumed as US$ 8000 [15].

Economic Costs of Clay Mining

The direct production cost of clay mining in economic costs was estimated by converting the market prices to shadow prices. The economic machine cost was estimated at US$ 15,115 while the total economic labour cost to excavate the sample pit was estimated at US$ 1349 [15]. Therefore, the economic production cost to excavate a sample clay pit of 20 acre feet was estimated at US$ 16,464 [15].

Analysis

The net present value equation for economic feasibility can be written from equation (1) as,

$$ENPV = - OCL + \frac{PEB_c}{(1+i)^{0.25}} - \frac{PEC_c}{(1+i)^{0.25}} \quad (7)$$

The estimated economic benefits and costs for the sample clay pit are depicted in Figure 2

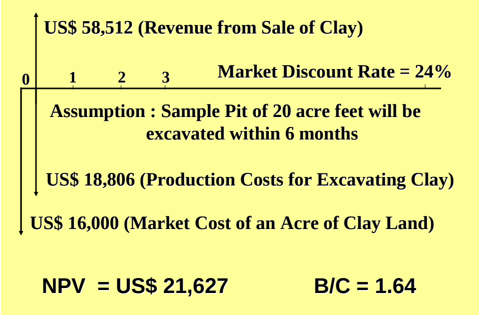

Figure 1. Private Profitability of Clay Mining

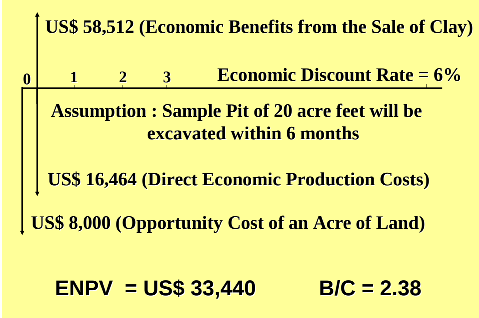

Figure 2. Economic Feasibility of Clay Mining

Assuming 6% economic discount rate [19], the economic net present value by mining the sample pit from equation (7) was estimated as US$ 33,440. The benefit cost ratio is 2.38 [15].

3.3 Environmental and Social Costs of Clay Mining

There are no conceivable environmental or social benefits from a mined clay pit. However, it could be argued that a mined clay pit could be converted to a fishpond, or used to dispose of solid waste. For the clay pit to be converted to a feasible fishpond, the depth should not exceed six feet, and there is hardly any clay pit in this category. Also, fishponds might not be acceptable in the study area for religious and cultural reasons [15]. Since these clay pits are located in a rural area, there is hardly any solid waste to dispose of. However, low-grade compost from solid waste in the Greater Colombo area could be a feasible fill material in the future. On the other hand, there are environmental costs of an excavated clay pit. Two environmental costs have been identified: health costs as loss of earnings and medical costs of the residents in the affected area, and costs due to productivity loss of adjoining rice fields and coconut lands. Costs due to the deterioration of village roads are identified as non-environmental social costs [15].

Environmental Costs

Health and productivity loss costs were identified as main environmental costs associated with clay mining. While the list could be extended to include loss of biodiversity, the study area consists of coconut and rice lands of small extents, which have been occupied by villagers for generations and there are no known habitats in the area. An acre of land, if it is well cultivated would loose approximately 65 coconut trees due to excavation [15].

The study on environmental costs of clay mining was done in two stages. First a detailed questionnaire survey was conducted in 280 households. Secondly, statistics were gathered from institutions such as Anti-Malaria Campaign Directorate, Respiratory Disease Control Directorate, and respective Medical Officers of Health (MOH) offices along both sides of the

Ma Oya River for health cost, Agrarian Services and Coconut Research Institute for productivity loss [15].

Health Cost

The stakeholders believed that incidence of Malaria and respiratory diseases have increased since the increase of mechanised clay mining. Doctors practicing both western medicine and native medicine confirmed this belief [15]. A questionnaire surveyed incidences of malaria and incidences of respiratory diseases from 280 households. From this data, health cost was estimated at US$ 1832, US$ 2.56, US$ 165.2 as maximum, minimum and average health cost of malaria due to the sample clay pit of 20 acre feet per annum respectively [15].

Increases in the common cough, wheezing and asthma were identified as the main impacts due to transportation of clay. These respiratory diseases occur more frequently during the dry season when clay transportation occurs. The estimated maximum, minimum and average health cost due to the sample clay pit were respectively, US$ 13.6, US$ 0.72, and US$ 4.0 [15].

Productivity Loss

A pilot survey revealed that stakeholders in the study area believe that there is a significant loss of productivity of rice fields and coconut lands adjacent to areas of clay mining. Abandoned rice fields are clearly visible in the area [15].

When asked in the questionnaire survey whether there was an impact on rice fields due to clay mining, 96% of the stakeholders involved in rice cultivation said that there was. The survey revealed that 46% of the rice fields have been abandoned. The reason attributed for this action is that the rate of drying up of water in the rice fields during the dry season is too severe for rice production. The cause for this rapid drying is that the Ma Oya river bed which, determine the level of the groundwater table during the dry seasons is now deeper due to extensive sand mining. This situation is aggravated by the large and deep clay pits that are located along the river [21]. The annual productivity loss in rice due to the sample clay pit was estimated to be US$ 34.80 [15].

The second aspect of the survey was to find out the impact on coconut lands due to clay mining. When inquired, 93% of the households were of the view that there was an impact. The annual productivity loss in coconuts due to the excavated sample clay pit of 20 Acft was estimated as US$ 400 [15]. Thus, the annual productivity loss in rice and coconuts due to the excavated sample clay pit of 20 acre feet in the study area is estimated at US$ 434.80 [15].

Non-Environmental Social Costs

The deterioration of village roads due to the transport of clay was identified as the main non-environmental social cost due to clay mining, where most of the village roads are classified as Class C or below. These roads were designed for low traffic volumes and, for economic reasons, nominal (which means non-existent) maintenance. Because of clay excavation, traffic in these roads has increased way beyond design volumes. Since about half of these trips are with clay, there is a rapid deterioration, long before normal design life. Hence, the annual non-environmental social cost due to the sample clay pit of 20 acre feet was estimated as US$ 5.80 [15].

Analysis

For analysis purposes a study period, *n*, of fifty years is assumed. Then, the equation for the Present Value of the Environmental Costs (*PVofEC*) can be written from equation (2) as,

$$PVofEC = \frac{ECT}{(1+i)^{0.5}} + ECA * \frac{(1+i)^n - 1}{i(1+i)^n} \qquad (8)$$

where *ECT* are the annual social costs due to transportation of clay assumed to occur during the middle of the first year and *ECA* are the annual environmental costs assumed to occur as long as the sample clay pit remains starting from the end of the first year.

It is assumed that the social costs due to transportation of clay, *ECT*, consists of annual health cost due to respiratory diseases (US$ 4) and the non environmental cost due to deterioration of village roads (US$ 5.8). The environmental costs per annum, *ECA*, are annual health cost due to malaria (US$ 165.2) and annual productivity loss (US$ 434.8). The estimated environmental and non-environmental costs for the sample clay pit are depicted in Figure 3.

Assuming 6% as the extended discount rate, the present value of the social costs due to transportation of clay is US$ 10; and of annual environmental costs is US$ 9457, respectively. Then, the present value of the environmental and social costs caused by the sample clay pit from equation (8) is approximately US$ 9,467 [15]. This is the minimum amount the affected stakeholders, the villagers and adjoining land-owners, should be compensated for the change caused by mining the sample clay pit. In other words, it is the lower bound of the stakeholder viewpoint of the cost of clay mining the sample pit as shown by Figure 4.

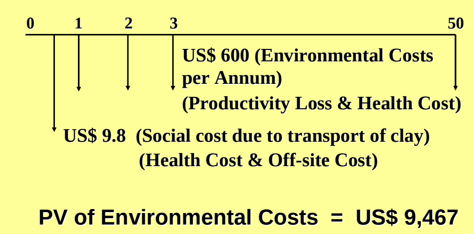

Figure 3. Social (Environmental/Non-Environmental) Costs of Clay Mining

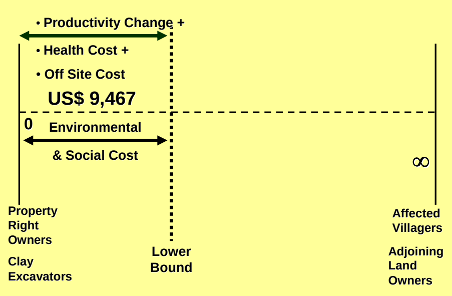

Figure 4. Stakeholder Viewpoint of the Cost of Clay Mining

3.4 Social Profitability of Clay Mining

Even though in principle, the economic analysis should take into account all benefits and costs to the economy due to an activity, little attention is paid to long term environmental impacts of that activity [12], [22], [23], [24]. At present, many indirect costs are included in the economic analyses by means of environmental and or non-market valuation [25]. This process is called the extended benefit cost analysis. Munasinghe [23] states that the first step in doing environmentally sound economic analyses is to determine the environmental and natural resource impacts of the project, and these physical impacts should be determined by comparing the "with project" and the "without project" scenarios. The second step involves valuing the identified physical impacts and relationships because an environmental impact can result in a measurable change in production and/or change in environmental quality.

This analysis included damage to roads as non environmental social costs; and health costs and costs of productivity loss as environmental costs; to the economic feasibility analysis to determine the social profitability of clay mining.

Condition for Social Profitability

The condition for social profitability of clay mining is,

$- OCL + NPB_c - SC_c > 0$ (9)

where OCL is the opportunity cost of the clay land, NPB_c $(= PEB_c - PEC_c)$ is net economic benefits of clay mining and SC_c is social (non environmental and environmental) costs of clay mining.

Only if this condition is positive, should clay mining be permitted in Sri Lanka. In addition, miners should either be required to restore the pits, or pay some sort of compensation to the local communities for the change they are causing to the environment. Clay miners may object to these requirements, but it is better than simply banning the industry because of its negative environmental impacts.

Analysis

For analysis purposes a study period, n, of fifty years is assumed. Then, the extended net present value ($ExNPV$) equation for this scenario can be written from equation (3) as,

$$ExNPV = - OCL + \frac{NPB_c}{(1+i)^{0.25}} - \frac{ECT}{(1+i)^{0.5}} - ECA * \frac{(1+i)^n - 1}{i(1+i)^n} \qquad - (10)$$

where OCL is the opportunity cost of clay land, NPB_c is net economic benefits of clay mining assumed to occur at the mid point of the six months mining operation for discounting, ECT are the annual social costs due to transportation of clay assumed to occur during the middle of the first year and *ECA* are the annual environmental costs assumed to occur as long as the sample clay pit remains starting from the end of the first year. The values are shown in Figure 5.

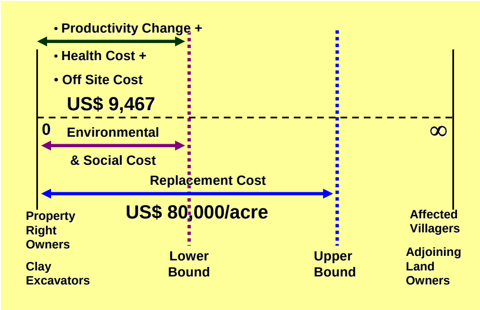

Figure 6. Stakeholder Viewpoint of the Cost of Clay Mining

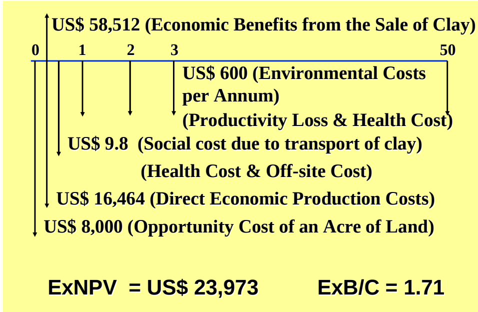

Figure 5. Social Profitability of Clay Mining

From equation (10), the net present value from mining the sample clay pit when the extended discount rate was 6% is US$ 23,973. The benefit cost ratio was 1.71 [15]. Therefore, clay mining in Sri Lanka is socially profitable. In other words it is not possible to justify banning clay mining on environmental concerns. However, the regulations that stem from the Minerals and Mining Act No. 33 of 1992 should be properly enforced to compensate the affected stakeholders and to internalize the externality caused by clay mining. Refilling of the clay pit after excavation would internalize the externality caused by clay mining. The replacement cost of the sample clay pit of 20 acre feet was estimated at US$ 80,000 [15].

4. Conclusions on Application of the Framework to Clay Mining

The following conclusions can be derived from the application of the framework developed for educated trade-offs to the conflicting issues of clay mining in the lower reaches of the Ma Oya.

1. Clay mining is privately profitable (feasible) as the discounted net private benefits of clay mining are positive and the benefit cost ratio was 1.64. Therefore, no matter what "command and control" measure is imposed clay mining will continue as a private economic activity.
2. Clay mining is economically feasible as the discounted net economic benefits are positive and the benefit cost ratio was 2.38. In other words, clay mining will create more net benefits to the economy than any other mutually exclusive alternatives from the clay land.
3. Clay mining is socially profitable (feasible) as the present value of net economic benefits are greater than the present value of social (environmental and non-environmental) costs of clay mining and the benefit cost ratio was 1.71. Therefore, regulated clay mining should continue as an economic activity in Sri Lanka.
4. Unregulated large scale clay and sand mining over a long period (about 25 years), primarily due to corruption, pressure from the politicians and official lethargy have destroyed the fertile land around the river banks of the lower reaches of Ma Oya.

5. The lower value of social (environmental and non-environmental) costs caused by a clay pit of 20 acre feet was approximately US$ 9,467. If the clay miners are not required to restore (refill) clay pits after mining, then the authorities should and must ensure that the miners pay compensation at least equivalent to the social costs to local communities to compensate for the change they are causing to the environment. The cumulative effect on the environment from a number of open clay pits can be significant.
6. The main contribution of the application of the framework is the bounding of an emotional problem on the Ma Oya basin as shown in Figure 6. The clay excavators now accept that there is a cost to be paid for changing the environment by clay mining. The affected villagers and adjoining land-owners accept that regulated clay mining could go on as long as the clay pits are rehabilitated. An emotional issue has been bounded, with upper and lower limits, as educated trade-offs, for rational decision making regarding clay mining in the Ma Oya river basin of Sri Lanka.

21st Century Hazards and the Built Environment : How Futures Thinking and the Foresight Principle Can Prepare Us

Professor John Ratcliffe
Director : Faculty of the Built Environment,
Dublin Institute of Technology,
(email : john.ratcliffe@dit.ie)

Abstract

There is the challenge to the professions of the built environment to create a mindset and a skillset within its ranks that promotes a greater awareness of risk and an improved facility in hazard appraisal and disaster management.

The aims of the paper are fivefold.

- To explain why 21st Century hazards are different.
- To explore the global hazards we face.
- To examine the attributes of global challenges.
- To evaluate the nature of 'foresight' and the potential role of 'futures techniques' in preparing for hazard appraisal and risk management.
- To espouse a futures-oriented mindset among built environment researchers, educators an practitioners in facing and addressing the natural, man-made and environmental hazards that lie ahead.

The overriding rationale being that:

"No problem can be solved from the same level of consciousness that created it. We must learn to see the world anew" [Albert Einstein].

Keywords: 21st Century challenges. Hazards. Foresight Principle. Futures thinking. Prospective

1. Exordium

There is a growing awareness that humankind is on a non-sustainable course which could lead to "grandscale catastrophes" [e.g. Lovelock, 2006; Rees, 2004]. At the same time, however, we are unlocking formidable new capabilities. This could be humanity's last century, or a century that sets the world on a new course towards a spectacular future. Echoing the warnings of Hawken *et al* (2000), and their promotion of 'natural capitalism' as a necessary fundamental change in the way of doing business, the global economy seems to be outgrowing the capacity of the earth to support it. As part of all this, there is also generally the need to understand, prepare for, and respond to natural, man-made and environmental disasters. Most particularly, in the context of this conference, there is the challenge to the professions of the built environment to create both a mindset and a skillset within its ranks that promotes a greater awareness of risk and an improved facility in disaster management. This paper proposes that 'futures thinking' through the adoption of the 'foresight principle' and the employment of 'scenario planning techniques' can contribute significantly to research and education in this field.

2. 21st Century Challenges

There is widespread recognition that we live in an era of rapid change in which new discoveries, philosophies and technologies play an ever more prominent part in shaping social and economic development. The world is becoming increasingly complex, more competitive and better connected. There is economic internationalistation on the one hand, yet cultural decentralisation on the other. Society has shifted from an industrial base to an information and knowledge orientation. Advances in genetics, materials, energy, computing, robotics, miniaturisation, medicines, therapies and communication proceed apace. The developed world is getting smaller, older and wealthier, whilst the developing world grows bigger, younger and relatively poorer. A blurring of boundaries between disciplines, industries and social enterprises is taking place. And, as those boundaries fade, the lines connecting the constituent parts become more critical, so that networks, systems and holistic thinking are more meaningful. Moreover, crucial issues on a global level – demographic, natural resources, the environment and human culture – have to be addressed. All in all, a veritable transformation, or great disruption, is occurring. Something old is coming apart at the seams, and something new is emerging.

2.1 Why the 21st Century is Different

Until relatively recently humankind retained a simplistic view of the world. Back in the 1960's, and early 1970's, it seemed possible to keep an overview of development, take future changes into account and make five to ten year planning proposals based on ten to twenty year forecasts. It was a period of trend projection, time series, network analysis and mathematical modelling. Above all, perhaps, it was an era with a belief that tomorrow would mostly resemble today. The future was a given, and planning of all kinds sought to adapt current trends to meet that predestined condition. During the 1970's, and into the 1980's, however, the view of the future changed. With sudden and significant economic disruptions and social upheavals the future did not seem as predictable as had previously been imagined. Indeed, it became recognised as uncertain. There was no longer only one likely future path of development, but several different and possible futures. All these futures, moreover, would be shaped by a number of **critical challenges.**

- ***Too many people***. As the world's population grows to about 9 billion around 2050, global tensions will climb as a result of dropping water tables, rising and changing consumer demand, uncontrolled migratory movements, demands for equality in healthcare, pollution, famine, congestion, unemployment, poverty, disease, starvation, social violence and the like. *The challenge is to determine and achieve a stable and sustainable population for the earth.*
- ***Not enough resources***. Conflict over valuable resources – and the power and wealth they confer – is fast becoming a prominent feature of the global landscape. International security experts argue that in the early decades of the new millennium, wars will be fought not over ideology, but over dwindling supplies of precious natural commodities. *The challenge is to shift economic thinking from an emphasis on human productivity to a radical increase in resource productivity through the concept of natural capitalism.*
- ***It takes time***. Many, if not most, of the major 'momentum trends' for the 21st Century are long-term in their formation, impact and necessary control. We need to 'stand in the future' and create a strategic view that is unrestricted by the exigencies of the present – imagine ahead and plan backwards. Whilst we cannot predict the future in detail or with surety, we can study the alternative directions it might take and how to influence them over time. *The challenge is to learn how to handle long-term, intergenerational, lead-times.*
- ***There will be new technologies***. With 20th Century technology, there was a massive gulf between natures systems and man-made systems. At the dawn of a new century we are witnessing new discoveries, innovations and adaptations that combine living and non-living systems. There are new forms of medicine and farming. There is also the prospect of new forms of 'artificial life'. *The challenge is to decide how to use these technologies responsibly and harness them to create a better world.*
- ***What's the risk?*** Risk in the future could reach magnitudes of harm unimaginable hitherto in modern times. Due to the interdependence of economics and societies, risks in one country can spread rapidly to others, so the notion of risk needs to be broadened and precautions put in place at global, regional and national scales. Vital systems need greater protection and citizens need to be more fully involved as partners in decisions. *The challenge is to build trust and share the burden between the public and those in charge.*
- ***Redefining the enemy.*** Increasingly we are at war not with enemy states or foreign armies but with small groups of people or specific individuals: fugitive terrorists, drug traffickers, warlords, dangerous dictators, rogue scientists, villainous zealouts and the like. The needs of safety, security and defence are different. Yet powerful institutional barriers to fundamental change remain. *The challenge is to alter radically how we organise to defend and to fight.*
- ***Economics are complex.*** When viewed in out-of-equilibrium formation, economic patterns are all too often simplified into the facile equilibrium of standard economic models. In reality, economics are everchanging, showing perpetually novel behaviour and emergent phenomena. *The challenge is to portray the economy not as*

deterministic, predictable and mechanistic; but as complex, process-dependent, organic and continually evolving.

- ***Détente with dilemma.*** Well-schooled in solving problems, governance at all scales needs to re-educate itself in the art of acting intelligently, and also compassionately, in situations that have no solution. Agencies and organisations of all kinds will have to find tools and processes for teasing-out the first-, second-, and third-order dilemmas in these situations. They will also have to reconcile multiple stakeholders and design processes that generate new value out of apparent conflicts of interest. *The challenge is to reach some kind of détente with dilemma in a world with no externalities.*
- ***Running the show.*** There will be a redistribution and relayering of power and governance at all scales and across all sectors of society. Representative government is fine in theory, but frequently fails in practice. Why? Three reasons are suggested. First, populations tend to elect the average. Second, elected representatives tend to be members of short-sighted, self-serving political parties. And third, large numbers of people in the democracies' feel alienated from the political process. *The challenge is to promote more effective leadership, bring about a step change in the degree of collaboration between key players in a process, and foster a deeper engagement between local people and large organisations.*
- ***There will be surprises.*** Wildcards or jokers will be played from time-to-time. Some of these might be totally unexpected – some could be unlikely yet predictable. Leaders in organisations at all levels, and in all situations, need to collect the information, study the signs and confront the issues surrounding the degree of probability and scale of impact of macro-uncertainties that might impinge upon their areas of responsibility. *The challenge is to avoid tragedy by both anticipating and preparing to mitigate damage done by 'predictable surprises'.*

Perhaps the main difference that distinguishes the 21st Century from those that proceeded it is *the need to develop a mindset that can tackle the conscious design of large systems* – cities, communities, corporations, countries, cultures, domains and the earth itself.

2.2 The Hazards We Face

All the dimensions of change – frequency, magnitude, complexity, rapidity and visibility – are happening at an ever-accelerating pace. In the past, there has been a discernible pattern to change. This time, however, it is different, for change is far less sequential and certain, showing much greater discontinuity and unpredictability. Evolutionary change, however, is largely in human hands, and humanity, it is argued, must learn the rules in order to see a transition during this century to a planet managed well enough to make its long-term survival more likely [Martin, 2006]. A starting point, in the context of 21C hazards, is some form of classification of the hazards we face. The following ordering has been compiled by the author from several authorative sources [Canton, 2006; Glenn and Gordon, 2006; Leggat, 2006; Martin, 2006]. It identifies the five most significant hazards in each sector – economic, environmental, geopolitical, societal and technological.

2.2.1 Economic

World Trade. Widening disparities in wealth and welfare could cause serious disruptions unless a global partnership emerges based on ethical market economies to reduce the gap between rich and poor.

Rising Energy Demand. World energy demand will probably increase by about 60% between now and 2030, so the time has come for an Appollo-like programme to increase the global supply of non-polluting energy safely and efficiently.

Extreme Poverty. Market economics and globalisation are lifting the bulk of humanity out of extreme poverty, but special measures are needed, funded by affluent countries, over the next few decades to help the planets 1 billion indigent populations out of conditions of dire poverty.

Natural Capitalism. A fresh economic paradigm is starting to emerge founded on four central strategies of radical resource productivity, biomimicry, service and flow relationships between producers and consumers, and investment in natural capital.

Corporate Responsible Behaviour. How companies manage their strategic, tactical and operational activities to produce an overall positive impact on society is becoming a powerful imperative in the world's economy.

2.2.2 Environmental

- *Global Warming.* Further exacerbated by the induced release of methane from the permafrost or from clathrates on the continental shelves.
- *Biota Extinction.* The eruption of continental flood basalts leads to the mass extinction of 95% of biota.
- *A New Ice Age.* Caused either by natural cycles or by abrupt climate change from reduced Atlantic thermohaline circulation, leading to a loss of 65% of current land biomass.
- *Quakes and Eruptions.* Especially the super-eruption of somewhere like Yellowstone, producing a five to seven year volcanic winter reducing solar and wind power.
- *Water Resources.* Ensuring that everyone, everywhere can have access to sufficient clean water without conflict.

2.2.3 Geopolitical

- *Peace and Security.* At the extreme, preventing war among nations using weapons of mass destruction. But also determining when it is right to use force to intervene in the affairs of another country.
- *Terrorism and Ethnic Conflict.* Promoting a set of shared values and new security strategies to reduce the means and motivations for terrorism and ethnic conflict.

- *Organised Crime.* In contrast to military spending of around $1 trillion a year, annual income for organised crime has passed $2 trillion and is impeding governments' ability to act.
- *Leadership and Ethics.* Global ethical standards are merging from a variety of sources, but the education and development of decision-making for policy makers is lagging well behind.
- *Global communication.* The use, control and reliability of the internet and any successor information system will be crucial as the majority of the world's population becomes connected.

2.2.4 Societal

- *Health and Medicines.* Reducing the threat of new and re-emerging diseases and immune micro-organisms that could threaten civilisation, and slashing the costs of treating the world's most devastating illnesses.
- *Population Growth.* Balancing population growth, resource availability and sustainable development is a key issue with inherent risk. As humanity swells toward nine billion in the next half century it will undergo historic changes in the balance between young and old, rich and poor, urban and rural, so that choices now and in the years ahead will determine how well we cope with our coming of age.
- *Opportunity and Capability.* Developing the capability latent in everyone, with particular emphasis on changing the status of women to improve the human condition, and helping young people everywhere understand the meaning of the 21C.
- *Decision Making.* Making policy formulation more sensitive to long-term prospectives, improving the capacity to decide as the nature of work and institutions change and incorporating more routinely ethical considerations into decisions at all levels.
- *Biodiversity.* Developing a new understanding of how species become extinct, and how to preserve them, is a hallmark of a civilised society.

2.2.5 Technological

- *Scientific Experimentation.* There is the danger that some scientific developments could change the fundamental fabric of the universe in a way not previously seen in nature.
- *Nanotechnology.* The theoretical threat exists of planet-wide spread of exponentially self-replicating nano-machines utilising DNA/chlorophyll ('green goo'), or bio-vorous fully artificial nanoreplictors ('grey goo').
- *Acclerating Technology.* Factors causing the acceleration of scientific/technological innovation are themselves accelerating, to such an extent that perhaps an international Sci/Tech agency or organisation may be needed to examine the potential consequences.
- *ICT Convergence.* Hazards prevail in determining how the global convergence of information and communications technologies can work for the benefit of everyone and be safeguarded from corruption, distortion and criminality.
- *The Singularity.* A number of scientists believe machine intelligence will surpass human intelligence within a few decades, leading to what has become known as the

‘singularity’, and producing in the words of Ray Kurzweil (2005) technological change so rapid and profound it could create a rupture in the very fabric of human history. What we have to do perhaps is understand how any ‘transhumanist’ changes to Homo sapiens can be made without negative consequences.

Then, of course, there are the real *‘wild cards’,* such as an asteroid or comet over 10km striking the earth, or the collapse of a supermassive star causing an intense pulse of x-rays, cosmic rays and muon particles. A ‘wild card’, however, need not necessarily be bad, it can be marvellous – a ‘benestrophe’ rather than a catastrophe [Cornish, 2004]. Those might include : war fades from history; energy that is almost free; a happiness pill is perfected; death becomes an ecstatic experience; permanent human settlements in space; drugs to boost human intelligence; a really effective ‘youth treatment’ is found; or a ‘world brain’ is constructed. But perhaps such ‘benestrophes’ raise more questions than catastrophes?

3. The Foresight Principle

3.1 Futures-oriented Thinking

Foresight is the principle producing the prime methodology for the practice of futures studies. The main purposes of adopting a futures approach have been listed elsewhere as follows [Gannon and Ratcliffe, 2006].

- Extending thinking beyond the conventional and fostering more forward thinking as a result.
- Forcing thoughts and stimulating conversations about the future.
- Helping identify assumptions about the future that might require examination, testing and subsequent modification.
- Encouraging people to have regard for the positive possibilities and opportunities that tomorrow might hold, as well as the potential threats and disasters.
- Making more intelligent decisions today concerning the future by focusing the mind on the most important questions that must be resolved in order to formulate better policy.
- Inspiring people to ‘think outside the box’.
- Widening perspectives and increasing the number of options available for exercising more deliberate decision-making towards positive change.
- Preparing for, and managing change better by enhancing the capacity to learn.
- Making response times to actual future events much shorter and reactions more relevant.
- Fostering active participation in strategic thinking leading to decision-making.

In the context of major disaster management, the use of futures methods offers a rigorous, comprehensive and integrated approach towards anticipating, planning and implementing recovery and reconstruction operations, relying, as it does, more on intuition, participation and adaptability than conventional strategic thinking and planning systems. Most excitingly, a futures approach can constitute an effective platform for collaborative planning. A collaborative futures process helps to develop successful solutions and ensures that the ownership of these solutions is embedded in the community so that they have a greater chance of implementation. It also enables the development of preferred visions of community futures through mobilisation – bringing together and facilitating the network of key stakeholders and sources of knowledge. Above all, perhaps, foresighting reduces risk. Thus, the 'foresight principle' enacted through 'foresight programmes' provides an opportune, seductive and feasible approach for studying the hazards that lie ahead and preparing ourselves to meet and overcome them.

3.2 The Foresight Process

Foresight is a systematic, participatory, future-intelligence-gathering and medium-to-long-term vision building process aimed at present day decisions and mobilising joint actions [FOREN, 2001]. There are said to be five essential elements of foresight – anticipation, participation, networking, vision and action (*ibid).* And the most important aspects of the Foresight process have been précised as being [Irvine and Martin, 1984]:

- communication between parties concerned;
- concentration on the longer term;
- co-ordination of research and development;
- consensus created on future directions and policies; and
- commitment generated among those responsible for implementation of policy.

A defining characteristic of foresight is that, in essence, it is a human capacity to think ahead and to forecast possible outcomes of present decisions. Turning towards the practical operation of the process, the stages of a strategic foresight activity, together with the relevant objectives for each stage and the intended outcomes are shown in Exhibit 1.

STAGE	OBJECTIVES	OUTPUT
Framing	Scoping the project : attitude, audience, work environment, rationale and purpose, objectives and teams.	Focal Issue
Scanning	Collecting the information : the system, history and context of the issue and how to scan for information regarding the future of issue.	Information
Forecasting	Describing baseline and alternative futures : drivers and uncertainties, tools, diverging and converging approaches, and alternatives.	Baseline and Alternative Futures
Visioning	Choosing a preferred future : implications of the forecast, and envisioning desired outcomes.	Preferred Future
Planning	Organising to achieve the vision : strategy, options and plans.	Strategy and Plans
Acting	Implementing the plan : communicating the results, developing action agenda and institutionalising strategic thinking and intelligence systems.	Action

Exhibit 1 : A Strategic Foresight Activity (Bishop and Hines, 2006)

Central to the use of Foresight, however, is a strong dose of common-sense. It is, at heart, about avoiding danger, reducing risk, optimising opportunity and developing a strategy to reach a preferred future.

3.3 Prospective Through Scenarios

A particularly progressive and proactive form of foresight is to be found in *prospective.* The prospective, or more familiarly "la prospective", has French origins, but is now bring more popularly applied across Europe in a variety of strategic planning settings. In the francophone context, however, 'prospective' refers to a much wider approach and activity than other futures methodologies as it comprises not only the study of the future, and an evaluation of alternative outcomes against given policy decisions, but also the will to influence the future and to shape it according to society's wishes. Furthermore, it is a very formalised, inclusive, comprehensive and rigorous methodology when compared to more generalised future studies. In many ways, it is similar to foresighting, but would be better understood as a specific means of applying the foresight approach.

One of the most popular and persuasive techniques used in futures studies and foresighting is *scenario analysis.* Scenarios have long been used by government planners, corporate strategists and military analysts as powerful tools to aid in decision making in the face of uncertainty. They are instruments for ordering people's perceptions about alternative future environments in which today's decisions might play out. In practice, scenarios resemble a set of stories built around carefully constructed plots. Such stories can express multiple perspectives on complex events, with the scenarios themselves giving meaning to these events.

Despite their story-like qualities, scenarios follow systematic and recognisable phases. The process is highly interactive, intense and imaginative. It begins by isolating the decision to be made, rigorously challenging the mental maps that shape people's perceptions, and hunting and gathering information, often from unorthodox sources. The next steps are more analytical : identifying the driving forces, the predetermined elements and the critical uncertainties. These factors are then prioritised according to importance and uncertainty. Subsequently, three or four thoughtfully composed scenario 'plots', each representing a plausible alternative future, against which policy options can be tested and implications identified, are developed. Then, the deeper structures and systems behind the scenario stories, and their underlying logics, are elaborated to explain them and reveal their crucial differences. Finally, the key events, or turning points, that would channel the future towards one scenario rather than another are identified.

At The Futures Academy, in DIT, an approach has been developed which combines the above methodologies and is known as Prospective Through Scenarios. It has been applied across a wide range of policy issues over the past ten years, and is confidently put forward as an effective means of getting those concerned with hazard appraisal and risk management to think, talk, plan and act, creatively and differently, together. This particular process is described in Exhibit 2.

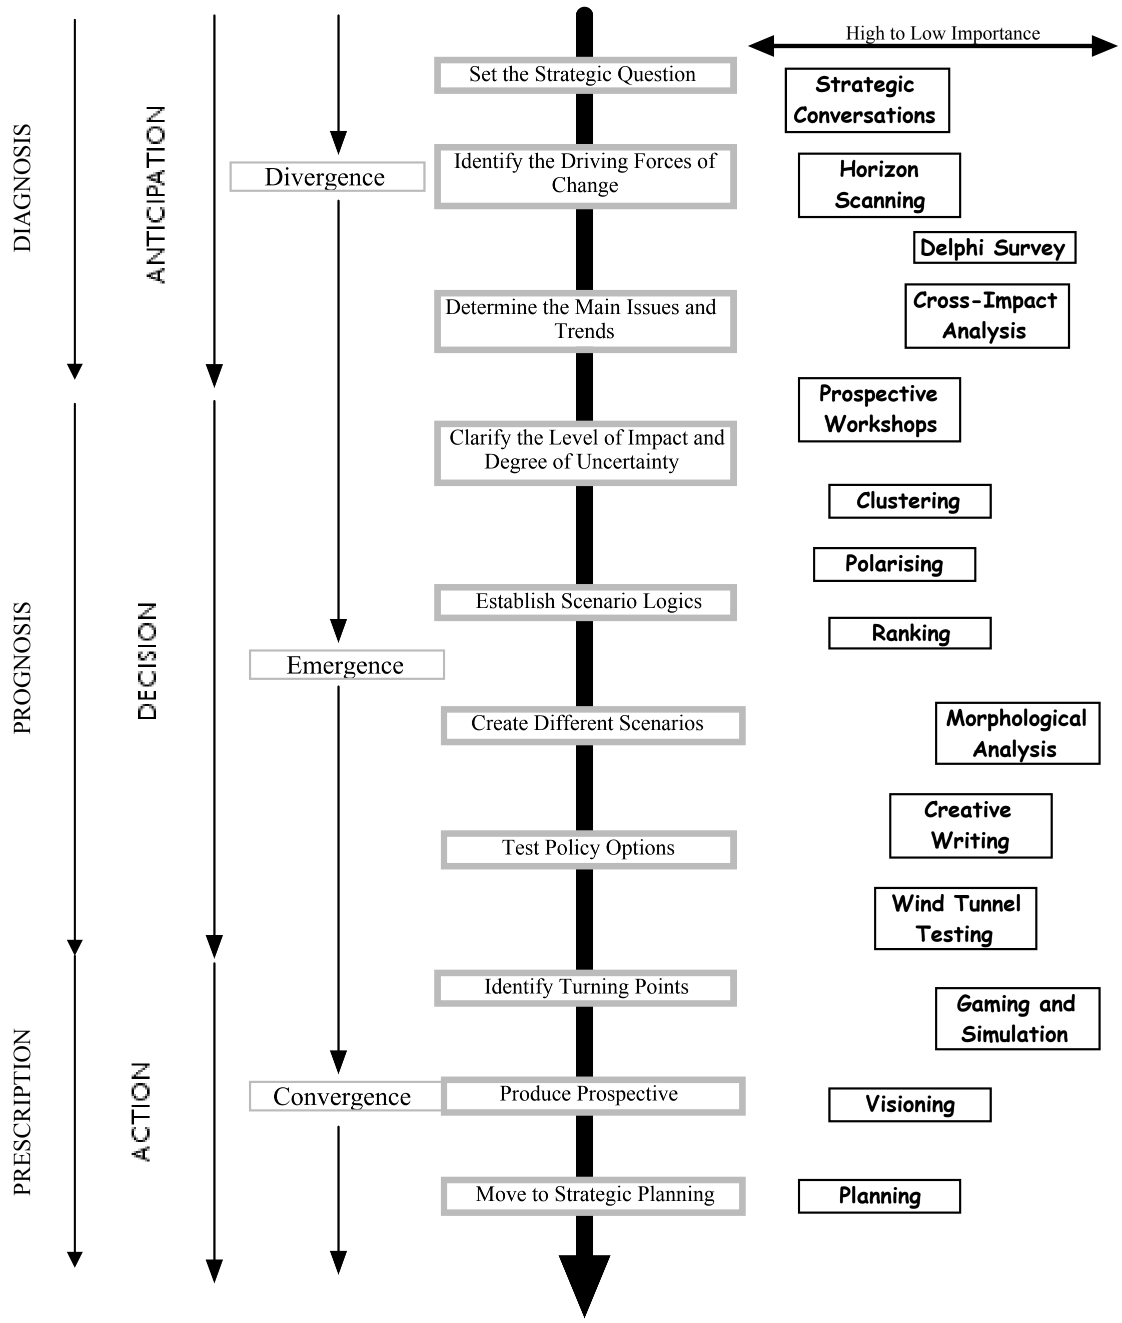

Exhibit 2: "Prospective through Scenarios' - Source: Ratcliffe and Sirr (2003).

4. Built Environment Foresight

The world is changing at a pace hitherto unknown, and previously unimagined. There is a need for academic institutions and professional bodies in the field of the built environment to play a more positive role in addressing the 21C hazards we face, and the potential disasters that might ensue. Some of the tasks that might be tackled include the following.

- Raising issues of common concern that may be overlooked taking the traditional short-term view.
- Highlighting dangers, alternatives and choices that require attention before they become critical.
- Publicising the emerging picture of the near-term future in order to involve the public and contribute to present-day decision-making.
- Contributing to a body of knowledge about foresight and the macro-processes of change and continuity that frame the future.
- Identifying the dynamics and policy implications of the transition to sustainability.
- Helping to identify aspects of a new world order so as to place these on the global political agenda.
- Facilitating the development and application of social innovations.
- Helping people to deal with fears and become genuinely empowered to participate in creating the future.
- Assisting organisations to evolve in appropriate ways.
- Providing institutional shelters for innovative futures work which might not be carried out elsewhere.

In proselytizing the simple yet profound message that we do not have to walk blindly into the hazards we face surrounding the future of the built environment, it is possible to pose a few questions to participants at this conference, or readers of this paper:

- How flexible is your organisation in adapting to change, and does it use outside 'visionaries' to question the basic assumptions held internally?
- Since planning invariably takes longer than events to happen, is enough time spent on contingency or parallel planning?
- Does your organisation devote enough time to 'relationship management', both internally for colleagues, and externally for actual or potential customers and collaborators?
- How ready is your organisation for significant shifts of 'culture' in the environment within which it operates – exploring the way people think, believe and behave?
- Is your organisation managing efficiently and effectively its intellectual capital and knowledge base to think and plan creatively and collaboratively?

5. Propositum

What does the future hold? Are we living at a turning point in human history? Can we master the hazards ahead, or does a new Dark Age menace? Contemplating the critical trends, issues and threats raised earlier in the paper, let alone their possible convergence, it is tempting starkly to suggest that without rapid and positive action we could actually be bringing history to an end. As one leading futurist, James Martin (*op cit*), succinctly states:

"We are travelling at breakneck speed into an era of extremes – extremes of wealth and poverty, extremes in technology, extremes in globalisation. If we are to survive, we must learn to manage them all"

Turning to another prominent futurist, Dr. Patrick Dixon [2004], it is imperative, he argues, to become 'futurewise'. It is an extraordinary time to be alive. The world is being transformed before our eyes from a technological twentieth century society into something altogether new and different. Either we take hold of the future, he concludes, or the future will take hold of us. At a practical level, Dr. Dixon offers ten proposals for organisations facing the hazards of planning and managing their affairs in the 21C.

1. Prepare for the unexpected.
2. Generate faster reactions times.
3. Create flatter structures.
4. Build teams and forge partnerships.
5. Learn to live in the global village.
6. Become more culturally aware.
7. Invest in technology.
8. Foster a family feeling with a sense of identity, value and belonging.
9. Develop purpose and meaning.
10. Recognise that leadership will be everything.

It is largely futures thinking through foresighting that helps achieve this.

On a more personal note, this paper ends with the proposition that to face the Grand Challenge of the 21st Century a more informed, structured and imaginative approach towards the study of the future is demanded of those professions concerned with the stewardship of the built environment and the promotion of sustainable urban development, and that this can most effectively be provided by the Futures Studies field through the adoption and adaptation of the Foresight Principle through Scenario Planning and associated techniques. We need a new mindset – a futures-oriented mindset.

"We are made wise not by the recollection of the past but by the responsibility for the future!"

[George Bernard Shaw].

International Community Perspectives in Disaster Mitigation in Developing Countries

Conrad de Tissera
UN-Habitat Programme Manager - Sri Lanka

Abstract

Disasters are exceptional events with overwhelming loss of lives and property. Natural disasters continue to strike and increase in magnitude, complexity, frequency and economic impact. Whilst the natural phenomena causing disasters are in most cases beyond human control, vulnerability is generally a result of human activity.

Today the world is increasingly interdependent. As a result the global community needs to act in a new spirit of partnership to build a safer world based on common interests and shared responsibility to save human lives. Natural disasters do not respect borders or countries whether developing or developed. Disaster prevention, mitigation, preparedness and relief are four elements which contribute to and gain from the implementation of sustainable development policies. Therefore, nations should incorporate them in their development plans and ensure efficient follow-up measures at the community, national, sub-regional, and international levels.

The Geneva Mandate for the world body on disaster reduction stresses the importance of developing and strengthening regional approaches dedicated to disaster reduction in order to take account of local specificity and needs. It emphasizes the need to support initiatives for strengthening regional, national and local capabilities, and applied research initiatives to ensure that prevention and mitigation policies and programmes for disaster management are in place in all countries particularly developing countries.

An example to demonstrate translation of these intentions into action by the international community can be seen in Sri Lanka where UN support in Landslide Hazard Mapping Project (LHMP) for local capacity building provided necessary technical expertise and assistance in introduction of standards, guidelines and codes of practice for human settlements planning and site selection for developments in hilly areas that are vulnerable to landslides. This included using state-of-art technology for preparation of Landslide Hazard Maps, early warning systems, dissemination of information relating to causes, identification of telltale signs, remedial measures etc. which has enabled Sri Lanka to decrease its vulnerability in relation to landslide disasters in the future.

This paper focuses on the International Communities commitment, their mandate and their interventions with regard to disaster mitigation in developing nations and the lessons learned in a case study where access to and application of advanced technology in natural disaster management was facilitated by such interventions.

Abstract

This study explores the notions of *theory as science*, and *practice as science*, in the pursuit of theory for the built environment. Whilst endorsing these notions, practice is differentiated with *scientific practice* suggesting that latter is part of theory, and that theory should be seen as science. The need for building theory for professional disciplines such as construction management is urged by reflecting on the engineering profession pointing out that practice without theory is akin to *action without thinking* or the practice of a quack-doctor.

The meaning of *theory* and *scientific practice* is explained in preference to definitions, portraying *theory* as *knowing* but of a particular kind of knowing, which is different to other ways of knowing such as authority, intuition, and experience, whereby logic (reason) is applied to questions. Theory is explained as *justified beliefs* as well. There is also a need to develop a structure with an accompanying narrative on *stories* about phenomena in the built environment in a way that it condenses knowledge, and informs practice.

Theory consists of answers to four elements, namely, 'what, how, why and so-what' with *what* identifying the phenomena, the *how* providing explanation (and prediction) and the *why* providing understanding. Other elements to include are responses to *when, where, who,* which are considered to be the limiting parameters (i.e. the context). Criteria for judging the value of theory are also given including a brief description of methodologies for building theory. By reflecting on the profession of engineering, it is proposed that theory for the built environment should consist of theory in the different professional disciplines (which often overlap) in an interactive and integrated manner.

With this synthesis of theory and practice, an 'unusual' phenomenon that has spanned well over a century is investigated with the intention of building theory. This phenomenon is the practice of holding a portion of the moneys due to a service provider from each and every payment until the project is fully completed. It is a practice which was originally enforced through legislation (in New Zealand), later abolished, and then re-enforced through contract.

Having explored different methodologies for building theory, metaphors was found to be a convenient and a powerful approach for building theory particularly for channelling knowledge, give it structure, and develop narrative, in a way that it condensed knowledge and facilitated practice. Accordingly, five theories were presented under *Images of Retentions* – an unfolding

story about the practice of retention. These theories were named as *Cash-Cow*, *Steroid*, *Beast*, *Stress*, and as *Chaos*. They were seen as providing a deeper understanding of the reasons for this phenomenon along with new insights on retentions.

These theories are accounts of *justified beliefs*; they describe, explain, and predict what might happen if certain courses of actions are taken, particularly in a New Zealand context. These must be criticised and modified, and refined as necessary in the pursuit of deeper understanding: this is the nature of theory; theory is neither complete nor perfect.

Individually, these 'theories' tell us a one-sided story by highlighting certain interpretations and forcing others to the background. This needs to be understood but importantly the theories needs to be viewed together as a collection rather than in isolation, understanding the opposing and complementary points of view, along with their interactions.

The theory (and theories) presented herein on retentions are not exhaustive. There are still a number of issues pertaining to retentions that need to be understood. However, it is believed that these theories should provide a good foundation for further deliberation and research. In this regard, the use of metaphor as a methodology cannot be underestimated; it is an interesting, valuable, and an exciting approach for building theory as evidenced through this study.

This is only a beginning of a *story on retentions*; there is much to be understood about this *'unwanted essential'*!

Keywords: built environment, construction management, theory and practice, monetary retentions

1. Background

2007 saw an important milestone achieved with the first symposium on 'theory for the built environment' held at the University of Salford. The call for papers re-kindled a dormant desire – to tell a "story" about a phenomenon that has been witnessed since the dawn of civilisation. Just over a decade ago, as I wrote the final chapter of my PhD thesis on strategies for managing the chaos in Sri Lankan brickwork, I mooted the idea for a 'theory of brickwork' [1]: Sri Lankan brickwork is unique in many respects. The environment within which this phenomenon is seen is rich in that it permits the study of forgone – taken for granted fundamentals - of building with bricks. If I were to write a book on brickwork today, its *structure* would very likely be different to the structure of a traditional text book where the focus to a large extent has been on 'how' than 'why'. I realised that many issues had been taken at the face value influenced by colonial traditions failing to realise the local context without a real *understanding* of, particularly production management issues, connected with time–cost–quality issues. The practice in Sri Lanka has been to prescribe English brickwork over 'Sri Lankan brickwork'! Delegates to this conference would no doubt see how chaotic Sri Lankan brickwork is but surprisingly enough there is an underlying order only if you care to understand *why.* And if you do, there is much opportunity to improve its productivity and economy, thus saving billions of dollars.

I believe, it is the case with 'monetary retentions' as well. It is this desire that I hope to explore in this paper on a phenomenon that has spanned over a century, enforced by legislation and through contractual provisions, with the hope of laying a foundation for understanding it better, through what I will refer to as a 'theory on contract retentions': Some countries have outlawed this practice, others have tried to follow suite but failed, yet others seem to find it useful and are content with the status-quo, which raises important questions on why this is the case.

During my undergraduate studies in engineering, *theory* was the order of the day. However, when I specialised in construction management, I realised that there was hardly any 'theory' to help make decisions as one would do in engineering; there wasn't a right or wrong way of doing things. It was, in this sense, a somewhat difficult and uncomfortable realisation, often having to draw on experience, intuition, and insight for managing projects. As I look back, I ask myself the question, could we not condense such knowledge into a form that we could classify as 'theory' which will assist in decision making, practice not for the sake of practice but with sound reason, and guide future research and help move our knowledge forward on important questions confronting the profession of construction management.

2. Theory as Science

No doubt, it is pertinent to raise the question as to what is meant by 'theory'. In engineering, theory is the foundation for many applications whether it is the design of a bridge, a building, or a road and so on which are part of the built environment. Not only does theory help to understand how these structures should be built and the reasons for it but also for their planning and maintenance from a technical perspective. In this regard, those from a background in engineering would find it easy to see the value and the relevance of 'theory'. If not for theory, one would have to use experience, intuition, and judgement instead, to create the built environment we live in, no doubt, with much trial and error, inefficiency, and waste.

If my perception is correct, *theory in civil engineering* (as it appears to me) is about understanding, explaining, and predicting how the natural world and the built environment interface with each other in an interactive and integrated way with particular relevance to the planning, design, construction, and maintenance of man-made facilities and services provided for and by human kind for their benefit. But what is *theory* and how has it been developed...?

In common usage, the word 'theory' is often used to signify an opinion as in "he has a theory that wearing hats makes men go bald". In fact, many of us seem to have theories about many things on how to 'choose a bait, a date, or mate' as eloquently put by Shoemaker *et al* [2]. In this **usage**, theory is not necessarily based on facts; and is not required to be consistent with true descriptions of reality. Such usage of the term 'theory' is confusing, incorrect and inappropriate for a professional discipline such as engineering or for that matter any other discipline that help fashion the built environment. However, this usage shows us that theory helps us to ***know*** but this is not enough; **it must work in practice** too. However, knowing is much more than this.

Interestingly, according to the Webster's New World Dictionary, the word science which is derived from the Latin word *sciens* means "knowing". However, it is the particular way of knowing that appears to distinguish 'science' from other ways of knowing such as authority, intuition, tenacity or even experience. Moreover, what makes science different to other ways of knowing is that 'science applies logic [reason] to questions constantly' for right understanding [3]. I propose therefore that **theory must be science** if it is to be of value to professions involved with the built environment. Professions that are backed by theory (as science) could then be referred to as scientific, as in scientific engineering (as against engineering) analogous with 'scientific medicine' or 'scientific farming' [4].

A widely held belief is that science uses the *scientific method* for building theory which is another reason why science is different to other ways of knowing. Additionally, science uses other *methods* and *methodologies* which may differ from profession to profession [5]. However, whichever methodology is used, it is useful to echo the sentiments of Nobel Laureate biologist Peter Medawar in relation to *scientific inquiry and method*:

> *'[The Scientific method]... is a potentiation of common sense, exercised with a specially **firm determination not to persist in error** if any exertion of hand or mind can deliver us from it. Like other exploratory processes, it can be resolved into a dialogue between fact and fancy, the actual and the possible; between what could be true and what is in fact the case. The purpose of scientific enquiry is not to compile an inventory of factual information, nor to build up a totalitarian world picture of Natural Laws in which every event that is not compulsory is forbidden. We should think of it rather as a logically articulated structure of **justifiable beliefs** about nature [i.e. with explanations as to why the belief is a true one]. It begins as a story about a Possible World—a story which we invent and criticise and modify as we go along, so that it ends by being, as nearly as we can make it, a story about real life."* [6]

What then is *theory...*? According to a definition given in the Oxford Learner's Dictionary (1989), theory is a 'set of *reasoned ideas* intended to *explain facts or events*' which aligns well with the above description, particularly with reference to 'justified beliefs'. However, Ron Weber, the Editor of MIS Quarterly explains that it is 'notoriously difficult' to define what 'theory' is, claiming that 'any definition … is sure to evoke disagreement among scholars' [11]. He states further that 'some even see the notion of theory as an anachronism – an idea that reflects earlier, naïve notions about our abilities to understand the world (the so called "modernist" view of the world)'. In fact, it is also claimed that *theory* has number of distinct meanings in different fields of *knowledge*, depending on their *methodologies* and context of *discussion* [4]. Furthermore, an online dictionary on medicine defines theory (of medicine) as '*science*, as distinguished from the *art*, or *practice'* (of medicine). Thus, it is not surprising why it is not easy to come to a universally agreed definition. Moreover, experience shows that definitions are difficult to come by. And even if it does, reaching agreement on controversial words such as *theory* is difficult. However, just as much as it is difficult to define an elephant as compared with explaining what an elephant looks like, there is no difficulty in explaining what *theory* is. In this regard, as argued before, *theory* is seen as *science*.

3. Practice as Science

"Actions without thinking, practice without theory are unimaginable..." [7], [8]

The main product of almost all professions associated with the built environment is practice whether it is engineering, medicine, architecture or construction management. I believe all these professions can be practiced by people, for example, by learning on the job, and is nothing new. Ask a bricklayer to build a wall and he will. Ask him *why* uses a particular size he might explain but ask him why it should be used for a wall which is plastered on both side and one without any openings, he might think hard, and he might not give a plausible answer (see [1]). He might even challenge the importance of this question! Consider another scenario – the application of critical path methods in project planning and control. Talk to a construction manager and he might explain how he uses these. This is *skilful mastery*. However, ask for reasons for choosing this particular technique over so many other techniques, he might be less able to provide a satisfactory answer unless there is a good theoretical understanding of the techniques. If he fails, his practice is not scientific. Indeed, practice that is not driven by science is akin to a quack-doctor practicing medicine [9]: there is a need to transform the 'art' of practice into a 'science'.

So what characteristics must be displayed before practice can be considered as science? According to one explanation, 'practice is science' when the practitioner can explain it in terms of 'knowledge, logic and prior experience' [4], [10]. However, this is not sufficient: The reasons for practice must be justifiable and indisputable. And, ideally, such reasons must be established and/or verifiable (and undisputable) according to an established standard of evaluation though it might prove difficult. This is part of the challenge of 'practice as science'. Practice without such evidence cannot be regarded as science.

There is a need to embrace *scientific practice* as against practice, in which case practice becomes part of theory! When practice-based professions accept scientific practice as fundamental to their profession, it no doubt strengthens professional identity. This is an important consideration for emerging fields such as construction management.

4. Building Blocks of Theory

As mentioned before, *theory* is about "knowing". Theory is also about *justified beliefs* (as noted before) where explanation of the reasons for a phenomenon or practice is fundamental. However, theory is much more; for instance, theory is expected to 'explain in order to predict' which is essentially about understanding [2]. Thus, understanding entails 'considerably more than explanation (or prediction): Ancient astronomers made excellent predictions of the future positions of the planets but were unable to say *why* (understanding) the planets behaved this way because they lacked understanding [12].

Well known scholars such as Abraham Kaplan and Robert Merton have asserted that *theory* is the answer to the questions of *why* [13]. Whilst this is fundamental, a complete theory should include answers to not only *why* but also to w*hat* and *how* viz. what factors should be considered to explain the phenomena, how these factors are related, and why this particular phenomena be accepted; while *what* and *how* describe and provide a framework for interpretation, *why* supplies the explanation[14]. These are not the only elements; a theory should include responses to *when/where/who,* which are considered to be the limiting parameters defining the applicable population of actions, actors, etc. This is what Weber [15] has referred to as the 'state space of a theory' and the 'event space of a theory', or the 'boundary conditions' (i.e. the context). The last element of theory is which is referred to as the "*so what"* element, which was thought to be necessary to demonstrate the implications and consequences of a proposed 'theory' [16]. To summarise (and as noted immediately below), we wish to take the position that a theory should respond to ***"what, how, why, and so-what'*** elements with ***'when, where, and who'*** describing the limiting or the contextual elements. As such, theory in the built environment should form the basis for explaining and understanding phenomena in the built environment. In fact, such understanding would serve a better purpose if they also respond to the *so-what* element referred to above.

5. Theory for the Built Environment

So what constitute *theory* for the built environment? What does *theory* look like...? How could we build and present *theory* in a way that it condenses scientific knowledge, permits practical applications, and guide research...? These are important questions that need to be looked at.

It was argued earlier that *theory* should be viewed as *science*. Moreover, it was also argued that *scientific practice* should also be part of *theory* separating practice which is not scientific as *practice*. Discerning readers would no doubt have noted that theory in the built environment (as discussed in this paper) is a collection of *theory* in the different professional disciplines which often overlap. Theory includes frameworks, concepts, facts, laws, models, rules and regulations (codes of practice) etc. integrated together that includes various 'theories' as well, such as theories on motivation, theories on chaos, and so on depending on the nature of the professional discipline.

According to Shoemaker *et al* [19], the beginning point of building theory would be a problem. These could be intellectual problems or practical problems, or a combination of both. Concepts (such as 'retentions') could also be a starting point for theory building particularly if they are problematic. Such concepts could lead to hypotheses (opinions) which could be tested for validity and thereby provide greater understanding. It is also possible that theory building could start with a hypothesis or even with a question about something that needs better understanding. Another possible beginning point for building theory would be to start with an area in which theory is vague or lacking. This is clearly the case with 'contract retentions'.

Theory building is said to be an ongoing process; it does not come to an end though it may come reach a point where it is useful and can be applied to solving problems [17]. Various *methods* (qualitative, quantitative, mixed-approaches, learning by doing) and *methodologies* (such as positivism and constructivism) have been, and are being, used for building theory. Such theories could be displayed through charts, graphs, diagrams or even mathematical equations as mentioned before. However, according to Shoemaker *et al* the creative side of theory building has often been neglected in textbooks and classes [18]. As an aide, they provide 12 ‘techniques of creativity’ that might be helpful for building theory, namely, attribute listing, forced relationships, morphological analysis, brainstorming, lists of ideas, lateral thinking, random input, setting up provocations, creative hit lists, visualization, writing techniques, and letting the unconscious (mind) do some work. Although not mentioned as a technique, these authors claim that metaphors may also play a very useful role by assisting the theory builder, particularly for expressing ideas or insights that have not yet been verbalised, for gaining new insights and fresh illuminations, and for formulating new theories on old themes.

Finally, if as noted before *theory* should respond to the questions of ‘what, how, why and so-what’ in relation to phenomena, how does one judge or evaluate theory? Shoemaker *et al* [19] provide ten criteria, namely, testability, falsifiability (i.e. capability of being criticised by observational reports), parsimony (least complex explanation for an observation), explanatory power, predictive power, scope, cumulative nature, degree of formal development, heuristic value (generate ideas for research and other theoretical ideas), and aesthetics (expressing the value of a theory by the application of aesthetic principles such as by referring to an idea as “beautiful”) noting that it is unlikely that all these criteria can be fulfilled simultaneously.

6. A Theory: Images of Retentions

The experience of moving from engineering to a practice-driven profession like construction management led to the observation that there was hardly any theory to inform practice. The situation is not much different today: educational curricula rarely if ever focus on theory. Part of the problem is that there has not been an attempt to differentiate practice with scientific practice. Moreover, neither has there been an attempt to build theory nor appreciate the need for it. Given this background, it is the intention here to explore and examine, monetary retentions, a practice that has spanned a century, a practice that was enforced through legislation in New Zealand (for almost a century), later abolished only to find that the practice is reinforced through contractual provisions, interestingly with a new imperative which is significantly different to the old imperative, in a manner that protects people who seek services as against those who provide services!

What is this practice...? As it stands today, those who seek services (principals) hold on to a portion of money usually in the range of 5 – 10% from every payment they make to those who provide services (contractors and subcontractors). When the project is over, only a part is returned at the end of the construction period (usually around 50%) with the balance retuned at the end of the defects liability period.

As mentioned before, some countries have outlawed this practice, others have tried to follow suite but failed, yet others seem to find it useful and are content with the status-quo, which indeed raises much curiosity as to why this is so. Could we have a better understanding of the issues at stake by attempting to develop theory...? There is no indication to suggest that there is a scientific basis for the practice of retention. No doubt, it is an enormously important concept to the extent that there have been parliamentary select committees commissioned (in the UK) to investigate whether or not to abolish retentions. Yet, there isn't a single book on construction management that appear to have a chapter on this issue. Not surprisingly, there is very little research done on this area. As such, the intention herein is to build theory, and hopefully lay the foundation for a better and deeper understanding of this practice.

One of the mind-boggling problems that arose initially was on a suitable *methodology* to build theory with the little that was known about retentions. An obvious choice was to use the six elements described as the 'building blocks' of theory using the 'attribute listing' and the 'forced relationship' techniques mentioned earlier. This approach generated interesting and useful avenues for understanding issues on retention; it appeared as a useful approach to set up a research agenda but for communicating theory to practitioners, it was found to be too unwieldy even with the use of visual methods (incorporating mind-maps). An attempt was also made to use taxonomies without success [20]. It was only then that the technique of using metaphors was explored as advocated by Shoemaker [23].

Investigations on, and experimentations with metaphors, was exciting as it became easier to give structure to thoughts on retentions. On pursuit of further knowledge on this area, the discovery of an interesting and a provocative book became a source of inspiration: 'Images of Organisations' by Gareth Morgan, a book which shows how it would be possible to 'see, understand, and manage organisations in new ways' cemented the approach contemplated.

Morgan's book is based on a simple premise: 'that all theories of organisation and management are based on implicit images or metaphors that lead us to see, understand, and manage organizations in distinctively yet partial ways'. It soon dawned that the use of metaphor was a powerful *way of thinking* and *seeing* to make us understand more about the world around us. He quotes as follows [21]:

> *'Each chapter invites you to engage in a mode of thinking that generates important insights while having major limitations. You are likely to be attracted to certain metaphors and be impatient with others. Or you may find competing metaphors equally compelling or attractive. As you pursue a favoured perspective you are going to find insights of others eliminated from view...In this way, the book invites you to explore and deal with the paradox of metaphor. So, absorb and enjoy the process. Gain comfort in dealing with competing viewpoints, for this is one of the key competencies that need to be developed as a basis for effective management.'*

He does not stop here. In the last three chapters of the book, he explains how managerial insights gained from the use of different metaphors could be integrated. In fact, it is this *methodology* that has been followed in the development of a set of theories on retentions.

6.1 Retention as Cash Cow

This expression is a metaphor for a dairy cow that can be milked on an ongoing basis with little expense after being acquired. In business, it is something that generates unusually high profit margins to the extent that it far exceeds the amount necessary to maintain cash-cow business, and the excess is used by the business for other purposes [24]. Likewise, in construction, retention is such a powerful facility that head contractors in New Zealand would very much like to protect.

It is well known in the construction industry as far back as the early 1940s, the sum of subcontract retentions deducted by the head contract would significantly exceed the head contract retention sum deducted by the employer [25]. However, this is not guaranteed unless the organisational buying behaviour is such that the level of outsourcing is high and the 'retention differential' (i.e. the difference between the rate imposed by principals on head contractors and the rate imposed by contractors on subcontractors) is considerable. In fact, there are many strategies that could be adopted to nest a large surplus of cash with no investment at all for contractors who outsource bulk of their work [26].

Under one of the retention regimes suggested in NZS 3910 [27], retentions are capped at $200,000 (see Table 6). This works out to a contract price of $9M. Not surprisingly, a project over this value entails an effective retention rate less than 2.2% (see Table 6). When compared with a retention rate of 10% that might be levied on subcontractors (for work less than $ 200,000 and when back to back contract terms with the retention regime shown in Table 6), there is a significant opportunity to generate surplus cash especially when head contractors negotiate for no retentions or when they have the opportunity to provide retentions bonds: Greater the retention differential, greater is the opportunity to generate surplus cash. This is what Abeysekera has labelled as the 'retention differentiation' strategy [26]. The surplus of cash so generated could be utilised for various purposes including short-term investments. No longer is it necessary for head- contractors to add financing costs for retention moneys. Planned profits are realised long before the project is over as a result of having access to surplus cash when the retention differentiation strategy is used!

It was mentioned earlier that a number of strategies could be adopted to increase the pool of cash. Consider the practice of offering back-to-back contract terms to subcontractors. This is often portrayed as a fair practice by head contractors. However, with a 'declining' retention regime (see Table 6), some head contractors deliberately limit the size of subcontract packages to $200,000 to ensure that subcontractors would be on the highest rate of retention (i.e. 10%) which in effect allows them to maximise the pool of cash to unprecedented levels. In an environment where outsourcing is high, head contractors would benefit tremendously to the extent that they would not have to borrow any funds from commercial banks. This is an interesting option particularly because commercial banks have constantly failed to understand construction when it comes to providing various facilities. There is no doubt that when retentions are used in this manner, it is a 'cash cow'. It would be surprising (and foolish) if large to medium scale head contractors fail to capitalise on this bountiful opportunity.

Given this background, it is easy to understand why head contractors in New Zealand are not keen to abolish retentions [28]; any attempts are likely to be met with stiff resistance. Interestingly, a survey of structural steel subcontractors in NZ have revealed that they do not mind retentions either, other than for expressing concerns about high rates, and the manner in which retentions are deducted and released [29]. This is in stark contrast to the views emerging from some other countries – particularly from the UK. Thus, head contractors cannot be expected to be complacent about this facility; they need to ensure that this opportunity is not taken away from them. However, as to what percentage of contractors in NZ actually use this strategy is unknown. According to business literature, cash-cow products seem to be common in markets with high growth rates, i.e. in immature markets. Whether this is the reason in NZ for the use of retentions as a cash-cow is matter that needs investigation.

Interestingly, retention regimes are fixed by people who seek services: principals or their professional advisors do so in contracts with contractors (and contractors have nothing to do with it!), whilst head-contractors do so with subcontractors. In the case of the former, investigations reveal that although the standard declining retention regime is a popular choice, other regimes are also being used (see Table 6); surprisingly, there is no rationale for setting up of such regimes; it is more an art than a science at present!

6.2 Retention as Steroid

Societies around the world have used performance enhancing substances for thousands of years. However, it is only in the recent past that this issue has received much attention, particularly with the use of Anabolic steroids (AAS) in sports as a means of increasing muscle mass and physical strength to gain a competitive advantage: The sports world was shocked when sprinters Canadian sprinter Ben Johnson was denied his 1988 Olympic gold medal, and just recently Marian Jones's was stripped off her 2000 Olympic gold medal, as a result of using AAS, which is a banned substance. However, anabolic steroids continue to be used for medical and non-medical purposes. Means of coping with adverse effects of such use have and are being developed. Given that the value of monetary retentions as an incentive for performance has been well argued for some time, it will be interesting to reflect on the metaphor of 'retention as steroid' to investigate new ways of using retentions, particularly for enhancing performance of subcontractors.

One such initiative is worthy of mention wherein an attempt has been made to 'marry' 'retentions' and 'performance' [30]: This initiative was based on the premise that subcontractors who perform well must receive better (favourable) retention regimes as a reward for their performance and as an incentive for achieving even higher levels of performance. The organisation for which this schemed was developed (by the author and a fellow researcher) had a performance database on subcontractors which was regularly updated as and when projects were completed. A number of different retention schemes were developed (see first column in Table 1) with the aim of developing a one-one to correspondence with a set of 'performance scores'. Take the 'discounted (retention) percentage' regime. In this, high performance scores were linked to discounted retention rates. As mentioned before a number of such schemes were developed and narrowed down to just five having first discussed the preferences with a wide cross section of executives (in the firm for which the scheme was developed). Thereafter, an attempt was made to reach consensus on a suitable set of schemes acceptable to the firm which were then shown to the subcontractors in order to exclude schemes which were not acceptable to them or as seen valuable. Subsequently, preferences of both the executives within the firm, and the subcontractors, were sought (using a scale rating). Then, the scores of both the executives and the subcontractors were added and ranked to select the most preferred (see Table 1). Positive and negative comments about this interesting scheme are shown in Table 2.

Table 1: Retention regime ranking summary [30]

Retention regimes	Firm	Subs	Total	Rank
Discounted percentage	14	12	26	1
Deduction Timing	23	20	43	4
Release Mechanism	12	16	28	2
Project Cap	17	17	34	3
Aggregated Project Cap	24	24	48	5

Table 2: Positive and Negatives [30]

Positives	Negatives
Improved performance for firm	More administration for firm
Improved performance for industry	Could impact adversely on company's cash flow
Early retentions fair for early trades	Creates unfair competitive between subcontractors
Reduced costs	Higher financial risk for firm if the subcontractor does not perform or goes into liquidation
Strengthen relationships with subs	
Clients aware of weeding off bad subs	
Encourages subs to give their 'A' team	
Increased desire to work for firm	
Client comfort knowing that they have high performing subs	
Better sub performance a financial gain for firm through less management	

What this study shows is that the metaphor of 'retention as steroid' brings to light a powerful message – one that is appealing not only to the head contractor but also to the subcontractor, one that is attractive but also repulsive to the head contractor. Used with caution minimising adverse effects, companies might just have an edge over those not contemplating such options. If embraced by the industry, perhaps, it might loose value at which point of time, a new scheme might have to be developed.

6.3 Retention as Beast

The word beast is used in many contexts – as an animal; as an irrational or aggressive part of somebody's personality; as somebody cruel or aggressive; or for something that is difficult or unpleasant. Do retentions display such characteristics...? If so, does this metaphor bring about new ways of understanding retentions?

There are many beastly characteristics of retentions to say the least. There is enough evidence to suggest that retentions are being abused. “Yes, it has come to the point that subcontractors now have to virtually add their retentions onto their costing… They’re not confident of ever getting them back. A lot of subcontractors will say that to me that they’re – whether they perceive their retentions to be is at least their profit. They cannot ever work on the assumption that they’ll see their retention because some of the builders will try to negotiate their last payment which will be a discharge against the monies that they’re owed. Some of them are quite unashamed about how they do it. They’ll basically say to the subcontractor, I owe $10,000 in retention, I’ll hold onto it, think up hundreds of excuses as to why I shouldn’t pay it to you. But, if you accept $5000 I’ll give you a cheque now. A lot of subcontractors would say, for god’s sake give me the $5000 and I’ll go, which effectively means that the main contractor has just extorted $5000 out of it. But that’s the way some main contractors behave!” [31]

There is also the issue that they may loose all their retention moneys (and this includes head-contractors too) if people to whom they provide services, go into liquidation, which raises serious concerns about security of payment. Financial failures often occur suddenly and unexpectedly [32] with no recourse to their funds. Such risks are accentuated by harsh retention regimes and release mechanisms. For instance, it is not common in the construction industry for head contractors to link the release of subcontractor retentions to theirs with the use of back-to-back contract terms; this is an overly long time to wait. Whilst there are good reasons for this, the practice is similar to the now illegal practice (i.e. in NZ and some other parts of the world) of the use of contractual clauses such as ‘pay-when-paid’. However, contractors (and also subcontractors in NZ) could seek the protection of the Construction Contracts Act 2003 in the event of payment delays with retentions. So how does one deal with this ‘beast’...? There are number of logical possibilities from shooting it down, to confining it, or taming it, and putting it for good use! It is an interesting way of understanding the nature of retentions.

Table 3: Strategies for coping with beastly features of retentions

Dealing with the beast	Dealing with retentions
Shoot it down	Abolish retentions #
Confine it	Use when essential
Tame it	Use retention bonds, payment bonds, trust accounts
Put to good use	Induce high performance (see Steroid Theory) **Set up a retention fund as a ‘construction bank’** [33], [34]

Research in NZ shows the contractors and subcontractors do not favour this option [28]

As mentioned before, what is interesting about using the ‘retention as beast’ metaphor is that it provides new ways of understanding issues related to retentions and gain new insights and new options for dealing with retentions. Consider the ‘put to good use’ strategy and the related option of a *central retention fund*. According to Hughes [35] such an approach is considered to be a revolutionary option, one that is 'new, and perhaps a radical approach' to moneys 'otherwise dissipated and diluted to such an extent that they are of little use to a nation'. This is an interesting and exciting option given that commercial banks have consistently failed to understand construction. Some of the main benefits of such a fund are shown in Table 4 [33].

Table 4: Benefits of a Central Retention Fund

The Costs and Benefits of a Retention-based Fund
i. Security of payment as cash retentions are held by an independent body. ii. Ownership in the hands of contractors and subcontractors provide greater opportunity to introduce construction-friendly services. iii. Reduced prices to clients. iv. Bonds and guarantees at cheaper prices (with nil/minimal collateral). v. Elimination of retention bonds. vi. Work in capital loans to subcontractors/contractors, secured on retentions held by the fund. vii. Higher leverage on retention-based investment (e.g. loans factored many times its value) viii. Higher returns with larger pools of money utilising expert fund managers ix. Use of contract receivables as collateral x. Trade bonding for 'performance' with 'retention' build up xi. Use of a third party for dispute resolution. xii. Targeted training for members xiii. An outward orientation (as a service than profit) with a greater focus on member development xiv. Use of innovative, contractor-friendly approaches understanding the nature of construction.

6.4 Retention as Stress

Interestingly, just as much as retentions display beastly characteristics, it displays stressful characteristics for almost the same reasons given above. To give an analogy as to what stress is like, consider the case of a concrete column. Increase the load, the column will take up the stresses but only up to point beyond which it will fail. This is very similar to what happens with human beings when subject to stress; the repercussions are well documented. This perspective suggests that retentions are acceptable up to a point beyond which there is bound to be adverse impacts. If so, there is a need to develop strategies to minimise such effects, if at all possible (Note: see 'retention as chaos'; stress a means by which systems could be move to 'edge of chaos'). Some of the strategies that could be adopted to minimise stress levels of humans in a work setting are shown in Table 5. Interestingly, when one reflects on these strategies, new insights can be gleaned. Indicative responses are given in Table 5.

Table 5: Strategies for dealing with retentions with the stress metaphor

Stress prevention at workplace [22]	Strategies for dealing with retentions
• 'Ensure workload is in line with workers' capabilities and resources	• Tailor retentions to suit contractor/ subcontractor capabilities
• Design jobs to provide meaning, stimulation, and opportunities for workers to use their skills	• Develop retention regimes to induce performance (see 'retention as steroid'); price discounts for nil retentions
• Clearly define workers' roles and responsibilities	• Define purpose of retentions (at present it is ambiguous as mentioned before)
• Give workers opportunities to participate in decisions and actions affecting their jobs	• Opportunity to negotiate retention regimes
• Improve communications-reduce uncertainty about career development and future employment prospects	• Tie-up retentions with current and future jobs; take a relationship-based approach
• Provide opportunities for social interaction among workers	• Transparent retention regimes
• Establish work schedules that are compatible with demands and responsibilities outside the job'	• Establish (fair/favourable) retention regimes by taking into account of work undertaken on other projects (e.g. cap total retentions when a contractor/subcontractor works on number of projects for the same client)

6.5 Retention as Chaos

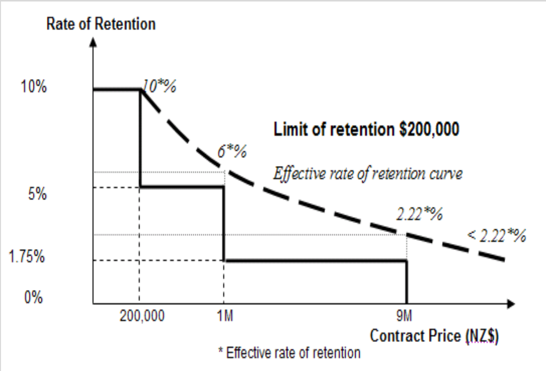
As mentioned before, the retention phenomenon examined in this paper, has spanned over a century in NZ. It was initially introduced through legislation in 1892 and then abolished with the repeal of the Contractor's and Workmen's Liens Act in 1982 (after amendments in 1908 and 1939) [36] but carried on through using contractual provisions which is used in almost all contracts in the commercial sector of construction. Moreover, the old and the new imperatives are very different; earlier, the emphasis of creating a retention fund was to protect those who were providing services, but today, it is used for protecting those who seek services from others [37]! Clearly, issues connected with retentions seems to be perennial; the sentiments expressed by Rt. Hon. Geoffrey Palmer, the then Minister of Justice, at the third reading of the 1987 Lines Act Repeal Bill sums it all: "I am completely satisfied that it is not possible to reach agreement with industry on the reform of the revised Liens Act, and the reason is that the interests of contractors and subcontractors are diametrically opposed to each other. Contractors prefer to hang on to retention money for as long as possible and subcontractors prefer to be paid as soon as possible. The time has arrived to let the building industry work out its own solutions…" [38].

Nothing significantly has changed since the repeal of the original Act but for the introduction of the Construction Contracts Act 2003 with the aim of dealing with payment delays. However, the practice of using retentions has continued unabated particularly with the sliding retention regime notwithstanding others (see Table 6). Despite its extensive use, there is no rationale for setting up such retention regimes whether it is about rates, limits - capped or otherwise, release mechanisms (amounts released on practical completion) and the length of time held. Moreover, different standard form contracts specify different clauses in relation to retentions. There aren't any explanatory or guidance notes on how to set up such schemes. Moreover, most contracts are silent on how to provide security for retentions monies but for a few specifying the use of trust accounts whether interest bearing or not!

Table 6: Retention regimes used in New Zealand

Work connected with head contractors

Sliding retention regime [27]



Project 1:	$4M - 5% of Contract Price with a limit of $ 125,000; Defects liability retention (DLR) 50%
Project 2:	$100 M - 10% on first $15M + 5% on next 30M + 2.5% thereafter; Limit of retention $3.5M; DLR 50% from last separable portion
Project 3:	$ 25M - Retention rate 10%; Limit of retention 5%; DLR 50% from last separable portion

Work connected with subcontract work [39]

TRADES	Current Practice									
	Retention %					DLP (months)				
	0	5	10	15	20	0	1	3	6	12
	% Of Respondents									
Front End Trades										
Demolition	40	10	50			40	20	30	10	
Excavation	10	20	70			30	20	40	10	
Piling		10	90			20	20	50	10	
Concrete work	40	30	30			40	20	30	10	
Pre Cast conc.	50	20	30			50	10	30	10	
Reinforcement Steel	80		20			80		20		
Structural Steel		20	80					70	20	10
Brick & Block Work	10	10	80			10		60	20	10
Drainage		10	90				10	50		40
Mid Trades										
Metal Windows & Doors			100					70	20	10
Carpentry	40	30	30			40	10	40	10	
Joinery	10	10	80			10	10	70	10	
Roofing		10	90					70	20	10
Plumbing & Gas		10	90					50	10	40
Mech. Services		10	90					40	10	50
Fire Protection		10	90					40	10	50
Electrical Services		10	90					40	10	50
Back End Trades										
Solid Plaster / Cladding			100					80	10	10
GIB Fix & Stop	20	20	60			20	10	60	10	
Suspended grid ceilings		20	80				10	80	10	
Floor Coverings		10	90				10	80	10	
Painting & Sp. finishes		10	90					80	10	10

None of the standard form contracts used in NZ define the purpose of retentions. Part of the problem lies in not understanding or agreement on what retentions are for: whether it is for performance, for defective workmanship, or not. Often contracts specify 'performance bonds' in addition to retentions. If these are for performance related matters during construction (including any defective work), the case for withholding moneys from progress payments is weak. The whole issue of who owns retentions (i.e. the principal or the contractor) is a matter for debate.

Consider the case of performance bonds valid until the end of the defects liability period. If so, is there a real need for monetary retentions? Some may argue that there is given that the 'power' of cash retentions far exceeds the power of bonds when it comes to getting contractors on site to finish defective work. It is also not clear whether retentions are for those defects arising during construction, or for those arising during the defects liability period, or both. Latent defects would, of course, not enter the fray (as the contract would be non-existent) by then. However, as to whether retentions relate to defects due to materials is a contentious matter particularly for materials specified by the designers which are found to be defective. Perhaps, these would be covered separately through material warranties and guarantees.

The practices differ significantly with subcontract work, particularly in the building sector. High rates of retentions (Table 6), excessively long periods of release, price discounts for retention-free contracts, trade related retention regimes are some examples [39].

In short, the manner in which retentions have been used is ‘chaotic’!

Given this state of affairs, it is interesting to explore an interesting and novel way of reflecting on retentions by making use of various theories on chaos in order to develop new insights on how to ‘live with chaos’ or to bring ‘order’. All the theories described thus far, such as the ‘cash-cow’ and the ‘beast’ theories indicate how to ‘live with chaos’ but not the latter. Before, such possibilities are explored, it is necessary to understand what chaos theory is about.

According to Hall ‘unlike relativity and quantum mechanics, chaos is a science of everyday things – of art and economics, of biological rhythms and traffic jams, of waterfalls and weather..., and is a new line of scientific inquiry which has caught the popular imagination [40]. Many would consider the hallmark of ‘chaos’ to be what is popular known as the “Butterfly Effect” after Edward Lorenzo’s paper on “Predictability: Does the flap of a butterfly’s wings in Brazil set off a tornado in Texas?” As the title suggests, a small alteration in the state of a dynamical system will cause subsequent states to differ greatly from the state that would have followed without the alteration [41]. To put it differently: it is about the small that can produce the great, or what others have referred to as ‘sensitive dependence on initial conditions’.

So what is the relevance of these observations...? The very nature of ‘sensitive dependency to initial conditions’ suggests outcomes which are apparently random and chancy [42]. However, this is a paradox [43] in that chaos is deterministic; meaning that later states evolve from earlier states according to fixed rules or laws. Nevertheless, minute uncertainties are amplified with the effect that even though the outcomes are predictable in the short term, these are unpredictable in the long term: Two paper cups floating side by side on top of a waterfall may well end up far apart at the bottom. This is considered to be one of the significant discoveries about chaos (related to dynamical systems; in fact, construction industry can be considered to be one such [1]). When these findings are translated into situations connected with retentions, it might mean that despite having the same retention regimes, slight differences in other project characteristics will result in significantly different outcomes! In fact, it can be very easily shown that this is very much the case in relation to say costs and benefits either to the client, contractor or to the subcontractor.

Another feature of chaos is that despite its randomness, there is ‘order’! It is this promise of finding a fundamental order and structure behind complex events that has aroused much interest in chaos. This randomness is said to have an underlying geometric form(s) or what is known as “attractor(s)” (pattern) [44]. Could such patterns be identified in relation to retentions...? Could these chaotic events be moved to a different attractor...? Interesting as it may be, these findings provide new insights on how 'retention chaos' could be resolved.

It must be pointed out that both chaos and order can be observed in juxtaposition within the same system with much interest in finding out how systems progress from chaos to order and vice-versa, as when water in a steady-flow state moves into turbulence (with eddies and whirlpools). According to Feiganbaum [45], there is astonishing regularity in the route to chaos, which he refers to as 'universality'. What is this route...? What are its characteristics...? If these can be found, we might be able to gain new insights on how to deal with retentions.

There has also been much interest in finding how systems could be moved from a chaotic state to an orderly state. Stacey [46] points out that 'when non-linear feedback systems in nature are pushed far from equilibrium into chaos, they are capable of creating a complex new order'. For example, atoms in a gas when subjected to an external impetus (say heat), can 'spontaneously re-organise' to create a complex new order [46]. However, it has also been found that as systems proceed through chaos, some options may represent yet further chaos whilst others may lead to more orderly forms, but which will occur is said to be unpredictable. Suppose for instance, the local association of consulting engineers issues a directive to the effect that subcontractors' retention moneys should be deposited in a trust account. This change is to be made through contractual clauses. If the consulting community adopted the change, what chaos theory points out is that it is not possible to predict the outcome (as this a feature of systems in chaos). Take another example. Suppose for instance the government introduced legislation stating that it is illegal to use the 'sliding retention regime' in an attempt to minimise the benefits of using the retention-differentiation strategy. Once again, the understanding provided by the chaos theory is that it is not possible to predict the outcome. However, if systems are pushed to the 'edge of chaos' through such interventions, the chances are that there may be a possibility of creating a complex new order. Consider the following example:

> *'Mediaeval bricks in the U.K. were burnt with wood fuel in kilns or clamps and from early 13th century sizes had varied from district to district 10 -15" long, 5-7.5" wide and 3 1/4" thick [which is chaotic]. Flemish bricks were smaller, nearer to the present day bricks 8 - 9 3/4" long, 3 3/4 - 4 3/4" wide and 1 3/4" thick. ... [T]hese latter sizes were used almost universally until 1784 when the tax of that date imposed on bricks produced an increase in size, as large bricks paid the same duty as small. When in 1803 the duty was doubled on bricks over 150 cubic inches in volume, the size settled down to approximately the present day dimensions, being that most suitable for handling by the bricklayer. This duty was ultimately repealed in 1850.'* [47]

The situation described is similar to the 'spontaneous self organisation' concept; the unexpected increase in the size of the brick by manufacturers (spontaneous self-organisation) caused revenue to drop as a consequence of the imposition of a duty (an external impetus) and the subsequent modification of the duty structure (for short-living the dissipative structure) resulted in the re-manufacture of smaller size bricks (spontaneous re-organisation to an orderly state).

Understanding behaviour of chaotic systems assists in taking new approaches for understanding, coping, and combating the 'retention chaos'.

7. Implications for theory and practice

> *"The purpose of scientific enquiry is not to compile an inventory of factual information, nor to build up a totalitarian world picture of Natural Laws in which every event that is not compulsory is forbidden. We should think of it rather as a logically articulated structure of* ***justifiable beliefs*** *about nature [i.e. with explanations as to why the belief is a true one]. It begins as a story about a Possible World—a story which we invent and criticise and modify as we go along, so that it ends by being, as nearly as we can make it, a story about real life."* [6]

Images of Retentions was an attempt to write a story about a practice that has spanned well over a century. Specifically, this was attempt to build a story through 'facts' in a way that it condenses what we know, capture and provide new insights, and facilitate scientific practice. The Cash-Cow Theory explains the value of monetary retentions for those who outsource their work with a desire to capitalise on the cash benefits on offer. It also explains how they may do so. Embedded within the theory are the responses to all the theory building elements discussed earlier. Furthermore, it also explains why contractors should not show any complacency in protecting the 'cash-cow'. The Steroid Theory of Retention explains the power of retentions to act as a catalyst for high performance (and not just performance). The Beast Theory highlights the woeful implications of retentions and how beastly features can be put into to good use. The Stress Theory defines the impact of its use, particularly extensive use, and strategies that may be used to minimise the adverse impacts in addition to providing various new insights as was the case with other theories. Finally, the Chaos Theory on Retentions portrays retentions as a chaotic phenomenon, and how features of chaos could be used to gain new insights particularly for moving retentions to a new order. These theories are accounts of *justified* beliefs; they describe, explain, and predict what might happen if certain courses of actions are taken, particularly in a New Zealand context. These are not perfect; there is opportunity to criticise and modify as we develop understanding: this is the nature of theory.

Individually, these 'theories' tell us a one-sided story by highlighting certain interpretations and forcing others to the background. This needs to be understood but importantly the theories need to be viewed together rather than in isolation, understanding the opposing and complementary points of view, along with their interactions. For example, if the aim is to 'live with chaos', each of these theories tells us how one might to do so in a way that betters current practice. On the other hand, if the intention is to bring order, each of these theories might be used for this purpose; create more chaos and push the current state to the 'edge of chaos' with the hope of producing a new order through 'spontaneous re-organisation'.

This is only a beginning; there is more to be understood about this *'unwanted essential'*!

8. Implications for Research

Theory is neither complete nor perfect! So are the *theories* that go to build *theory*. There is a need for such an appreciation through which new theories could be developed, or existing ones modified, thereby refining our understanding in a way that informs practice: The theories presented herein should be a good foundation to undertake further investigation and exploration.

The theory (and theories) presented on retentions are not exhaustive: These theories do not explain, for instance, why retentions are mainly used in commercial construction and not residential construction or why retentions are not used in supply contracts. Nor does it explain why it is only meant to protect those who seek services and not those who provide services. There is a need for further explorations with the aim of building theory and theories. In this regard, the use of metaphors as a methodology cannot be underestimated; in deed, it is an interesting, valuable, and an exciting approach for building theory, as evidenced in this study.

> *'Theory building is difficult because it requires both great discipline and great creativity, and although a person may possess one of these attributes, few people seem to possess both. In fact, we suspect that those who possess one of these attributes are likely not to possess the other – that those characteristics that make for a great disciplinarian do not make for great creativity, and vice-versa. But that is just an untested hypothesis we have. What we do know, tried and tested from many personal experiences, is that theory building requires excruciating attention to detail coupled with wild flights of imagination. About the only solace we can give you is that it probably won't kill you and that if it doesn't kill you it probably will make you stronger'* [48]

COST PLANNING AND CONTROL

Security of Payment and Payment Bonds: A New Zealand Perspective

Abstract

Security of payment legislation does not seem to provide any protection for the contracting community when the principal or the funding institution goes into liquidation. Losses arising out of such failures are a major concern for such communities of practice and this study examines this issue from a New Zealand context, particularly as to whether a statutory bonding mechanism would be a way forward. In this regard, the practice of using 'payment bonds' in the USA is examined which is found to be of less value for the two types of payment losses this study focuses on, namely, the loss of interim payments, and retention monies. Thus, in order to find a suitable solution to this problem, the nature of the risks associated with these losses is examined. It is found that the risks associated with interim payments and retentions are significantly different. As such, the provision of two different types of bonds, i.e. 'principal bonds' and 'retentions bonds' (as prescribed in NZ standard form contracts) appears to be a sensible approach when compared with the 'payment bonds' used in the USA. Nevertheless, these are of little value as they are rarely ever used: Examination of industry practices reveal various ad-hoc arrangements which are mainly of value to main contractors but not to subcontractors. Given the power of cash-retentions and the many benefits that it offers to main contractors when employed with the 'retention-differentiation' strategy (in an environment where large volume of work is outsourced) given a unique and a comparatively 'contractor-friendly' retention regime used in NZ, there is little opportunity for the subcontractors to manage the retention risk. Given this background, the industry has the opportunity to lobby the government for a solution (i.e. for a statutory bonding mechanism through the Construction Contracts Act 2002 or otherwise) if the benefits far outweigh the costs, and also by lobbying the consulting and project management community for a solution through contract documents. In the alternative, industry could self-regulate through a central retention fund (either public or private) which would no doubt provide security for retention monies and also for interim payments (by the issue of suitable bonds or otherwise); such an approach has the potential to usher a new era for the construction industry through a construction bank that better understands the commercial realities of construction. Further investigation is necessary before a sustainable solution can be found to a major national problem.

Keywords: guarantee, payment bond, retentions, security of payment

1. Introduction

Security of payment is a major concern of contractors, subcontractors, and suppliers alike in an industry that is widely perceived to be risky. In a breakthrough piece of legislation, contractors (including subcontractors) and some suppliers can now seek the protection of an Act of Parliament known as the Construction Contracts Act 2002 [1]. The main intention of the Act is to facilitate progress payments and to set in place a mechanism by which related disputes could be resolved speedily. In particular, a major relief for the subcontracting community was the abolition of pay-if-paid and pay-when-paid contractual provisions making it illegal to use even if the parties agreed to.

Whilst such legislation exists in number of countries, they seem to fall short in providing protection to contractors, subcontractors and suppliers when the 'principal' or the 'funding institution' ceases to exist. This is the case in New Zealand. Indeed, the situation is such that many construction companies, some first tier companies have gone bankrupt particularly during the last decade leaving the subcontracting community to absorb the perils of such failure with a detrimental impact on an industry that is well known for its high rate of bankruptcy. With outsourcing a common practice in NZ, the impact of such failures place huge strains on this community. As Meng [2] has pointed out, such strains, shuns the development of an industry that is so vital for national development: It is timely, and logical, that this issue be investigated further.

Interestingly enough, as far back as 1892, New Zealand had legislation that protected contractors, subcontractors and workmen for the payments due to them. Known as the Contractors' and Workmen's Liens Act, at the time the Act was enacted, there was no equivalent legislation either in the United Kingdom or in Australia although similar legislation was widespread in the United States and Canada on which the NZ Act was based [3]. The provision of security for contractual debt was such that the Act provided a right of payment to any contractor, subcontractor, supplier of materials, or workman by way of security given over money (called a charge) or security given over the owner's interest in land or chattels (called a 'lien'). The Act required a percentage of the value of the work (i.e. 25% of the money payable) be retained by the payer (the owner, employer, or builder) for a specified period of time (i.e. 31 days after the completion of the work), out of the monies that would othe payable for the work, so providing a fund against which the charge could operate. Whilst these percentages reduced over the years, the Act was repealed in 1987 as there were many problems with its implementation [4]. Almost after 15 years since its repeal, there is a new Act in force (as mentioned before), which provides various protections for payments in the construction industry but not when the principal or the funding institution goes into liquidation. The 'principal' as referred to herein can either by the client (in the case of the client-contractor relationship) or the contractor (in the case of the contractor-subcontractor relationship).

2. The Problem and a Standard Solution

Payment risks are mainly of two types, firstly, those due to payment delays, and secondly, those due to 'payment losses' (PL) when the principal or the funding institution goes bankrupt. This study focuses on the latter type of risk, as it has no protection under the CCA when compared with the former. What possible solutions exist for the latter problem...? Indeed, one of the simplest would be the use 'payment bonds' (PBs).

In essence, a PB is a ‘surety’ bond wherein one party, i.e. the surety (an insurance company or a bank) guarantees to another, the obligee (say the contractor), that a third party (say the principal) will perform a contract in accordance with the contract documents [5]. In the event the principal fails to perform all obligations diligently, the surety agrees to compensate the obligee with financial costs, up to an agreed limit [6]. As to what this agreed limit needs further investigation. In the USA, it seems to be not less than the penal sum of the performance bond with regard to the contract [7].

According to Powelson [8], a payment bond (in the USA) is intended to guarantee the employer (i.e. the client employing the contractor) that subcontractors and suppliers will be paid the monies that are due from the contractor. In certain states in the US, this is a statutory requirement as per the Miller Act [9]. Understandably, such a bond would no doubt be in the interest of the project (and of course the client) to ensure that project progress is not hampered by payment delays. Moreover, if it extends to situations where the contractor goes bankrupt, the client and the subcontractors including suppliers are further protected. If so, the PB (as used in the US) appears to provide an opportunity for wider protection than available in NZ. However, there does not appear to be any evidence to suggest that clients reciprocate such arrangements by giving a similar bond to contractors. In fact, as noted by Powelson [8], the practice in US is such that it is the main contractor that guarantees payment to certain subcontractors, workers and suppliers and not the client to the contractor. However, note that only first-tier subcontractors and suppliers who contract directly with the main contractor and certain second tier parties are entitled to a payment bond’s protection.

This raises the question as to whether a PB could not be used as a means of ensuring security of payment to main contractors in the USA, or more to the point, in NZ. Interestingly enough, the practice in NZ seems to be different in relation to who provides the bond and its coverage. The main standard form of contract for building and civil engineering works, i.e. NZS 3910 [10], provides a format for a guarantee (vide Fourth Schedule) where the security comes in the form of a bond referred to as the Principal’s Bond (and not payment bond) to ensure the performance of the Principal’s (i.e. the client’s) obligations under the Contract. As per Cl. 2(b), the expectation is that the Surety shall pay to the contractor up to the ‘amount of the bond any unpaid balance of the Contract Price and of any other monies payable under the Contract Documents, and of the damages sustained by the Contractor in respect of all default by the Principal’. However, it is not clear whether this bond could be used in situations where the principal goes bankrupt; it will be necessary to investigate the bond conditions. Moreover, as things stand, it is neither mandatory nor enforceable as it is left to the discretion of the Principal to agree. Furthermore, it is not clear whether banks/funding institution would accede to terms and conditions referred to therein. In fact, according to Kangari and Bakheet [11], the process involved in assessing risks for underwriting purposes is complicated wherein factors such as financial strength of the contractor, performance reputation, contractor’s capacity and project characteristics, and business continuity and the like, need to be considered. Thus, the situation in NZ is such that contractors, subcontractors and suppliers are exposed to a particular kind of risk without a ready mechanism to deal with such types of risk, i.e. loss of payment for work performed (including consequential losses and retentions) when the principal or the financing institution goes bankrupt. Hence, one of the questions that spring to mind at this stage is as to what type of bond could be used either through contract provisions or through other arrangements.

3. The Focus of This Study

In order to understand the use of PBs for PLs, it is important to understand the nature of the PL risk, and as to how the industry has responded to it this far. In fact, this is a risk that cuts across all communities of practice including the contracting and consulting communities which includes contractors, subcontractors, suppliers and consultants. Given the widely held belief that it is the contracting community (i.e. contractors, subcontractors and to a lesser extent suppliers) that is heavily exposed to this risk, this study focuses on the contracting community (excluding suppliers). It is expected that on completion of this preliminary study, it would be possible to establish a broad set of objectives for a much in-depth study to ascertain the feasibility of using PBs to provide security for PLs.

4. The Nature of the Payment Risk

In order to understand whether or not PBs are an effective strategy for dealing with the security of contractual debt related to PLs, there is a need to understand the nature of the risks involved. Number of issues and factors impacting on this are considered in the following sections.

5. Types of payment and payment risks

There are three types of payments to be considered when focussing on payment risks through bankruptcy: The first relates to interim payments (i.e. for work done during a particular period, say a month). The second relates to payments made for materials (either on or off site, or on order) and finally, the third relates to sums of moneys retained from interim payments generally as a protection against poor workmanship. However, according to Hughes [12], such sums are held partly as security in the case of non-performance, and partly as leverage to persuade them to come back and complete the final few items of work after practical completion. The actual intentions may need to be gleaned through contract provisions and statutory provisions. The type of payment risk with respect to the contractual relationship is shown in Table 1.

Table 1- Payment risks

Relationship	Community at risk	Defaulting party	Payment risk
Principal-Contractor	Contractors	Principal (P)/ Funding Institution (FI)	Interim payments Retention moneys Payment for materials (on or off site, or on order)
	Principal	Contractor	Advance payment#
Contractor-Subcontractor	Subcontractor	Contractor	Interim payments Retention moneys
	Contractor	Subcontractor	Over payment
Contractor – Supplier	Supplier	Contractor	Materials on credit

Rare in New Zealand; hence, not discussed.

5.1 Types of principals

The practice of obtaining a PB from the principal who in fact selects the service providers seems an unusual and unpopular preposition as there does not seem to be any benefit to the principal other than perhaps to secure the services of a top quality provider in times of high demand. Moreover, principals have different risk profiles; some more risky than others. For example, when the government commissions projects, it is rare for them to go into liquidation or fall short of funds for payment. Whist this may be the case in New Zealand (or for that matter in the developed world), it is not an uncommon in developing countries to fall short of funds as they sometimes budget for more projects than for which funds are available (in order to counteract underperforming projects), or when funds already pledged do not materialise. On the hand, private sector clients, especially property developers in comparison with government clients, are considered to be less trustworthy at least on the face of anecdotal evidence. Thus, there is a need to understand the ***payment risk profile of principals*** in order to make decisions on strategies for dealing with payment losses (described earlier).

5.2 Construction sectors

Main contractors operate across many sectors of the industry from residential, commercial to infrastructure. Clearly, the risks of working across these different sectors are not the same. For instance, there is anecdotal evidence that those who work in the property development sector are exposed to a greater level of payment risk than in other sectors. Such differences need to be understood before any attempt is made to promote solutions to payment risks. The situation is much the same when it comes to subcontractors with further differences depending on the type of work they do (say different trades in building projects) and also depend on whether it is labour only, or a full contract, or whether nominated or otherwise.

5.3 Project characteristics and interim payments

Big or small, projects vary in length. Interestingly, the size of the projects and its duration is linked with the nature of the payment risk. Interim payments of a project which is 10 months long would roughly be 1/10th of the contract sum which appears to a large sum of money to lose when compared with general profit margins; and in the case of a 5 month long project, this may be roughly 1/5th. Clearly, the nature of the payment risk would be higher in the latter than the former for projects of similar value. On the other hand, the payment risk in a larger project with the same duration would be comparatively larger than a smaller project. In other words, larger the rate of turnover, larger appears to be the payment risk (in relation to interim payments). However, as for retentions, the risk would appear to be different with larger and longer duration projects (with longer defects liability periods) having a larger risk. Thus, with such different profiles of payment risks, applying a single PB seems unsuitable, unless of course the PB is geared to reflect the nature of the risk that is currently being understood.

5.4 Types of work and nature of trades

First consider the case of the subcontractors in the building industry. According to the findings of a study by Abeysekera and Soysa [13], contractors do not view all trades as equally risky which would mean that the amount of retention moneys held would also be different. Results of the study mentioned earlier show that contractors do reflect on trade-risk when fixing retention rates and release mechanisms. As to whether this is the case with civil engineering work is unknown and needs to be investigated.

5.5 Type of sub-contract and the time lag

The type of sub-contract seems to have an impact on payment risk. For example, if the work is labour-only, it is usual (in NZ) to receive payments on a fortnightly basis but given that the first payment is received only after about a week or two, the payment risk period is approximately 3 to 4 weeks. When compared with work involving ‘labour and material’ there is a significant difference as payments for such work are made usually on a monthly basis which amounts to a payment risk period of around 2 months. If this period can be reduced, then the risk involved could also be reduced.

The question of whether this period is either too long or too short may depend partly on whether the principal is seen as creditworthy; in other words, the risk profile of the principal. Thus, in order to understand the issues at stake, it appears necessary to investigate how businesses assess creditworthiness of their customers (which may also impact on the price-discounts they may or may not secure for say material purchases). However, in the case of construction contractors (or subcontractors as the case may be), they may not have much of a choice other than to make a decision whether or not to take the job depending of course on market conditions. If so, they would have to accept the risk which may have unfortunate and debilitating repercussions in the event the risk eventuates.

5.6 Retention regimes

Take the case of retention regimes imposed by clients on main contractors. Examinations reveal that the commonest regime used in NZ is a sliding one as shown in Table 2. Accordingly, as the contract price increases, the effective rate of retention reduces. Of course, this is not the only regime used. Other examples are given in Table 2. It appears that there isn’t a rational explanation as to why such regimes are being used.

In formal construction, it is common for main contractors to enforce back to back terms on subcontractors; in essence, smaller the value of the subcontract, larger is the rate of retention. For example, if the value of the subcontract package is less than $ 200,000, the applicable retention rate would be 10%. This creates a retention differential as noted by Abeysekera [14] which in essence creates a surplus of cash for the main contractor. This is indeed the case if main contractors adopt the same retention release mechanisms that are applicable to them. However, examinations show that this is not the case always as some trades, particularly the front end trades in the building industry have been able to get their retentions released after a stipulated period from their practical completion as against main contractor’s practical completion [13]. It is not clear whether this is a common practice or not. Nevertheless, what is clear is that subcontractors are exposed to a comparatively higher financial risk than main contractors, and if the main contractor goes bankrupt, the amount of retention moneys held by clients may not be sufficient to meet subcontractors’ retention monies, particularly after taking into account of other debts a contractor may have when they liquidate.

Table 2- Retention Regimes

<table>
<tr><td rowspan="4">
The contractor-friendly sliding-scale retention regime used in New Zealand</td><td>Project (2005)</td><td>Retention Regime</td></tr>
<tr><td>A</td><td>$4M; 5% of Contract Price with a limit of $ 125,000; Defects liability retention 50%</td></tr>
<tr><td>B</td><td>$25M; Retention rate 10%; Limit of retention 5%; Defects liability retention 50% from last separable portion</td></tr>
<tr><td>C</td><td>$ 100M; 10% on first $15M + 5% on next 30M + 2.5% thereafter; Limit of retention $3.5M; Defects liability retention 50% from last separable portion</td></tr>
</table>

6. Risk Management Strategies: Current Practices

There is no doubt that contractors and suppliers adopt various strategies to cope with payment risks, from receiving payment in advance (before work/supply is completed) undertaking work only to the extent of funds made available, and many others which will be described later. However, as mentioned before, one of the solutions used particularly in the United States (see Miller Act) is to use payment bonds (i.e. principal bonds) for the protection of not only contractors and subcontractors but also suppliers (although not much is known about its success or failure). Of course, such a payment bond could theoretically provide protection for retention moneys as well, but the risks involved for regular payments and retentions moneys are *significantly different* as explained earlier which will require different type of payment bonds and release mechanisms.

6.1 Principal-contractor relationship

One of the solutions that have been used in large scale projects is to enter into a tripartite agreement wherein the funding institution is included as a party to the traditional bi-party agreement between the principal and the contractor. This seems to be a common practice in large property development projects. Though there is a possibility of using Principal Bonds (as made available through NZS 3910), not surprisingly, there does not appear to be any evidence of it being used.

With regard to retention moneys, top tier contractors in NZ would no doubt attempt to exclude retentions from contracts they enter into leveraging their reputation particularly if a performance bond is called for. Of course, they could also seek to submit a bond in lieu of retentions (referred to hereinafter as retention bonds as in NZS 3910) thereby eliminating the retention-payment risks altogether. However, the principal has to agree to it in the first place (and not otherwise) which appears to be a much easier option than a Principal Bond. However, it would obviously fall short of protecting contractors with respect to interim payments risks. Moreover, as to whether PBs would be valid when the contractor has gone bankrupt needs to be established.

The fact that standard form contracts in NZ provide for the above mentioned bonds (i.e. principal bonds and retention bonds) is interesting. Moreover, it is an impetus to a solution through a bonding mechanism. However, given that there is no evidence that PBs have ever been used in NZ (and that

RBs seem to have been used sparingly), there is, perhaps, a need to investigate why these have not been used (by main contractors) despite being available at least through standard form contracts.

With regard to retention moneys, there is a number of risk management strategies which go beyond RBs including the use of trust accounts (whether interest bearing or not) and also whether as a combined performance and retention bond [15]. Another option would be to channel all retention moneys to a central repository [16] which according to Hughes [12] is a ‘new, and perhaps radical’ approach to moneys ‘otherwise dissipated and diluted to such an extent that they are of little use to a nation’. These ‘new’ strategies have not been seriously explored in NZ construction industry but for an initial attempt by Abeysekera [17]. Of course, there is also an extreme option, i.e. the abolishment of retentions altogether – an option which is unlikely to be accepted by the contracting community in NZ which perceives retentions as being a fair practice [15] perhaps given the many benefits available to them through the ‘retention differentiation’ strategy [18]. The extent of its use as a business strategy is unknown (across different construction sectors) in order to weigh the benefits of the retention differentiation strategy against the costs of losing retentions in the event the principal goes bankrupt. In other words, there is a need to understand the costs and benefits of using retentions in order to make a decision on whether or not to use (a) a payment bond which provides protection for both interim and retention payments, (b) whether two different types of bonds, one for interim payments and the other for retention payments should be used given the different nature of the risks involved (as explained earlier), and (c) a strategy for implementing such bonds (as for instance, through contract documents or through legislation).

There is of course another option than the use of bonds, i.e. letters of credit which is used extensively when importing materials and to a lesser extent domestically. This is another option that needs to be investigated fully.

6.2 Contractor-subcontractor relationship

Subcontractors appear to be at a higher level of risk when compared with main contractors both with respect to interim payments and retention moneys partly because they do not seem to have access to either PBs or RBs even when such facilities are available to main contractors. Moreover, there is evidence that retention moneys in the hands of some contractors have been abused increasing the risk of non-payment [17]. This seems to be the case even with the CCA in force which raises the question whether the Act itself needs to be amended, which in essence is a legal solution to the issue of security of payment.

In relation to retentions (as against regular payments), it is interesting to point out that NZ subcontractors are not totally averse to the concept of retentions. Abeysekera and Price [19], seeking the views of structural steel fabricators found that most were at ease with retentions but for the manner in which retentions were used (larger rates, smaller contract packages to increase the differentiation of retention rates, lack of security, etc.). In fact, some large steel fabricators saw retentions as a positive business strategy which allows them to compete with smaller fabricators! However, whether the trade-off is so significant to the extent that they would not mind losing interim and retention payments in the event of a collapse of a contractor is unknown.

Just as much as main contractors negotiate for better deals with clients by using their reputation for example, subcontractors too negotiate favourable retention regimes with contractors but large many still find it difficult. Some subcontractors have attempted to provide price discounts in lieu of retentions as a way of managing this risk. Others, particularly those involved in specific trades (i.e. front-end trades in the building industry) have been able to obtain lower retention rates and better than normal retention release mechanisms [13]. Thus it seems there are more issues impacting on the retention-payment risk and consequently on its magnitude (i.e. the combined effect of exposure, severity, and likelihood) when compared with the interim payment risk. What seems to be emerging is that the risks connected with interim and retentions payments are significantly different and as such having one type of bond for both types of risks may not be commercially viable option particularly with regards to risks faced by subcontractors.

Whilst this may be so, the power of cash retentions through the retention differentiation strategy [18] appears to be very strong to the extent that it is difficult to see how contractors would let go of cash retentions (without the possibility of having access to cash either through a trust-account or may even be a central retention fund). Thus, it seems doubtful that subcontractors would be successful in obtaining PBs or RBs unless the clients insist that they do so. If they do, no doubt, clients will have to pay extra (for the bonds, and also for financing costs); there does not appear to be any real incentive for them to do so. Thus, to move forward the agenda for the use of PBs, there appears to be a need for government intervention. However, if the industry is to self-regulate (or be regulated by the government), the solution may come through a 'retention fund' which could (a) provide protection for retention moneys whilst providing a return, and (b) issue PBs using retention moneys as collateral and also through funds generated by investing retention moneys, whilst serving as a bank that understands construction. This seems to very interesting and promising option that must be evaluated.

There are other possibilities. For example, subcontractors could explore the use of performance bonds in lieu of retentions although there is no evidence to suggest that it has been tried out. The downside is that obtaining a performance bond from a bank is not easy (without collateral). Moreover, bank bonds usually drain working capital facilities provided by banks which in turn restrict the ability of a subcontractor to undertake new work. Although insurance bonds may be a more welcoming solution, contractors may be sceptical about bonds from insurance companies.

It should be clear from the above discussions that there are various risk management strategies that contracting parties adopt. However, there is little understanding on which of these would be better for the long term sustainability of the industry. Moreover, as to whether these approaches increase the overall costs of construction without commensurate benefits need investigation too. Furthermore, whether existing financial institutions would provide bonding facilities (and at what price) need investigation. In the alternative, whether a new organisation which serves as a central repository of retention funds whilst providing various facilities for the contracting community including the issue of various bonds could usher a new era for the construction industry needs further investigation. Clearly, there are many issues impacting on the security of payment problem without a clear cut strategy emerging from the above discussions; there is a need for greater understanding to find a sustainable business solution.

7. Conclusions

Security of payment is a fundamental premise for creating a sustainable business environment. The CCA is a major piece of legislation in that direction but fails short when it comes to meeting this important premise. Over the last decade, a number of well known construction companies have gone bankrupt raising the need for an effective strategy for managing this risk, the risk of losing interim payments and also retention payments.

It was seen earlier that the nature of the interim payment and the retention payment risk appears to be significantly different which raised the issue of whether or not one type of bond would be suitable. The practice adopted in NZS 3910 is to create two types of bonds, one for interim payments and the other for retention payments; the former to be given by the principal and the latter by the contractor. The former deals with both the interim payment and retention payment risks and is therefore comprehensive. The need for such bonds and costs of such bonds would no doubt depend on the nature of the risk as explained earlier. Given that it is difficult to imagine principals voluntarily agreeing to such bonds, one option would be for the government to intervene through legislation. This would not be a reality unless there is a strong case for it. On the other hand, if industry prefers a hands-off approach, it could create a climate for such bonds through enforceable contractual provisions (or otherwise) particularly if benefits outweigh costs. Additionally, industry could self-regulate itself by channelling all retention moneys to a central repository which would certainly provide security for retentions, and also for interim payments through a cost-effective arrangement for PBs whilst providing various other services as noted by Abeysekera [16]; in essence, such an arrangement would act as a (private) bank exclusively for the use and benefit of the construction industry. The government could also be part of such a mechanism. Given that commercial banks have consistently failed to understand construction, this is an interesting option to be evaluated; indeed, an option that Hughes [20] has labelled as a ‘new, and perhaps radical’ approach to moneys ‘otherwise dissipated and diluted to such an extent that they are of little use to a nation’.

Estimation of contractor's project overhead rate as research on building cost

Li-Chung Chao
Department of Construction Engineering, National Kaohsiung First University of Science and Technology, Taiwan
(e-mail: chaolc@ccms.nkfust.edu.tw)

Abstract

The contractor's project overhead costs are the on-site related costs for production support in undertaking a project, such as those for supervision, office, utilities and services. Unlike direct costs, they are not directly connected with the performance of any particular element of a project, but are required for running the project as a whole. Despite the recommended practice of estimating the contractor's field overhead for a project as line items, the alternative method of applying a selected rate as a percentage of direct cost still is used widely. As an ongoing research on building cost, Empirical models of project overhead rate have been developed from historical data in the present study. The nature and significance of the contractor's project overhead are first explored, along with factors that have an influence on the overhead rate. The bid data for 173 building projects collected from a large construction firm in Taiwan covering a variety of work is analyzed and a classification is established whereby the projects' overhead rates range between 0.0171 and 0.2912. The data is divided into two parts for model development and model testing according to order of time. Then, two methods of estimation are compared in their modeling and prediction errors: the cluster center method of categorizing projects into 24 groups and the multiple regression method using four variables, i.e. size, duration, type of work, and location. Either method can achieve an average error of about 3% of direct cost in modeling as well as in prediction. An improvement on the subjective rate-applying method, the model may coexist with the itemized estimation method as a checking mechanism and is potentially useful to contractors as well as owners and consultants. Implications for the building industry and recommendations for future research are also discussed.

Keywords: cost estimation, project overhead, empirical model, statistics

1. Introduction

The contractor's project overhead costs are the on-site related costs for production support in undertaking a project. Unlike direct costs, they are not directly connected with the performance of any particular element of a project, but are required for running the project as a whole. Depending on the practice of categorizing costs, they generally include costs of supervision, office, utilities and services, insurance, safety etc. The sum of direct costs and project overhead costs is the contractor's project construction cost representing all expenditures internal to a project and essential for completing it according to specifications. In contrast, the project's share of the contractor's home- office overhead costs and profit (so called the bid markup) is business-oriented and external to the project, for which a higher or lower level may be charged as deemed appropriate. Since the project overhead costs often constitute a greater part of the contract price than the markup, project overhead estimation deserves no less attention than markup determination. Even the owner in preparing the budget of a project should not overlook the importance of a fair estimate of project overhead costs. Traditionally, to obtain a reasonably accurate estimate of the contractor's project overhead costs, the formal practice is to establish line items and calculate how much is needed for each item, based on a plan that meets project conditions and requirements. For example, salaries of management and supervision are estimated according to the planned field office organization and the durations of the positions. Costs of various categories of insurance and bonds are estimated individually as a percentage of the estimated bid price and relevant direct costs. Usually the estimator is assisted by a checklist and evaluates each possible item in turn. Detailed examples can be found in McCaffer and Baldwin [9], Halpin [7], and Diamant [6] etc.

However, precise definition of project overhead charges is time consuming and may not guarantee the correctness of the results. Hence, when all estimates are complete, often the ratio of project overhead to direct cost (referred to herein simply as "project overhead rate") is calculated as representing the level of project overhead and compared with those for past similar projects as a check on abnormality. On the other hand, the alternative method of applying an experience-based rate (say 10%) to cover the contractor's project overhead costs still is used widely. Some contractors and owners/ consultants even fix all the contractor's overheads and profit as a percentage (say 20%) of the estimated direct cost to arrive at the bid price or budget for a project. Naturally, such a simple method is prone to inaccuracy, as the applied rate often is selected without the support of a modeling methodology. To remedy the rate-applying method's subjectivity and to improve its accuracy, this paper presents a research that set out to develop more reliable models founded on historical data, which can be used for estimating or checking for coming projects. Establishing the relationships between project attributes and project overhead rate, two empirical methods, i.e. cluster center and linear regression, are compared about their performance in modeling and prediction, based on a contractor's past bid data. The objective is to find out what would be the best method and how accurate the best method could be according to some error measures for evaluation. Related researches and factors influencing project overhead are reviewed prior to describing the data and the models. Model results are discussed and model limitations addressed at the end.

2. Related researches

Holland and Hobson [8] found from a survey that there is a lack of consistency among construction firms concerning categorization of costs as direct costs and indirect costs, i.e. project and home-office overheads. For example, the construction manager is equally likely categorized as project overhead or home-office overhead, whereas field engineers may be categorized as direct cost as well as project overhead. However, the inconsistency of different firms does not affect the models in the present study, since they are oriented towards one firm, as long as it has its own way of categorization and categorizes costs consistently for different projects. In any case, to avoid confusion, the firm in provision of data for model development has to be specific as to what constitutes project overhead costs to it.

Determination of the bid markup rate to be applied on top of the estimated project construction cost has attracted much research interest over the past decades. For example, Ahmad and Minkarah [1], Chua and Li [4] studied factors that influence the markup, which can be categorized broadly into internal and external factors, or environment, company, and project factors. Using identified factors as inputs, many markup models built upon past bid experiences, case data, or experts' opinion have been proposed, such as those in Chua et al [5], Chao and Liou [2], and Chao [3]. Although they serve a different purpose from the present study, the modeling methodology employed may be referred to, since both deal with very complex estimation problems.

3. Factors influencing project overhead

Like direct costs, the project overhead costs are entirely project-oriented and consumed on site. The project overhead rate presumably varies according to some project conditions and project features as reviewed broadly below. Generic project factors identified by previous researches to have an effect on the bid markup may also influence the level of project overhead, e.g. a small size project located in a remote area with a long duration area is likely to have both a high bid markup and a high project overhead rate. First, common to all construction projects, many overhead costs exhibit economies of scale, e.g. the larger the work, the lower the manpower required for supervision per unit of work due to a more efficient deployment, and so the project size as represented by total direct cost could be a factor. Next, the charges for several items of overhead costs such as office rents and utility fees are mostly in proportion to the time that a project lasts, and hence project duration is likely another factor. Average direct cost per month derived from the above two factors can indicate the intensity of activity and may be considered as an alternative measurement of project size.

The main type of work of a project, i.e. road, building, etc, influences the number of specialty trades involved, the proportion of labor cost, and the character of the site, concentrated or spreading, and thus has an effect on supervision, coordination, and transportation requirements, which impact on the overhead rate. Similarly, the project location, urban or rural, influences setting-up and maintenance costs of offices, shops, and quarters. In particular, the country in which a project is located is an important factor as the contractor's operation is subject to customs, practices, and laws applicable. In developing countries, numerous taxes and fees are levied on a construction project by various authorities, resulting in higher overhead costs in some categories that have to be allowed for in estimates. In a large country, China, for example, there are even regional differences in this regard.

Other possibly relevant project attributes include scope of contract, i.e. construction only or design and build (D/B), and proportion of subcontracted work. D/B and subcontracting affect resources distribution and lead to changes in interfaces and communication links with effects on costs for attendance, coordination, and engineering in support of production. Last but certainly not least, the quality level required of a project is believed to impact significantly on the staff and documentation efforts for quality control and hence overhead costs. The quality level is to some extent implied by work type and project size, e.g. large mass rapid transit contracts tend to require higher quality than common road contracts. However, it would be better to stand as a separate factor since same size facilities such as buildings can have very varied qualities.

4. Description of data

Ideally, actual costs of completing projects should be used for model development. However, estimated costs of a firm in preparing bids were the only data available to this study and so the models built later would try to capture knowledge containing in the firm's estimates, whose consistency and level of noise would affect model performance. The estimate summaries of 200 projects comprising bids submitted between March 2000 and March 2006 were collected from a large general contractor whose business spreads all over Taiwan covering a variety of types of work. For each project, the data shows project name, owner, project address, bid date, project duration, and a summary of various categories of direct costs, project overhead costs, and markups. Although the firm has standardized cost classification and reporting forms for use by all estimators, some problems in the data were found upon close examination. For example, safety costs for some projects are missing as a result of being bill items and conveniently included in direct costs, while a few projects have major materials as owner-supplied and hence a lower direct cost, which would artificially jack up project overhead rates. Since detailed estimates were not available for corrections, the data for 27 projects was discarded and a usable collection of 173 projects was complied at last.

Numbered from one to 173 in chronological order, the sample projects range between 60 millions and 30 billions NT$ in bid amount (note: 1NT$ ≈ 0.03 US$) and between 3 months and 106 months in duration. The following are classified in this study as project overhead costs: salaries for administration and supervision, office and shops, utilities and services, insurance and bonds, transport, safety, surveys and tests, environmental protection, and public relation. The calculated project overhead rates range between 0.0171 and 0.2912, with a mean of 0.0793 and a standard deviation of 0.0428.

All the projects were located domestically and of the construction-only contract. As the firm has long since adopted a policy of subcontracting almost entire work, there is little difference in proportion of subcontracting among the projects. Moreover, the data available gives very limited project information that does not allow a separate indicator for quality level to be set up. Therefore, only the following factors were considered as inputs in modeling: total direct cost, total duration, mean direct cost per month, classification of work, and classification of location. First, the coefficients of correlation among the quantifiable factors and project overhead rate for the projects as shown in Table 1 were examined. The strong and positive correlations among direct cost, duration, and mean direct cost and between duration and overhead rate appear reasonable. The weak correlation of project overhead rate with either direct cost or direct cost per month may be explained by the lessening of effects of economies of scale by large projects' more demanding quality and other factors at the same time, e.g. the overhead rates of the largest ten projects with a concentration of metros and tunnels average 0.0964 versus the overall mean of 0.0793.

A classification scheme is required for the two categorical attributes, type of work and location. With respect to type of work, a project is classified according to limited project description available into one of eight groups (Table 2). With respect to location, a project is placed into one of three classifications based on its address in Taiwan (Table 3). Tables 2 and 3 also show the statistics of each group ranked in order of increasing mean project overhead rate. Standard deviations within the groups are quite large and statistical tests of the difference between the mean overhead rates of any two adjoining groups conclude that the null (equality) hypotheses all cannot be rejected except for work type groups #5 and #6, suggesting that different groupings may be used.

Table 1- Coefficients of correlation among quantifiable factors and project overhead rate for sample projects

	Total direct cost	Total duration	Mean direct cost per month	Project overhead rate
Total direct cost	1			
Total duration	0.4697	1		
Mean direct cost per month	0.9289	0.2838	1	
Project overhead rate	0.1059	0.3613	-0.0537	1

Table 2- Statistics of project overhead rates for sample projects by type of work

Group number (type of work)	Number of projects	Mean project overhead rate	Standard deviation of project overhead rate
1 (Site works/parks)	16	0.0573	0.0277
2 (Buildings)	30	0.0597	0.0249
3 (Highways/airfields)	52	0.0665	0.0213
4 (Water structures)	5	0.0726	0.0167
5 (Bridges)	33	0.0728	0.0292
6 (Ports/marine facilities)	9	0.1072	0.0488
7 (Tunnels)	11	0.1217	0.0633
8 (Metros/high-speed rails)	17	0.1465	0.0510

Table 3- of project overhead rates for sample projects by project location

Group number (location)	Number of projects	Mean project overhead rate	Standard deviation of project overhead rate
1 (Cities/townships)	89	0.0730	0.0419
2 (Metropolitan areas)	62	0.0820	0.0360
3 (Remote areas)	22	0.0976	0.0577

5. Description of models

5.1 Data representation

While project overhead rate is the model output and project duration a model input, whether direct cost or mean direct cost per month represents project size, another input, requires consideration. Trials later showed that the conversion of direct cost to mean direct cost per month did not enhance model performance. Furthermore, in the presence of duration, mean direct cost per month is somewhat redundant for modeling the estimation. Therefore, it is direct cost that is used as an input to represent project size. As direct cost, duration, and project overhead rate are quantitatively defined, they are suitably represented by their measurements.

For the other two inputs, type of work and location, both categorical, two ways of representation, decimal and binary, are used. With decimal representation each input is assigned a number according to the order of mean overhead rates, i.e. group numbers in Tables 2 and 3, meaning that an increase in the value of each input variable corresponds to an increase in the overhead rate. With binary representation a series (number of categories minus one) of 0/1 variables are used for each input: seven for work type and two for location, bringing the total number of input variables to 11.

5.2 Arrangement of data for model development

The readied data is arranged into two sets for developing and testing models: 152 cases from 03/2000 to 03/2005 and 21 cases from 03/2005 to 03/2006. Data for the first five years are used as a large base of estimates from which a model is developed. Data for the last year is external to the model being developed and is used as future cases for testing its prediction performance in estimating overhead rates. The above arrangement agrees with the fact that a contractor makes estimates for coming projects based on experiences from various kinds of prior projects, which grow with time. Because disruption of time sequence will violate the reality and a model's prediction performance cannot be fairly tested with a completely new case, for each model shown later the steps of modeling and prediction will use the two successive data sets strictly in chronological order of the bids.

5.3 Error measures for performance evaluation

Three error measures are used to evaluate modeling and prediction performance: root of mean squared error (RMSE), mean absolute error (MAE), and mean absolute percent error (MAPE), as defined below:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(outputted_i - applied_i)^2} \qquad (1)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|outputted_i - applied_i\right| \qquad (2)$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\frac{|outputted_i - applied_i|}{applied_i} \quad (3)$$

where n = number of cases used in the evaluation; $outputted_i$ = overhead rate produced for case i by the model; $applied_i$ = overhead rate actually applied to case i according to the firm's estimates.

RMSE inherits the efficacy of mean squared error (MSE), which is used by most algorithms including regression to represent overall system error to be minimized in modeling. Furthermore, RMSE refers directly to the deviation between model output and target output like MAE. It is therefore a consistent and convenient performance indicator for the present single output problem. In the following, RMSE is used as the main evaluator to measure model accuracy in monitoring performance and comparing different models, while MAE and MAPE are used as secondary measures.

5.4 Cluster center and regression methods

Two methods, cluster center and regression, were used to model overhead rates for a comparison. Using the cluster center method, the projects are classified according to combinations of work type and location into clusters, with the maximum number of clusters at 8x3=24. The mean overhead rates for each cluster are calculated as the modeled rates. Where there is a missing cluster, the mean for the work-type group is used in its stead. Using the regression method, two multiple regression equations involving all four inputs were built: one with the decimal representation and a total of four independent variables and the other with the binary representation and a total of 11 independent variables. The built equations are then used to produce overhead rates for cases within the modeling set as modeled rates and those for cases within the testing set as predicted rates.

For each model above, the RMSE, MAE, and MAPE of modeling representing closeness of fit and those of prediction representing test accuracy are calculated using (1), (2), and (3), respectively. The results are shown in Table 4.

Table 4- RMSE, MAE, and MAPE of modeling (152 cases) and prediction (21 cases)

Models	RMSE of modeling	RMSE of prediction	MAE of modeling	MAE of prediction	MAPE of modeling	MAPE of prediction
Cluster center method	0.0289	0.0395	0.0207	0.0273	0.2870	0.3673
Regression with decimal rep.	0.0336	0.0373	0.0243	0.0273	0.3291	0.4377
Regression with binary rep.	0.0305	0.0409	0.0218	0.0266	0.3099	0.4202

6. Discussion and conclusions

Compared with the large standard deviation (0.0428) of overhead rates, all of the three models represent a significant improvement (error reduction by more than 1% of direct cost) as a result of explaining factors being introduced, meaning that the input factors are relevant for modeling. Overall, the cluster center method outperforms the regression method and the regression model with binary representation outperforms the regression model with decimal representation. This indicates that linear regression with decimal representation is unsuitable for the problem as it fails to improve performance by picking up the extra factors of project size and duration left out by the cluster center method.

An empirical model's accuracy is inevitably affected by the level of noise in the data used for developing the model, so its performance must be judged considering this influence. For the present study, noises in the overhead rates for the sample projects come from over- or under-estimates of direct cost (inaccuracies in the denominators) and over- or under-estimates of overhead cost (inaccuracies in the numerators), both causing the rates to deviate from what they should be. Since a project's cost estimate can achieve ±3 percent accuracy with the total design available [7] and the direct cost constitutes the bulk of it, the best result of about 3 percent error of direct cost achieved by either the cluster center method or the regression method with binary representation is considered acceptable for the problem, although there is room for improvement. However, the fact that the cluster center method using only two factors achieves comparable or better performance in closeness of fit and test accuracy than the regression method with binary representation requires further consideration.

Although the overhead costs of a project have a lot to do with its legal and business environments and have to be considered within a local context, the presented approach is general and can be applied in any country. As the data used for model development relates to a firm's costs, the models constructed are intended for use by that particular firm, but other organizations can use their own data to the same effect. While subject to limited availability of data with a lot of noise, heuristics from this study suggest that suitable factor selection and data representation are required for producing better results. Continual model updates with the buildup of estimates would be helpful for improving performance as the base of cases expands with time.

Because of the exploratory nature of this research, the presented models are just prototypes that still need to be refined and improved. As their effectiveness is limited by the correctness of the bid data, it is suggested that future researches collect actual costs for use in model development. However, even actual cost data is available, it may not be more dependable than estimate data because of errors in assigning and reporting costs. Checking the data's consistency is important whichever is used. As the present study left out some potentially significant factors affecting model accuracy, such as level of required project quality and type of contract, they can be considered for inclusion as well as more detailed classification schemes for work type and location. Based on the findings of this study, the use of a nonlinear model such as artificial neural networks for dealing with the complex relations existing between the inputs and output of the stated problem is called for in attempts to improve modeling and prediction performance.

Abstract

Proper risk allocation in construction contracts is emerged to be prominent, because risk identification and risk allocation are influential factors in risk handling decisions. To handle risks properly, it is necessary to identify risks and properly allocate them. This can only be achieved if all parties do comprehend their risk responsibilities, risk event conditions and risk management capabilities. This paper reports a study carried out using multiple case studies, to identify various risks inherent in Sri Lankan road projects and the allocation of those risks between contractual parties. Semi-structured interviews were used as the primary data collection method and documentary evidence has also been used. Data analysis was approached using the code-based content analysis. The study revealed that road projects are dealing with many risk sources, and parties not allocated with some risks through contract clauses also happen to bear consequences of those risks, urging all contractual parties to have a thorough understanding on such risk events.

Keywords: Risk Identification, Risk Allocation, Road Projects, Contractual Parties

1. Background

Dey and Ogunlana [1] have stated that every human endeavour involves risk and that the success or failure of any venture depends crucially on how we deal with it. Therefore, it is apparent that risk and uncertainty are inherent in all construction work, and as it has been stressed by Flanagan and Norman [2], ‘the construction industry is subject to more risk and uncertainty than many other industries.’ This nature of uncertainty in a construction project is emerged by the long and complex process from its inception to completion and presence of various kinds of people with various ideas, experience, skills and interests. There are many ways of defining and classifying risks. Chapman and Cooper (cited in [3]) defined risk as ‘exposure to the possibility of economic or financial loss or gains, physical damage or injury or delay as a consequence of the uncertainty associated with pursuing a course of action'.

Having realized the ever increasing tendency of traffic volume, the Road Development Authority (RDA) of Sri Lanka has planned for the future development of the national highway network [4]. However, road projects are exposed to the uncertain environment because of such factors as, presence of various interest groups, resource availability, climatic environment, economic and political environment and statutory regulations, etc.

The aim of this research study is to be of assist to Sri Lankan road contractors and employers to identify risk sources inherent in road projects and understand their risk responsibilities so that they would be able to optimize the scarce resources and enhance the socio-economic value of Sri Lankan road projects. Against this background, the study objectives are to identify risk sources associated with Sri Lankan road projects, and the proper allocation of those risk sources among the contractual parties.

The paper is organized into several sections. Starting with the background to the research followed by the methodological framework, the next two sections discuss the theoretical framework. The fifth section discusses the analysis of risks in Sri Lankan road projects and the allocation of those risks based on two case studies whilst the sixth section concludes the paper.

2. Methodology

The research was conducted by means of the case study approach. In this research study, two foreign funded road projects which had significantly been completed were deployed. The Contract Sum was more than Sri Lankan rupees 500 million in each project. Multiple sources of evidence comprising of semi-structured interviews, documents such as letters, weather records, bills of quantities, claim reports, non-conformity reports, variation orders, project programme, public complaint reports, certified monthly bills, monthly progress reports, and also archival records such as past weather records have been used in this study for the collection of data. The list of interviewees, which represents the three contractual parties, namely the Employer, Contractor and Consultant in two cases, Case 1 and Case 2, is shown in the Table 1. The party to whom an interviewee had belonged to is indicated against the designation of the interviewee.

Table 1: List of interviewees

Case 1	Case 2
Additional Director (Employer) Project Manager (Contractor) Quantity Surveyor (Consultant) Site Engineer (Contractor) Quantity Surveyor (Contractor) Quantity Surveyor (Contractor) Insurance Manager (Contractor)	Chief Engineer (Employer) Quantity Surveyor (Consultant) Planning Engineer (Contractor) Public Officer (Contractor)

Triangulation, which is the rationale in using multiple sources of evidence, has been addressed here. The content analysis was used to analyse data, in which the software named QSR NVivo1.0 was used to codify interview transcripts and results were arrived at after a cross case analysis. The methodological framework was discussed in this section, and a literature synthesis has been made in next two sections in order to assimilate knowledge in fields of risk management in construction and risks in road projects.

3. Risk Management in Construction

Bufaied (cited in [5]) has described the risk in relation to construction as, 'a variable in the process of a construction project whose variation results in uncertainty as to the final cost, duration and quality of the project', and Dey [3] has argued that, such a variation is due to absence of risk management techniques in project management. Hence, risk management refers to a procedure which controls the level of risk and that mitigates its effect, as it had been comprehended by Toakley (cited in [6]). Important elements of this procedure are discussed within this section, with regard to the stipulated objectives of this research.

3.1 Risk identification and classification

According to Flanagan and Norman [2], a risk management framework would consist of: risk identification, risk classification, risk analysis, risk attitude and risk response. Therefore, risk identification and classification become important in minimizing the probability and consequences of adverse events. Dawood (cited in [7]) describes that a systematic risk management allows the early detection of risks. Therefore, there is no need for contingency plans to cover almost every eventuality. Risk identification involves identifying the source and type of risks. According to Flanagan and Norman [2] an identified risk is not a risk, but a management problem. It is also said that a bad definition of a risk will breed further risks. What is significant here is that having a clear view of a risk event is the first requirement, focussing on the sources of risk and the effect of the event. Risk identification is influenced by the risk perception of the risk management team, which again is influenced by belief, attitudes, judgement and feelings of the people.

Classifying risks is by identifying the consequence, type and impact of risk. Wiguna and Scott [8] have derived a risk hierarchy under four risk categories: external and site condition risks, economic and financial risks, technical and contractual risks, and managerial risks. This classification of risks has been adopted in this study. According to Bunni [9], when a risk has been identified, assessed and analysed, it must be allocated to various parties in order to keep them under control, prevent the occurrence of harmful consequences. Therefore, it is required to study the allocation of those risks.

3.2 Risk allocation

Andi [10] converses that, 'construction risks, however, can hardly ever be eliminated. They can merely be transferred or shared from one party to another through contract clauses.' The above statement is further strengthened, as Mak and Picken [11] have stressed that contractors are required to accept a certain level of risk due to unforeseen costs they incur during construction and that, the risk is also an issue for clients. The consultant may also carry certain risks depending on his role and the scope of work assigned to him. Hence, the significance of risk allocation is emphasized and such allocation of risk becomes a part of the risk management process.

Thompson and Perry [12] suggest that the careful analysis for a contract strategy will also lead to the selection of the right allocation of responsibilities in the same way which determines the type of contract and tendering procedure for a project. This gives an understanding that the significance of the role of each constituent in the contract, such as the contract agreement, Particular and General Conditions of Contract, specifications, preamble notes, bills of quantities and drawings are the determinants to the allocation of risks. Risks can also be transferred beyond the limits of contract clauses also but with the consensus of both parties as it becomes evident from the study of Wang and Chou [13].

Thus, a party to whom a risk is allocated is considered to have the “ownership of risk” and according to Godfrey (cited in [7]) it has several meanings. They are: having a stake in the benefit or harm that may arise from the activity that leads to the risk, responsibility for the risk, accountability for the control of risk, and financial responsibility for the whole or part of the harm arising from the risk should it materialize. Hartman (cited in [7]) further suggests that the principle in determining whether a risk should be transferred is whether the receiving party has both the competence to fairly assess the risk and the expertise necessary to control or minimize it. Contracting parties who do not have a shared understanding of its accountability may mismanage the risk event by assuming the event or its consequences are not their responsibility.

Section 4 describes risks in relation to road projects and especially the consideration has been given to such projects in Sri Lanka. Having realized the importance of risk identification, risk classification and risk allocation, there is the potential to operate on risks with minimal conflicts among interests of contractual parties.

4. Risks in Road Projects

The development of basic physical infrastructure becomes a pre-requisite to underpin the main types of real estate investment and especially investments in roads are large-scale so that their success or failures will have long-term implications. According to Kitazume, Miyamoto and Sato [14] road projects are social capital development projects and are subject to various risks throughout their life cycle. The reason behind that is the long construction and maintenance periods and wide geographical coverage. The longer the time scale, the more likely that there will be some interference or outside events those affect the project.

When Sri Lankan road projects are considered, their sources of risks might be specific because of its developing nature and the geography. In this type of an environment, there are evidences that contractors and owners do not pay much attention to those risks, thereby causing schedule delay, cost overrun and poor workmanship. In the recent past, many Sri Lankan roads have been reconstructed or rehabilitated mainly due to deterioration where continued maintenance was not sufficient to bring them back to standard and increase in traffic to the point where widening or realignment was necessary in certain sections. This process will be never ending and is happening so intensively at present too. Therefore, this tendency has to be realized and risks involved in this process of construction are also required to be identified and properly allocated to contractual parties in order to make them understood regarding their risk responsibilities so that the aim of the research is properly addressed.

5. Results and Findings

5.1 Risk sources associated with road projects

Identification of risk sources in Sri Lankan road project is the first finding of the research. The study started with 26 risk sources which were gathered through the literature review and concepts generated from interview transcripts. However, it could be found out that 23 risk sources were pertinent to the two cases. Those 23 risk sources have been classified in Figure 1 under four types of risk sources in order to formulate a risk classification framework based on the literature review. Those risk sources could be identified as it has been discussed within this section.

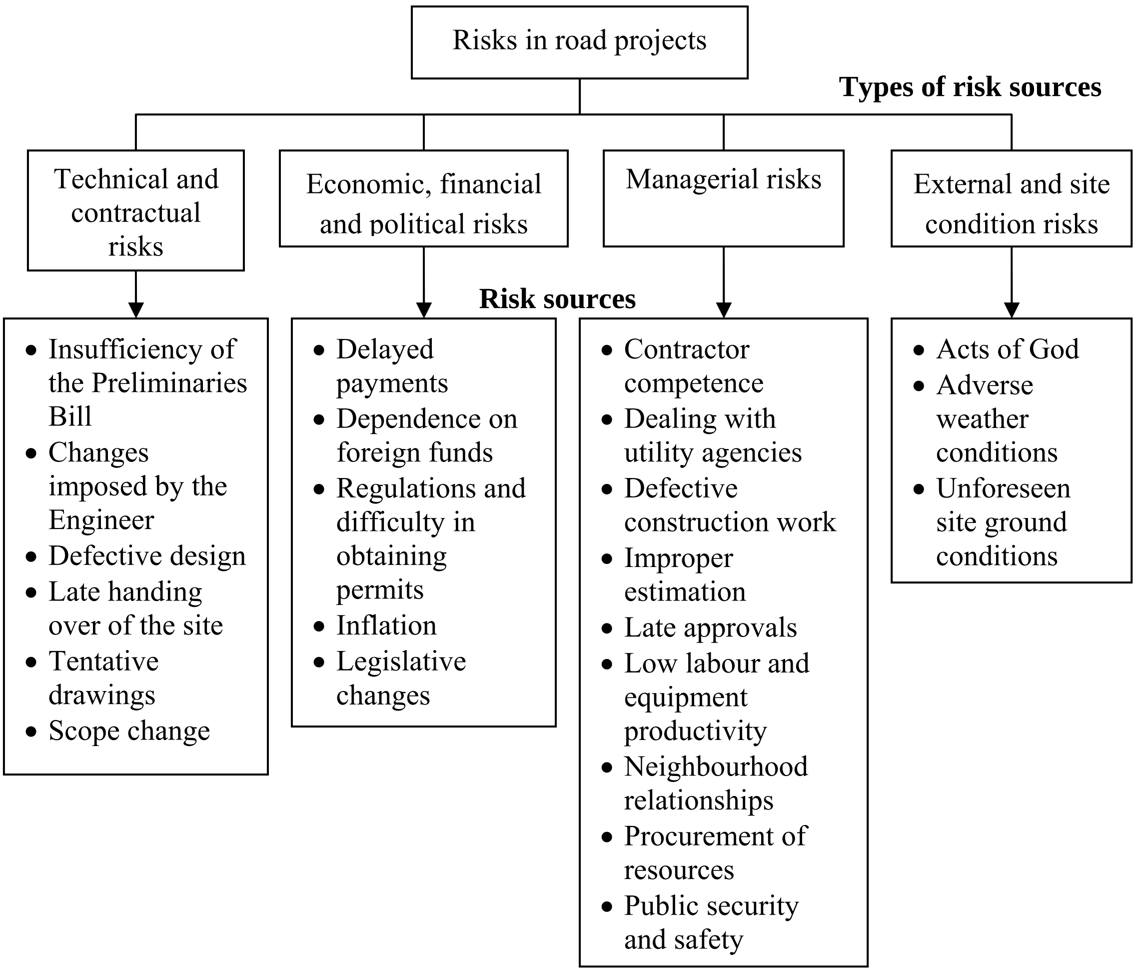

Figure 1- Risk classification framework

There were only two risk sources those were not common in two cases. They were **delayed payments** and **insufficiency of the preliminaries bill**. There had been a delay in two interim payments in one case and contractor's facilities had not been included in the preliminaries bill of that same case. In one case, construction activities had to be halted for few days after the Tsunami disaster and with regard to the other, there were several earth slips. That was the impact of **Acts of God**. The impact of **adverse weather conditions** was such that, there were materials washed away, and critical works affected due to the unexpected rainfall. Though the **contractor competence** was not much significant in relation to these two cases, this required much attention or otherwise there could have been more adversarial impacts. **Changes imposed by the Engineer** was much more significant causing many difficulties to the Contractor, and it was the same with **dealing with utility agencies, late handing over of the site** and **late approvals**. Obtaining approvals had more often been late for the reason that, not enough laboratory assistants had been there in the site to carry on required tests.

Defective construction work was marginal encountering only a few non-conforming works. The risk of **defective design** could not be underestimated since this could certainly lead to poor performance of the completed road and it could be identified such defects in the design. The **dependence on foreign funds** too was a risk as the contract sum in both projects had exceeded the forecasted sum and the amount of funds was limited. **Insufficient estimation** was a risk mainly because price escalation had not been considered for recurrent preliminary items. The increase of contract sum by more than fifty percent was due to the **inflation. Legislative changes** were also significant as there was a change in labour act requiring salaries of labourers to be increased, fuel adjustment charges on electricity bills, and also the removal of VAT (Value Added Tax) from diesel while the market price of diesel was remaining unchanged due to escalation. Thus, the possibility of claiming price escalation for diesel was restricted since the price increase had not been reflected in price indices.

Special attention had been given to overcome the risks of **low labour and equipment productivity** and **procurement of resources**. With regard to **neighbourhood relationships** a lot of complaints had been received from the neighbourhood such as, house damages due to cracks, damages to boundary walls and access paths, and land fill, endangered houses due to land cutting, accumulation of waste in paddy lands. The risk of **public security and safety** was also a major risk in this type of an infrastructure project. **Regulations and difficulty in obtaining permits** was also a risk as it was required to obtain permits for use of explosives in road works and in the quarry, and to pay royalty as the quarry that was used had been in a forest land. **Scope change** was another risk which contributed the most to the cost and time overrun in both cases. Increase of the road width, change of the road surfacing from DBST (double bituminous surface treatment) to asphalt paving in one case, and addition of a binder course layer and introduction of hard shoulder instead of the earth shoulder in the other case were due to the change in scope. **Tentative drawings** in one case had caused lot of difficulties to the Contractor because of frequent changes to dimensions and levels during constructions. Eventually, the risk of **unforeseen site ground conditions** was also significant as the difficulty in identifying underground cables, changes in sub grade to use rock fill or type-1 soil in areas where the water table was high, extra excavations for places where soil conditions were weak, difficulty in identifying underground cables because of the presence of boulders thus, ultimately requiring additional excavations.

Having identified risk sources, the proper allocation of them becomes the second finding.

5.2 Risk allocation in actual

The Conditions of Contract that had been used in both projects was the Conditions of Contract published by the International Federation of Consulting Engineers [7]. Since risks are allocated to contracting parties through contract clauses, the administration of construction risks was first analysed using the Conditions of Contract used in two cases. Since the Conditions of Contract used in the two cases was the same, it provided a similar basis for the analysis. The actual allocation of these risks was also analysed according to views of respondents and archival analysis in particular.

The risk of **adverse weather conditions** was a risk to the Employer by the sub clause 20.4(h) and from the sub clause 21.1[*Insurance of Works and Contractor's Equipment*] the Contractor was also allocated with this risk. **Changes imposed by the Engineer** is a risk to the Contractor under sub clauses 51.1[*Variations*] and 7.1[*Supplementary Drawings and Instructions*]. The Employer is also allocated with this risk under clauses 52 and 53. The risk of **contractor competence** is allocated to the Contractor by the sub clauses 39.2 [*Default of Contractor in Compliance*] and 10.1 [*Performance Security*]. By the sub clause 8 [*Co-operation with Utilities*] and in particular conditions the risk of **dealing with utility agencies** had become a risk to both the Employer and the Contractor. The risk of **inflation** as per the sub clause 70.1 [*Increase or Decrease of Cost*] of Particular Conditions of Contract in both cases, had been allocated to both the Employer and the Contractor. The former had accepted this risk in both cases while the latter in one case too had to bear this risk because of the nature of funding arrangements and due to the unexpected inflation prevalent in the country. Through the sub clause 22.1(b) [*Damage to Persons and Property*] and 32.1 [*Contractor to Keep Site Clear*] the risk of **neighbourhood relationships** had been allocated to the Contractor while the sub clause 23.1 [*Third Party Insurance- including Employer's Property*] had allocated the risk to both parties and to the Employer though the sub clause 22.2 [*Exceptions*]. The assignment of risk in **regulations and difficulty in obtaining permits** was through the sub clause 26.1 [*Compliance with Statutes, Regulations*] to both the Employer and the Contractor. It was revealed in this study, that these risk sources had been shared by both the Employer and the Contractor as it had been allocated through contract clauses.

The sub clause 8.1, 36.1 and 13.1 have delineated that the risk of **defective construction** has to be taken by the Contractor, and it was the same with the risk of **insufficient estimation** which was allocated to the Contractor through the sub clause 12.1 [*Sufficiency of Tender*]. The latter also allocated the risk of **insufficiency of the preliminaries bill** to the Contractor. The ownership to the risk sources of **Low labour and equipment productivity a**ccording to sub clauses 16.1, 54.2 and 20.1, and **procurement of resources** according to sub clauses 8.1 [*Contractor's General Responsibilities*], 28.2 [*Royalties*], 34.1 [*Engagement of Staff and*

Labour] and 36.1(a) [*Quality of Materials, Plant and Workmanship*] have been allocated to the Contractor. It was also found out that all these risks had been borne by the Contractor.

The risk of **Acts of God** becomes a risk to the Employer through the sub clause 20.4(h) [*Employer's Risks*]. However, it was revealed that the Contractor too had to share this risk. Although the risk of **late handing over of the site** had been allocated to the Employer under the sub clause 42.2 [*Failure to Give Possession*], the Contractor too had to share this risk because of irrecoverable difficulties he had to face. The Employer had borne the risk of **scope change** in both projects as in the sub clause 52.3 [*Variations Exceeding 15 per cent*], while the Contractor too had to carry a certain risk with him by delaying the project to complete. Thus, all these three risks have been shared by the two parties though the allocation was only to the Employer through contract clauses.

The Employer was supposed to undertake the risk of **delayed payments** if the Employer fails to make any interim payment as in the sub clause 60.10 [*Time for Payment*]. It is the responsibility of the Employer being dependent on a limited fund for not going into insolvency according to the sub clause 69.1(c) [*Default of Employer*]. Thus the risk of **dependence on foreign funds** has been assigned to the Employer. The Contractor was also entitled to claim increased costs due to **legislative changes** in both of these cases under the sub clause 70.2 [*Subsequent Legislation*]. Therefore, the effects of all these risk were borne by the Employer. Hence, it was the Employer, who had assumed these risk sources in actual.

According to sub clause 20.4(g) [*Employer's Risks*], loss or damage to the extent that it is due to the design of the Works other than any part of the design provided by the Contractor or for which the Contractor is responsible, **defective design** constitutes a risk to the Employer. The risk also lies with the Contractor according to the sub clause 8.1 [*Contractor's General Responsibilities*]. However, in both cases this risk had been transferred to the Consultant through a separate agreement between the Employer and the Consultant since the Consultant had been appointed as an independent party and also, it could be seen that the Employer in one case had taken measures before the start of the project in eliminating design defects. Accordingly this risk had been shared by all three parties in actual. In accordance with sub paragraphs (a), and (b) of sub clause 19.1 [*Safety, Security and Protection of the Environment*] and the sub clause 22.1(a) [*Damage to Persons and Property*], the risk of **public security and safety** lies with the Contractor and as in the sub clause 23.1 [*Third Party Insurance*], it is a risk to both the Employer and Contractor. With regard to the two cases it could be clearly seen that this risk was borne by these two parties including the Consultant also.

The risk related to **unforeseen site ground conditions** has been allocated to the Contractor through the sub clause 11.1 [*Inspection of Site*] and as well as to the Employer through the sub clause 12.2 [*Not Foreseeable Physical Obstructions or Conditions*]. It was also evident that this risk had also been shared by all three parties. The risk of **late approvals** has been allocated to the Engineer as per the sub clause 37.3 [*Dates for Inspection and Testing*], but they were the Employer and the Contractor who were happened to carry the risk. It could be considered that the risk of **tentative drawings** is assigned with the Contractor according to the sub clause 7.1

[*Supplementary Drawings and Instructions*]. However, all three parties had borne this risk with regard to two cases.

The Table 2, shown below compares the actual risk allocation (denoted by the dark circle - ●) against risk allocation through contract clauses (denoted by the light circle - ○).

6. Conclusions

The research was initially begun with twenty six risk sources, and during the analysis it was found out that there were very few trivial or irrelevant risks with regard to the two cases that were studied. As it had been realized through the literature review, the observance of real cases revealed the nature of the environment within which the construction works were operated, being exposed to many risks throughout their entire construction process.

It could be seen that the relatedness of Acts of God was specific to the geographical location of the construction project, so that any party to a contract in a construction project is expected to identify the probability of occurrence of such events. In the same way, the effect of dependence on foreign funds was also specific to each project as the terms of funding arrangement are not the same in different projects.

Only the project risks of delayed payments and insufficiency of the Preliminaries Bill were not common in the two cases. The risks of defective construction works, insufficiency of the preliminaries bill, low labour and equipment productivity, project programme and Contractor competence were not much significant.

Risks of defective design, late approvals, late handing over of the site, tentative drawings, and unforeseen site ground conditions had thwarted the Contractor in many occasions. Other than that, neighbourhood relationships, and public security and safety, were also of the essence in pursuing these social capital development projects. Inflation of the country and the scope change were also deterministic factors in failing to confine to the cost and time limits of the two cases. Therefore, these risks were identified as more vital.

Another important aspect in risk identification is that, the contractual parties have to have a continuous learning approach. Past projects and past events are real scenarios to gain a good experience in liaison with this, so that probable risks that might be encountered in a new project could be identified beforehand to avoid triggering of a those risk events. Thus, early identification of a risk source was felt much essential in its proper allocation.

It is a fact that the Employer allocates construction risks through contract clauses before the contract is awarded, and this urges Contractors to have a clear understanding on risks they are allocated with. Disagreements may also occur from the absence of related contract clauses, unclear stipulations and queries about the fairness of risk allocation.

In most of the situations, though some risks had been specifically allocated to a party through contract clauses, it could be realized that, the party who was assigned with those risks was not carrying the consequences on his alone, but the other parties were also happened to bear the consequences arisen because of those risks. Acts of God, defective design, late approvals, late handing over of the site, public security and safety, scope change, tentative drawings and unforeseen site ground conditions are examples for such risk sources.

The risks of delayed payments, dependence on foreign funds, and legislative changes had been borne by the Employer himself while the risks of contractor competence, defective construction work, insufficient estimation, insufficiency of the Preliminaries bill, low labour and equipment productivity, and procurement of resources had been borne by the Contractor.

Risk sharing had proved to be more effective with regard to dealing with utility agencies, neighbourhood relationships, regulations and difficulty in obtaining permits. Those risks, including adverse weather conditions, changes imposed by the Engineer, and inflation were shared by the Employer and the Contractor.

The study helps the contractual parties to identify and classify risk sources and also to improve their understanding on proper allocation of those risk sources.

7. Acknowledgements

The authors wish to thank the employers, contractors and consultants who took part in the consultation and interviews. Their openness and cooperation towards this study is highly appreciated. Reviews made by referees for the BEAR 2008 Conference is also appreciated for their many helpful comments and valuable suggestions. Nonetheless, the opinions expressed are solely those of the authors.

Abstract

For accurate cost estimating in the initial design stage of a project, various factors related to the characteristics of the project should be reflected in the cost planning. It is impossible, however, to reflect all the side factors on the construction cost. Therefore, at least the cost factors from similar conditions in similar projects must be reflected. For the effective method used at this time, the unit price for the measurement of the quantity could be the most suitable cost model. This research aims to study the utilization goal and the current utilization status of the standard methods of measurement of some countries, and to propose new directions for the domestic standard methods of measurement. Not only are the standard methods of measurement utilized in the detailed design stage, but a method of interconnecting the information to be utilized in the initial design stage is also required.

Keywords: SMM(Standard Methods of Measurement), Cost Estimating, Design Stage

1. Background and Goal

Cost planning model can be applied to cost factors based on quality methods of measurement with respect to the characteristics of the construction project. Many studies have been performed in domestic until now, but they have various problems regarding their utilization in practice.

Therefore, this study propos the cost model, through it is compared and analyzed with the standard methods of measurement(SMM) of developed countries and that can reflect the construction cost factors based on quantities unit by design stage.

This cost model is to support decision-making by the owner and the architecture considering cost and design simultaneously

This study first examined the primary theoretical base for performing the conceptual cost calculation model, and then studied the prototype of the calculation system as an advanced study. This study is meant to be a practical study that will make possible systemization and computerization through consistent review of and complementation by succeeding research.

1.1 Research Process

This study examined the methods of utilization of standard methods of cost measurement and calculation by stage based on related literature and standard methods of cost measurement in other developed countries.

(1) Study of the Cost Calculation Method by Design Stage

(2) Study of the Current Status of Advanced Foreign Countries' Standard Methods of Measurement

(3) Analysis of the Cost Estimating Utilization Model in the Planning Stage with the Standard Methods of Measurement in the Construction Documents Stage.

The abovementioned research process aimed to study the utilization of standard methods of measurement and the method of connecting cost calculation methods in the construction documents stage and the initial design stage based on the quantities of unit or elements.

2. Cost Estimating Method by Design Stage

The cost estimation method is generally classified into three types. The first type is the Conceptual Estimation Method, which is used for incomplete designs.

For example, the conceptual estimation method is used in the planning stage or the schematic design stage. The second type is a combination of the conceptual estimation method and the semi-detailed cost estimation method. The semi-detailed cost estimation method is generally used in the design development stage. The design development stage is the stage in which the entire plan design is completed even as other designs in other construction-type projects are still partly uncompleted. Lastly, the construction documents stage is calculating the Quantities Take

Off from the complete plan and specifications. The following sections examine the cost estimation method by design stage.

2.1 Planning Stage

There are three types of conceptual estimation methods in the planning and schematic design stages. The first method is the ROM (rough –order –of magnitude) method, or the calculation method by pyeong or ㎡. This calculation method estimates the construction cost based on the total gross area. The second method is the assemblies cost estimation method, which estimates the cost based on the database of the costs of the individual components of a building such as the base, roof, upper structure, lower structure, exterior wall, interior wall, interior, machine and electricity, etc. The third method is the calculation method by cost index. This method estimates the cost using region, time series, or construction economy indices of similar types of projects.

2.2 Design Development Stage

The semi-detailed cost estimation method was developed for use in decision-making on the design within the budget of the owner. The major decisions related to the construction, including the outline of the project, the use of each room, and the land arrangement. However, Some parts of design or engineering construction are generally yet determined. Cost estimation is possible only when the design has been complete. Therefore it is used with conceptual estimation, when the design is incomplete or has yet been completed. This means that for incomplete designs, cost estimation can be performed using the actual results database; (reference historical data). And in complete designs, detailed cost estimation is performed through the market price or labor cost calculation method, take off quantities. In other words, the semi-detailed cost estimation method is applicable depending on the completeness level of the development design. Both methods are practically performed in a mixed manner in each type of design stage.

2.3 Construction Documents Stage

Detailed cost estimation is performed when the design specifications have been completed. The estimator performing quantities take off all types of construction materials used in the project and adds indirect costs to calculate the total construction cost.

In Korea, public and private organizations differ to the Standard Methods of Measurement. In the USA, both types of calculation standards are used. The types are more widely known as Uniformat(GSA) and Masterformat(CSI) in Korea. The selection of the format depends on the personal preference or the strategy of the detailed estimation.

3. Current Status of the SMM in Developed Countries

3.1 Status of SMM in Developed Countries

The details of the standard methods of measurement of other developed countries are based on the study of AIQS (The Australian Institute of Quantity Surveyors) and RICS (Royal Institution of Chartered Surveyors). The purpose of this study is to examine the current status of utilization by developed countries of standard methods of measurement (SMM) and the roles of these SMMs. Through this, it aimed to propose new domestic standard methods of cost measurement and utilization SMM methods through a review of the current SMM. In the case of Australia, it has about 10 years of history in SMM, and it went through four times the revision process. In the case of the UK, three main concepts on SMM were introduced in the 1970s, and a calculation concept related to the calculation method, time and quantities was proposed. In the case of the UK, where the level of utilization of SMM is high, it aimed to enhance the utilization level with respect to the integrated information concept of the project. The details were introduced in SMM 7, which was announced through CPI (Coordinate Project Information) in 2000. CPI aims to integrate all the factors related to quantities measurement details to reduce repetitive and wasteful factors, specifications and plans and to use them as a cooperative information system.

3.2 Comparative Analysis of the SMM

The results of the current status of the SMM of each country are shown in Table 1. The results explain the concrete details of the standard methods of measurement. In the case of Singapore, the analytical details are shown in Table 1 (Singapore ; Purpose of SMM is to provide a uniform basis of measurement, and Enabling the exchange of date between SMM, National Productivity and Quality Specifications CAD drawings)

Table 1- General Rules and Recommendations – Identified similarities and differences

classification country	Comparison analysis
Australia	Purpose of SMM is to provide a uniform basis of measurement
Canada	Work measured as net in position
Ireland	Allows for the provision of Location Drawing and Bill Diagrams to aid the descriptions of time
United Kingdom	Location to be provided in descriptions unless evident from drawings or other information required to be provided by these rules
Singapore	Purpose of SMM is to provide a uniform basis of measurement Enabling the exchange of date between SMM, National Productivity and Quality Specifications CAD drawings

3.3 The Prototype of Cost Estimating by Utilized SMM in Initial Design Stage and Construction Documents Stage.

The details of estimation, it is necessary to operate the Masterformat in the construction documents stage. The Uniformat is able to utilization of the standard methods of measurement in the schematic design and design development stages. The figure 1 is concept of utilization SMM for cost estimating which is connecting in the construction documents stage and the initial design stage through with the quantities take off (figure 1.) It is connecting labor cost and equipment cost with the Quantities Take Off the works in each design stages.

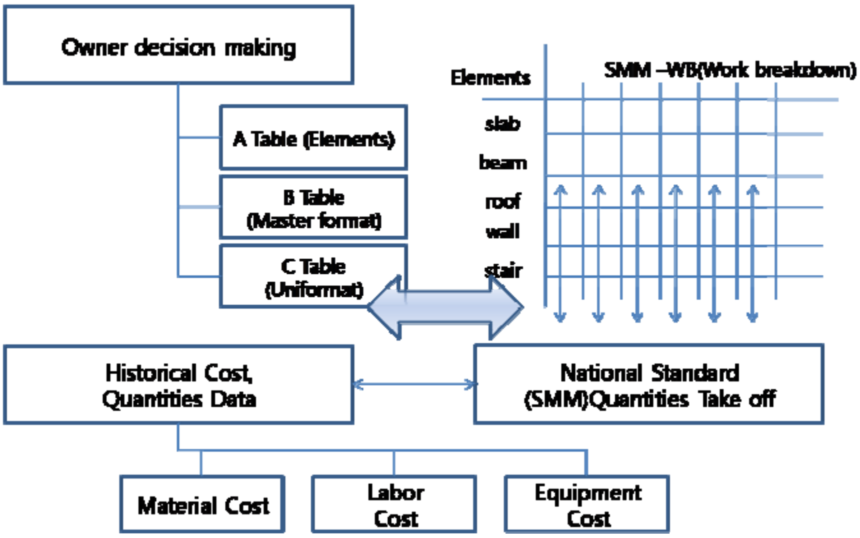

Figure 1- The concept of cost estimating by connected SMM in design stage.

4. Conclusions

The Uniformat is a standard method of measurement that can be used as a semi-detailed cost estimation method by forecasted the quantities take off in the initial design stage. It is to used subject to building components of the base, superstructure, substructure, the exterior walls and finishing, etc. In spite of even in dazzling construction development in korea, effective cost estimating methods such as Uniformat standard methods of measurement haven't practically been established yet. To enhance the accuracy of cost estimating in the planning design and the development design stage, the quantities measurement methods of transforming from the Masterformat to the Unitformat should first be performed. This study aims to encourage future studies on a method of connecting the Masterformat and the Unitformat through case studies with the historical data.

Abstract

Cost estimates at the pre-tender stage of project development could determine whether a project is dropped or continued. Thus accuracy of early stage estimate is an important piece of information needed for decision-making at the pre-tender stage. This study explores project-related factors which influence variance between conceptual cost estimate and tender sum and in that regard investigates how the accuracy of early stage estimates could be improved. The research comprised a postal questionnaire survey of quantity surveyors in Australia. The main findings are: (1) the majority of the respondents believed that early stage estimating was either an important or very important facet of the service offered by a Quantity Surveyor with between 10% and 40% of the total workload of their company being early stage estimating. However, the majority were dissatisfied with the current level of estimating accuracy in Australia Construction Industry (2) the three most important project-related factors influencing bias in early stage estimate were project procurement method, location and project size while consistency in estimates was believed to be mostly influenced by the three factors but with project size ranking first, followed by project procurement method and location (3) Quantity surveyors slightly agree on the relative effectiveness of 13 methods for improving accuracy of estimates. The three most effective methods were: ensuring sufficient information is available at the time of estimating, followed by 'increased cost planning and control during the design phase' and 'checking all assumptions with clients and consultants during the estimating period'. Quantity Surveyors should note that there may be need for different approach to estimating projects of different complexities, different location, with different procurement method. They should also take note of the most effective ways of improving estimate accuracy identified in this study.

Keywords: Estimating, Conceptual cost, Estimate, Tender sum, Quantity Surveyors, Australia

1. Background

A large part of the Quantity Surveyor's role in the construction industry is to provide certainty of cost through estimating process. Estimates are typically carried out by the Quantity Surveyor early in the project at the design and feasibility stage and again at tender stage. When the project is finished, the Quantity Surveyor is often left with three figures namely the initial (conceptual) cost estimate, the tender estimate and the final completion cost. These three figures are often different, raising the question of estimate accuracy.

Early stage estimating accuracy is particularly important as these estimates are often prepared within a limited timeframe, without the aid of a finalised project scope. Decisions with large consequences regarding project and investment are often based largely on the outcome of this estimate. Biases in estimates can be attributed to two areas associated with the process, namely, biases associated with the project itself (will be the same regardless of the estimator) and biases associated with the estimating technique and environment (which would change depending on the estimator). This aim of this research is to explore project characteristics influencing the variances between conceptual cost estimate and tender estimate and in that regard investigate the most effective ways of improving the accuracy of early stage estimates.

This study is important because the knowledge gained could help quantity surveyors and estimators so that they are aware of which project areas may need special attention and what information or practices would be most effective in improving the accuracy of their estimates.

2. Theoretical Framework

2.1 What is Early Stage Estimating Accuracy

Serpell defines conceptual (early stage) estimating as "the forecasting of project costs that is performed before any significant amount of information is available from detailed design and with still incomplete work scope definition" [1]. (Skitmore describes the accuracy of early stage estimates as a comprising three aspects, namely bias, consistency and accuracy of the estimate when comparing the forecast (estimate) with the contract price [2]. Bias is concerned with "the average of differences between prices and forecasts", measures of consistency are concerned with "the degree of variation around the average" and accuracy is considered as an overall combination of both bias and consistency. This study examined accuracy of early stage estimate in terms of bias and consistency and is concerned with the variances between forecast and the accepted tender or contract sum.

2.2 Importance of Early Stage Estimate

After an early stage estimate has been produced, it will serve many purposes for the client. The estimate becomes one of the most important pieces of information for decision making at the conceptual stage [1]. It determines whether the project proceeds or is scrapped. The estimate provides initial information that are used to (a) decide on the financial feasibility of the project (b) evaluate alternatives to the project [3] and when the project proceeds, the estimate will (a) serve as a tool for budgetary control and (b) serve as a management tool [4]. Should further estimates on the project be required, the accuracy of the initial estimate is important, as Trost and Oberlender stated – "Early estimates, even when grossly inaccurate, often become the basis upon which all future estimates are judged"[5]. However, if estimates are inaccurate, they lose their effectiveness as tool for these outlined purposes. Clearly, an estimating error at early stage of the project development cycle could lead to misguided business decisions being made, which may not only jeopardize the success of the investment but could also have long term consequences for the performance of the investor.

Therefore, in order to enhance clients' satisfaction in the Quantity Surveyor's professional services, there is a growing need to provide accurate early stage estimates, so that cost certainty from the early stages of project development is assured.

2.3 Factors Driving the Accuracy of Early Stage Estimate

Gunner and Skitmore summarised the factors relating to accuracy, bias and consistency identified in previous studies [6]. These were building function, type of contract, conditions of contract, contract sum, price intensity, contract period, number of bidders, good/bad years, procurement basis, sector, number of priced items, number of drawings and price forecast. When analysis was performed on 181 projects from the office of a Singapore Quantity Surveyor, the results found that bias existed for the vast majority of the variables measured. Ling and Boo found similar results when they compared 5 variables against Gunner and Skitmore's work using 42 traditional procured projects from the offices of a Singapore Quantity Surveyor [7]. Skitmore and Picken studied the effect that four independent variables (building type, project size, sector and year) had on estimating accuracy and tested these variables against 217 projects from a Quantity Surveyor based in the USA [8]. They found that bias existed in project size and year, and consistency errors existed in project type, size and year. Trost and Oberlender in their study of 67 process industry construction projects from around the world, identified 45 variables contributing to early stage estimate accuracy and arranged them into 11 orthogonal elements affecting accuracy, the five most important being basic process design, team experience and cost information, time allowed to prepare the estimate, site requirements, bidding and labour climate [5]. Together, these studies tend to all suggest that a large number of variables substantially contribute to early stage estimating accuracy. The present study investigates project-related factors influencing the accuracy of early stage estimate.

2.4 Methods for Improving the Accuracy of Early Stage Estimate

Ling and Boo investigated the causes and suggest 13 measures to improve estimate accuracy [7]. When industry professionals were surveyed, ensuring proper design documentation and information management was found to be the most popular measure to improving estimate accuracy, followed by checking all assumptions during the estimating process and thirdly, providing a realistic timeframe in which to undertake the estimate. However, a possible shortfall exists in this research, as the respondents appear to have only been able to select from the thirteen options, which may have restricted some responses

3. Research Method

3.1 Data Collection and Sampling

A quantitative research method was adopted to address the objectives of the study. A questionnaire was designed for data collection. The questions relates to the profile of the individual completing the questionnaire and the company profile; respondent's views regarding importance of early stage estimate; respondent's company workload on early stage estimate and whether they are satisfied with current level of estimate accuracy; respondent's views regarding 7 project characteristics that could influence the accuracy of early stage estimate and 12 potential methods for improving the estimates. Depending on the nature of the question, respondents were asked to indicate their answers on a five-point Likert scale. To anchor the Likert Scale, relevant nomenclatures were assigned to the response options.

The questionnaires were sent to Quantity Surveying firms around Australia. The respondents were selected from the list maintained by the Australian Institute of Quantity Surveyors (AIQS), the most recognised Quantity Surveying body in Australia [the list may be accessed at www.aiqs.com.au/Find_a_member/QSFirms.asp). Sampling for the survey was done at random, with two out of every three Quantity Surveying firms listed by the AIQS selected to be surveyed, starting with the first company listed. Surveys were mailed to 102 Quantity Surveying firms and included an invitation/plain language statement and a stamped self addressed return envelope.

3.2 Response Rate and Characteristics of Sample

Of the 102 quantity surveying firms sampled, 41 responded representing a response rate of 41%. Figure 1 shows the questionnaire distribution and response rate according to 8 states in Australia. Return rates were greatest for Western Australia and Queensland, with 54.5% and 54.1% return rates respectively. Seventy-three percent of the firms have more than 6 technical staff. Ninety percent of survey responses were completed by either a Director or Associate of the firms. Eighty-one percent of survey respondents have had over 15 years experience as a Quantity Surveyor.

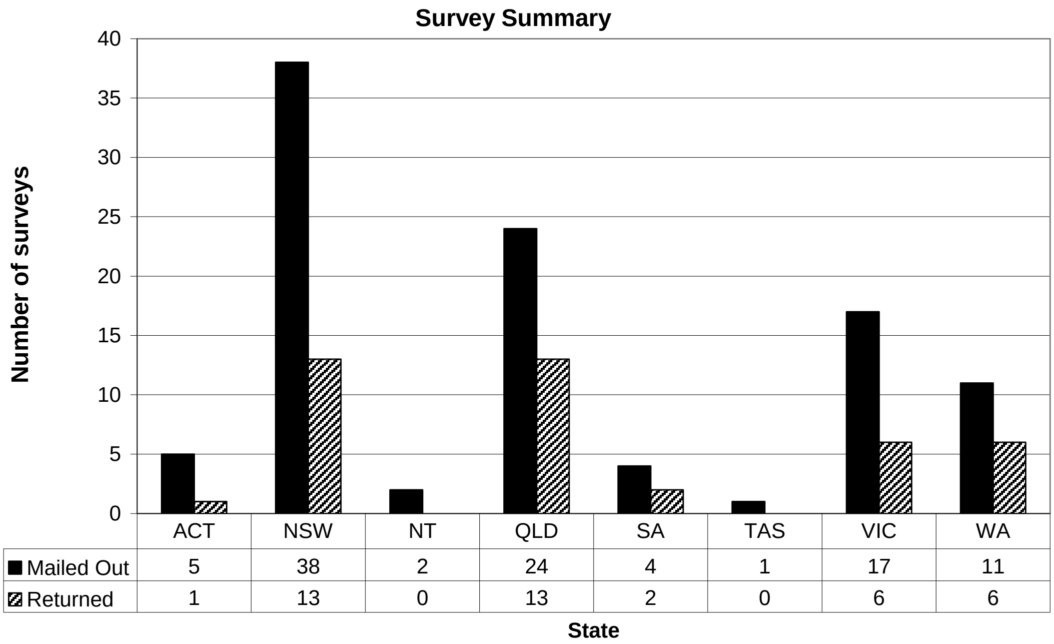

Figure 1- Questionnaire Distribution and Response

With the experience of the respondents and their designations in their respective firm, it was understood that the data came from the highest echelon of the Quantity Surveying profession in Australia, and can therefore be relied upon with confidence.

3.3 Data Analysis Approach

Relative Importance Indices were determined and used to rank methods identified to contribute to bias and inconsistencies in early stage estimate, and methods used to improve early stage estimating accuracy. Relative importance Indices was computed for each factor or method using the following expression:

$$\mathrm{RII} = \frac{A}{B \times C}$$

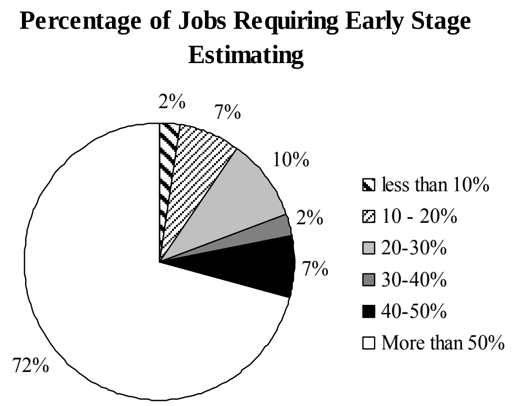
A = total Score; B = highest response option; C = total Number of responses

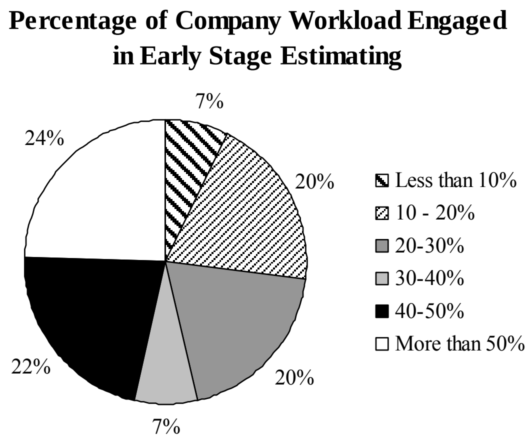
Agreement among Quantity Surveyors regarding the ranking of the methods for improving early stage estimating accuracy was tested using Fleiss' kappa statistics. Fleiss' kappa statistics is a measure of inter-rater reliability and is able compare multiple sources of data.

4. Results

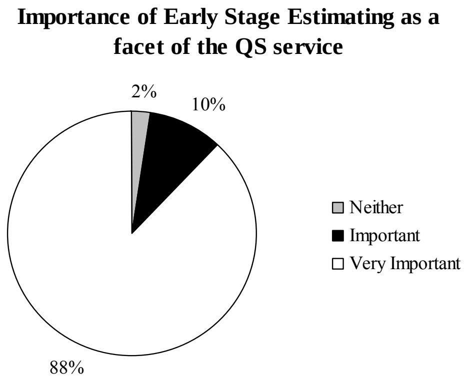
4.1 Importance of Early Stage Estimating and Workload of Respondents' Firms

Analysis of survey questions revealed that for 71% of the respondents, more than 50% of the projects brought to them by clients included some form of early stage estimate. For 68% of respondents, between 10% and 40% of the total workload of their firm is on early stage estimating. Based on these results, it was understood that the respondents and respondents company have sufficient experience on early stage estimating. Thus their responses can be relied upon.



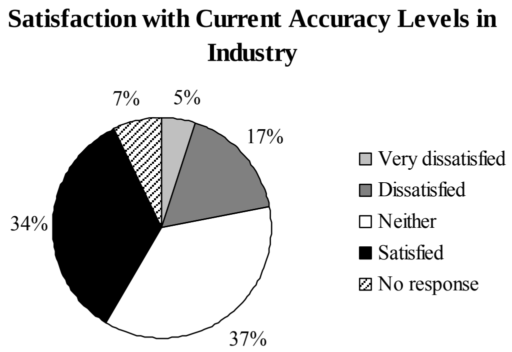


Ninety-eight percent believed that early stage estimating was either an important or very important facet of the service offered by a quantity surveyor. Similarly, 98% indicated that accurate early stage estimates were either important or very important in terms of overall project success.



4.2 Satisfaction with the Current level of Estimating Accuracy and Acceptable Tolerance level

When the respondent were asked on their satisfaction with the current level of estimate accuracy in the industry, 63% indicated they were either very dissatisfied, dissatisfied or neither satisfied nor dissatisfied. No respondents indicated they were very satisfied with current levels of early stage estimate accuracy. The results suggest that the respondents are not satisfied with the current level of estimating accuracy. When asked about acceptable tolerances in terms of deviation between early stage estimate and accepted tender price or contract sum, 78% of respondent indicated that a deviation of ±10% is acceptable.



To explore the accuracy of early stage estimate, sample cost data on 56 projects completed in the last 10 years was analysed. The contract value of the projects range from A$712,774 to A$543,875,324 and have a combined value of A$1,805,681,596 when brought to 31 December 2006 price. The projects have gross floor area (GFA) ranging from 168 m^2 to 276,094 m^2 while the combined GFA for all the projects stands at 1,103,223 m^2. It was found that the early stage estimates of the projects are on the average biased and are overestimated by 4.29%.

While the findings suggests that the accuracy of early stage estimate is unsatisfactory in practice, the level of bias in the estimate of the sampled projects seamed to fall within the tolerance level ±10%. The reason for the inconsistency may be because the cost data used are from projects procured in Melbourne while survey data is from quantity surveyors across

Australia with only 14% from Melbourne (Victoria). Thus the accuracy of the cost data is limited to projects in Melbourne. Future research need to make use of cost data from around Australia so as to obtain accuracy level that may be generalised for Australia.

4.3 Factors Influencing Bias and Consistency of Early Stage Estimate

Table 1 shows the results of Relative Importance Indices analysis of the respondents' perceived extent to which different factors (project characteristics) contribute to systematic bias and consistency of early stage estimates.

Table 1 Project Factors Influencing the Accuracy of Estimate

	Bias				**Consistency**			
Project Characteristics	**Mean Score**	**Total Score**	**RII_c**	**Rank**	**Mean**	**Total**	**RII_c**	**Rank**
Project Size	3.59	140	0.718	3	3.78	151	0.755	1
Type	3.10	121	0.621	5	3.38	135	0.675	5
Procurement Route	3.74	146	0.749	1	3.75	150	0.750	2
Year of Construction	3.49	136	0.697	4	3.55	142	0.710	4
Sector	2.92	114	0.585	6	2.98	119	0.595	6
Location	3.69	144	0.738	2	3.75	150	0.750	2
Principle Structural Material	2.90	113	0.579	7	2.95	118	0.590	7

RII_{fi} = Relative Importance Indices of factor

The results (Table 1) indicate the way a project is procured, followed by its location and size would contribute most to overall bias experienced in the early stage estimate. These three factors were also perceived to have the most significant effect on consistency of estimates, with the size of project ranking first followed by the way it is procured and location. The principal structural material and the project sector were perceived to contribute least to both bias and consistency of early stage estimates when compared to the other factors.

4.4 Effectiveness of Methods for Improving the Accuracy of Early Stage Estimate

Results in Table 2 indicate that 'ensuring sufficient information is available at the time of estimating' is the most effective method of improving early stage estimating accuracy. This is followed by 'increased cost planning and control during the design phase' and 'checking all assumptions with clients and consultants during the estimating period'.

Table 2 Ranking and T test of Methods for Improving the Accuracy of Early Stage Estimate

Improvement Method	Mean	Total Score	RII_M	Rank	t test (one tailed) (t > 3)	
					t value	p value
M_1	4.13	157	0.826	5	6.85	0.0000
M_2	4.18	167	0.835	4	8.23	0.0000
M_3	4.62	180	0.923	1	14.98	0.0000
M_4	4.20	172	0.839	3	7.81	0.0000
M_5	3.65	146	0.730	10	4.11	0.0001
M_6	3.88	155	0.775	7	6.49	0.0000
M_7	3.44	134	0.687	11	2.74	0.0047
M_8	3.38	132	0.660	12	2.07	0.0230
M_9	3.82	149	0.745	8	5.14	0.0000
M_{10}	4.33	169	0.845	2	9.27	0.0000
M_{11}	3.82	145	0.744	9	6.57	0.0000
M_{12}	4.03	153	0.785	6	7.15	0.0000

RII_{Mi} - Relative Importance Indices of Method

Legend:

- M_1 - Ensure proper design documentation
- M_2 - Establish effective communication and co-ordination between members of the project team
- M_3 - Ensure sufficient information is available for estimating
- M_4 - Check all assumptions with clients and consultants
- M_5 - Establish formal feedback for design and estimating activities
- M_6 - Provide a realistic timeframe for estimating activity
- M_7 - Use a more rigorous method of estimating
- M_8 - Incorporate market sentiments and economic conditions into the estimate by way of simulations, probability and utility functions
- M_9 - Incorporate other market sentiments and economic conditions into the estimate
- M_{10} - Increase cost planning and control activities during the design stage
- M_{11} - Improve methods of selection, adjustments and application of cost data
- M_{12} - Update cost database with new cost analyses and provide feedback for improving estimate accuracy

The result is different from findings of Ling and Boo in Singapore where

4.4.1 Testing for Agreements

To check whether all quantity surveyors agreed with the raking of the effectiveness of methods used to improve accuracy, Fleiss' kappa statistical measurement (κ) was estimated. The result of Fleiss' kappa statistical measurement shows that:

$\kappa = 0.045$

According to Landis and Koch agreement between respondent is Almost Perfect if $\kappa = 0.81 - 1.00$; Moderate if $\kappa = 0.41 - 0.60$; Fair if $\kappa = 0.21 - 0.40$; Slight if $\kappa = 0.0 - 0.20$ and Poor if $\kappa < 0.00$ [9]. In this study the measurement $\kappa = 0.045$ indicates that quantity surveyors only slightly agree with each other on the effectiveness of methods for improving early stage estimating accuracy. However, a one sample t test (table 2) shows that all the methods are effective (mean greater than 3 at $p < 0.05$). Thus it is likely that quantity surveyors consider all method to be an effective means of increasing the accuracy of early stage estimates. However, each firm uses a differing combination of improvement methods, which could explain the slight value of agreement between firms.

5. Conclusion and Recommendations

Early stage estimating is an important or very important facet of the service offered by a quantity surveyor. The accuracy of early stage estimates is important in terms of overall project success and it forms a substantial part of quantity surveying firms' workload in Australia. Despite the importance, there is dissatisfaction with the current levels of early stage estimating accuracy within the Australia construction industry. Project procurement method, location of project and project size are the three most important project-related factors driving the level of bias and inconsistencies in early stage estimates when compare with the accepted tender sum. Quantity surveyors should note that there may be need for different estimating approach and process when working with project of varying size and complexities, varying procurement method and in different locations in Australia. Also, the accuracy of early stage estimate could be improved by ensuring that sufficient information is available at the time of estimating, increasing cost planning and control during the design phase and checking all assumptions with clients and consultants during the estimating period. More time and effort should be directed at understanding client's requirements during early stage estimating process. Accuracy of estimates could be improved using other methods such as giving adequate time for estimating, effective communication between project team, rigour in estimating process, adequate update of cost data base.

Techniques for Calculating Unabsorbed Overhead

Amarjit Singh,
Department of Civil Engineering, University of Hawaii at Manoa
(email: singh@eng.hawaii.edu)
Thomas Taam,
U.S. Army Corps of Engineers, Fort Shafter
(email: ttaam@yahoo.com)

Abstract

The technique for calculation of home office overhead damages, a claim category on construction projects, has been widely debated. The Eichleay Formula is a well known technique for such claims, that evolved over the past 47 years. This paper provides concepts of compensable home office overhead damage due to a project delay, the evolution and required prerequisites for using the Eichleay formula, and alternate formulas and techniques used. A "Direct Method" is proposed, which is simpler to apply. In the final analysis, obtaining a 100% accurate estimate of home office expenses is impractical, if not infeasible.

Keywords: Eichleay, Compensable, Home Office, Claim

1. Introduction

Home office overhead expense damages incurred due to project delay are called 'unabsorbed overhead'. The most commonly applied method for calculating home office overhead claims for damages due to delay is the "Eichleay Formula". This paper focuses on several areas relating to the Eichleay Formula and its evolution, and provides an explanation of the elements of the formula and alternate formulae for calculating unabsorbed overhead. The paper will present criticism surrounding the use of the Eichleay Formula. Various techniques for calculating unabsorbed home office overhead will be presented, and the results will be compared and analyzed. All known techniques have been pulled together in this study.

2. Items in Home Office Overhead

Home office overhead normally consists of costs such as rent, utilities, furnishings, office equipment, executive staff salaries, support and clerical staff salaries, project related staff (engineers, estimators, schedulers), mortgage costs, outside legal and accounting expenses, depreciation, auto travel, professional trade licenses and fees, employee recruitment, relocation, training and education, photocopying, entertainment, contributions, donations, postage, cost of preparing bids, review of submittals, taxes, advertising, insurance premiums, interest costs, and data processing/computer costs. The contractor needs to pay or recover these costs by allocating these costs to the projects it performs (Taam and Singh, 2003). The unabsorbed home office overhead that will be discussed here consists of the home office overhead for which the contractor is not paid for work that is really compensable.

3. Evolution of the Eichleay Formula

3.1 History of the Formula

Before 1940, unless expressly permitted by the contract, the contractor could not recover consequential damages for government delay (*McCord v. United States)* [i]. The bias towards owners is found to increase as one checks case law further back in history. The U.S. government's position in earlier centuries was simply that it had paid for the right to change the contract. In 1945, however, in the case of *Fred R. Comb Co. v. United States* [ii], the Court of Claims found the government liable to the contractor for home office damages caused by delay. The court also found that the government, having breached its contract, had no right to state that a contractor will go uncompensated. This laid the foundation for the emergence of the Eichleay formula, which set up criteria and formulae for calculating compensation due to the contractor.

The Eichleay Formula originated from a decision by the Armed Services Board of Contract Appeals in 1960, *Eichleay Corporation v. United States* [iii]. In its appeal before the Board, the Eichleay Corporation proposed a formula for calculating the damages. The Board accepted this formula as a reasonable method for calculating the damages (Trauner, 1990).

3.2 The Eichleay Formula

The Eichleay formula is a three-step process as per the following formulae:

(Actual Billings for Delayed Contract x Total Actual Billings for Period (All Contractor Contracts)) ÷ Total Home Office Overhead for Period = Overhead Allocable to Delayed Contract (OACD) -(1)

OACD ÷ Days of Performance = Daily Contract Overhead for Delayed Contract -(2)

Daily Contract Overhead for Delayed Contract x Number of Days Delay = Overhead Claim Amount for Delayed Contract -(3)

A step-by-step example of the Eichleay Formula, using the data in the example shown later, yields a value of $6,667.

The Eichleay Formula first determines the allocation of home office overhead for a particular project. Next, it takes a portion of the allocation and applies it to the total days of performance, which results in a daily home office overhead cost. Finally, the Eichleay Formula calculates compensation due to a contractor for an owner-caused delay by multiplying the daily overhead rate with the days delayed. The formula is an attempt to provide a realistic basis for allocating home office overhead costs.

3.3 Acceptance of the Eichleay Formula

Since its inception, the Eichleay Formula has gained considerable acceptance, but courts and boards have generated numerous opinions concerning its application, going alternately back and forth on it. For example, in *Excavation-Construction, Inc. v. United States* [iv], the board recognized the use of the Eichleay Formula to determine the cost not only of a suspension of work, but also of a delay caused by extra work. In *Wickham Contracting Co. v. Fischer* [v], the 3rd Federal Circuit held that the Eichleay formula was the exclusive means available for calculating unabsorbed overhead, overruling the earlier decision by the GSBCA (General Services Board of Contract Appeals). In *Capital Electric Co. v. United States*[vi], 1984, the 2nd Federal Circuit reaffirmed the applicability of Eichleay. However, disputes continued as to whether the Eichleay formula was the only correct method and whether other formulas led to a more accurate calculation of unabsorbed overhead (Peckar and Abramson, 1999).

3.4 Arguments against the Eichleay Formula

The most common argument against the use of the Eichleay Formula is that the contractor is already compensated for home office overhead in his markup of direct costs on changes, and therefore, requires no further compensation. The problem with this argument is that a contractor receives the markup regardless of whether or not the change causes a delay.

The Eichleay formula is often challenged and criticized in two principal areas by auditors, private and government attorneys, and judges. These two areas are (1) the overall concept of unabsorbed overhead, as covered in the Eichleay formula; and (2) the accuracy of the formula. In *Wickham Contracting Co. v. U. S. Dept of Defense* [vii], the GSBCA claimed that Eichleay was entirely theoretical, and that *the Eichleay formula, which is a simple proration, cannot give a correct result because it has no mechanism for allocating wasted overhead where there are two or more delay sources* (Kaufmann and Holman, 1995).

Cibinic (1991) also took issue with the Eichleay formula by stating:

> *The Eichleay formula does not take into consideration the first and most important factor --- how much fixed overhead would have been allocated to the contract. In addition, it calls for a determination of the total overhead incurred during the contract period. This too, is defective; since fixed overhead (the subject of unabsorbed overhead) is incurred for accounting periods (usually the contractor's fiscal year), not contract periods (which would equate with the contractor's fiscal year in only the most rare and unusual coincidence).*

3.5 Abrasion and Reinstatement of the Eichleay Formula

As a result, courts minimized the formula in the late 1970's and early 1980's. A judge for the GSBCA predicted its complete demise. Non-government contract forums were the first to reject the use of the Eichleay formula; courts in New York[viii] and Texas[ix] both refused to apply it in construction delay cases. The low point for Eichleay was the GSBCA decision in *Capital Electric Co.*[x], where Judge Lieblich stated:

[We can be confident] … that the government will never again go along with any payment to a contractor for "extended overhead" nor will it ever again agree to the application of the Eichleay formula to any overhead calculation in a construction case. Whether distinguished or overruled, those prior decisions will be dead letters hereafter.

Within one year, however, the U.S. Court of Appeals for the 2nd Federal Circuit reversed the *Capital Electric* decision and reinstated the contractor's right to utilize Eichleay.

3.6 Compensability Criteria for the Eichleay Formula

Since the inception of Eichleay in 1960, courts have required prerequisite criteria to determine whether a particular situation would qualify for application of the Eichleay Formula. The first criteria is the uncertainty of the delay or standby period, and the second criteria is the "practicality" and "possibility" for the contractor to take on additional work, which would "absorb" the home office expenses during the period of delay. "Standby" is defined as an order by a contracting office to not perform any further work on a contract until requested to do so by the contracting officer.

The first criteria was upheld in *Community Heating & Plumbing Co., Inc. v. Kelso* [xi]. Again, in *C.B.C. Enterprises, Inc. v. United States* [xii], the contractor appealed the Navy's denial of an extended overhead claim. The courts found that there was no suspension, delay, or disruption of work and that the period of performance was known. Recovery is permitted only when a "cloud of uncertainty" exists regarding the period of performance.

In *Interstate General Government Contractors v. West* [xiii], the contractor claimed unabsorbed overhead costs because of government-caused delay subsequent to a standby. In this case, the project was completed 13 days early, but the standby was prolonged. The Federal Circuit implemented a three-part test that needed to be met whenever a contractor completes a contract early:

- The contractor must prove that it intended to complete the contract early.
- the contractor must prove that it had the capability to do so, and
- It must prove that it actually would have completed early, but for the government's action.

The test is to assure prevention of a contractor receiving double payment on its overhead claim.[xiv] However the universal rationality of this test does not seem to have been established. The test is much like the victim of an injury in torts having to prove he had no intention to injure himself, a requirement that is not entertained in modern tort law.

In *Wickham Contracting Co. vs. Fischer*, the Federal Circuit court affirmed that the Eichleay Formula was the exclusive formula to use to calculate home office overhead damages when the Eichleay prerequisites were met. The prerequisites for use of the Eichleay formula are standby with uncertainty, and the impractical ability to take on additional work during the delay period to absorb the home office overhead. Since Wickham, the question in most government delay damage cases has been more a question of entitlement instead of a contractor having to prove damages in order for use of Eichleay.

In *West v. All-State Boiler* [xv], the court found that the government could not meet its burden by showing either: "(1) that it was not impractical for the contractor to obtain other work to which it could reallocate its indirect costs; or (2) that the contractor's inability to obtain other work was not caused by the government's suspension…" This decision further clarified the second prerequisite of a contractor not having to prove that it was impossible to take on new work, but only that it was impractical to do so (Peckar and Abramson, 1999).

In *Melka Marine, Inc. v. United States* [xvi], the Court further clarified that when the government identifies with certainty the date on which its delay will end, the standby test is not met. Standby requires an uncertain delay period where the government can require the contractor to resume work.

Naturally, many of these prerequisites are harsh and unwarranted, making recovery quite an onerous task for the contractor.

4. Alternate Techniques and Formulas

4.1 Other Formulae and Techniques

Critics of the Eichleay formula have suggested the use of various formulae and methods for use in calculating unabsorbed overhead damages, depending on the situation. Alternate techniques include ten methods, including one designed by the authors. These are the Comparative Absorption Rate Method (CARM), Burden Fluctuation Method, Carteret Method, Allegheny Method, Canadian Method, Modified Eichleay Method, Calculation based on Actual Records, Total Direct Cost Allocation Method (DCAM), Specific Base Allocation Method (SBAM), and Direct Method. Not all the methods can be discussed here for want of space, but the most important and representative ones will be described. The interesting factor about these alternate techniques is that they do not come with strings attached, such as the prerequisite criteria of Eichleay. Such is the nature of case law on this topic.

The following example will be applied to above methods to calculate unabsorbed home office overhead (McDonald and Baldwin, 1989). A summary of the results for comparison purposes is provided later.

4.2 Example Situation

The example applied to the formulas and methods to follow, is described: A project could have been performed by the contractor for a price of $400,000 over a four-month duration assuming no change orders were issued, and no suspensions of work or other delays were encountered. The contractor, in this example, has a fixed home office overhead rate of $40,000 per month, has $100,000 of monthly billings on this contract, has $400,000 per month from other contracts, and thus regularly does $500,000 worth of total business per month including the contract in question.

Under the contractor's "potential performance," contract billings are made through months 1 and 4 (both inclusive). Total billings stay at $500,000 for all months and reflect what would have happened but for any changes or delays by the owner on this project.

In the "actual performance", there is a one-month suspension in the third month: the contractor has to forego contract billings for that month, but still must carry a home office overhead. Thus, while total billings are $500,000 for all months, they fall by $100,000 in month 3.

4.3 4.3 Burden Fluctuation Method

This method determines unabsorbed overhead by finding the increase in the absorption rate and allocating that increase to the non-contract work, which was forced to bear more than its fair share of overhead expenses. The burden fluctuation method has been used by courts and boards to calculate manufacturers' unabsorbed overhead claims.

Total Billings - Contract Billings = Other Contract Billings -(4)

Actual Overhead Rate - Potential Overhead Rate = Burden Fluctuation -(5)

Burden Fluctuation x Other Contract Billings = Unabsorbed Overhead Claim -(6)

Under the Burden Fluctuation Method, the contractor could claim a 0.33 percent increase in his overhead rate for the example considered, resulting in a claimed amount of $6,600.

4.4 Modified Eichleay Method

The Eichleay Formula tends to understate the overhead rate because it considers and includes the delay period in the formula calculation for the disputed contract. The Modified Eichleay Method changes this by deleting the days of delay from the number of days in the contract performance period (Equation 8). The result will be a higher Daily Overhead Rate. The Modified Eichleay Formula is provided below. A simple calculation yields unabsorbed overhead = $8,333.

Actual Billings for Delayed Contract ÷ Tot. Actual Billings for Period (All Contractor Contracts) x Total Home Office Overhead for Period = OADC - (7)

OADC ÷ Days of Performance (less delay period) = Daily Contract Overhead for

Delayed Contract - (8)

Daily Contract Overhead for Delayed Contract x Number of Days Delay = Overhead Claim Amount for Delayed Contract - (9)

4.5 The Canadian Method

This method is used extensively in Canada (Trauner, 1990). The Canadian Method uses the contractor's actual markup for overhead in its calculation. This markup is based on bid documents or audit records. An audit of the contractor's records will determine a percentage based on history. The result for the example is $8,000.

Percentage Markup (from bid docs or audit) x Original Contract Sum ÷ Original Number of Days in the Contract = Daily Overhead Rate - (10)

Daily Overhead x Number of Days of Compensable Delay = Compensation for Home Office Overhead - (11)

4.6 The Allegheny Method[xvii]

This formula focuses on the difference in overhead rates between the actual period of performance and the originally expected period of performance. The excess overhead rate is multiplied by the contract base costs to determine the unabsorbed overhead amount. This method yields only a rough order of magnitude estimate of the damage, since the two periods will be intermixed and the excess overhead is calculated on the costs of the contract amount (Cibinic, 1991). For the example, unabsorbed overhead = 0.33% * $2,400,000 = $7,920.

Incurred Overhead Rate during Actual Period - Incurred Overhead Rate for Projected Performance Period = Excess Rate of Overhead - (12)

Excess rate of Overhead x Base Costs of all Contracts = Unabsorbed Overhead - (13)

4.7 Total Direct Cost Allocation Method

The Total Direct Cost Allocation Method allocates the direct costs incurred to calculate the overhead rather than what has been billed (Hewitt, 1986). The calculation for the method is as follows. For the example, unabsorbed overhead = $10,000 * 1 = $10,000.

Overhead Applicable to the Disputed Contract, OHDC = Disputed Contract Direct Costs x Total Company Overhead ÷ All Other Contract Direct Costs - (14)

Daily Overhead Rate, DOR = OHDC ÷ Days of Contract Performance (less delay days)- (15)
Overhead Cost Claimed, COH = DOR x Days of Delay - (16)

The total direct cost approach suffers from a number of weaknesses. It does not consider the differences in the cost components from a contractor's various projects. The methodology assigns the same overhead rate calculation to every project. Normally, rates are determined based on the type of work involved in the contract. Overhead rates would vary based on the level of effort required.

4.8 Specific Base Allocation Method (SBAM)

SBAM is a substantially accurate allocation approach, but is also considered the most complicated and expensive to use (Hewitt, 1986). SBAM allocates overhead costs based on the specific characteristics of a job and each overhead cost element. SBAM would only be a practical approach if the methodology for collecting data was already in place or when the claim amount can justify the analysis expense. The method involves creating indirect cost pool accounts and a basis for allocating the accounts to each contract. This involves developing, comparing, and establishing cost relationships for all elements. The costs for overhead items are allocated to each job based on the established percentages of the overall item cost. Of the various established techniques, SBAM comes closest to counting the dollars in detail the exact way they are allocated. This is, of course, time consuming and tedious. For the example, unabsorbed overhead = $8,000.

Allocation Basis (AB) = Allocation Item Cost on Disputed Jobs ÷ Allocation Item Cost on All Jobs - (17)

Allocated Overhead of Pool Account (AH) = Pool Account Cost x AB -(18)

Average Daily Overhead (ADOH) = AH ÷ Total Contract Days - (19)

Claimed Overhead Cost s= ADOH x Days of Delay - (20)

4.9 Calculation Based on Actual Records

In the calculation of damages based on actual records, the contractor needs to provide detailed accurate records of his home office overhead expenses that will support his claim. In providing the records, the contractor will need to determine the percentage of effort expended for this project performance period or during the delay period. This percentage can be applied to the fixed home office costs, which will result in an allocation for the particular project (Trauner, 1990). This procedure requires detailed accounting procedures, from a record-keeping standpoint, which can be quite onerous. However, the effort may produce substantial benefits to the contractor, which might otherwise not be realized (Ernstrom and Essler, 1982). This method is very accurate if used precisely, and requires no formulas, which is a welcome benefit.

4.10 The Direct Method

The Direct Method is a method proposed by the authors, since it espouses a one-step calculation.

Planned Overhead Rate x Planned Earnings during the delay period = Unabsorbed Overhead - (21)

For the example, unabsorbed overhead = 8.00% * $100,000 = $8,000. The calculation of unabsorbed overhead should really not be more complex than this, and this reflects exactly what the contractor would have earned on the home office overhead had there been no delay or standby. The expected (i.e. planned) production during period of delay can be known from client-approved contractor schedules, the information for which should be readily available. On complex, high-volume projects, especially those of the Department of Defense, earned value reports are mandatory, so the expected earnings should be available and easily acquired. For this particular example, the result of the Direct Method agrees with the Canadian, Comparative Absorption Rate, the Carteret, and Specific Base Allocation Methods. The important factor in the "Direct Method" is that the planned earnings are based on the latest updated schedule. There needn't be any interference from Total Billings in the calculation of unabsorbed overhead for a specific project, and the Direct Method has taken this into account. The Direct Method is much less convoluted than the other methods presented. It consequently appears evident that attorneys and judges, in their ignorance of construction engineering and management, have made a simple process as complicated as possible.

5. Summary of Unabsorbed Overhead Calculations

The results for unabsorbed home office overhead damage calculations for each alternative are provided below:

Burden Fluctuation Method	$6,600
Eichleay Method	$6,667
Allegheny Method	$7,920
Canadian Method, CARM, Carteret, SBAM and Direct Methods	$8,000
Modified Eichleay Method	$8,333
Direct Cost Allocation Method	$10,000

6. Discussion

The median result of all methods is $8,000. The mode is the same, as well. The Eichleay Formula calculation, at $6,667, is approximately 20% lower than the median. It appears that various claimants have used different, but rational approaches to calculate the value of unabsorbed home office overhead, each which have been upheld by courts and boards.

Results for the various alternatives and methods vary, predicated by the particular situation, conditions, and assumptions used in each particular method. All the alternative methods have been used at some time or the other to calculate *compensable damages for unabsorbed home office overhead due to delay*. Each alternative and technique is based on assumptions, have their own formulas, their individual issues and weaknesses, and they all result in estimates or approximations of the damage.

7. Summary and Conclusions

The history and evolution of the Eichleay formula for unabsorbed overhead expenses, first developed in 1960, were presented and discussed. The calculation of unabsorbed overhead still continues to dog owners and contractors alike. Multiple issues and criticism has risen on the use and application of Eichleay. Case law and court decisions that shaped the prerequisite criteria for use of the Eichleay were studied, and alternate methods and formulae for the calculation of damages for unabsorbed home office overhead due to delay were presented. The calculation of the results were summarized and discussed.

The alternate methods have similarities and differences. Even critics of the Eichleay formula acknowledge the difficulty in the determination and calculation of delay overhead damage costs. However, many of these alternate methods utilize questionable assumptions, end up approximating the damages, and often result in some of the same problems alleged against the Eichleay formula.

An exact method or calculation is probably quite impossible to develop, unless actual overhead expenses are accepted, in which case dividing the extra expenses from contractual expenses can be a knotty problem. Therefore, the goal, given the circumstances, is to determine a fair allocation for compensating a contractor for the delay. Consequently, the Direct Method is proposed as an alternate method for the calculation of unabsorbed overhead. The Direct Method is a simple, straightforward, and realistic method for calculating unabsorbed overhead damages and is simpler to use and apply, using, as it is, only a one-step process. Subsequent to all the convoluted techniques studied, it appears reasonable to recommend the straightforward Direct Method, better even than the widely adopted Eichleay.

Factors that Influence Contractor's Risk Response Planning in Controlling Cost of Road Construction Project in Indonesia

Bambang Trigunarsyah,
School of Urban Development, Queensland University of Technology
(email: bambang.trigunarsyah@qut.edu.au)
Nila Putrianti,
Civil Engineering Department, University of Indonesia
(email: neela_purple@yahoo.com)

Abstract

Infrastructure projects, such as road construction, are one of the most important projects In Indonesia. They contribute significantly to the national economic growth. Data from Indonesian Bureau of Statistics shows that budget for road construction project is still the largest compared to other infrastructure projects. Effective cost control in Indonesia's road infrastructure project need to be done in order to better support the economic development. Controlling cost overrun can be done in several ways. Before-process variance is the most effective way because cost overrun is measured early in the beginning of project phase. This makes contractor can focus to develop option of responses planning to avoid such cost overrun through risk avoidance, risk transfer, risk reduction, or risk absorption. This paper discuss the factors that influence contractor's risk response planning in controlling and monitoring cost of road construction project in Indonesia. The research was done using case study in two major contractors in Indonesia. Data analysis is done by Analytic Hierarchy Process (AHP) method in order to obtain priority of the factors. The analysis indicates that personnel's risk attitude as the most influence factor. Risk identification and macro level external factor have the equal rank in second place, and project level external factor is the least influencing factor in construction contractors' risks response planning.

Keywords: Infrastructure, road, construction, risk response, cost control

1. Introduction

Infrastructure projects, such as road construction, are important part of Indonesian economic development. It provides infrastructure for other economic sectors such as agriculture, tourism, manufacturing, trade and others.

Road construction project is the highest government annual spending in terms of providing public infrastructure. In 2005, for example, road construction projects constitute about 15 percent of government budget [1]. Therefore it is important to effectively control the cost of road construction.

Road construction project is susceptible to risks and uncertainties, which could affect project cost performances. Road construction contractors respond differently to those risks. Their responses could be to absorb, transfer, reduce or avoid the risks. Decision to select the type of risk response to be performed is influenced by several factors which include attitude toward risk. As contractors responsible for the construction phase of road construction projects, their respond toward risks would affect the project cost performance. The better the risk response the better the project cost performance.

The purpose of this paper is to identify factors that influence contractor's risk response planning in controlling and monitoring the cost of road construction projects in Indonesia. Case studies on state owned construction companies, which specialised in road construction was used to identify those factors. The paper starts with a review the risk response as a tool for project cost control. Following these reviews, the paper describes the method use to collect and analyse the data. Finally, the paper presents and discusses the research findings.

2. Risk Response Planning as a Tool for Project Cost Control

Project cost control is important to project management as it provides early detection of actual or potential cost overruns. This early detection provides the opportunity to initiate remedial actions and increases the chances of eliminating such cost overruns or minimising their impact [2].

Cost control for road construction project can be divided into control for direct cost and indirect costs. Direct cost includes labours, materials, equipment and subcontractors cost. Indirect cost includes cost related to general condition, tax, risk and overhead [3]. Control for project cost variance includes controlling labours, materials, equipments, subcontractors and overhead [4].

According to Zahn [4], based on the timing of their identification, project cost variances can be divided into three layers: before-process variance, in-process variance and after-process variance. Before-process variances mostly occur in the planning stage before actual construction starts. In-process variances happen during the process or before the measurement results are known. After-process variance is reactive and after-the-fact, but reflects the project performance most realistically, provided that accurate data are captured.

Zahn [4] further stated that before-process variances and in-process variances should be the major targets of a project management team who wants to effectively manage a project in a proactive, aggressive, and professional way. One approach that should be considered to do this is risk management approach. By identifying and assessing risks that can cause project cost variance, project management team can develop a risk response plan.

Risk response planning is a process of developing options and determining actions to enhance opportunities and reduce threats to the project's objectives. It also identifies and assigns individuals or parties that responsible for particular risks. Risk response planning must be appropriate to the severity of the risk, cost effective in meeting the challenge, timely to be successful, realistic within the project context, agreed upon by all parties involved, and owned by a responsible person [5].

Risk response planning can be used as a tool for controlling construction project cost. As part of risk management activities, risk response planning can be used to deal with risks and uncertainties in construction project cost [6]. It can be implemented in every phase of construction project.

Construction projects, including road construction, are affected by risks and uncertainties. Risks and uncertainties occur due to the limitation of knowledge in forecasting, which lead to favourable products (opportunities) as well as unfavourable products (risks). Risk management is often used to change risks to opportunities. Construction risks which related to human factors and technology, for example, if managed properly can reduce the negative impact to projects cost or even improve project cost performance.

Risk management process starts with risk identification, which is identifying the type and the source of risks. It continues with classifying the types of risks and their impact to the project. Risk analysis will filter and prioritise the identified risks. Following the risk analysis, risk response plan is then developed. During project implementation, the risks identified and their responses are monitored and reviewed [7].

Response to risks can be done in the followings [7]:

- Risk absorption, which is accepting the risks and preparing the cost for such risks if happened
- Risk reduction, which is reducing the impact of the risks by implementing preventive or corrective actions
- Risk transfer, which is transferring the risks to another party based on agreement
- Risk avoidance, which involves changing project management plan

The selection of the type of response will be influenced by management attitude toward the risks.

Any individual or organisation can have different risk attitude toward a particular risk, which will be influenced by time, situation, condition, experience and its environment [8]. Webb [9] stated that risk attitude can be influenced by: maturity of management in communication; credibility and flexibility of management behaviour related to disciplinary, compliant to conditions and requirements, proactive in identifying problems and using structured approach in solving the problems; and management preparedness in facing possible changes.

In general, risk attitude can be grouped into four types: [9]

- Risk averse, tend to avoid a risk
- Risk neutral, to consider benefit and losses due to the risk occurrence
- Risk seeking, to find or challenge the risk
- Risk tending, to manage the risk by developing available responses

3. Research Method

Case studies were used to identify factors that influence road construction contractors in developing their response plan. The case studies were performed on two state-owned construction companies, which are specialised in infrastructure construction projects.

The factors are grouped into internal and external factors. Internal factors related to risk management aspects of the project, which mainly related to risk identification and risk attitude. The external factors are divided into project level and macro level. Table 1 list the variables under each group.

Table 1 - Research variables

NO.	Research variables
1.	Internal Factors
1.1	Risk Identification X1 = project size X2 = project location in relation to sources of materials X3 = project complexity X4 = project duration X5 = condition of exist traffic in relation to traffic management X6 = construction method X7 = resources availability (professionals, skills, materials and equipments) X8 = local weather condition
1.2	RISK ATTITUDE X9 = maturity in communication X10 = preparedness in facing possible changes X11 = discipline of project personnel X12 = compliant to conditions and requirements X13 = proactive in identifying problems X14 = using structured approach in solving the problems
2.	External Factors
2.1	Macro level X15 = level of market competition X16 = economic condition X17 = political condition X18 = uncertainty in legal enforcement
2.2	Project level X19 = historical database in similar project X20 = availability of other project stakeholders (subcontractor, supplier and insurance) X21 = capabilities and experience of other project stakeholders (subcontractor, supplier and insurance) X22 = liquidity of project owner X23 = state of technology development

Data collection was done using structured interview to five senior project managers from the two state-own companies. The questionnaire for the interview was designed as such so it can be analysed using Analytic Hierarchy Processes (AHP).

AHP is a multi-criteria decision making method which is developed by Saaty in 1970 [10]. AHP was used because there are multi criteria that have to be considered in selecting a risk response. It will recommend priorities based on the criteria used.

AHP uses a pair-wise comparison in its mathematical formulation. Several analysis and assessment which are performed in AHP include calculating weight factors, assessing consistency and analysing rank correlation. For any comparison matrix which has consistency ration (CR) more than 10%, a clarification was made to respected respondents.

Data analysis was done using a computer application 'Expert Choice', which is an application that was designed to perform AHP analysis.

4. Factors Influencing Risk Response

Data analysis shows that most of the responses have consistency ratios (CR) less than 10%, which within the requirement. Only one response that resulted in a CR of more than 10%. After clarification with the respondent, the CR result is less than 10%. Table 2 shows the consistency ratios of the responses.

Table 2- Consistency Ratio

Pair-wise comparison matrix	Respondent				
	1	2	3	4	5
Criteria toward goal	0.06	0.02	0.09	0.05	0.04
Sub-criteria toward risk identification	0.09	0.09	0.07	0.06	0.08
Sub-criteria toward risk attitude	0.08	0.07	0.09	0.08	0.09
Sub-criteria toward macro level factors	0.04	0.07	0.03	0.08	0.09
Sub-criteria toward project level factors	0.04	0.07	0.05	0.04	0.02
OVERALL	0.07	0.05	0.07	0.06	0.06

Table 3 to 7 show the pair-wise comparison matrix at criteria (factors) and sub-criteria (variables) levels. The coefficients in the matrices are based on the median of the responses.

Table 3- Pair-wise comparison matrix toward goal

	Risk identification	Risk Attitude	External Macro	External Project
Risk identification	1	½	1	2
Risk Attitude		1	2	2
External Macro			1	2
External Project				1

Table 4- Pair-wise comparison matrix toward risk identification

	X1	X2	X3	X4	X5	X6	X7	X8
X1: Project size	1	½	1/3	1	1/3	1/5	¼	½
X2: Project location		1	1/3	3	2	¼	1/3	½

X3: Project duration			1	3	2	1/3	½	½
X4: Traffic condition				1	1/3	¼	1/3	½
X5: Construction method					1	½	1	1
X6: Resource availability						1	2	3
X7: Weather condition							1	2
X8: Complexity								1

Table 5- Pair-wise comparison matrix toward risk attitude

	X9	X10	X11	X12	X13	X14
X9: maturity	1	½	½	½	1	½
X10: preparedness		1	1	1/3	½	1
X11: discipline			1	1	2	2
X12: compliance				1	3	2
X13: proactive					1	2
X14: structure						1

Table 6- Pair-wise comparison matrix toward external factors (Macro level)

	X15	X16	X17	X18
X15: level of market competition	1	1/3	1/3	½
X16: economic condition		1	½	2
X17: political condition			1	3
X18: uncertainty in legal enforcement				1

Table 7- Pair-wise comparison matrix toward external factors (Project level)

	X19	X20	X21	X22	X23
X19: historical database	1	1/3	1/3	1/6	½
X20: availability of other stakeholders		1	1	1/5	2
X21: capabilities & experience of other stakeholders			1	1/5	2
X22: liquidity of project owner				1	5
X23: technology					1

The matrix coefficients from Table 3-7 were used as input for AHP analysis using Expert Choice software. Figure 1 shows the results of the analysis. It can be seen from Figure 1 that the first ten variables contribute about eighty percent toward risk response planning.

The ten variables that influence the risk response plan, on the descending order, are:

1. compliant to conditions and requirements (X12)
2. discipline of project personnel (X11)
3. political condition (X17)
4. resources availability (X7)
5. proactive in identifying problems (X13)
6. preparedness in facing possible changes (X10)
7. using structured approach in solving the problems (X14)
8. local weather condition (X8)

9. economic condition (X16)
10. liquidity of project owner (X22)

From the ten main variables, five are part of risk attitudes factor (X12, X11, X13, X10 & X14). There are two variables (X7 & X8) from risk identification factor and also two variables (X16 & X17) are considered external factors at macro level. There is only one variable (X22) from the external factor at project level. The respondents agreed with the results when these variable factors were validated to them.

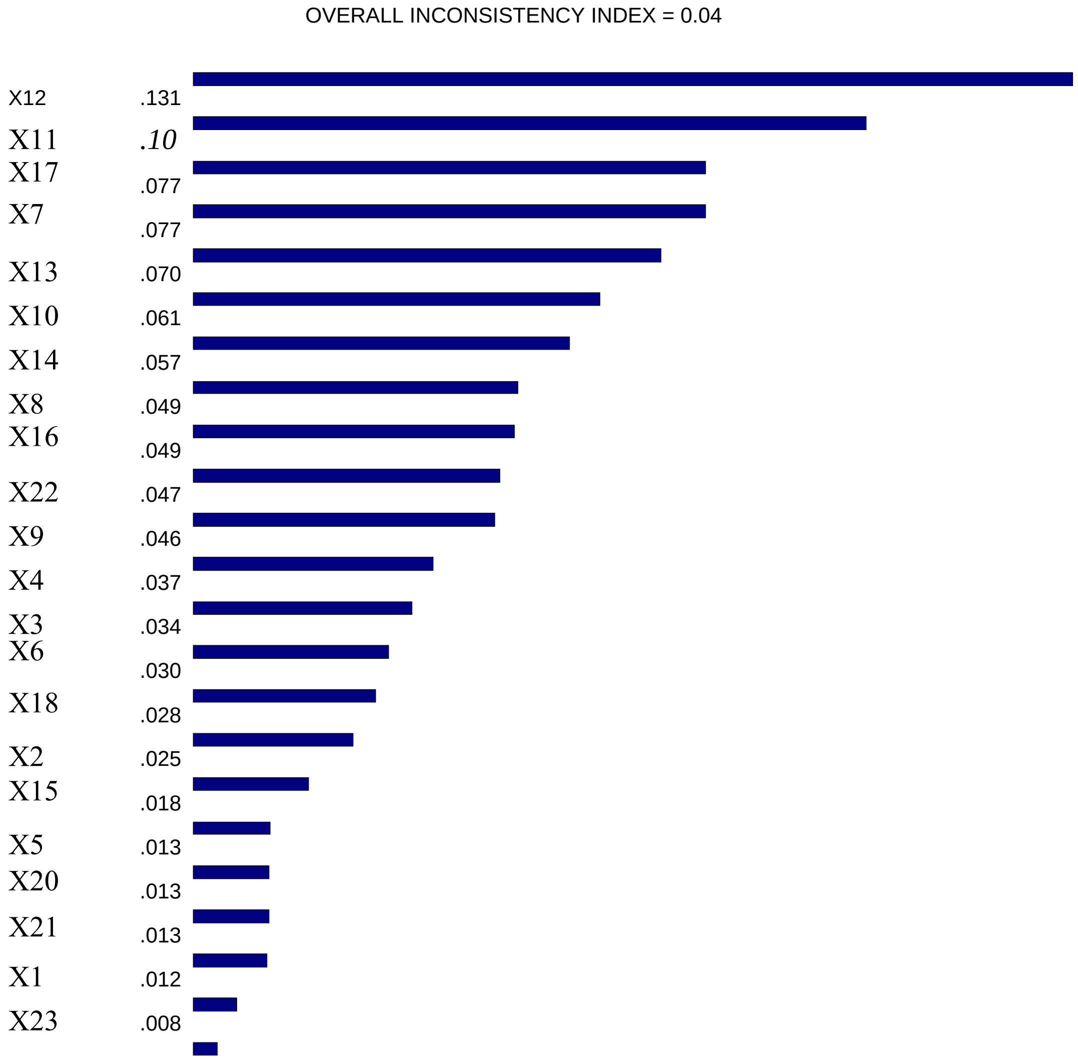

Figure 1- AHP Analysis Result at sub-criteria (variables) levels

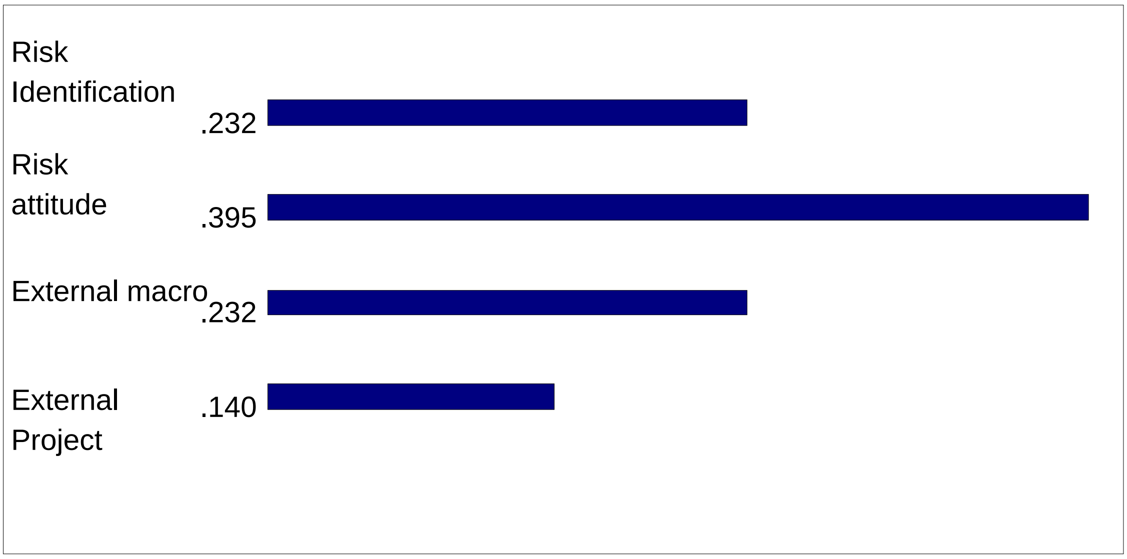
At the criteria (factors) level, as shown in Figure 2, risk attitude contribute about forty percent toward the risk response plan. This result indicates that risk attitudes is the main factor in selecting a response plan It is not surprising as attitude toward the risks would most likely influence selection of response to particular risks. The attitude would be influenced by project team compliance to conditions and requirements, project personnel discipline, proactive attitude toward problem identification and project team preparedness in facing any possible changes.

Most of the respondents agreed that project team personnel compliance to conditions and requirements, their discipline and proactive attitude toward problem identification are important variable not only for selecting a response plan but also for identifying and assessing the risks. Conditions and requirements to be complied with include project contracts, company's policies as well as government rules and regulations.



Inconsistency Ratio =0.02

Figure 2 AHP Analysis Result at criteria (factor) level

The external factor at the macro level and the risk identification has the same contribution of about twenty-three percent each toward the risk response planning. The main variables affecting the external factor at macro level are the political and economic condition. Indonesia has just changed from a centralised government into more regional autonomy. This condition, unquestionably, is affecting the way construction companies select their risks response as the condition in different region can be different.

The main variables that need to be considered in risk identification for road construction projects in Indonesia include availability of resources and local weather conditions. Road construction is affected by water, therefore weather prediction need to be done intensively and continuously to schedule the activities that required dry condition. As road construction performed across the country, availability of resources becomes important factor.

The least influencing factor in developing response plan is the external factor at project level. The main variable that affects this factor is the project owner liquidity. Road construction projects are mostly considered public sector project. The fiscal year adopted by the Indonesian government has an effect to budget disbursement which is the main source of project payment.

5. Conclusions

Road construction is an important aspect of infrastructure development in Indonesia. It is the highest government annual spending for infrastructure projects, which contribute about 15% of overall government budget. Controlling road construction projects costs is, therefore, very important.

Risk response planning can be used as a tool for road constructions project cost control. The paper shows that risk attitude is the most influence factor in developing risk response planning in road construction projects. The risk attitude is influenced by project team compliance to conditions and requirements, project personnel discipline, proactive attitude toward problem identification and project team preparedness in facing any possible changes. The least influencing factor is the external factors at project level.

The study reported in this paper was limited to two state-owned construction companies that specialising in infrastructure project. The future study need to expand the scope to more construction companies.

SECTION III

CONSTRUCTION MANAGEMENT

Measuring Quality: how does this improve construction performance?

Vaughan Coffey,
School of Urban Development Queensland University of Technology, Australia
(email: v.coffey@qut.edu.au)

Abstract

The paper charts the history and development of the Hong Kong Housing Department (HKHD) Performance Assessment Scoring System (PASS) from 1990 to the present day and examines its effect on facilitating change to the quality of construction work of building contractors engaged in the production of public sector housing projects Hong Kong. The paper builds partly on empirical research carried out by the author as part of a doctoral thesis from 2000 to 2005, on experiential knowledge and also on some relevant case studies. The outcomes from this earlier research and validation of PASS based on results derived from the system since the research was originally undertaken are of benefit to practitioners and academics working and studying in the areas of performance assessment and organisational culture and change. The conclusions presented in the paper further underpin the connection established in previous research between strong organisational culture and project and corporate success. Organisational culture was measured using a survey instrument originally developed by Denison and Neale (1994), adapted for the environment of the study, and corporate success was measured by the PASS system mentioned above. The major results of the original study indicate that there is significant linkage between strong organisational cultures and business success and the detailed findings were that, (1) strong organisational culture was positively associated a high level of company effectiveness, (2) a high level of company effectiveness was positively associated with the cultural traits of 'consistency', 'adaptability' and 'mission', and (3) a high level of company effectiveness was positively associated with the combined cultural traits represented by the dimensions of 'external focus' and 'stable culture'. Several opportunities to take forward this research have been identified, including extending the study to other countries and also longitudinally re-evaluating some of the original case studies to ascertain how organisational cultures have changed or further developed in relation to the changing construction climate in Hong Kong.

Keywords: Public housing construction, performance measurement, organisational culture, procurement, quality.

1. Background

1.1 Public housing in Hong Kong – a brief history

Public housing in Hong Kong has a fairly modern history, which began in 1953 with a fire at Shek Kip Mei that destroyed a large area of 'squatter' huts housing predominantly families of refugees from China who had descended on the territory between 1947 and 1949 following the civil war on the mainland (Leung, 1999: 23). This fire left over 60,00 people homeless overnight and the story of how this tragedy was one of the triggers that over the next 55 years has lead to the roll-out of one of the largest and most successful public housing programmes in the world is well documented (Agassi, 1969; Drakakis-Smith, 1979; Bristow, 1984; Leung, 1999). Whilst fascinating, this is not the topic of this paper, but the story that maybe does require telling here (albeit very briefly) is a description of what happened to the quality of public sector housing construction during the late 1970s and early 1980s, that then leads us to a consideration of the topics covered in this paper.

Early on in the housing construction efforts that occurred after 1953, familiar low-rise building techniques were prevalent (*the Bowring Bungalows)* and much assistance was rendered by the British Army and a small dedicated band of professionals employed by the Public Works Department to overcome the immediate housing problems of those made homeless by the original fire disaster. However, as more and more refugees continued to flow down from the mainland of China, the problems of where and how to house thousands of people meant that the early temporary barrack-style accommodation would not suffice in the longer term. A series of simple low-rise multi-storey buildings were developed and constructed and in various forms formed a workable solution until the late 1960s; amongst these were the 'H' shape resettlement blocks built on the site of the original fire in Shek Kip Mei. With land in urban Hong Kong being in such short supply, it was maybe logical that planning densities should be maximized and taller buildings constructed to house more people in a shorter programme time. However, this approach was not without its downside, much of which was not immediately visible at the time the new 'high-rise' apartments were actually handed over and it would only be a decade down the timeline when the devastating problems of these buildings would become horrifyingly obvious. Lack of technical expertise by the construction companies which had sprung up in Hong Kong over the preceding 20 years, coupled with insufficient financial resources and a small number of qualified supervisory professionals meant that the core superstructure and rather poor standards of very basic finishes did not possess the structural integrity or durability needed for the task in hand.

An increasing spate of serious maintenance issues began to grow in intensity in the early 1970s and after investigation by the new breed of architects, engineers and surveyors who had been recruited from overseas by the HK government or had been employed by private developers to lead the new private housing boom that was taking off in the territory, 26 multi-storey low and high rise blocks were deemed to have serious or dangerous structural deficiencies. They were classified into several distinct types according to severity of the defects and placed on short-term, median and long-term demolition schedules with the worst being demolished almost immediately. Once this disastrous situation became public knowledge, all government departments and especially the Hong Kong Housing Authority (HKHA) and it's executive arm, the Hong Kong Housing Department (HKHD), were forced to reconsider their construction quality control systems to assure a distraught public that this could never happen again.

1.2 Ensuring the quality of public housing in Hong Kong

Whilst the HKHA was now firmly committed to obtaining good quality, because of public funding, this needed to be at a fair price and was driven by a belief that quality assurance starts at the beginning of a project not at the end. New leadership in the HKHA and highly- qualified professional staff in the HKHD were committed to a vision that quality is not something which is applied by rectifying defects in buildings found at the final inspection, it requires managing from the top downwards and throughout the life of the project. The unprecedented levels of public housing expenditure on capital works that was now being provided to the local construction and allied industries, entitled the HKHA to expect and receive full value for money. The underlying philosophy has always been, certainly since the late 1980s, "quality is a value and will not be foregone" (Mortiboys, 1991: 4).

At this time, contractors from the Works Branch (WB) List I and II were employed by the Authority on its building contracts, which meant that up to 220 (Group A, B & C) firms were invited to tender by means of open gazette and usually at least 50 tenders were returned for every major contract. Whilst this method of tender invitation ensured that the whole process could be deemed 'fair' and 'competitive', it also meant that companies with reasonably unknown or even poor track records in building work could tender and be awarded quite sizeable contracts. Although any known past performance was taken into account when appraising firms for the award of contracts, the methodology for assessing such performance was somewhat crude and subjective, relying on a simple tick-box grading system based on appraising just a few major building elements..

As by 1989, the HKHA was the major user of the larger Group C companies on the WB List, the establishment of the Authority's own list of contractors seemed a logical development. It was also apparent by that time that some contractors tended to concentrate only on the work of the Authority and had set up specialized operations within their companies to handle such work.

A list of contractors was therefore promulgated in April 1990, which was to be dedicated only to the HKHA works. A comprehensive set of *Rules for Administration of the List* (the "Rules") was produced to regulate all listing matters. Using only companies from its own list meant that the HKHA could exercise direct control in the vetting, prequalification and subsequent performance monitoring of these companies. It also allowed the Authority to operate a reward and penalty mechanism for good and bad performance.

In order to be admitted onto the HA List, contractors were required to fulfill the following basic criteria as advocated in the "Rules':

(a) Certified to of ISO 9000.
(b) Ability to meet List financial requirements
(c) Company organization and staff resources capable of taking on work in the appropriate List group and category and of a relevant value.
(d) A good relevant performance track record.

Once listed into various categories (i.e. new works or maintenance), contractors were then subdivided into groups based on thresholds related to the financial workload limits that accountancy and organisational checks determined they could safely work within without serious risk of causing disruption to the HKHA's all-important housing programme. Should the companies fail to deliver on time, cost and quality, they would be seriously censured including being removed from the List. The new list of contractors was administered by three high-level committees of the HKHA and HKHD shown in Figure 1 below:

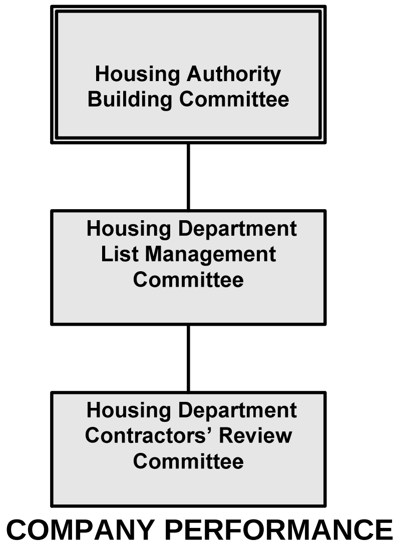

Figure 1- The Hong Kong Housing Authority and Department committee structure

As the 'owner' of the list, the HKHA;s Building Committee (BC) approved all recommendations from HKHD's List Management Committee (LMC) regarding new contractors to be admitted onto the list and changes to the listing status of the existing listed contractors. It set out the "Rules" and executed the authority to implement the laid down policies, and approve disciplinary actions against contractors.

On a quarterly basis, the LMC selects eligible tenderers for upcoming new works contractors and awards tendering opportunities based on previous 6 months performance as measured under a robust and objective performance-based methodology known as the Performance Assessment Scoring System (PASS). The Housing Department Contractors' Performance Review Committee (HDCPRC), on a quarterly basis considers project performance and provides project scores and recommendations on performance and penalty/reward consideration to the LMC.

1.3 The Performance Assessment Scoring System (PASS)

A simplified model of the constituent measures used in PASS 1997 to generate an effectiveness (i.e. performance) score is shown in Figure 2 below.

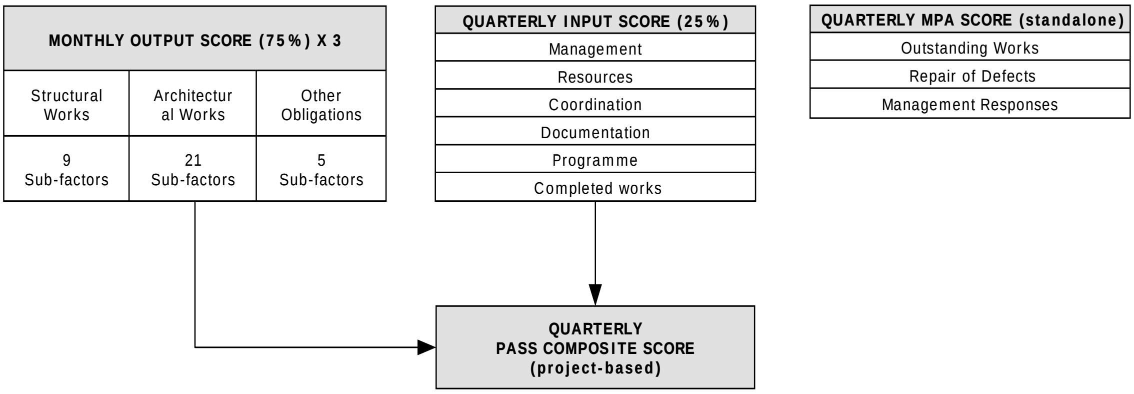

Figure 2 - Simplified model of PASS 1997 Version

Every 3 months, the Quarterly PASS Composite Scores (QPCS) of all projects being undertaken by individual contractors are then amalgamated to form a Quarterly Contractor Score for each active company, an important component of the PASS Contractors' Score-league measuring the comparative achievement of building contractors across all of their public housing contract works, as follows:

a) <u>Project League</u> – shown in Table 1 below, reflects contractors' performance on individual projects. It triggers discussion of, or action on, poor performance of a contractor for a particular project. The league is categorized into three bands with two benchmark lines:

- Composite Target Quality Score (CTQS) is drawn at the upper quartile (25 percentile) of the league.
- Composite Lower Score Threshold (CLST) is drawn at the lower quartile (75 percentile).

Table 1- Sample of the Quarterly Project Score League

Project	Contractor	QPCS	
Project 1	Contractor A	93.05	
Project 2	Contractor A	92.90	
:	:	:	
Project 9	Contractor B	91.25	
Project 10	Contractor B	91.09	Composite Target Quality Score (CTQS)
Project 11	Contractor B	90.89	
Project 12	Contractor C	89.20	
Project 13	Contractor C	89.14	
Project 14	Contractor B	87.38	
Project 15	Contractor D	87.25	
:	:	:	
Project 27	Contractor D	87.01	
Project 28	Contractor E	86.86	
Project 29	Contractor E	*6.68	
Project 30	Contractor F	86.08	Composite Lower Score Threshold (CLST)
Project 31	Contractor F	85.60	
Project 32	Contractor A	85.27	
:	:	:	
Project 39	Contractor B	84.18	
Project 40	Contractor C	83.50	

b) Contractors' League – shown in Table 2 below, considers overall performance of contractors across all projects being undertaken (i.e. a contractor's composite score would be the average of all it's individual project scores).

The CTQS and CLST lines, drawn from the Project League, are superimposed onto the Contractors' League. Higher tendering opportunities would be given to those contractors who fall in the upper band of this league (i.e. above CTQS). These contractors will normally be invited to tender for all upcoming contracts in the next quarter, whereas contractors in the lower band, i.e. below CLST, will not be invited to tender for any projects during the next quarter. Those contractors falling between CTQS and CLST will be given varying tendering opportunities, as decided by the LMC.

Table 2- Sample of the Quarterly Contractors' Score League

Contractor	Composite Score	Eligibility to Tender	Based on 6 Projects to tender in the Quarter under Consideration
Contractor A	92.98	6	
Contractor B	91.03		Composite Target Quality Score (CTQS)
Contractor C	90.01	4	
Contractor D	87.11		
Contractor E	86.55		
Contractor F	86.01		
Contractor G	85.89	2	
Contractor H	85.77		
Contractor I	85.01		
Contractor J	84.69		Composite Lower Score Threshold (CLST)
Contractor K	84.12	NIL	
Contractor L	84.01		

1.4 The impact of PASS on performance of contractors

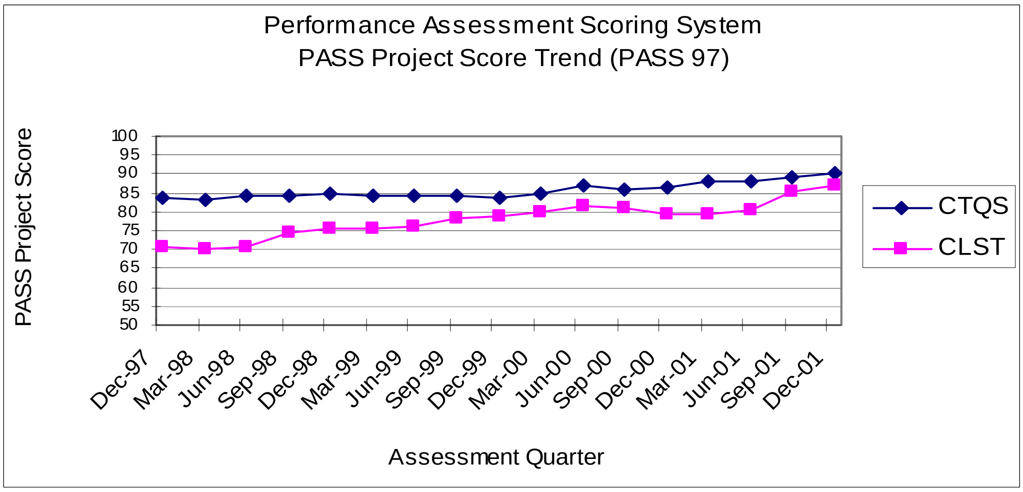

Figure 3- PASS Score Trend 1997- 2001

Figure 3 above clearly demonstrates the overall performance improvement of contractors on projects during the first four years of introducing PASS 1997. This improvement was in part due to the reward component of the system, but also to the disciplinary actions imposed on poor performers. These actions ranged from a 3-month restriction from tendering through to longer periods of formal suspension, and in extreme cases, removal from the list. With the exception of the removal in 1993 of 63 companies, due to their not attaining the required ISO 9000 Standard certification by the official deadline date set by HKHD, the actual number of removals from the HA list and suspensions for disciplinary reasons of companies on the list has been quite small. However, the numbers of contractors restricted from tendering for a prescribed 3-month interval due to poor PASS results since 1997 has been much more significant. Given the existence of quality problems described in the earlier section of this paper that directly affected both the business success of companies involved in the construction of public housing as well as the customer satisfaction of recipients of their product, the possession and maintenance of a robust and accurate performance monitoring system is one important of the most important assets to the HKHD's construction managers and project teams.

1.5 PASS – The future

To ensure the continued effective operation of PASS, HD has needed to constantly monitor, review and enhance the system, the last major review being undertaken in 1997. The reviews identify the main areas of performance shortcomings revealed on projects and raised by assessors, contractors and client. In 1998, following concerns expressed by the Building Committee, HD's senior management decided that a major system review and if necessary, system overhaul should occur. Various system reviews have occurred since the introduction of the 1997 version of the system and the latest review was undertaken in early 2006. In a bid to streamline the system operation and facilitate project teams to concentrate on managing projects, all major monthly PASS assessments are now carried out by dedicated independent teams and project teams contribute by way of daily site inspection records and Management Input scores on a quarterly basis. Figure 4 below shows how the newest major version of the system (i.e., PASS 2000) has continued to improve performance in the years following 2001:

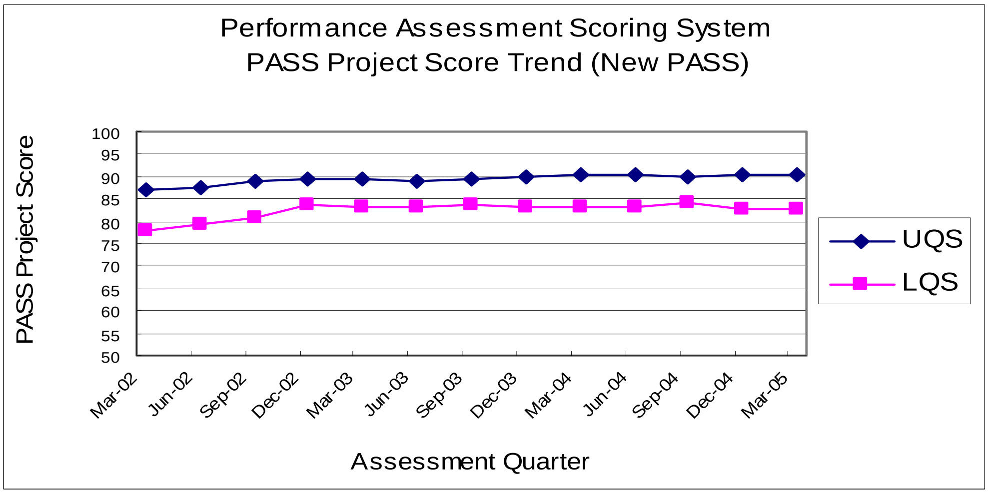

Figure 4- PASS Score trends 2001 – 2004

Given such a robust system, it was logical to use the measured performance outcomes as a basis for determining the varying organisational and business success of HKHA listed companies. However, given that by the mid-1990s all companies were constructing a highly standardized product (i.e., public housing was using standardized modular building types and identical construction methods, particularly mechanized formwork and large-panel precast facades), what determined the differences in performance, as there certainly were such differences? It was clear to the author (who was managing projects at this time) that the largest determinant of differing performance appeared to be due to the different cultures, approaches and attitudes of the various companies and so the research problem evolved from this consideration. The next major question became "how to ascertain a suitable methodology for measuring organisational culture?"

1.6 Measuring Organisational Culture

Following a detailed investigation of the wide range of definitions of 'organisational culture' that exist in the extant literature, a fairly concise operational definition of culture taken from Bates and Plog (1990) was used for this study "Culture is the system of shared beliefs, values, customs, behaviours, and artefacts that the members of society use to cope with their world and with one another, and that are transmitted from generation to generation through learning."

Several methodologies and instruments used previously for measuring organisational culture were examined and the Denison Organizational Culture Survey (DOCS) was eventually selected as being the most suitable to use in the context of this research due to its suitability for use in, and wide acceptability by, the business environment. Based on 15 years of research drawn from data obtained from over 1,000 high and low-performing organizations, Denison and Mishra (1996) found that the following four culture traits have a significant impact on organisational performance:

- Involvement
- Consistency
- Adaptability
- Mission

Figure 5 below shows the operational dimensions of the Denison Organizational Culture model, which has been derived from the DOCS results over a period of years:

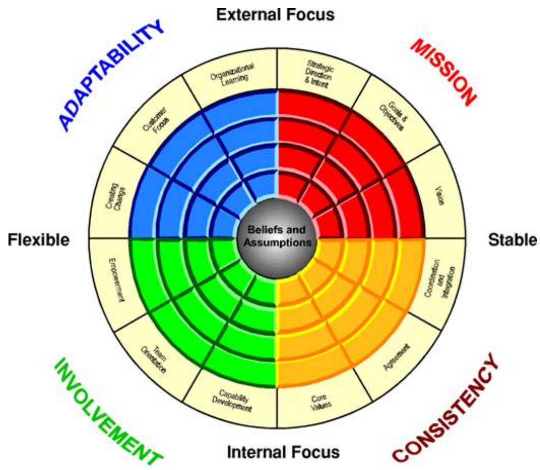

Figure 5- Denison Organizational Culture Model Denison, Cho and Young (2000)

According to Brislin (1976), there are problems relating to the use of such instruments outside of their ethnic development environment due to the difference in *emic* and *etic* perspectives and as it was necessary to allow respondents to DOCS to input in English and/or Chinese and in order to overcome any potential translational equivalence problems, DOCS was taken through a de-centering and back-translation process as shown diagrammatically in Figure 6 below:

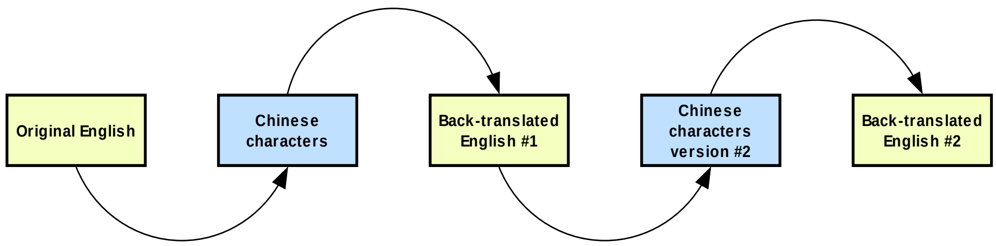

Figure 6 - Adaptation of DOCS for use in Hong Kong

1.7 Measuring corporate performance

As discussed briefly in the introduction of this paper, much of the previous research on organisational effectiveness undertaken since the early 1970s has relied on the use of financial measures to determine performance levels, typically individual accounting indices such as return on investment (ROI), return on assets (ROA) and return on equity (ROE) have been used (Grinyer & Norburn 1975; Karger & Malik 1975; Thune & House 1970). Longitudinally measured multiple financial accounting indices were used in some later studies (Hitt, Ireland, & Stadter 1982; Rumelt 1974) and the capital asset pricing model performance indicators evolved by Lubatkin (1983) were also used as a basis for research by Hitt and Ireland (1984). Despite the popularity of such models and indicators, their use to represent organisational effectiveness has been criticized over the last twenty years. Hitt (1998: 30) notes that they "have deficiencies as 'true' indicators" and their use "does not capture the essence of organizational effectiveness." As had been the case with the lack of consensus amongst both researchers and managers on defining organisational effectiveness, a similar dilemma existed in relation to agreement on the most effective measurements of the phenomena (Bourgeois 1980; Cunningham 1977; Hrebiniak 1978; Molnar & Rogers 1976; Steers 1975; Tsui 1990). Some researchers questioned whether in view of the lack of agreement on such fundamental questions as definitions and measures, organisational effectiveness should even be researched at all Hannan and Freeman, 1977; Bluedorn, 1980).

In an attempt to utilise measures which were determined on a non-financial basis and also reflected ‘customer satisfaction’, the objective *dependent variables* used to operationalise ‘organisational effectiveness’ in this research were the success ratings of building contractors employed on public sector housing contracts awarded and operated by the HKHA. These variables were drawn from the component assessments of the HKHD’s PASS scores of contractors and based therefore on quantitative and objective evaluation and measurement of the real-time quality of built output against the specification requirements, over the period from 1997 to 2002.

1.8 The link between organisational culture and performance

Several researchers and authors have presumed a link between organisational culture and corporate performance and some of these research studies have established evidence of such a link and thus concluded that it does indeed exist Denison (1990), Gordon & DiTomaso (1992), Kotter & Heskett (1992); Petty et al. (1995) and Wilderom & van den Berg (2000). However, other critical reviews of the methodologies and findings used in such research challenge such conclusions, Lim (1995).

Following a detailed examination of 10 studies conducted into the OC performance link in Europe and the United States since 1990, Wilderom, Glunk & Maslowski (2000, p. 201) state “Nevertheless, the great intuitive appeal of the C-P linkage, the preliminary evidence found so far and the many research challenges involved in obtaining the evidence give some reason to still believe in this link.” These authors observed that whilst there are some similarities in the organisational culture dimensions investigated/measured, of the variety of performance measures used, most relied on financially based data sets.

It was this previous predominant use of financial measures to evaluate company success, coupled with the criticisms evident in the extant literature on measuring organisational effectiveness in this manner that prompted me to use a different measurement base, particularly in view of the fact that companies being evaluated were in the construction sector and there was an apparent lack of available financial information specifically related to their work in the public housing sector (i.e., most of the companies were not publicly listed and had parent companies whose financial results were generated based on their total development sector performance).

2. The Research

2.1 The research model

Based on the research objectives and main research problem described in the introduction of this paper, the three resultant research questions were:

Question 1: Do Hong Kong construction companies possessing relatively high combined levels of the four organizational cultural ‘traits’ i.e. adaptability, involvement, consistency and mission (as indicated by the Denison Organizational Culture Model) perform more successfully on public housing projects than those exhibiting lower levels of those traits?

Question 2: Are any of the four traits more significant in contributing to success levels than others?

Question 3: Are any combinations of the four traits, based on a horizontal or vertical split of the Denison Organizational Culture Model, more significant in contributing to success levels than others?

Figure 7 below presents the research model developed and used in the study, however in a short paper it is not possible to fully state all of the nine hypotheses which constitute the model and so the description which follows is restricted only to the three basic research questions giving rise to the various hypotheses.

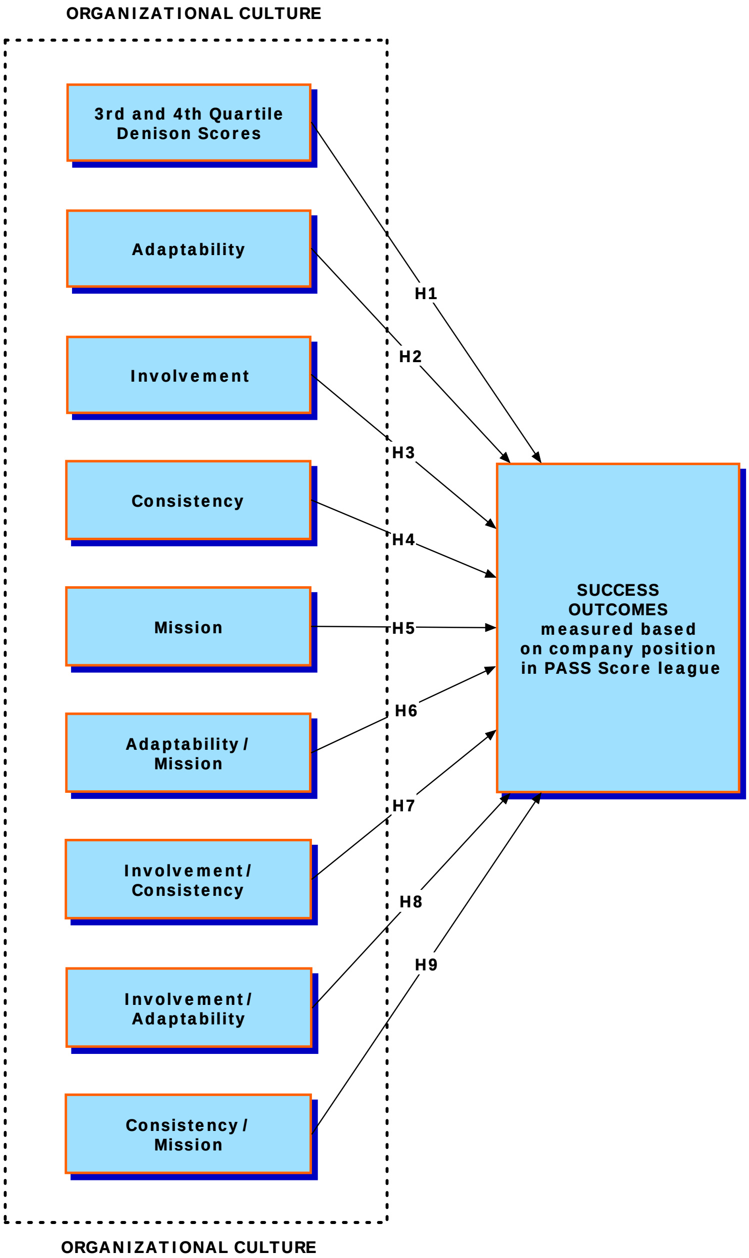

Figure 7- The research model

The nine research hypotheses associated with the questions described above were:

(a) *Question 1 associated hypothesis* -

H$_1$: Position of 'successful' building contractors on the PASS score-league, is significantly associated with high (i.e. third and fourth quartile) combined organisational culture scores, as measured by 'The Denison Organisational Culture Model'.

(b) *Question 2 associated hypo*theses -

H_2: Position of 'successful' building contractors on the PASS score-league, is significantly associated with 'adaptability' in their organisational culture as measured by 'The Denison Organisational Culture Model'.

H_3: Position of 'successful' building contractors on the PASS score-league, is significantly associated with 'involvement' in their organisational culture as measured by 'The Denison Organisational Culture Model'.

H_4: Position of 'successful' building contractors on the PASS score-league, is significantly associated with the 'consistency' measure in their organisational culture as measured by 'The Denison Organisational Culture Model'.

H_5: Position of 'successful' building contractors on the PASS score-league, is significantly associated with the perception of 'mission' in their organisational culture as measured by 'The Denison Organisational Culture Model'.

(c) *Question 3 associated hypotheses* -

H_6: Position of 'successful' building contractors on the PASS score-league, is significantly associated with third and fourth quartile 'Denison' rankings in 'adaptability/mission'.

H_7: Position of 'successful' building contractors on the PASS score-league, is significantly associated with third and fourth quartile 'Denison' rankings in 'involvement/consistency'.

H_8: Position of 'successful' building contractors on the PASS score-league, is significantly associated with third and fourth quartile 'Denison' rankings in 'involvement/adaptability'.

H_9: Position of 'successful' building contractors on the PASS score-league, is significantly associated with third and fourth quartile 'Denison' rankings in 'consistency/mission'.

Sample

The DOCS was distributed to all 53 building contractors on the HKHA's list in the Building (New Works) Category and the total number of returned survey sets was 29 (54.7%) and of these some 23 sets were eventually useable in the study data set (43.40%), based on post-return established cut-off criteria. As each company provided several returns drawn from different levels of management and control with in the company, there were some 159 useable returns overall.

3. Results And Analysis

Question 1 explores the overall theoretical concept of a presumed link between organisational culture (OC) and organisational performance (OP) and so correlation was investigated between the *overall* organisational culture raw scores of contractors and their PASS-measured performance.

Table 3- Pearson correlation results for overall organisational culture and overall performance scores

Correlations

		Overall Cultural Score	Overall PASS Score (00-01)
Overall Cultural Score	Pearson Correlation	1.000	.532*
	Sig. (2-tailed)	.	.019
	N	23	19
Overall PASS Score (00-01)	Pearson Correlation	.532*	1.000
	Sig. (2-tailed)	.019	.
	N	19	19

*. Correlation is significant at the 0.05 level (2-tailed).

As can be seen in Table 3 above, the results show that in companies possessing high combined DOCS scores, their 'strong' organisational culture is positively and significantly associated with high levels of organisational performance measured by PASS. Based on the above results, hypothesis $\mathbf{H_1}$ is supported. Question 2 explored the original concept proposed by Denison (1990) and further developed with Neale (Denison & Neale, 1994) that the four cultural traits of 'Mission', 'Consistency', 'Involvement' and 'Adaptability' have a strong influence on organisational performance. The four cultural trait scores obtained from the DOCS and success levels of the respondent contractors measured as their overall PASS scores was tested and the results are shown in Table 4 below:

Table 4- Pearson correlation results for four organisational culture traits and overall performance scores

Correlations

		Overall PASS Score (00-01)	Involvement	Consistency	Adaptability	Mission
Overall PASS Score (00-01)	Pearson Correlation	1.000	.367	.522*	.543*	.526*
	Sig. (2-tailed)	.	.123	.022	.016	.021
	N	19	19	19	19	19
Involvement	Pearson Correlation	.367	1.000	.796**	.795**	.756**
	Sig. (2-tailed)	.123	.	.000	.000	.000
	N	19	23	23	23	23
Consistency	Pearson Correlation	.522*	.796**	1.000	.737**	.798**
	Sig. (2-tailed)	.022	.000	.	.000	.000
	N	19	23	23	23	23
Adaptability	Pearson Correlation	.543*	.795**	.737**	1.000	.820**
	Sig. (2-tailed)	.016	.000	.000	.	.000
	N	19	23	23	23	23
Mission	Pearson Correlation	.526*	.756**	.798**	.820**	1.000
	Sig. (2-tailed)	.021	.000	.000	.000	.
	N	19	23	23	23	23

*. Correlation is significant at the 0.05 level (2-tailed).

**. Correlation is significant at the 0.01 level (2-tailed).

The Pearson correlation analysis shows a positive relationship between each of 3 cultural traits of 'Consistency', 'Adaptability' and 'Mission' with the overall PASS score at the 5% significance level. Out of these three trait measures of organizational culture strength, 'Adaptability' has the strongest correlation; 'Consistency' has the least correlation, whilst 'Mission' is of moderate significance. Only the correlation between 'Involvement' and overall PASS score cannot be justified in this research study. Adaptability', according to Denison

(2000), is the organisational trait that demonstrates the capability of a company to receive, interpret, and translate signals from its environment into internal behavioral changes that increase its chances for survival, growth and development, i.e., to turn the demands of the business environment into productive and effective action. Three aspects of adaptability impact an organisation's effectiveness and these are:

- Creating Change
- Customer Focus
- Organizational Learning

The high significance of the relationship between 'adaptability' and performance strongly underpins the fact that in a sector such as the construction industry, where the business environment is so volatile and subject to massive and often swift changes, the companies most able to survive are those that are most capable of adapting to these changes. This is particularly pertinent in relation to the public housing sector where housing production levels, cost yardsticks and competitiveness are so dependent on public policy, as well as being directed and driven by altered public sentiment, peoples' increasing aspirations and media and political pressure.

The significant relationship between the traits of 'consistency' and 'mission' and performance highlights the necessity for successful companies to possess core values that are understood by all players and well integrated throughout the organisation through commonly shared goals and objectives and a strong agreed strategic direction. These traits are strongly related to the stability of companies, that creates well-being, loyalty and satisfaction amongst staff. This stability must importantly be reflected in a long-term mission focus which although it may have to adapt, should not significantly change over short spans of time. Denison (2000: 356-7) states that "The most troubled organizations are often those that have had to change their basic mission…when an organization's underlying mission changes, corresponding changes in strategy, structure, culture, and behaviour are also required."

The low significance of the relationship between 'involvement' and performance is an interesting and somewhat surprising result as according to Denison (2000), organisational cultures characterized as "highly involved" strongly encourage employee involvement and create a sense of ownership and responsibility. Their internal management systems are based on informal, voluntary and implied control rather than on formal, explicit or bureaucratic control and strong commitment to an organisation develops from a sense of personal ownership and an increasing capacity for autonomy. Highly involved organisations seek input from their members in order to improve the quality of the decisions made and their subsequent implementation.

Question 3 explores the generic theoretical concept proposed by Denison and others (Denison, Cho & Young 2000; Denison, Hoojiberg, & Quinn 1995; Denison & Mishra 1996) that there are a set of tensions and contradictions existing within organization, which depending on if they are well or badly managed, also have a significant effect on organisational performance. In DOCS, four meaningful combinations of the cultural traits and their directions of influence can be made as follows:

- External focus: Adaptability + Mission
- Internal focus: Involvement + Consistency
- Flexible: Adaptability + Involvement
- Stable: Mission + Consistency

Measurement of the four combinations was obtained by taking average of the corresponding constituent cultural scores. The correlation was then investigated between them and company success represented by overall PASS score. The results of the correlation test are summarised in Table 5 below.

Table 5- Pearson correlation results for four combined organisational culture traits and overall performance scores

Correlations

		Overall PASS Score (00-01)	External Focus Culture	Internal Focus Culture	Flexible Culture	Stable Culture
Overall PASS Score (00-01)	Pearson Correlation	1.000	.552*	.463*	.486*	.543*
	Sig. (2-tailed)	.	.014	.046	.035	.016
	N	19	19	19	19	19
External Focus Culture	Pearson Correlation	.552*	1.000	.853**	.927**	.952**
	Sig. (2-tailed)	.014	.	.000	.000	.000
	N	19	23	23	23	23
Internal Focus Culture	Pearson Correlation	.463*	.853**	1.000	.925**	.911**
	Sig. (2-tailed)	.046	.000	.	.000	.000
	N	19	23	23	23	23
Flexible Culture	Pearson Correlation	.486*	.927**	.925**	1.000	.866**
	Sig. (2-tailed)	.035	.000	.000	.	.000
	N	19	23	23	23	23
Stable Culture	Pearson Correlation	.543*	.952**	.911**	.866**	1.000
	Sig. (2-tailed)	.016	.000	.000	.000	.
	N	19	23	23	23	23

*. Correlation is significant at the 0.05 level (2-tailed).

**. Correlation is significant at the 0.01 level (2-tailed).

From these results, it can be seen that all four combinations of the cultural traits correlate positively with the overall PASS score at 0.05 significance level, but comparatively, 'external focus' and 'stable culture' correlate more significantly than do 'flexible' company structures' and 'internally focused' companies. The purpose of examining these combined cultural trait combinations and their relationship with performance levels was to ascertain whether companies that could manage these apparently contradictory competing dimensions of the Denison Organisational Culture model performed better than those companies that did not handle them well. Denison (2000: 357) states that "Effective organizations find a way to resolve these dynamic contradictions without relying on a simple trade-off." The trade-offs are:

- Stability versus flexibility;
- Internal versus external focus;
- Internal consistency versus external adaptation; and,
- Top-down mission versus bottom-up involvement.

4. Conclusions

4.1 Major findings

The main findings from the research are:

- A high level of company effectiveness is positively associated with strong organisational culture;
- A high level of company effectiveness is positively associated with the cultural traits of ‘consistency’, ‘adaptability’ and ‘mission’ but not with “involvement” trait; and,
- A high level of company effectiveness is positively associated with the combined cultural traits represented by the dimensions of ‘external focus” and “stable culture’.

These findings support the previous research of (Denison 1990; Gordon & DiTomaso 1992; Kotter & Heskett 1992; Petty, Beadles, Lowery, Chapman, & Connell 1995; Wilderom & van den Berg) and underpin the robustness and reliability of the DOCS for use in multi-cultural settings and in a technological business sector (construction) other than those such as commerce, production, manufacturing and information technology where the instrument had been previously tested.

The results of this research add to theory in the following areas:

- They support the outcomes of work of other researchers who have investigated the presumed link between organizational culture and organizational performance, in that there appears to be a strong association between the two constructs;
- They use an entirely new set of measures to operationalise business success and performance (i.e. the HKHD’s PASS scoring system) in a new sector of research (i.e. the construction industry) in which robust research effort is only recently beginning (e.g., CIB TG23 and CIB W112 initiatives);
- The original DOCS instrument of Denison and Neale (1994) has undergone a rigorous process of decentering and back-translation to better adapt it for use in a new research environment, i.e., Hong Kong, Construction, Public Sector Housing;
- Support for mixed method research approaches is provided by way of the use of simple qualitative enquiry to underpin quantitatively obtained data; and,
- These results posit the possibility to further develop the DOCS for specific use in the construction industry setting and as a longitudinal metric for change measurement in this dynamic industry.

4.2 Further research opportunities

Further research is needed to obtain a more detailed and deeper understanding of the organisational culture of the construction industry where study has so far been somewhat limited and longitudinal use of the DOCS and PASS in the research population established for this research would develop and hopefully strengthen the findings described in this paper. The organisational culture (OC) and organisational performance (OC) link

a) The organisational culture and performance link

Whilst much has been achieved by way of research into the OC-OP link since the late 1980s, many authors share the view expressed by Sparrow (2001:102) that “…in taking the more functionalist and positivist perspective of high performance culture research, it is important to stress that this form of assessment [*i.e., the OC-OP research perspective*] need not be limited to quantitative methodologies. Qualitative tools and techniques can sit just as easily in the consultant's toolkit…there must be room for culture and climate diagnostics, informed by richer – and in some instances more qualitative–investigation, that tap the most relevant individual sense making processes." Certainly, the qualitative investigation carried out for this thesis clearly indicated a rich source of alternative data to better inform the purely quantitative results of using an organisational culture measuring instrument and this accords with the view of the said instruments author who stated (Denison, 2000: 367) "Perceptive insiders and outsiders need to be involved in order to help translate the findings from a model-based analysis of the culture…depth of analysis is needed to support the insights from the survey data and bring them to life." Clearly then, there is a need for more qualitative work to be linked with quantitative studies to increase our knowledge of organisational structure, culture and its affect on performance and although current studies are beginning to move us more swiftly in this direction, further work is required to strengthen this whole field of study.

b) The metrics of organisational performance

Hopefully, this thesis has clearly demonstrated the benefits of considering alternative ways to operationalise organisational performance other than by the use of purely financial measures. As mentioned previously, Kennerley and Neely (20021) have summarised the main components of an effective performance measurement system as follows:

- Must provide a "balance" picture of the business,
- Needs to present a succinct overview of the organisation's performance;
- Should be multi-dimensional;
- Requires comprehensiveness;
- Must be integrated both across the organisation's functions and through its hierarchy; and,
- Business results need to be seen as function of the measured determinates.

Andy Neely's own integrated and stakeholder-focused 2001 performance measurement model, the Performance Prism, appears to satisfy the parameters described above and should be more widely used, together with other instruments such as the Balanced Scorecard (Kaplan and Norton, 1992), in order to become more universally accepted measures of organisational effectiveness. This would then allow the development of local, national and global performance databases for use by both researchers in academic studies but by businesses themselves for benchmarking and setting up strategic organisational change programmes.

c) The Hong Kong Construction Industry

Researching the culture of the 23 companies involved in constructing public sector housing in Hong Kong has been a first step only into an area where more research is clearly needed (Root, Hancock & Chapman 1996; Chinowsky and Meredith,, 2000; Fellows and Seymour 2002), however the results of this research need to be extended both laterally (i.e., launched into construction companies outside public sector housing) and longitudinally (i.e., how have the organisational cultures of companies surveyed using DOCS changed since the time of the original study and what affect have changes had on organisational performance as a result?). Through the efforts of the CIB Task Group TG23 and later CIB W112, research into organisational and corporate culture in the construction industry is now progressing ahead and this will be at a global as well national level of consideration. It is interesting to note in this context that the chosen instrument of culture measurement is the Organisational Culture Inventory (Cooke and Rousseau, 1983) and this methodology promises to build up a global database of cultural profiles of construction organisations user-friendly and highly useable at a national and global level for research purposes. The measures and instruments used for determining organisational culture traits and strengths matter less than the actual studying of what differentiates one company in an industry from another and hopefully this author's research has added to the extant knowledge of this, particularly in the construction field.

4.3 Final reflections

The topic extracted from this author's thesis and embodied in this paper was conceived from the researcher's interest and belief in the existence of a demonstrable link between the cultures of organisations and the impact that different levels of cultural strength may have upon effectiveness and performance of these organisations. Building on the theory which has developed out of the many studies carried out in the last decade or so that have demonstrated such a link exists (Denison, 1990; Gordon and DiTomaso, 1992; Kotter and Heskett, 1992; Chapman and Connell, 1995; Wilderom and van den Berg, 1998), whilst at the same time recognising the important contribution of other studies which have been critical of the validity of such presumptions (Saffold, 1988; Siehl and Martin, 1990; Lim, 1995; Wilderom et al, 2000), this research thesis was designed to test both sets of views.

A large part of the doubt expressed by the latter group of authors related to the measures of organisational culture and effectiveness currently being used in such research, in particular the reliance on financially-based measures of effectiveness rather than other tangible metrics. This discussion on differing theoretical opinions, methodologies and measurement tools for investigating the existence of the culture-performance link, presented a fascinating opportunity for further research and given this researcher's long-time experience and specific placement in the construction industry since 1977, a topic developed that not only examined the organisational culture and performance link, but also carried the research specifically into construction industry organisations and public sector building projects, which according to some authors, (Chinowsky and Meredith, 2000), is a sector of business where a need exists for more research into those management and organisational issues that impact on the efficacy of construction companies to perform more effectively. The basic research question addressed within this thesis was born, i.e., why are some companies able to produce built output that better satisfies their customers, when many others cannot and does the organisational culture of the construction company impact on its performance?

Using the list of new works building contractors of the Hong Kong Housing Authority (HKHA), secondary data drawn from that organisation's objective quality measurement tool known as the Performance Assessment Scoring System (PASS) as an alternative objective measure of effectiveness and the *Denison Organisational Culture Survey* (DOCS) instrument developed in 1984 by Dr. Daniel Denison, research was then undertaken on the relationship between organisational culture and organisational performance.

The outcome of the research was that a link does indeed exist between the two and that also there is significant correlation between the strength of an organisation's culture and its comparative effectiveness in performance terms when investigated in the specific setting of Hong Kong. The thesis makes a contribution to theory by further validating the work by Denison (1990) and others not only in that it successfully demonstrates a link between organisational culture and performance, but it also contributes to management and public policy by identifying particular cultural factors in organisations that appear to be significantly responsible for achieving successful outcomes and reveals opportunities for further research into the organisational culture of construction companies.

Abstract

The construction industry is a major contributor to the development of economies in Sri Lanka. However, it faces significant challenges and difficulties which are unique to the specific industry. Therefore, it is a vital role to recognise them and offer solutions. This paper presents findings of a research which was carried out to identify challenges face by the Sri Lankan construction industry and effective mechanisms / motives to overcome such aspects from the consultants' and contractors' perspectives. An industry-wide questionnaire survey was carried out to observe the views of professionals in the building construction industry during June-July 2005. Forty six critical challenges which need immediate attention were identified. Further, 20 mechanisms and motivators were tested to explore solutions in overcoming the above challenges to enhance the image of the construction industry. Thirteen mechanisms were identified and five effective factors were extracted and recommended for up-lifting the image of the construction industry.

Keywords: Construction industry, Challengers, Sri Lanka, Developing countries

1. Introduction

It has been documented that the construction industry is being faced many problems and challenges. In developing countries, these problems are compounded alongside a general situation of socio-economic stress, chronic resource shortages, institutional weaknesses and a general inability to deal with the key issues by inadequate investment plans and changing government priorities due to various sociological, economic and political constraints [1-3]. Some studies evidenced that these problems have become greater in extent and severe in recent years in many countries [4-5]. In Sri Lanka, the fluctuating construction workload, unfair competition by foreign contractors, skills drain and shortages and high cost of developing skills were the main identified problems [6].

However, in Sri Lanka, the construction industry places a vital role in economical and physical development. Further in Sri Lankan economy, construction is the fourth highest sector after services, manufacturing and agriculture [7]. Therefore it is important to consider the present context of the industry to identify precincts and to get counteractive measures in order to uplift the industry to meet the future challenges. This research has focused to identify critical challengers which need immediate attention and effective mechanisms for development of the construction industry in Sri Lanka.

2. Research Design

Research was designed to identify its objectives through an industry-wide questionnaire survey. Since consultants, contractors, suppliers and specialist contactors are the main parties dominating the construction industry, it was decided to elicit their knowledge as experts views to explore the research objectives. However, due to the limited time and other several constrains, suppliers and specialist contracts were omitted. The vacuum in the knowledge extraction due to omission of suppliers and specialist contracts from the survey was minimised by selecting experts from large consultant and contractor organizations (eg. Grade 1 to Grade 2), which handle a wide variety of construction activities.

2.1 Sample Selection

The survey sample was selected randomly (using simple sampling methods). The contact list of leading consultants (Architects, Engineers and Quantity Surveyors) was obtained from the yellow pages of the telephone directory and from respective professional institutions. Contractors were selected from the Institute for Construction Training and Development (ICTAD) registered contracting organisations under Grade 1 to Grade 2, either from the field of building construction works or civil engineering construction works. The sample size for each group was selected as 40.

2.2 Questionnaire Design and Questionnaire Survey

The questionnaire was developed into three sections. Several important questions were grouped under section one to identify the profile of the respondent. Section two was focused to identify challenges and problems of the construction industry. In this section 61 existing challenges and problems obtained from the literature were shown under 10 areas including, financial, government policies /practices, technology, management and coordination, research and development (R&D), resources, safety, training and development, social, and skills [4, 8-16]. In the third section, 20 motivators to improve the image of the industry were listed. A seven-point “likert” scale where 1 represented “very critical” or “very effective”, 4 indicated “neutral”, and 7 stood for “not critical at all” or “not effective at all” was used in the sections 2 and 3 to solicit the judgment of respondents regarding the criticality, effectiveness and efficiency of the proposed (listed) industry challengers, and motivators.

The questionnaire survey was started from a pilot survey which was carried out to ensure the reliability of the survey. Three experts were involved in this task and their feedbacks were used to fine-tune the format of the questionnaire. The improved version of the questionnaires was distributed among the selected group. Hand delivery was used to deliver and collect the questionnaires to increase the rate of return.

3. Discussion

T-test was used as a tool to identify the significant challengers, and motivators. Evaluation was carried out by using "Statistical Package for Social Science" (SPSS) software. To test the null hypothesis Ho: $\mu = \mu_o$ against the alternative hypothesis H1: $\mu < \mu_o$, where μ_o is the population mean. μ_o is the critical rating above which the issue was considered agreeable or ineffective. In this analysis, μ_o was fixed at 4 because, by definition, given in the rating scale, 4 is neutral.

Further, factor analysis was carried out to understand how the significant challengers and motivators work together. Here, the most effective and leading factors that could change the current practices in the industry to achieve a good image can be established using factor analysis (FA). In this analysis, the important factors were established from those whose Eigenvalues are greater than or equal to 1, since an Eigenvalue is a measure of how a standard variable contributes to the principal components. A component with an Eigenvalue of less than 1 is considered as less important and can therefore be ignored and omitted [17].

3.1 Critical Industry Challengers

Forty six significant challengers identified through the t-test are listed in the Table 1. They are grouped under ten different areas including financial, government policies, technology, management and coordination, R&D, resource, safety, training and development social and skill levels.

Table 1 - Significant Challengers

No	Challenge	Mean	Sd.	T	Sig.
A.	Financial				
01	Rapid changes in the national economy	5.05	0.91	7.59	0.000
02	Inadequate support from banking sector	4.84	0.96	5.79	0.000
03	High inflation rate	4.82	0.99	5.46	0.000
04	Narrow profit margins	4.82	1.04	5.22	0.000
05	High interest rates	4.77	1.12	4.59	0.000
06	Limited credit facilities	4.39	1.17	2.20	0.033
B.	Government Policies / Practices				
07	Government policies on taxes	5.09	1.18	6.15	0.000
08	Political instability	4.84	1.2	4.65	0.000
09	Low level of government support on construction	4.89	1.33	4.41	0.000

No	Challenge	Mean	Sd.	T	Sig.
10	Bribe/corruption and favourism	4.59	1.09	3.61	0.001
C.	Technology				
11	Low level of new technological development	5.02	1.09	6.23	0.000
12	Inadequate technological knowledge	4.68	0.80	5.65	0.000
13	Low level of technology transfer	4.61	1.13	3.62	0.001
14	Low level of usage of IT	4.41	0.97	2.79	0.008
D.	Management and Coordination				
15	Poor cost planning	4.8	0.88	6.01	0.000
16	Poor documentation process	4.64	1.10	3.83	0.000
17	Extensive time slippage in contracts	4.55	1.00	3.62	0.001
18	Poor communication	4.55	1.04	3.46	0.001
19	Lack of progress monitoring	4.41	0.97	2.79	0.008
20	Low level of administrative flexibility	3.66	1.01	2.24	0.03
F.	Research and Development				
21	Government involvement in R&D	5.02	1.13	6.00	0.000
22	Limited allocation of funds for R&D	4.91	1.03	5.85	0.000
23	Lack of opportunities for R&D	4.86	1.03	5.59	0.000
24	Reluctant in using innovative building materials	4.68	1.12	4.05	0.000
25	Low level of participation of institutes in industrial oriented R&D	4.7	1.30	3.58	0.001
G.	Resource				
26	High labour turnover	4.73	0.87	5.53	0.000
27	Insufficient integration on design and built operation	4.89	1.13	5.23	0.000
28	Lack of high technical construction equipment	4.8	1.05	5.04	0.000
H.	Safety				
29	Inadequate safety precautions	4.86	0.82	6.95	0.000
30	Undefined specification of construction safety	4.86	0.85	6.73	0.000
31	Improper implementation of safety rules	4.7	0.79	5.88	0.000
32	Limited funds for safety precautions	4.59	0.76	5.18	0.000
33	Low level of employment of safety officers	4.77	1.01	5.08	0.000
34	Limited knowledge on safety precautions	4.59	1.15	3.42	0.001
I.	Training and Development				
35	Limited allocation of funds for employee trainings	4.93	0.87	7.08	0.000
36	Inadequate carrier development programmes	4.93	0.95	6.51	0.000
37	Inadequate support from Institutional organisations	4.66	1.08	4.06	0.000
38	Currently practicing government grading systems	4.27	1.11	1.63	0.110
J.	Social				
39	Inadequate health on construction sites	4.41	0.87	3.12	0.003
40	Low level of facilities provided for workers	4.3	0.73	2.67	0.011
41	High environmental impact	4.34	1.03	2.19	0.034
K.	Skill				
42	Inadequate skill development programmes	4.86	1.03	5.59	0.000

No	Challenge	Mean	Sd.	T	Sig.

44	Low level of skilled workers	4.7	0.90	5.17	0.000
45	Skills of fresh graduates joint in the field	4.84	1.10	5.08	0.000
46	Scarcity of skills availability in the construction	4.59	0.95	4.14	0.000

Financial – Six financial challengers were shown as significant. Financial health of clients and contractors is very important for the success a project. However, respondents felt that it can deteriorate due to other external factors such as rapid changes in the national economy which is a most critical challenge observed from the t-test, followed by inadequate support from the banking sector, high inflation rate, narrow profit margins, high interest rates, and limited credit facilities.

The construction industry has always had a close relationship with the banking system since the money transferring is enormous. However, in Sri Lanka, most of the bankers behave only as money lenders in extending financial facilities. Further, obtaining of a loan from a bank is a tedious procedure which, in some cases, takes months. This longer time period discourages the contractor who requires short term bridging finance. Respondents felt that the higher interest rates of the lending institutions too have made national practitioners not competitive with foreign counterparts who are able to get loans from their bankers with undercutting rates of interest. Further, many contractors do not have reasonable access to commercial borrowings and other facilities at reasonable and comparable rates as available in the developed countries. The lack of credit facilities is another constraint. Short term financing sometimes is available to construction enterprises from local banks, and is expensive. Most enterprises, therefore, operate without access to credit facilities.

Government Policies – It is identified that the construction industry has been experiencing lot of difficulties due to the lack of government policies or ineffective policies to support the construction industry. For instance, government tender procedures based on low price-based are sometimes shown very inefficient [18]. According to respondents, tax policies are another one of main concerns. Political instability of the country created rapid changes of certain policy decisions taken by the previous governments. For instance, decisions to awarding of contacts were revised in many instances. Therefore, the political instability of the government can affect the construction industry and its productivity. Therefore, the government of Sri Lanka should consider that there is a need for clear and effective policies for the construction sector. These policies should be developed by identifying objectives of national construction priorities and for providing guidance for the mobilization of investment. Further, such policies are able to provide a framework for enabling and facilitating the development of the domestic construction sector through professional development, business enterprise and productivity enhancement. However, corruption and favourism is one of the main drawbacks created with the open economic policies in many countries.

Technology – Historically, Sri Lanka has developed largely a craft based construction technology, emanating from the experience gathered over 2000 years. This level of technology was sufficient to meet the construction needs even in the post-independence era. However the large scale rapid development projects such as irrigation, power and industrial building construction work that were launched in the fifties; demanded a high level of technology input. The local industry was not fully geared to meet the entirety of this increased technological demand as such; some of the large scale construction projects were carried out by foreign contractors due to lack of technological development, knowledge and transfer. For example, during the phase of the "accelerated Mahaweli development programme", in late 70's, the foreign contractors had dominated the industry. Further, a conscious effort does not appear to have been made to ensure a sufficient degree of local participation and technology transfer. However, during the last decade, it appears that a fair degree of technology transfer was achieved with a fairly well equipped technology and management base. But, still there is a lot more to achieve. Making use of IT in the construction industry is still at its adolescence stage though the IT industry is booming very fast. This was identified as one barrier for its development.

Management and Co-ordination – Management and co-ordination of projects are shown as great difficulties in the construction industry. In this survey, cost planning, documentation management, time management, communication, progress monitoring, administrative issues were shown in high profile. The cost planning plays a significant role in ensuring that company objectives are compatible with its resources. Poor cost planning of both parties due to lack of proper budgeting results in poor quality of work. For instance, for a contractor to use his mobilisation advance payment to purchase equipment which he cannot depreciate entirely on the particular job or even for other purposes outside the contract, leaving little or nothing to finance the work. A proper documentation process which can be transparent to all parties in the process is another important fact yet not practised in many construction projects. Further, proper time management and progress monitoring strategies are yet to develop to make sure of its delivery on time.

Research and Development – Lack of initiatives, funds, opportunities and attitudes were identified as major issues for inculcating R&D culture in the construction industry. It was identified that most of the firms were reluctant to carry out R&D programs. This may be due to the fact that benefits are not quick and straightforward. Further, most of the practitioners believed that the government should encourage more on R&D as the construction industry plays a major role in the economy. Research projects conducted in universities can be more focused on industrial needs, rather than basic researches. Also, staff members who are carrying out these projects should be encouraged and recognised within the university system. Research forums and awareness programmes can be organised by training institutes for researchers highlighting the research areas to be needed, and providing various sources of funding for these researches.

Resource – Lack of labour, equipment, knowledge and integration are observed in this survey. Today, many construction workers are hired on a project basis and made redundant on project completion. This is a common fact to most of developing countries [8]. As a result, the construction industry is characterized by a pool of labours who works for a variety of contractors in different types of construction. Lack of integration on D&B operations for improving the industry performance is another main challenge. This may be due to lack of experience and knowledge. However, knowledge can be improved by getting various exposures from different projects carried out specially by foreign firms to a certain level.

Safety – The extent of construction accidents is more severe when compared to other industries [19-20]. From the survey results, inadequate safety precautions, lack of implementation of rules, limited fund; knowledge and qualified officers were identified for the extent of unexpected accidents and social problems in the construction industry. Further, the annual report published in 2002 by ICTAD also highlighted that the safety practices that are being adopted at construction sites are far below acceptable standards. On the other hand, low educational levels of many construction workers may be one of a main barriers to imply the safety at sites. Most of the workers do not understand the importance of the site safety rules for their health and safety.

Training and Development – Training and development was highlighted as another significant issue among other concerns. Limited allocation of funds for employee training is one of major barriers of many organisations. On the other hand, the existing situation of many organisations is rather depressing for the employees, due to the reluctance in allocating funds for training and development. At the moment with the government involvement National Apprentice and Industrial Training Authority (NAITA), ICTAD, and a few other technical training institutes are conducting training and developing programs. But this support is not enough to satisfy the demand. In this regard, technical institutes, universities, etc., can take, as part of its responsibility to win the challenge.

Social – There are many social factors being neglected at the site level. They are highlighted in the survey as poor health, hygienic and welfare facilities for the workers. On the other hand, low educational level and attitudes of many workers may be responsible for the poor performance of health and hygiene at the site. This is another area that researchers should focus on finding mechanism to improve the existing conditions. Due to Low profit margins of contactors often intend to complete the projects with minimum supply of facilities to their workers. This may sometimes result even unacceptable hygienic conditions within the site.

Skill – The construction industry suffers from inadequate supply of professionals, less skill levels of fresh graduates and skilled labour force. High demand for the professionals in many countries and low level of salary schemes in the local industry may reduce the number of professionals retained in the local construction industry. This problem is not confined to the local industry, but is a common fact in many developing countries [1]. Less skill levels of fresh graduates may be due to inadequacy of the industry oriented training obtained during the degree programme. Further, it was revealed that less than 4% of the workers in Sri Lanka have been systematically trained and carry certificates that are indicative of their skill [21]. Lower skilled workers may be due to several reasons such as lack of training opportunities provided by the organisations and lack of comprehensive training courses, skill development short courses and individuals less interest on attending such courses.

3.1 Industry Motivators

Out of 20 motivators shown in the questionnaire, 13 were shown as significant and they were further grouped using factor analysis to explore further relationships. Factor analysis was carried out to ascertain if there is any further relationship among the motivators to help the construction industry enhance its image. By using the principal component analysis as the extraction method, four factors with Eigenvalue greater than 1 were extracted (Table 2). The Eigenvalue corresponding to the each factor is shown below to the factor number in the Table 2. The Table 2 also shows the rotated factor loadings. A factor loading can be expressed as a correlation coefficient between an original variable and an extracted factor. To increase the factor loadings which indicates which variables were highly related to each factor, factor rotation was carried out with "varimax" rotation.

Table 2- Industry motivation factors

Motivators	Factor 1(2.33)	Factor 2(2.22)	Factor 3(1.87)	Factor 4(1.56)	Factor 5(1.01)
Enhancing R&D	0.90				
Increase skill levels of employees	0.82				
Promote joint-ventures with foreign construction companies	0.64				
Construction safety practice		0.84			
Offering incentives for encouragement of employees		0.87			
Institute involvement in training and development		0.51			
Opportunities for career development programmes			0.80		
Increase buildability practices			0.73		
Maintain the construction quality standards			0.66		
Improve the professional standards				0.74	
Enhancing the relationship between construction companies				0.73	
Offer knowledge on industry at the primary education system				0.61	
Introduction of new forms of procurement systems					0.90

These five factors are as follows,

Factor 1: enhancing skills and efficiency

Factor 2: adopting incentive awarding mechanism

Factor 3: imposing quality practices

Factor 4: improving professionalism

Factor 5: improving procurement strategies

Enhancing Skills and Efficiency – Enhancing skills and efficiency was identified as the first factor. Respondents felt that the enhancing skills and efficiency in many ways could improve the image of the construction industry. It is noted that, it can be achieved through improving the skill levels of employees, R&D and promoting joint-venture. Individual organisations can take the leading role in improving skills of the employees. Further, they can initiate R&D to identify effective mechanisms of improving the efficiency of organisations. Different case study researches can be carried-out with especially international organisations that have shown great success in their business activities. Respondents have built-up their faith on promoting joint-venture with foreign companies to improve the skills and efficiency. This may be due to the different exposures and experiences gained through foreign companies to improve their current practices.

Adopting Incentive Awarding Mechanism – Respondents felt the incentives can help employees to encourage and motivate themselves. Incentives can be given as performance bonuses or providing training opportunities to improve their knowledge and skills. The organisation can provide financial incentives for staff to undertake long-term training programmes and continuously, professional development programmes such as short courses, seminars, conferences are also be considered. Further, respondents felt that giving incentives for practising and improving health and safety is important to develop the image of the construction industry. This can be implemented at two levels; government and individual organisational level. At the organisational level, incentives can be offered to their workers who observe health and safety rules. These practices can help the management to inculcate health and safety habits. However, this issue should be addressed by the government together with organisations as industry as a whole is performing far behind the acceptable levels of health and safety rules [22]. Further, the government could take a leading role in promoting organisations to adopt safety and health rules through introducing different incentive awarding mechanisms to organisations.

Imposing Quality Practices – According to respondents, the quality of the construction works can be enhanced through improving quality of woks, employees, and quality standards. Pre-defined quality standards of a construction work can be easily achieved if the work is well defined which, in turn, reduces the errors. Respondents felt that the construction errors can be minimised or eliminated, adopting highly buildable designs. In order to raise the buildability, there should be closer cooperation among designers, contractors, specialist contractors, material suppliers and component manufacturers during the design and construction stages. Quality standards play a great role in guiding the construction team to achieve the pre-defined quality of the final product. Therefore, existing quality standards should be reviewed, maintained and improved yearly. The strategies like total quality management mechanisms can be implemented. Further, respondents also felt that the career development of the construction team would help to improve the quality. For instance, career development programmes can improve employees' carrier achieving quality outputs. Further, organisations can identify individuals' career paths and help them to develop their careers to motivate them to retain in the same organisation which in-turn raise the performance levels of the organisation.

Improving Professionalism – Improving professionalism was identified as the fourth factor. Respondents felt that professionalism can improve through enhancing professional practices, relationships and knowledge. Respondents proposed that the improving knowledge of professionalism can be started at the primary education level and continuously carried out up to the practitioner level. At school and institutional education, several modules can be included to their curriculums, where, as at the practitioner level, individuals can convert their knowledge in to practice. Further, certain guidance can be given through codes of conduct and exposures through making various relationships between different parties in the industry.

Improving Procurement Strategies – In the fifth factor, improving procurement strategies was observed. In Sri Lanka most of the contracts are based on traditional procurement method. Other procurement systems like joint-ventures, partnering, etc., are still at a very low profile. However, respondents felt that if these new strategies are developed, it will lead the industry towards the international market.

4. Conclusions

The research revealed that currently, there are many problems faced by the construction industry in Sri Lanka as seen by consultants and contractors. Sixty one challengers were tested and 46 are shown significant. They are from ten different areas including financial, government policies, technology, management and coordination, R&D, resource, safety, training and development social and skill levels. Further, the research identified 13 main motivators to help construction industry participants to improve the performance. Among these motivators, factor analysis revealed that some sub-factors were more important than others. Based on Eigenvalues, the five important factors were established to enable the construction industry to enhance its image. They are: enhancing industry skills and efficiency, adopting incentive awarding mechanism, imposing quality practices, improving professionalism, improving procurement strategies. These findings will create a momentum to all who are in the construction industry to look back on their existing practices and performance. Further, the recommendations given by identified factors will provide a simple guidance raising the image of the construction industry.

Abstract

Construction industry is highly susceptible to be benefited from teams as the construction products are delivered by a collection of diverse professionals. However, effective teams cannot be created at a stroke, and, they need time and opportunity to mature. This is normally referred as team development; and, this area has been subjected to various researches. However, there is a deficiency in published researches on team development with regards to construction teams and none is reported in Sri Lanka. Therefore, this study explored how the construction project teams in Sri Lanka go through team development process. This research problem was approached through case studies of three construction projects, which were operating under the traditional procurement method with re-measurement contracts. Semi-structured interviews were conducted with five distinct participants of construction team during data collection. Based on findings, a new model of team development with regards to Sri Lankan construction teams was developed. The new model indicates that construction teams progress basically in a linear sequence (forming-storming-norming-performing-adjourning) as suggested in the literature. However, the study unearthed that within this basic linear sequence, several cycles can be created due to the conflicts that may occur when the team is at performing level. The results further revealed that construction teams in Sri Lanka lacking with mutual accountability; and, formal attempts to get long-term benefits.

Keywords: Construction teams, Sri Lanka, Construction Industry, Team Development

1. Background

Even though, issues on teamwork has been frequently addressed by the contemporary management researchers in a more structured way, the practice of teamwork has its roots spanned up to the very beginning of human life. For example, according to Cornick and Mather [1],

“when early man started to hunt something that was bigger than any one person could handle, he started to do it with others. The hunting party was a group with a very important common goal- to obtain food to survive.”

Various researchers have defined the term "team" in various ways. However, amongst the different definitions for team, the following given by Katzanbach and Smith [2] is one of the commonly cited:

"a team is a small number of people with complementary skills, who are committed to a common purpose, performance goals and approach for which they hold themselves mutually accountable."

This definition by Katzanbach and Smith [1] is clear and comprehensive to an acceptable extent.

Researchers all over the world have highlighted the significance of teams in organisational perspective. Most organisations which seek improved efficiency have embraced teams in the belief that they are the way to meet the demands of a turbulent and challenging market place [3]. A research carried out by Bacon and Blyton [4] indicated that teamworking has a greater positive impact upon both organisational performance and human resource outcomes. Further, usage of teams in organisations results in increased productivity [5]. In addition, Murray and Moses [6] have stressed the idea that teams play a central role in organisational learning process.

This concept of "teamwork" is very much appropriate for the construction industry as the construction products are delivered by a collection of professionals. Various authors have highlighted the importance of teamwork in construction. In a survey of AEC (Architectural/ Engineering/ Construction) companies in the U.S., Arditi and Gunaydın [7] has identified that collaboration among parties in the design team was ranked first among the many factors that affect quality in design phase. Further, according to Albanse [8], teambuilding approaches in projects has contributed to lower the total project cost by avoiding rework; improving trust; reducing scope definition problems; lowering variation order rates; and, improving understanding of project objectives. In addition, improved teamwork in construction projects will increase the project participants' job satisfaction [9].

Since, teams offer numerous benefits both in organisational and construction perspectives; the knowledge on how teams develop is of paramount importance for team leaders. Over the years, many researchers intended to identify how teams in general organisational perspective develop, and, offered different models to represent this process. According to Gersick [10], amongst these models, the model developed by B.W. Tuckman in 1965 is frequently cited today in management literature. According Tuckman's model, a team has to go through four stages called **forming** (team comes together and gets the initial awareness about the each other), **storming** (conflict and the competition within the team rise to higher level), **norming** (team members try to set norms for appropriate behaviours) and **performing** (team maturing as an effective team) during its life.

Later, in 1977, Tuckman and Jenson have revised this model and proposed a new model of team development with the addition of adjourning stage which occurs after the performing stage (see Figure 1). Moreover, by addressing the issues untouched by Tuckman (1965), several other researchers too have come up with different team development models. These models include; five faces model [11], two barriers model [12] and integrated team development model [13]. Amongst aforesaid team development models, the model of Tuckman and Jenson remains more appropriate for the construction context since, it is based on the fundamental assumption that teams has a finite life.

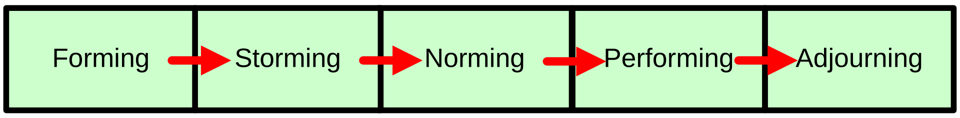

Figure 1- Tuckman-Jenson model (1977) Source: Rickards and Moger [13]

However, Winch [14], highlighted that members in construction teams are lacking with mutual accountability and a mutual objective. Some researchers have identified that the teams in construction are virtual in nature since, they have to work together from many different locations over the life of the project [1] [15]. Further, Cornick and Mather [1] and Walker [16] suggest that since, construction project teams comprises of members from different organisations, it can also be regarded as inter-organisational team. In addition, there is sufficient evidence in the literature regarding construction teams to argue that construction team is a cross-functional team [16].

When reviewing the construction related literature, it was evident that a little consideration has been given to the issues relating to team development. By looking at the characteristics of construction teams, it is evident that it deviates from the ideal team definition of Katzanbach and Smith [2]. Therefore, team development models which have been developed in general organisation perspective can not be solely applied in construction context. However, if the construction team leaders are knowledgeable about the issues relating to nature and types of teams; and, team development in construction, they are in a better position to determine what types of resources and support will be most helpful to the team, based on the specific challenges they are facing in each stage. Thus, this research intends to fill the research gap by studying how the concepts of team and team development applied in Sri Lankan construction context.

2. Method Of Study

The empirical study consisted of cases studies of three building construction projects namely projects A, B and C which are operating under the traditional procurement method with re-measurement contracts; and, whose construction duration is more than one year. Data collection was mainly done by conducting semi-structured interviews with five key participants of the construction project team: client or his representative, contractor’s site manager, architect, structural consultant and the cost consultant (quantity surveyor). The data gathered from the interviews were analysed by code-based content analysis with the assistance of computer soft ware called N-vivo. In the same time, cognitive maps were developed in order to enhance the data displaying capabilities of the findings. Finally, conclusions about the overall research problem were drawn by critically analysing the findings.

3. Research Findings

The findings reveal the nature of the team; types of teams; and, team development with regards to Sri Lankan construction context. These are discussed in detail in the following sections.

3.1 Nature of the Construction Team

The nature of the construction team is discussed in terms of disciplines of the members, team leader, accountability, interdependencies, consistency of the members, and, objectives of the members as illustrated below.

Disciplines of the Members

Case studies had identified that the construction team consists of the members from various disciplines. Projects which were selected in this study were either very large projects or very complex ones. Project A and Project B has high contract sums. Project C which has the lowest contract sum (170 millions), was a very complex project. Therefore, it can be argued that these issues contributed significantly to the existence of members from various disciplines.

Team Leader

The empirical data disclosed that in construction teams, the leader's role is significantly governed by the contractual conditions. For example, the structural engineer of the project C indicated "*the leader did not have much work to do rather than just a facilitator or a coordinator. We all have obligations and responsibilities under the contract and there were penalties set up in case of breach of those obligations. Therefore, we all know what is expected from us and there was not much need for the leader to supervise us*." Therefore, it is evident that in construction teams, the leader's role was substituted by the contractual obligations up to some extent and hence, leadership positions become decreased importance.

Accountability

The case study findings revealed that in most of the situations the accountability within the team was at the organisation level. Most of the members were from different organisations and each organisation's accountability was clearly documented in the contractual conditions. Therefore, most of the time mistakes by each member were treated based on the contractual obligations. For example, the Architect from Project C stated "*since, there were several organisations, they are accountable at organisation wise. Accountability of each party is specified in the contract documents. Therefore, each member's mistake is treated based on that*".

Interdependencies

Most of the interviewees disclosed that they have to depend on other team members to a higher extent when performing their tasks. As explained earlier, projects within the case study sample were either very large projects or very complex ones and, hence, various people with various expertises are required to handle such projects. But, the tasks of these members were interrelated and each member needs inputs from other members to carry out their functions. Therefore, higher level of interdependency among members was evident in Sri Lankan construction project teams.

Consistency of the Members

Case study data revealed that most of the construction project teams were not much consistent through out the life of the project in terms of parties. The projects selected in the study were adapting traditional (separated) procurement method. Because of that, some of the team members came into the team at various stages and even, some had completed their work and went away prior to the project completion. But, if the integrated (design and build) method was adapted some kind of consistency of parties can be expected as there is only one party to carry out both design and construction (design and built contractor), and, also due to fact that the design and built contractor is selected at early stage in the design process.

Objectives of the Members

Case study findings showed that the objectives of most of the members were inline with the project objectives. But, there were some situations where the contractors have experienced some sort of a conflict between their business objective and the project objective. When compared to the jobs undertaking by the other members the contractor's job is somewhat risky than the others. Therefore, their financial objective is quite strong and that objective sometimes found incompatible with the project objectives. The contractor's site manager from Project C explained this "*normally our main objective is to fulfill the client's requirement which is the objective of the project. We also have another objective to have a reasonable profit for the works we executed. But, there were some situations, where we felt that we were not paid enough for our work especially, during variations. In such situations, those two objectives were clashed a bit*."

3.2 Types of teams in Construction

The types of teams construction is discussed in terms virtual, cross-functional, and, inter-organisational teams.

Virtual Teams

As per the definition given by DeSanctis and Poole [17], geographically, temporally, and/or organisationally dispersion and, the communication through information and communication technologies can be seen as the main features of virtual teams.

The empirical data revealed that construction team members were from different organisations. Thus, the teams can be regarded as organisationally dispersed. Further, since most of the members were from different organisations and also they were involved in various projects simultaneously, they have to work from different locations. Therefore, team can be viewed as geographically dispersed. In addition, despite the fact that they were geographically dispersed, the team members managed to meet each other at least once a week. Therefore, those teams can also be viewed as temporarily dispersed.

Since, the construction teams were geographically dispersed; they used information and communication technologies such as telephone, E-mail and faxes to maintain communication between them. Therefore, by looking at all of above empirical findings the construction teams can be viewed as virtual teams.

Cross-functional Teams

As per Ford and Randolph [18], Cross-functional team usually works together for a limited time, team members are also members of other teams and members have reporting relationship to functional managers as well as multiple team or project leaders.

Majority of the interviewees unveiled that they were involved in various projects simultaneously. Further, due to the fact that the construction teams consisted of members from different organisations, in addition to reporting to the project leadership they also has to report to the management in their parent organisations. For example, the Quantity surveyor of the Project A indicated "In my organisation I have to report to the chairman of my organisation and in the project; I have to report to the project leader." Therefore, it is evident that they had multiple reporting relationships.

Because of above two reasons and also due to the fact that construction teams have a finite life, the construction teams can be regarded as Cross-functional teams.

Inter-organisational Teams

Inter-organisational team refers to the team, which is made up of representatives from various organisations who are involved together in producing the results [8].

The case study findings revealed that almost all the team members were from different organisations. Further, it is obvious that those team members were drawn together to produce a result (get the project done). Therefore, the construction team can also be considered as an inter-organisational team.

Based on the findings under the sections 'Nature of the construction team'; and 'Types of teams in construction', the definition for the ideal team given by Katzanbach and Smith [2] can be altered in the Sri Lankan construction context as follows.

> *"The construction team is a collection of two or more people with complementary skills, who come from different disciplines and organisations, to perform a common objective, but with individual objectives and, operating from different locations with multiple reporting relationships, whose accountability and leadership are significantly governed by the contractual arrangements."*

3.3 Team Development

The issues relating to team development with regards to Sri Lankan construction teams were identified by testing the Tuckman and Jenson model (1977). This model was selected after an extensive evaluation process due its high compatibility with construction teams. The 'feelings and thoughts of the members' and 'observable behaviours of the members' at different stages of team development as suggested by Tuckman and Jenson were questioned during the interviews to know about the existence of each stage.

The empirical findings disclosed that Forming and Storming stages were not experienced by the construction team members to the same extent as suggested by Tuckman and Jenson. However, Norming, Performing and Adjourning were almost identical to the Tuckman and Jenson. The Observed feeling and thoughts of the members; and, Observable behaviours of members at each stage of team development were illustrated in Table 1 and Table 2 respectively.

The interviewees were in general agreement that aforesaid stages were incurred in sequence as Forming-Storming-Norming-Performing-Adjourning in the selected projects. They further mentioned that when the team was at the performing stage, it has undergone some conflicts. Therefore, the team was fallen again into storming stage and then has to follow the same sequence to become an effective team. This scenario has happened in several occasions and led to creation of several cycles within the team development process. For example the architect of the project A stated that "*it has this leaner sequence. But, some times when the team is functioning as an effective team it went through some conflict situations. Then it followed the same sequence to become an effective team. This created several cycles between stages.*"

Most of the members perceived that those conflicts occurred when the new team members joined the team. For example the client's project manager of the project C stated that "*this happened mainly due to the arrival of new team members at different stages. For example, when a subcontractor joined the team at latter stages, it is very difficult to maintain coordination between them since they were not familiar with the existing way of working. It was a very significant issue in this particular project as there were about twelve subcontractors and they were responsible for almost half of the work.*"

However, some members indicated that conflicts occurred when the team is transferring from design to construction or from one trade of works to another. For example, the client's representative of the Project B denoted "*it happened normally when the existing way of working changed. For example, when the team is transferring from design to construction stages or when scope is changing from structural work to finishes or from finishes to services*." When the team is transferring from design to construction the contractor came into the scenario. Further, when the team is transferring from one trade of works to another such as structural to finishes or from finishes to services new subcontractors came into the team. Therefore, it can be argued that those conflicts were due to entrance of new members than any thing else.

Quite a high proportion of team members indicated that the changes to the existing scope of work such as variations also gave a reasonable contribution to such conflicts. For example, the contractor's project manager of project B indicated that "*these conflicts were mainly arisen when the existing scope of the project changed. For example, if the client requested a huge variation, then it was difficult to rearrange the works, agreeing to a rate and agreeing for time extensions, etc. those things normally led to conflicts*."

Table 1- Observed feeling and thoughts of the members at each stage of team development during the case studies

Stage	Forming	Storming	Norming	Performing	Adjourning
Feeling and Thoughts of the Members	• Optimistic and full of anticipation • Pride in being chosen for the team	• Confusion and loss of interest on the team • Fluctuations in attitude about the team	• Sense of belonging to a team • High confidence • Feel a new ability to express criticism constructively • Acceptance of all members in the team • General sense of trust • Assured that everything is going to work out okay	• Freedom to express and contribute • High commitment • Fun, excitement and creativity • General sense of satisfaction • Continual discovery of how to sustain feelings of momentum and enthusiasm • Empathy for one another • Trusting friendships with others	• Think about life after the project • Pride about your contribution for the team • Sadness about loosing relationship with the other team members.

Table 2- Observable behaviours of members at each stage of team development during the case studies

Stage	Forming	Storming	Norming	Performing	Adjourning
Observable Behaviours of Members	• Attempts to define tasks, processes and how it will be decided • Politeness • Orienting with others personally	• Arguing among members • Differences in points of view and personal style • Lack of progress • Establishment of unrealistic goals • Concern over excessive work	• Agreeing of processes and procedures • Attempts to make consensus decisions • focus and energy on tasks • Setting and achieving task milestones • Shared problem solving • developing routines • Comfort with relationships • Effective conflict resolution skills	• Functioning fully as team • Clear and interdependent roles • Ability of the team members to organize themselves • Flexibility and well-functioning individually • Better understanding of each other's strengths and weaknesses and insights into group processes	• Recognition and celebrating of accomplishments of team • Seeking to learn from mistakes of the team • Expressing appreciation for each other's contributions • Evaluating results • Preparing to move on

Life of the Team after Adjourning Stage

Case study findings revealed that majority of the team members were involved in various projects simultaneously. Therefore, they continued with those projects after the adjourning stage. Further, since all the team members were permanent employees in their respective organisations they were assigned to new jobs and they were engaging on those as well. Since, the team in the project B was repeatedly used in next two phases of the project B, they were involving in those two phases. But, the members from the other two projects mentioned that there was not any formal arrangement in their projects to get long-term benefits from the team.

Based on the findings of the empirical study, Tuckman-Jenson Model (1977) has been altered in the construction context as shown in the Figure 2. This can be presented as a new model of team development with regards to Sri Lankan construction teams.

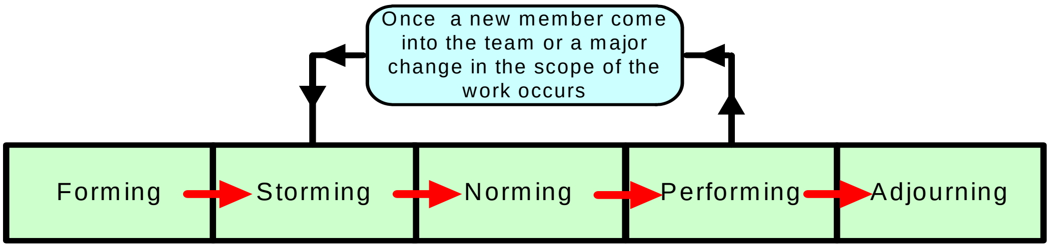

Figure 2- Revised Tuckman-Jenson Model in construction context

The model represents the cyclical nature of the team development process through the backward link from performing to storming. Conclusions drawn from this study will be discussed in the next section.

4. Conclusions

It is clear that construction teams are fairly different from the ideal teams mainly due to the lack of mutual accountability and common objective. Further, it was also evident that most of the key issues relating to construction teams such the leadership and the accountability were significantly governed by the contractual conditions. In addition, construction teams possess characteristics of virtual, cross-functional, and, inter-organisational teams.

Construction teams undergo a team development process fairly similar to the process suggested by the Tuckman and Jenson model (1977). However, the forming and storming stages are not experienced by the team members to the same extent as suggested by the Tuckman and Jenson. The basic linear sequence of the team development stages was identical with Tuckman and Jenson. But, within this linear sequence, several cycles existed due to the conflicts that occurred when the team was at performing level.

The model suggested by this study is important for construction team leaders to have better allocation of resources and leadership support for the team based on the specific challenges which the team is facing in each stage of team development.

It was also identified that progression through team development process has a strong positive relationship with the team learning Thus, after carrying out this research it seemed appropriate that further research may focus on team learning in Sri Lankan construction context.

Abstract

The paper sets out the results of a questionnaire survey and a series of interviews with clients, contractors and consultants involved in nine construction projects recently undertaken in Sweden. Despite the fact that risk management was a part of each project, many projects suffered from variations in cost affecting one or more actors. Risk management was not carried out systematically in those projects. Both identified and unforeseen risks often occurred in the projects and generally had a significant effect on the project cost. The purpose of the paper is to examine project risk management in practice and to understand how managing project risks from a process-oriented perspective could improve the situation. In particular, the involvement of the actors in risk management in individual projects is examined. Risk transfer and communication of risks between the project phases are explored. Finally, the factors that determine whether or not the actors consider an open discussion on risk management and risk sharing as beneficial are analysed. The main conclusion is that a shift from project-oriented to process-oriented risk management is required.

Keywords: Risk management, construction, Sweden, process modelling

1. Introduction

According to a report of the Swedish Construction Commission [1], increased construction costs, project delays and deviations in quality are the most common problems in the construction industry. Risk management is a process that aims to maximise opportunities and minimise the consequences of a risk event and is an important part of the project management process. As such, it is intended to help in safeguarding project objectives, even to increase their value to the client. When considering the effect that risk management has on the project's goals in terms of quality and cost, it would be reasonable to expect that it was an open process across all phases of the project. Furthermore, a specific project risk should be managed by the actor who is best able to deal with it. Instead, it is often the case that the various actors try to avoid risks as far as possible and let somebody else in the value chain deal with them. Relatively little attention has been paid in the Swedish research community to deeper investigation of the possible changes in the traditional construction process in which each actor focuses on short-term economic results and protects his/her own interests rather than the whole project. The purpose of the paper is to examine project risk management in practice and to understand how managing project risks from a process-oriented perspective could improve the situation.

The paper sets out the results of a questionnaire survey and a series of interviews with clients, contractors and consultants involved in nine construction projects recently undertaken in Sweden. The objective of the study is to explore the factors that lead, more or less, to effective risk management in the projects. In particular, we examine the actors' understanding of risk management process and their involvement in risk management in individual projects. We analyse risk transfer and communication of risks between the project phases. Finally, the factors that determine whether or not the actors consider an open discussion on risk management and risk sharing as beneficial are analysed. Since the paper focuses on the findings of research, most space here is given to reporting empirically-derived findings instead of presenting familiar arguments on the nature of risk and the purpose of the risk management process. Nonetheless, we outline the critical issues connected with the risk management process and its application within the construction industry.

Project risks are uncertain events or conditions that may have an impact on project objectives [2, 3]. A risk has a cause and, if it is triggered, also a consequence. A questionnaire survey conducted by Akintoye and MacLeod [4] shows that the majority of project actors perceive risk as a negative event. Ward and Chapman [5] discuss the concept of risk in detail and suggest using the more general concept of *uncertainty*. Risk management is a formal process directed towards the identification, assessment and response to project risks [2, 5, 6]. Risk identification is aimed at determining potential risks, i.e. those that may affect the project. There are several approaches to classifying project risks and risk sources [7-10]. In general, the sources of risk in construction projects may be divided into external risks (e.g. financial, economic, political, legal and environmental), internal risks (e.g. design, construction, management and relationships) and force majeure risks. Several surveys conducted among construction industry actors [4, 11, 12] show that checklists and brainstorming are the most often used techniques in risk identification. During risk assessment, identified risks are evaluated and ranked. The goal is to prioritise risks for management. Several authors [4, 11, 12] cite subjective judgment, intuition and experience as being most commonly used in risk assessment. The risk response process is directed to identifying a way of dealing with project risks and consists of three main techniques: risk reduction, risk transfer and risk retention [13]. Baker et al. [14] identified risk reduction as the most frequently used technique within the construction industry in the UK. Our treatment of risk management in this paper follows broadly along the lines outlined above in terms of the recognised stages in that process.

2. Research Approach

The main part of the study was a questionnaire survey followed by a series of interviews with project actors. The survey sample comprised clients, contractors and consultants who employed risk management in a given project. The respondents from the client's side were the representative signing the contract and the project manager. From the contractor's side the respondents were the representative signing the contract, site manager and estimator. Finally, the respondent from the consultant's side was the architect or design manager.

A draft questionnaire was developed consisting of five sections. The first section contained general questions about the respondent. In the second section, aspects of the risk management process through the different phases of the project were covered. The third section investigated relationships between the actors in the project. The fourth section focused on software management systems, which the company used in the risk management process. The fifth section was a concluding one for miscellaneous comments regarding the risk management process in the project. In total, 54 questionnaires were sent and 36 completed, usable responses were received, representing a two-thirds' response rate.

Based on the compiled results of this questionnaire survey, 18 interviews across eight projects were then conducted. The objective of the interviews was a deeper analysis of the risk management process in the projects. Since it was impossible to interview all survey respondents within the time constraints, the number of interviewees was limited to the two or three persons responsible for risk management in the project. From the client side, it was a project manager, from the contractor side a site manager and from the consultant side an architect or design manager. Each interview took approximately one and a half hours and consisted of three main parts. First, the important definitions in risk management were discussed. Since the questionnaire contains the terms risk, risk management, risk identification, risk assessment, risk response etc., it is important to understand the perception of these terms by the respondents. Next, the results of the survey were presented and the respondents were asked to explain their answers. Finally, the respondents were given an opportunity to express their thoughts about risk management in the project.

3. Description of Construction Projects

The study involves nine construction projects recently undertaken in Sweden.

Project 1 included the new construction of a house for meetings at the university campus in the northern part of Sweden. The project was executed over 15 months between 2003 and 2004. The contract sum was 41.1 MSEK and the final cost was 43.5 MSEK. Design-build, with a lump sum payment mechanism, was the chosen form of procurement. The project implementation was very good in terms of time and fairly good in terms of quality. In terms of budget, the project was very good for the client and fairly bad for the contractor. The identified risks occurred in the project, but their effect on the project cost was fairly small. The unforeseen risks during the project execution led to a fairly large increase in the project cost.

Project 2 included the rebuilding, refurbishment and additional construction of university premises, located in the northern part of Sweden. The project was undertaken between 2004 and 2005 and took 10 months to complete. The contract sum was 17.9 MSEK and the final cost of the project was 19.6 MSEK. A lump sum payment mechanism was chosen and a performance-based contract was signed between the client and the contractor. The technical characteristics of the final product were evaluated as high and the time constraints for project execution were kept. However, the poor quality of design documents increased the contractor’s costs significantly. Identified risks occurred in the project and had a large effect on the project cost; even so, the consequences of unforeseen risks were fairly small.

Project 3 included the construction of infrastructure in the north of Sweden. The project was executed over 13 months in 2006 and 2007. The contract sum was 53 MSEK and design-build procurement, with a lump sum payment mechanism, was chosen. The project execution in terms of function, time and cost was fairly good. Both identified and unforeseen risks occurred in the project and had a moderate effect on the project cost.

Project 4 included the construction of a road in the north of Sweden and was performed under 14 months between 2005 and 2006. The contract sum was 19.7 MSEK and the final cost was 24.5 MSEK. The contractor was procured on a performance-based basis, with a lump sum payment mechanism. The project implementation was fairly good in terms of cost and function and very good in terms of time. Both identified and unforeseen risks occurred in the project and had a fairly large effect on the contractor’s cost.

Project 5 included the construction of road in the north of Sweden and took 10 months between 2005 and 2006 to complete. The contract sum was 4.9 MSEK and the final sum was 4.7 MSEK. The performance-based form of procurement with a lump sum payment mechanism was chosen. The project execution was fairly good in terms of function and cost and fairly bad in terms of time. An insufficient geotechnical survey led to identified risks occurring in the project, but their effect on the project cost was fairly small. No unforeseen risks occurred.

Project 6 included the construction of a residential building in Stockholm. The project was executed between 2005 and 2006 and took 17 months. The contract sum was 81 MSEK and the final sum was 84 MSEK. The procurement form was design-build, with a lump sum payment mechanism. The quality of the final product was evaluated as very good, time constraints were kept to a fairly good level. In terms of cost, the client evaluated the project execution as very good while the contractor’s evaluation was fairly bad. Both identified and unforeseen risks occurred in the project, but had a fairly small effect on the project cost.

Project 7 included the reconstruction of a residential building in Stockholm and was executed over 12 months between 2004 and 2005. The contract sum was 47.7 MSEK and design-build procurement, with a lump sum payment mechanism, was chosen. The project implementation was very good in terms of time and function, very good in terms of cost for the client and fairly good for the contractor. Neither identified nor unforeseen risks occurred during the project execution.

Project 8 included the reconstruction of infrastructure facilities in Stockholm. The building period was three years between 2004 and 2007. A performance-based contract with a lump sum payment mechanism was chosen for the project. The contract sum was 95 MSEK. In terms of cost, project implementation was very good for the contractor and very bad for the client.

Unforeseen risks caused significant delays and high costs for the client. The quality of the final product was fairly good. The identified risks occurred and had an impact on project cost.

Project 9 included the reconstruction of a residential building, located in Stockholm. The reconstruction was executed in 2005 and took 6 months. The project was implemented as a form of partnering with a cost reimbursable payment mechanism. The contract sum was 15 MSEK. The project implementation in terms of function, cost and time was good. Together, the client and the contractor succeeded in decreasing project costs. Both identified and unforeseen risks occurred in the project, but did not have a large effect on the project total cost.

4. Results

Despite the fact that risk management was a part of each project, many projects suffered from variations in cost for one or several actors. Risk management was not carried out systematically in those projects. Both identified and unforeseen risks often occurred in the projects and generally had a significant effect on the project cost. In sections below we discuss the factors that lead to more or less effective risk management.

4.1 Understanding of risk management

The majority of respondents have what might be described as a fair understanding or knowledge of risk management and did not have any special training in the subject. Experience within construction industry is the main source of knowledge. To quote from three respondents:

"I have worked very long time in construction; no one can do it better than me". (Client in project 7)

"Experience takes over, you learn during all these years of working in construction". (Contractor in project 7)

"I have only my experience; it would be good to get more theoretical knowledge". (Consultant in project 9)

Some companies organised internal courses in risk management but most respondents identified the lack of the theoretical understanding or knowledge. Many companies have a set of procedures to follow in the risk management process. The largest problem identified with the procedures is their complexity and documentation requirements.

"To do risk management systematically on paper is a big problem. We get a lot of documents from the system and nobody looks at them later". (Client in project 4)

"Many people do not like to fill in papers; therefore they skip documentation of risks". (Contractor in project 6)

In the risk management process, simple tools are familiar to the respondents: checklists and brainstorming for risk identification; probability-consequence judgment in risk assessment; and risk transfer as a way to respond to risk. In practice, the use of theoretical tools was limited.

"When assessing risks we do not use any theoretical tools but [instead use] experience, feelings and relationship with the client". (Contractor in project 2)

Insights into this more theoretical view of risk management is shown in figure 1, which is based on best practice advice informed by numerous studies and reapplied from one project to the next.

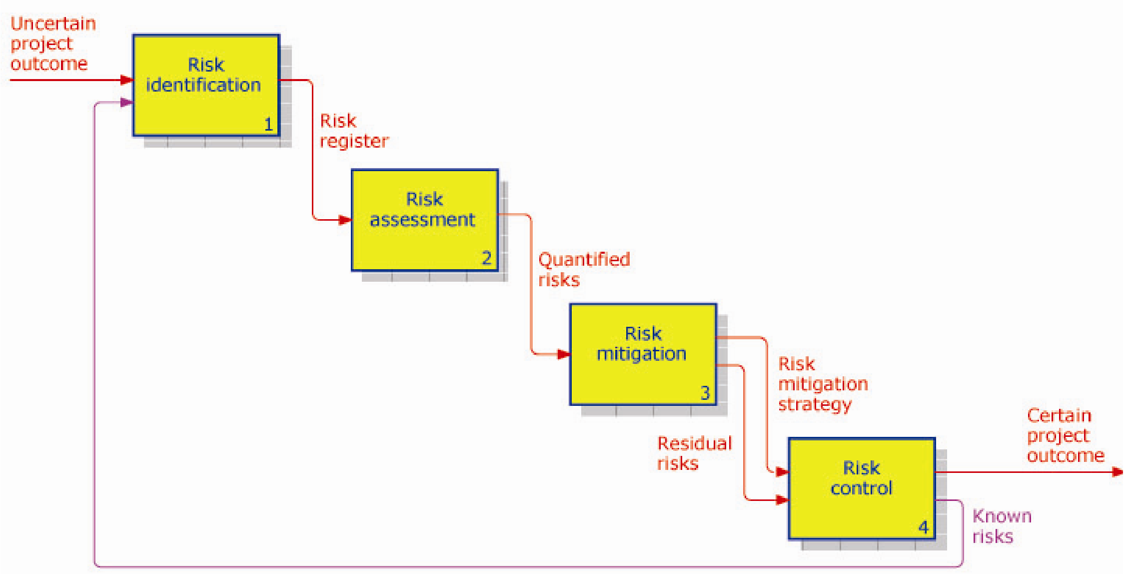

Figure 1 - A more theoretical and formal treatment of the risk management process.

Figure 2 decomposes the higher level activity of risk identification into a lower level of analysis.

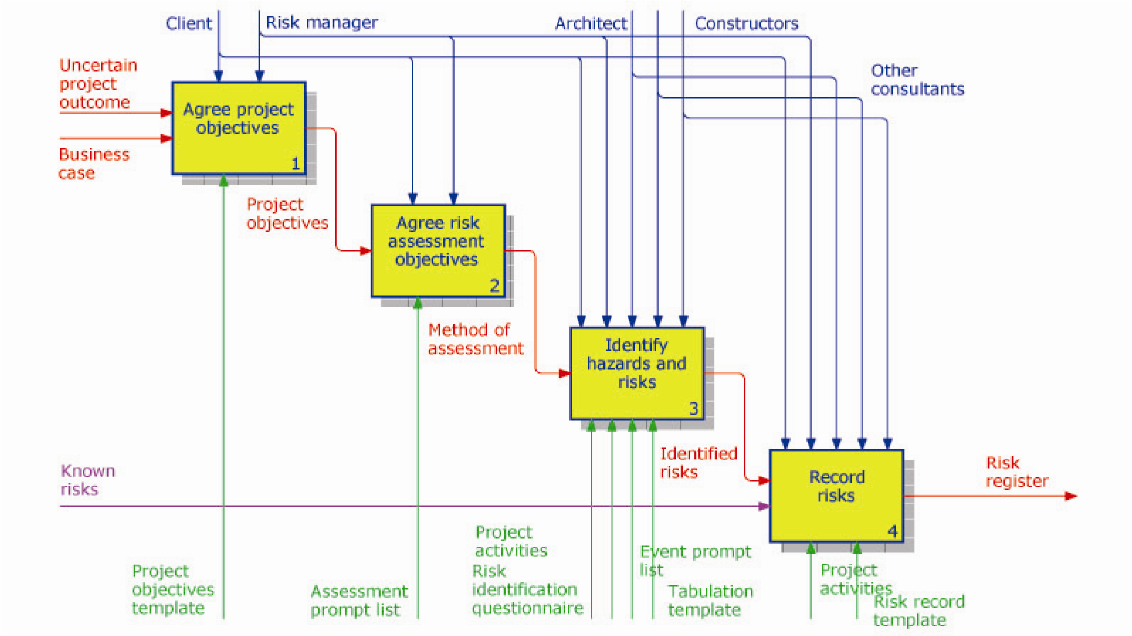

Figure 2- Decomposition of the risk identification activity.

4.2 Participation in different project phases

A construction process is sequential by nature and many actors are involved only in some project phases and focus on their own part of work rather than on the whole project. This leads to the less effective communication of identified risks and the loss of knowledge between the phases.

"It happens very often that people involved in different phases do not see the overall picture". (Client in project 7)

There was a very low participation in the programming (planning) phase overall. In particular, no contractors participated in this phase of the projects. However, the respondents recognised that the early involvement of the contractor is important for effective risk management. It allows the actors to choose the best technical solutions, decrease costs and obtain a deeper understanding of the potential problems.

"The sooner we get the contractor's expertise in the project, the greater is a chance to avoid the problems in production". (Client in project 4)

"We lose a lot of important information if we join the project when design is done". (Contractor in project 2)

The actors felt that the newer organisational forms like partnering can help in ensuring early involvement of the actors and, therefore, better understanding of project risks.

4.3 Risk identification, assessment and response

Systematic scrutiny of potential and possible risks in the project was identified by interviewees as a very important factor for successful risk management. Systematic means that risk identification, assessment and response are performed in each phase of the project and the results of the processes are communicated between the project actors. However, in just one project were these steps in the risk management processes carried out systematically.

"We identify and assess risk, fill in the template and it's done! Then we start construction, everybody is busy and forgets about risk management and early assessments". (Contractor in project 1)

The design and production phases are critical for risk management. Risk identification, assessment and response were mostly performed in these phases. Despite the recognised importance of the programming (planning) phase, very little work in risk management was performed.

"The programming phase is very important… We did not work systematically in the programming phase; we did not talk in terms of risks". (Client in project 1)

"Historically we have not worked with risks in the programming phase, but now it is coming". (Client in project 8)

"We have little focus on risks in the programming phase because the project is very abstract". (Contractor in project 2)

Within three groups of actors, contractors were the most active in performing risk identification, assessment and response in the project. Almost all contractors documented potential project risks and preventive measures. Moreover, contractors had the largest influence on risk management in the project.

"Contractors have to deal with most risks; we are forced to be active in risk management". (Contractor in project 2)

Consultants were not involved sufficiently in work with risks and had a low influence on risk management. The actors agreed that consultants should play a more important role in risk management, because design-related risks can affect the project's performance significantly.

"Consultants still have a passive behaviour when it comes to risk management. Risk management is not a part of their assignment". (Client in project 2)

"I think our competence is not used by 100%, probably we have to start talking that we are good and can much more". (Consultant in project 1)

The role of the client in risk management depends on the form of contract. In the performance-based projects, where the clients were responsible for a design, they had a larger influence on risk management and were more active in risk identification and risk response. The clients concurred that even in design-build projects, where the contractor is responsible for a design, the client has to play an active role in risk management.

"The client is always responsible for commitment of other actors. I don't believe in 'good' contractors and consultants, they adapt to the clients' requirements". (Client in project 8)

Risk identification, assessment and response are needed in each phase of the project. This iterative approach, as illustrated in figure 3, is at odds with the previous portrayal of the risk management process in figure 1, which tends to regard the risk management process as a rather sequential activity running across the project phases.

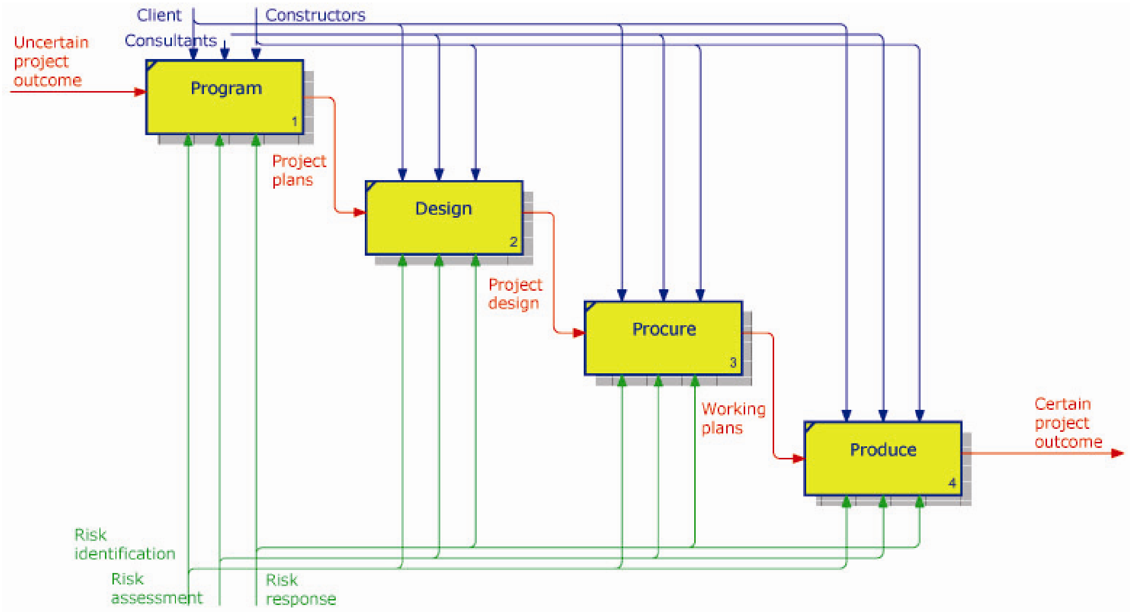

Figure 3- An iterative view of the risk management process to be applied at each phase in the project life cycle

4.4 Risk transfer and communication of risks

The majority of respondents agreed that the risks always are transferred between the project's actors. Clients transfer risk to contractors because they believe that they, the contractors, have better ability to manage risks. Some risks stay with the client, for example environmental and market risks.

Two ways of risk transfer were identified by the actors: positive and negative. A positive way means that the risk is identified and the actor who will manage the risk is aware of it. This way demands open dialogue about known risks between the actors. A negative way implies, for example, that the client lowers the cost by omitting important investigations and information before the project start date with the effect that risks appear in the production phase.

"Prior investigations are expensive and sometimes the client does not do all necessary investigations". (Client in project 4)

The contractor transfers risks to the subcontractors and sometimes back to the client; for example, design risks in those cases where the client was responsible for the design. The majority of contractors are convinced that the client tries to transfer all possible risks to the contractor. Despite the fact that risk allocation is formalised by general contract conditions, which are used in all projects, clients tend to make some changes and include special conditions which imply more risk allocated to the contractors.

"The client's way of thinking is 'risks to the contractor, opportunities to us!'". (Contractor in project 2)

The communication of known risks in the procurement phase was very low from both the client and the contractor. Two opposite views were shown: one group stated that it is a strategic choice not to show all risks in the procurement phase in order to keep the bid price at a lower level.

"The client feels that he can transfer risks to the contractor and pay a lower price. The contractor thinks there is a possibility for earning more money and keeps silent". (Contractor in project 8)

The other group said that it happens because the actors, especially the client, are not aware of all possible risks. Both groups agreed that there is a need to change the situation. When risks are not communicated at a detailed level, the chance that they will occur is much higher and their consequences can impact more.

"In any case somebody pays for mistakes made by others". (Client in project 7)

"We can put more money to the risk pot but in this case the client will pay higher price for those risks which never will happen". (Contractor in project 2)

Due to the limited participation of the actors in some project phases, the communication of project risks between them does not function properly. Many problems appear when the consultant and client are not involved in the production phase. Additionally, risk management processes are carried out most intensively in the production phase, which implies more responsibility in managing risks for the contractor and more passive behaviour by other actors.

4.5 Joint risk management

According to the respondents, joint risk management means that each actor is aware of all project risks and takes responsibility for them. It is important to start risk discussions early in the project and risks are discussed continuously. Known risks should be communicated at a detailed level between the actors and the project's phases. Fair sharing of both risks and opportunities is an important driving force for joint management of risks.

In seven of the projects, the actors had good collaboration in risk management. The actors in two projects stated that there was no joint risk management. Most of the actors responded that collaboration existed in the risk identification and risk assessment processes. The risk response process had a lower degree of collaboration according to the contractors. They stated that contractors are usually forced to manage most of risks alone.

To achieve good collaboration in risk management and an open discussion of project risks and risk sharing, the following factors are considered important:

- Active participation of all project actors in discussions on risk and risks;
- Open and effective communication and information exchange: all risks are "placed on the table":
- Project actors' ability to raise the problems as soon as they appear, dare to ask questions and work without prestige;
- Personal commitment, motivation and responsibility;
- Trust;
- Respect for each others' roles and competence;
- Fair distribution of opportunities.

5. Conclusions

The findings of our research show that risk management is not carried out systematically in all phases of a project. The actors' participation in the risk management process is generally limited by their roles in the project. The absence of systematic risk management is especially noted in the programming (planning) phase, where it arguably has the greatest potential impact. The production phase is where most interest and activity is to be found. Unfortunately, this can easily prove to be too late in the day to mitigate some risks, including those that might have been avoided at an earlier phase. Whilst this is self-evident, scant attention to early identification of risks confirms this practice as commonplace. As a concept and matter of practice, the communication of risks between the actors simply does not work to the extent that it must if projects are to be delivered with certainty, irrespective of the form of procurement. If risks are to be properly managed, it is also self-evident that the risk management process must be present, transparent and activated within each phase. It is the lack of an iterative approach to risk management that is a weakness in current procurement practices and this aspect must be addressed if the risk management process is to serve projects and, thus, their clients. Implicit in this thinking is that the project's other actors will be better able to cope with circumstances that might threaten the time, cost or function of the project if they can be engaged in the risk management process from the outset. A shift from project-oriented to process-oriented risk management is required in order to manage project risks successfully.

Factors affecting the use of sustainable waste management practices in small and medium sized construction enterprises

Illesanmi Osunlola, School of the Built Environment, Heriot Watt University, UK and Chris Fortune, School of the Built Environment, University of Salford, UK

Abstract

Sustainable construction practices amongst all members of the building project production supply chain are being introduced in an incremental fashion. This paper explores the current state of awareness related to sustainable building production practices amongst small and medium sized construction enterprises (SMEs) located in Edinburgh, Scotland, UK. The work was funded by a donation from the Edinburgh and District Master Builders Charitable Trust. The paper reports in particular on the practices involved in site waste management amongst the industry participants indicated above. The different strands of sustainable practices although identified are not considered in this paper.

A qualitative methodology was used for the research using semi-structured interviews with eight practitioners located in construction SMEs to seek out information from carefully selected respondents in the industry. The results from these interviews were then analysed for similarities, disparities, and patterns. The findings from the study found that there was awareness of the significance of good site waste management and recycling practices towards the achievement of sustainability in building production but that overarching factors of organisational size, project specifics, and time availability and costs were affecting such SMEs potential to adopt such practices on a consistent basis. The study is limited in scope, depth of data collection and geographic location but nonetheless offers an insight into the state of the art in this aspect of the overall agenda related to sustainable site based construction practices

Keywords : site waste management, factors, implementation, SMEs

1. Introduction

Work that contributes either directly or indirectly to the implementation of change in the practices and approaches of the UK construction industry is at the core of built environment research. The broad multi-headed research agenda related to sustainability and its application, implementation and evaluation in the practices of the construction industry is well established and tackled by large scale publicly funded research initiatives. It is posited that holistic solutions are required that address issues across the themes of waste management, energy management, supply chain management and lean thinking are required to respond to the need to achieve cultural change. Nonetheless, individual small scale research projects that focus on a single aspect of the sustainable research agenda can also make a contribution. One such study is reported in this paper. This paper reports on an exploratory postgraduate study that was funded by the Edinburgh and District Master Builders Charitable Trust. The work contributes to the agenda on sustainable construction by examining how small and medium sized construction enterprises (SMEs) in the Edinburgh region of the UK can best adopt sustainable practices within their work approaches. In particular, this work places emphasis on exploring factors affecting the implementation of site waste management and recycling practices as a means of making a contribution to the implementation of more general sustainable construction practices.

A qualitative research design was used as the research approach for the study and data were collected from a series of case studies that involved site observations and interviews with key decision makers involved in the project delivery team. The initial section of the paper analyses relevant literature so as to identify potential measures and overarching strategies could be used to develop better construction production practice in relation to waste management and recycling. The analysis of literature allowed a conceptual model to be developed that was used as the initial data analysis framework for the data collected. The paper concludes by advancing a framework of factors found to affect SMEs looking to optimise their performance in terms of this area of sustainable production practices.

2. Literature Review

The then DETR (1999) conducted a review of existing guidelines on sustainable development and identified environment, social and economic themes as areas in which all sustainability measures could be classified, targets identified and performance measured. These three strands are interlocking and generally form the core of issues to be addressed in the achievement of sustainable development in general and construction project sustainable practice in particular. Talbot and Addis, (2001) identified four main priority areas for organisations operating within the European Union (EU) which included; (a) climate change, (b) nature and bio-diversity, (c) environment and health, and (d) natural resources and waste. The identification of such broad themes and overall frameworks are thought to have proved to be beneficial in communicating the concept of sustainable practice across industry participants. In terms of the construction industry specific targets subsequently emerged (DETR 1999) in three major areas, namely, (a) reducing resource and energy use, (b) minimizing pollution and waste, and (c) enhancing economic efficiency and social objectives. These targets were to be achieved through a re-engineering of the construction process to take full advantage of lean construction principles. In terms of (b), which is the sub area of the overall sustainability agenda at the core of this paper, there emerged the need to think in terms of the whole life use of the buildings and structures. This included especially the assessment of the consequences of recycling and/or final disposal, efficient manufacture/use of construction materials and general waste management during and after building project production completion.

Brownhill and Rao, (2002) report the development of a plethora of checklists for action, such as the BREEAM, EcoHome, and others (Building Research Enterprise, DTi, etc). However, this study adopts the position that notwithstanding such checklists the construction industry is still finding it difficult to adopt sustainable practises and especially those organisations that are classified small and medium sized enterprises. Urooj *et al*, (2006), commented that such checklists are in themselves inadequate and but suggested that there was a need for knowledge-based decision mechanisms that can be used by SMEs to effect change.

The UK construction industry is characterised by its reliance on large numbers of small sized business organisations combining together through a recognised procurement system to physically produce a building project. Given this business landscape it became inevitable that if the targets and improvements called for by Government agencies were to be met then awareness and preparedness to implement changed practices needed to become embedded in the myriad of small and medium sized construction enterprises (SMEs) that make up typical supply chains involved in the project delivery cycles of projects located in the UK.

In response to the above change agenda designs are more and more emerging with a range of features included in them that are focussed on the achievement of more sustainable building project practices. Such initiatives include measures to achieve zero carbon emissions, eco-buildings, zero waste, and lean site waste management practices. Of the common design initiatives indicated it is measures related to site waste management and recycling that are the most resonant with the SMEs that make up typical building project production supply chains. In particular academe is calling for such organisations to devise and implement strategies that make savings in or eliminate waste, or reduce it, or re-use it, or re-cycle it and dispose of it only when necessary.

3. Conceptual Approaches To Waste Management

The effective management of waste has been identified as one of the most important priorities towards achieving sustainable developments. However it is difficult to define waste itself as it is sometimes subjective. (Wills, 1995) gives a definition of waste as being, “Any substance which constitutes a scrap material or an effluent or other unwanted surplus substance arising from the application of any process; and any substance or article which is required to be disposed of as being broke, worn out, contaminated or otherwise spoiled”. The Scottish Environmental Protection Agency (SEPA, 2006) highlighted that the concept of waste cannot be interpreted restrictively and case law defines that whether something is waste must be determined by reference to all the circumstances, having regard to the waste framework directive and the need to ensure its effectiveness is not undermined. This suggests that waste maybe determinable upon circumstances and already established legislation or even precedence. Waste generation by the UK construction industry is significant in terms of its direct cost to the industry itself and its relative contribution to the overall national waste burden (Saunders and Wynn, 2004).

Given the above wide ranging definition of waste it can be accepted that the current waste statistics in the UK (Hyder, 2007), suggest that the construction, refurbishment and demolition of our buildings and structures produce around 120 million tonnes of waste in the UK each year, which is 33% of all UK waste and 21% of all UK hazardous waste. Of these overall figures it has been estimated that some 13 million tonnes of materials that delivered to building project sites and never used and that such resource inefficiency is significantly affecting the profit margins and image of the industry.

This situation is being addressed at high levels by the introduction of mandatory site waste management plans (SWMPs) for the overall construction sites. There is some evidence of eco-management waste policies being developed at organizational levels and such policies are seen as being aids through which project stakeholders can act in a structured manner to assess construction site activities to ensure that they are carried out to an environmentally acceptable standard (Yahya and Boussabaine, 2006). These policies if they are to be successfully translated into changed practices should include site activities and encourage industry participants, irrespective of organizational type, size, and classification to focus on the importance of effective waste minimization and its benefits throughout the lifecycle of building asset design, production, and operation. Such approaches are increasingly being seen as opportunities to lever competitive advantage across building production supply chains. (Yahya and Boussabaine, 2006).

Other work by Dainty and Brooke, (2004) has demonstrated that careful consideration of waste issues combined with effective education of the workforce and robust audit procedures have the potential to result in radical improvements to waste minimization performance. However despite governmental efforts at promoting benefits and savings of effective waste minimization strategies, there is evidence that such initiatives have been met with the some scepticism within the industry. There is a lack of consensus on the causes of the site based waste as according to Yahya and Boussabaine, (2006) the main causes of waste generation could include among, (a) errors in contract documents, (b) changes to design, (c) materials ordering errors, (d) accidents, (e) lack of site control, (f) lack of waste management, (g) damage during transportation and (h) off-cuts from having to cut materials to length. No matter the causes of site based waste there is some agreement in what Denton, (1996) suggested that "pro-active companies which see the environment as a cost, rather than as a chance to gain a competitive advantage are perhaps missing the best opportunity to develop leverage and gain increased business".

Other factors that are suspected to be instrumental in the achievement of sustainable building production waste management practices relate to the capacity of the SMEs within a project production supply chain to adopt lean thinking and supply chain management principles. Similarly Douglas *et al* (2001) suggested that the sector within the SME operates, especially if it is operating within a brown field / demolition / refurbishment project environment may well have an influence on the capability of the SME to adopt work practices and so enhance its profile as an organisation with capacity to deliver changed practices towards sustainability. The literature reviewed above indicates a range of factors that are thought to impact on the capacity of SMEs within the UK construction industry to plan for, adopt, and implement site based work practices that could achieve change in the approach of the construction industry towards sustainability. The study reported in this paper now addresses an exploration of actuality in the field through a data collection and analysis exercise that was focussed on the Edinburgh region of the UK. This region was selected due to funding opportunity offered by the Edinburgh and District Master Builders Charitable Trust. This body has its membership drawn from locally operating SMEs and so its involvement in terms of funding the work set the geographical boundaries for the work.

4. Research Approach, Data Collection Processes

The nature of the problem identified above and the composition of the target population of SMEs within the UK were overwhelming factors that resulted in the study adopting an explorative, qualitative research design. Fellows and Liu (1997) and Denzin and Lincoln (2001) set other factors that impacted on the selection of this strategy namely, (a) the ability to capture an individual participants point of view, (b) the capacity to uncover and gain an understanding of the constraints faced by a participants everyday life, and (c) the opportunity of gaining rich, deep data from which understanding and theory refinement can be achieved. Of the data collection approaches appropriate to this research strategy it was resolved to adopt a case study approach within which semi structured interviews were conducted with key project participants so as to optimise the collection of relevant data. As an approach this research strategy focuses on understanding the dynamics present within single organizational settings (business unit and project environment) and as such the results of the exploration are limited in terms of reliability, validity and generalisability as acknowledged by Amaratunga *et al*, (2002).

4.1 Participant selection and data analysis processes

The respondents interviewed were all industry professionals in the form of three construction managers, three directors of construction, and two site managers. The interviews were conducted and analysed in two waves (1-2) and (3-8). For the purpose of this study the interviewees were numbered 1-8. All respondents had an interest in the area of sustainable development and had also prior experiences of working on projects which had either had a theme of sustainability involved, or had some sustainable criteria as part of the key performance indicators or as clients' success criteria. The data obtained resulted from the following processes, namely the use of descriptive questions, the use of compare and contrast questions, and the use of probing questions about the way projects are currently carried out with respect to sustainability practices within SMEs being set as a major success criterion.

Data analysis started by examining the raw data to search for patterns (Fellows & Liu, 1997). Similarities and dissimilarities were identified in the nature of the respondents interviewed and the organisations they worked for towards creating concepts to act as a backbone support for the data analysis. Patterns were broken down as (Howard & Sharp, 1996) into (a) those showing association amongst variables, (b) those showing groupings, and (c) those showing order or precedence relationships between variables. The findings from the first wave of interviews (Ints 1 and 2) were as follows,

Interviewee 1 immediately associated sustainable practices to site waste management and commented on how his organisation was working actively to reduce the amounts of waste generated on site and they were currently using a waste contractor to calculate the amounts of waste generated on a monthly basis to try and determine patterns in their waste generation on site. He commented that *"You get different types of waste on site, you get plaster wood, you get the metal off cuts, and you get timber and your fifth package if you like, is probably anywhere packaging"*.

It was explained that everything now comes with packaging which is waste in itself, even parts of block, brick and plaster board all comes in with shrink wrap on it. He further commented that although it was their sub-contractors who brought such waste materials to the site it was their responsibility to deal with all this waste and he opined, *"Long term, what obviously will have to happen is, the brick layer will have to bring in his own bricks/blocks, and eventually whoever brings in the material will be held responsible for the wastage generated"*. In terms of waste segregation it was found that at the moment what we've got are dedicated skips for different types of waste material generated on the project. Such metal skips and recycling bags were then removed by specialist waste contractors who were also used to develop strategies towards minimizing waste on site.

Interviewee 2 also followed a similar pattern highlighting the use of skips for segregation as well but with a note of caution suggesting that segregation of waste us sometimes limited by the nature of the sites and the projects they work on; he commented that *"whilst the intentions may be best in terms of planning towards waste segregation their were constraints such as size of the site, its location and the cost implications to be considered"* He went further to suggest that sometimes on the smaller sites it can be difficult to bring in as many skips as would be needed for the segregation of waste. The he suggested was the use of smaller sized skips and use strategically placed shutes to pass waste into them. However he also quickly pointed out that these was only possible on smaller sites and for the larger sites the only option may be the use of very frequent waste contractors to collect waste from site.

The second wave of data analysis followed the same pattern and Interviewee 3 opined that his organisation had fully adopted the principles of waste management including re-use, reduction and recycling. In his view organisations have had to look for ways of recycling waste materials to reduce the costs of their disposal which he claimed were also passed onto clients. Interviewee 4 also commented that cost savings were a huge incentive for them. He opined that *"The highly competitive nature of the industry means we as an organisation have to ensure we look at opportunities to make savings on every project without compromising on the clients requirements"*. Recycling was also seen as a means of solving some of the issues depending upon site / project circumstances. Interviewee 5 on the same topic of waste management also commented in similar terms suggesting that his organisation had an integrated management system for their sites (IMS). For instance *"within our IMS there are very specific rules and regulations laid down to how we manage a building site, and it includes things like dust pollution, air pollution, noise pollution, and the way that we store materials on site, for example they way that we deal with chemicals on site"*

Interviewee 6 elaborated further on site waste management practices by commenting that the nature of the activities carried out by his organisation meant they were dealing with huge amounts of different forms of waste from the different sections of the organization. In his case the organisation had a timber section, a construction section and a housing section as well. He suggested that they have had to look for solutions to deal with the different wastes produced by these sections, and when asked on the drivers pushing this inventiveness, he simply replied “costs”. This same organisation recycled timber off cuts from its timber producing unit to be used by the building unit for material such as MDF (a form plastic wood which is suitable for details and finishing), also using materials from demolition in the construction unit to be processed into alternative materials for other sites an example being processed aggregate stones suitable for foundation works. However they did highlight that major stumbling blocks to the advancement of these opportunities for recycling was the issue of getting these recycled products accredited and approved by the industry. Interviewees 7 and 8 both had similar ideas in terms of site waste management and suggested that a lot more needs to be done by the sub-contractors and they would need to come on board with the main contractors in reducing the amounts of waste generated on these construction sites. Citing that waste contractors tend to benefit when they take waste away from construction sites, firstly by means of the payment they charge to take the waste away and secondly as a result of the usefulness of the recycled product to them. They also agreed with earlier respondents that a major factor which affected the effectiveness of site waste management was the size and location of the site.

Interviewee 7 suggested that the cost implication of recycling waste on site was sometimes not profitable to the organisation particularly when it was for an external client, whilst also identifying that time could sometimes not allow for the proper segregation of these materials on site. He however suggested that on their housing sites where there were building houses for resale they had much more control over these sites in terms of cost and time factors and were thus able to practice these site waste management activities more effectively.

5. Findings

All the respondents interviewed had identified different solutions to address waste management on their sites. There seemed to be a general enthusiasm when this topic was mentioned and most of the respondents were also aware of the recent introductions of the proposed site waste management plans by the government. It was the view of the generality of the respondents that a lot of these practices were already being carried out by their respective organisations over the years and were all actively seeking ways to ensure that waste generated on their sites did not end up at land fills. However the approach to waste management was found to be varied. The respondents who restricted their view on site waste management highlighted the use of skips to segregate waste on site (which involved the classification of the different wastes generated on site and classifying these using criteria such as hazardous and non-hazardous materials).

They also highlighted the use of waste management contractors who took the already segregated waste from their sites to be recycled and processed, and also identified the possibility of partnering with suppliers and sub-contractors in terms of returning packaging and the possibilities of returns of unused materials. They however highlighted that a major factor which affected the effectiveness of site waste management was the size and location of the site. It was found that the larger sized organizations in the study had a wider ranger of operations and not only practiced all the processes identified above but only used their waste management contractors as a last resort. A lot of the organisations in this size category had extensive waste management processes within the organisation which can be associated to recycling at various levels. An example was a respondent organisation who and sub-units within the organisation to reflect its activities; However it was highlighted that major stumbling blocks to the advancement of these opportunities for recycling was the issue of getting these recycled products accredited and approved by the industry. Also another constraint identified was time and cost implications. One respondent suggested that the cost implication of recycling waste on site was sometimes not profitable to the organisation particularly when it was for an external client. A further factor identified as impacting on practice was that time could sometimes not allow for the proper segregation of these materials on site.

6. Conclusions

This small scale regional study has shown that there is general awareness of site based waste management issues and the impact that effective policies could make to the delivery of sustainable construction practices amongst the SMEs involved in the building project production supply chain. The study has revealed the impact that organizational size and project circumstances have on the opportunities to contribute in this area of the sustainable construction practices agenda. The study recognizes the need for holistic approaches to be adopted across all sectors of the building project production supply chain and the potential that a knowledge based decision support framework could have on the opportunity to improve practice in this area.

Abstract

The construction industry is perceived as one of the knowledge-based value creating sectors of the economy; however, it faces many challenges, especially in terms of performance, due to its intrinsic nature. Different knowledge-based solutions have been proposed in the past to overcome this problem. However, the process-based solutions, enhancing personalisation strategies and interactions between construction workers to generate and share tacit knowledge, would be much more relevant to overcome KM problems in construction organisations. As the initial step towards the management of tacit knowledge, this paper examines the nature and importance of tacit knowledge in the construction industry. Based on research findings a definition for tacit knowledge is synthesised to: understanding, capabilities, skills and the experiences of individuals; often expressed in human actions in the form of thoughts, points of view, evaluation and advice; generated and acquired through past experiences, individuals, and repositories; utilised for the benefit of individual and organisational development.

Keywords: Tacit knowledge, Construction industry, Generation and utilisation.

1. Background

Despite various definitions and classifications of knowledge, work by Polanyi [1], Nonaka and Takeuchi [2], divided knowledge into tacit and explicit. Although knowledge could be classified into personal, shared and public; practical and theoretical; hard and soft; internal and external; foreground and background, the classification of tacit and explicit knowledge remains the most common. As Nonaka *et al.*, [3] defined; tacit knowledge represents knowledge based on the experience of individuals, expressed in human actions in the form of evaluation, attitudes, points of view, commitment and motivation. Recent discussions on knowledge reflect on two perspectives: 'knowledge as an asset' and 'knowing as a process.' When knowledge is seen as a 'thing', codification strategies, which specifically disseminate explicit knowledge through person-to-document approaches, are considered; whilst personalised strategies, which specifically disseminate tacit knowledge through person-to-person approaches, are considered when knowledge is seen as a 'flow'. Accordingly, two distinct strategies have been identified for developing Knowledge Management (KM) systems: codification and personalisation [4]. A codification strategy revolves around explicit knowledge, captured and leveraged using IT-tools i.e. software such as expert systems, artificial intelligence and data mining tools, which are known as 'KM technologies' [5]. Personalisation, at the other extreme, revolves around tacit knowledge, using non-IT tools or human interactive systems such as knowledge sharing networks [6], communities of practice [7], brainstorming, action learning, post- project reviews and so forth, which are known as 'KM techniques'.

Different knowledge based solutions have been proposed in the construction industry to promote knowledge sharing. However, previous work on KM in the industry has concentrated heavily on the delivery of technological solutions [8,9], hence also on KM technologies, mainly due to the increased focus on IT during the past decade. The tacit knowledge of construction employees has often been ignored or placed with less importance, as evident from the current focus on KM in the construction industry [9], and inadequate empirical studies carried out in the construction industry. In the context of the knowledge economy, the utilisation of tacit knowledge is considered to be the real driver for the performance of the industry [10]. A number of authors, such as Egbu *et al*., [9], Carrillo *et al*., [11], Robinson *et al*., [12], Pathirage *et al*., [13], have highlighted the importance of the tacit knowledge of employees in the construction industry. An understanding of what constitutes tacit knowledge would be central to its effective management.

The paper aims to explore the nature and importance of tacit knowledge in the construction industry, based on a doctoral study that investigated the process of tacit knowledge management in a construction organisation. Accordingly, the paper is broadly divided into four sections. Initially, tacit knowledge, and its generation and utilisation are discussed. Secondly the paper introduces the research methodology followed for the research. Next, findings from the pilot interviews and case study investigation are presented. Finally, the paper culminates with a discussion on the nature and importance of tacit knowledge in the construction industry.

2. Tacit Knowledge

As Herrgard [14] and Empson [15,16] contended, organisations' knowledge resources can be described as an iceberg. The structured, explicit knowledge is the visible top of the iceberg, which is easy to find and recognise and therefore also easier to share. Beneath the surface, invisible and hard to express, is the momentous part of the iceberg. This hidden part applies to tacit knowledge resources in organisations. It cannot be managed and taught in the same manner as explicit knowledge, which is often defined as codified knowledge. Even if coded knowledge is easier to diffuse, the role of tacit knowledge is often essential for being able to use coded knowledge. Tacit knowledge could further be classified into two dimensions knowingly: the technical and the cognitive dimension [14]. The technical dimension encompasses information and expertise in relation to 'know-how' and the cognitive dimension consists of mental models, beliefs and values [17], in short, conception of reality. Thus, this division in tacit knowledge could be explained by considering the underpinning epistemological differences in Western and Japanese thinking on tacit knowledge, its codification and diffusion. Literature reveals two fundamentally different and competing schools of thought regarding diffusion and codification of such knowledge. One believes that tacit knowledge can and must be made explicit for sharing and the other regards tacit knowledge as always being tacit, representing the Japanese and Western thinking respectively.

Polanyi [1] sees tacit knowledge as a personal form of knowledge, which individuals can only obtain from direct experience in a given domain. Further, he encapsulates the essence of tacit knowledge in the well-known phrase ‘‘we know more than we can tell’’. According to Polanyi [1], this knowledge is held in a non-verbal form, and therefore, the holder cannot provide a useful verbal explanation to another individual. Moreover, as he contends, tacit knowing is such an elusive and subjective awareness of the individual that it cannot be articulated in words. It is from Polanyi’s argument that the differentiation between tacitness and implicitness was apparent, and from his terminology, tacitness was evidently different from implicitness. Implicitness, another form of expressing knowing, does exist. It implies that one can articulate it but is unwilling to do that because of specific reasons under certain settings such as, intrinsic behaviour in perception, cultural custom, or organisational style. [18]. Therefore, by describing implicit knowledge, Polanyi was referring to the technical dimension of the tacit knowledge, whereas cognitive dimension purely represented the tacit knowledge that he considered as always being tacit.

In Japanese thinking, knowledge is traditionally seen primarily as something not easily visible and expressible, that is, tacit by its nature. Nonaka and Takeuchi asserted that their view on knowledge was human knowledge, and they defined knowledge as a dynamic human process of justifying personal belief toward the ‘‘truth’’ [2]:

“...we classify human knowledge into two kinds. One is explicit knowledge, which can be articulated in formal language including grammatical statements, mathematical expressions, specifications, manuals, and so forth.... A more important kind of knowledge is tacit knowledge, which is hard to articulate with formal language. It is personal knowledge embedded in individual experience and involves intangible factors such as personal belief, perspective, and the value system” (p.viii).

When Nonaka and Takeuchi used Polanyi’s dichotomy of knowledge in their well known SECI (Socialisation, Externalisation, Combination and Internalisation) model, they did not make any distinction between tacitness and implicitness. Therefore, what they referred to as tacit knowledge included implicit knowledge, which they believed to be made explicit for sharing through externalisation. Since implicit knowledge, which resides in human beings, is converted to explicit knowledge through externalisation, Nonaka and Takeuchi perceived explicit knowledge as human knowledge too. This explains the two fundamentally different schools of thought regarding diffusion and codification of tacit knowledge; however, it is important to examine the cognitive human process to understand better tacit knowledge, and how it is generated and utilised.

3. Tacit Knowledge Generation And Utilisation

Researchers like Varela *et al*., [19], von Krogh & Roos [20] and Venzin *et al*., [21] have based their work on cognitive science, which has been the most influential [22] for scientists studying organisational knowledge. Accordingly, three different epistemologies are suggested i.e. Cognitivist epistemology (represented by Simon, [23]), Connectionistic epistemology (represented by Zander and Kogut, [24]) and Autopoietic epistemology (introduced by Maturana and Varela, [25]), to explain some core questions such as; what is knowledge, how is it generated, and what are the conditions for knowledge to generate? Cognitivist epistemology considers organisations as open systems that develop knowledge by formulating increasingly accurate representation of their predefined world. Data accumulation and dissemination are the major knowledge development activities, the more data that can be gathered the closer the representation is to reality. Hence, as Koskinen [22] asserts, this approach equates knowledge with information and data. In Connectionistic epistemology, however, the rules on how to process information are not universal, but vary depending on the relationship. Organisations are seen as self-organised networks composed of relationships and driven by communication. Similar to the cognitivist, information processing is the basic activity of the system, yet relationships and communication are the most important facets of cognition. Autopoietic epistemology provides a fundamentally different understanding of the inputs into a system. Input is regarded as data only. Autopoietic systems are thus both closed and open i.e. open to data, but closed to information and knowledge, both of which have to be interpreted inside the system. These systems are self-referring and the world is thus not seen as fixed and objective; the world is constructed within the system and it is therefore not possible to ‘represent’ reality [26]. Vicari and Troilo [27] describe this epistemology with the following example;

“When a teacher delivers a speech, two students build different knowledge according to their own attitudes, intelligence and previous knowledge. The transmission by the teacher is the same for the two of them, but the knowledge produced is different” (p. 5).

Hence, Autopoiesis epistemology claims that cognition is a creative function and knowledge is a component of the autopoietic, i.e. self-productive process [19]. This closely relates to the cognitive process of tacit knowledge, thus autopoietic epistemology is embraced as the philosophical basis of understanding tacit knowledge generation. To assist organisations to generate and utilise their tacit knowledge resources, it is necessary to focus on ‘how’ to support the generation of tacit knowledge held by individuals who work in an organisation. The construction industry is characterised with on-the-job learning and experience [28,29]. Kolb’s [30] experiential learning model describes learning through ‘doing’. Hence, Kolb’s four-stage cognitive model (refer to Figure 1), which expounds the theory that learning is cyclical, closely resembles tacit knowledge generation and utilisation in construction employees, which has been widely used and respected for its validity and reliability.

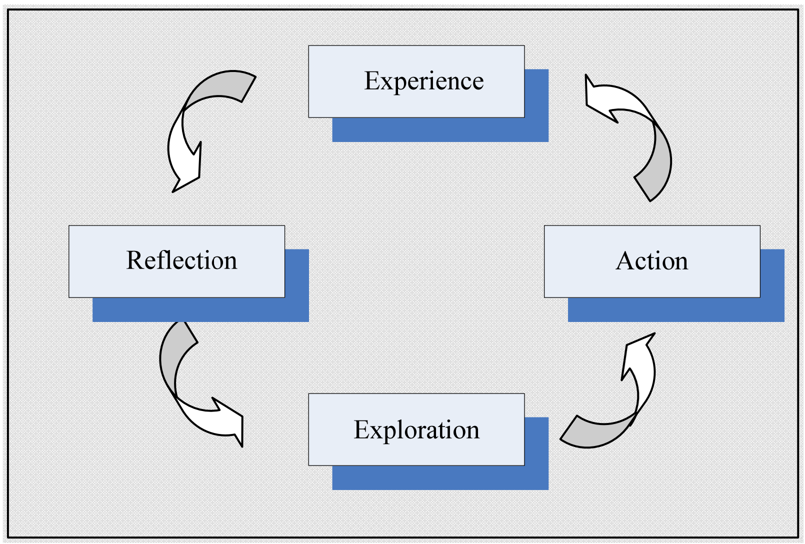

Figure 1: Kolb's Experiential Learning Model
(Adopted from Kolb, [30])

These four stages could be described as: Experience - provides the basis or trigger for the tacit knowledge generation process e.g. active involvement, new problem; Reflection - gains an understanding of the current experience and process it in a way that makes sense of the experience; Exploration - assimilates and distils the observations and reflections into theory or concept; Action - based upon knowledge gained, develops a way to use and start to put into action. According to Kolb [30], reflection after experience is paramount in order to learn from the past lessons and to generate tacit knowledge. This is further described by Schon [31] who explains how practitioners reflect, based on their tacit knowing. Therefore, Kolb's experiential learning model is embraced within this study to represent the cognitive process of the tacit knowledge generation and utilisation of construction employees.

4. Research Methodology

The researcher took the view that more work needs to be done in terms of managing tacit knowledge in construction organisations. However, due to the paucity of literature relating to tacit knowledge management, particularly construction industry related, it was decided that pilot interviews should be carried out to identify the nature and role of tacit knowledge in the construction industry. Accordingly, four leading academics that had extensive knowledge and experience in the subject areas were interviewed. All the respondents were actively involved in the areas of KM and also had close collaboration with respective industries. Three of the academics had backgrounds in the construction industry, whilst one had a background in general management. In addition, the case study approach was selected to investigate tacit knowledge management with a construction organisation. Due to the need for an in-depth, critical, longitudinal examination of the phenomenon, the single holistic case study design was preferred, through which a holistic emphasis on tacit knowledge management process was placed. The study opted for a theoretical sampling strategy to select a theoretically significant and representative construction company. The selected case study was a UK company employing nearly 8,500 employees, involved in building and infrastructure projects, including facilities management. The overall case study investigation included two phases: an exploratory phase and an explanatory phase. However, this paper reports the findings based on the exploratory phase of the case study investigation only. Eight interviews with company employees representing different levels of the staff i.e. senior level (two directors), middle level (two managers) and operational level (four line employees) were carried out to explore the nature of tacit knowledge.

Interviews, both unstructured and semi-structured, were used as the main research technique for data collection in this study. Unstructured interviews were carried out during the pilot interview phase and semi-structured interviews were used during the exploratory phase of the case study. Exploratory phase interviews were carried out among all three levels of the staff, representing different departments. Hence, the research deployed a triangulation of data combining more than one source of data collection; to develop converging lines of inquiry. A combination of textual analysis and mapping technique, aided by computer software, was used as the main research techniques of data analysis for data collected from unstructured and semi-structured interviews. This began with qualitative content analysis, which is the main technique for analysing data under textual analysis, with the aid of NVivo software (version 2.0) to generate codes, based on related concepts from data collected. Later, cognitive mapping was undertaken, which is the main technique for analysing data under mapping techniques, using Decision Explorer software (academic version 3.1.2) to build relationships among concepts and for better data presentation. This triangulation of data analysis techniques enabled the rigor of structuring, organising and analysing multiple sources of data, and maintenance of the richness of original data.

5. Pilot Interview Results

In recent years, the importance of tacit knowledge has been discovered, rather than invented, with the popularisation of the concept of the knowledge worker. Interviewees described tacit knowledge as the knowledge that resides within the ‘knower’ - i.e. the person - which is very sticky and messy, problematic to codify, transfer and share, and also difficult to exploit; which is attributable to the person’s experience, exposure and context. According to the interviewees, examples of tacit knowledge within the construction industry can be related to project and organisational level, and from senior management level to operational employee level. These included the talents and skills of construction trade specialists such as plumbers, masons, and electricians, acquired over time; skills to manage project teams, knowledge of construction tender markets, interaction with clients/customers and project team members in the supply chain, as well as understanding design and production information. Within the context of construction, tacit knowledge production is triggered through ‘learning how’ and ‘learning why’, when faced with complex projects. As interviewees argued, problem solving is considered the main trigger for tacit knowledge generation, which incorporates both learning how and why, within the industry. Moreover, interviewees agreed that workers fall back on experiences, friendship and collaboration when faced with real complex projects, as they are the first to know that IT is not working. Hence, it is contended that explicit knowledge is not highly useful when dealing with complex problem solving situations. All the interviewees therefore recognised the importance of tacit knowledge within the construction industry, and the fact that it is not fully exploited by the construction industry. They considered tacit knowledge as the key to the performance of the industry. As one of the interviewees highlighted:

"…if one tries to find out the types of knowledge that contribute more to innovation and competitiveness, it is tacit knowledge as opposed to explicit knowledge. So there is a need to say tacit knowledge is important and there is even more need to explore that fully, because we still haven't learned how this sticky knowledge works, especially when you look at knowledge as a stock or a flow across chains, supply chain and networks, intra and inter…"

Furthermore, interview respondents acknowledged that most of the KM initiatives within the construction industry have concentrated on explicit knowledge, whilst the necessity is for tacit knowledge. As they explained, this was due to several reasons, but mainly due to the fact that the origin of modern KM issues has been driven by a technocrat approach, hence driven by IT. Thus, KM has been considered as a mere extension of data management, information management, and knowledge-based systems, and this legacy is still considered to be in existence. In providing further insights on this, one interviewee cited the fact that:

"there is a good reason to suggest that explicit types of knowledge lend themselves more readily to the use of IT and exploitation of IT than the tacit form of knowledge and also, due to the simple reason that explicit knowledge is more codifiable, you can feel it, you can hold it and you can mess around with it"

In summary, interviewees provided insights on tacit knowledge in the construction industry, also admitting the importance of tacit knowledge and the fact that existing KM work in the construction industry is driven by IT.

6. Case Study Findings

Key concepts on tacit knowledge were elicited from the interview participants (representing directors, managers and operational level employees) of the case study company. The identified concepts were categorised into three aspects of tacit knowledge: 'what' constitutes tacit knowledge; 'how' can tacit knowledge be generated and acquired; and 'why' tacit knowledge should be generated and acquired or utilised.

Tacit knowledge was frequently referred to as the understanding, capabilities, skills, abilities, intelligence and experience gained, which often expresses itself in human actions in the form of thoughts, points of view, evaluations and advice. Understandings, capabilities, skills, abilities and experiences varied dependent upon each individual, however, all related to employment within the case study company. An understanding of work activities, processes, procedures and pressures were mostly cited among operational level employees, whilst directors and managers mostly referred to their skill and capability to manage, coach, mentor the team members together with their understanding of business opportunities and new markets. Thereby, at operational level, understanding and capabilities, hence tacit knowledge, was more concerned with the internally focused activities of the company; whereas at senior level, tacit knowledge seemed to be more concerned with the externally focused activities. However, the ability to provide thoughts, points of view, evaluations and advice was apparent from all levels of employees.

Different sources and triggers of tacit knowledge were explored with the interview participants. Sources of tacit knowledge acquisition included education, training, colleagues, repositories, and prior experiences, whilst new challenges and first time experiences were cited as main triggers for tacit knowledge generation. Directors and managers had sufficient educational background or extensive prior experience to fall back on when faced with problems. Further, they had the greatest opportunity to undergo training programmes and directors mainly participated in external seminars, workshops and training programmes. Hence, they interacted with external peers and maintained a good network, through which they could acquire tacit knowledge. However, for operational level employees, colleagues and peer groups were considered as the major source for acquiring tacit knowledge within the company. Despite the contextual differences of problems, the tacit knowledge acquired from colleagues was considered as highly beneficial to overcome such problems. Moreover, operational level employees relied on their past experiences and rarely on repositories such as company manuals, documents and intranet. An analysis of tacit knowledge sources is given in Figure 2 based on individual and organisational level considerations.

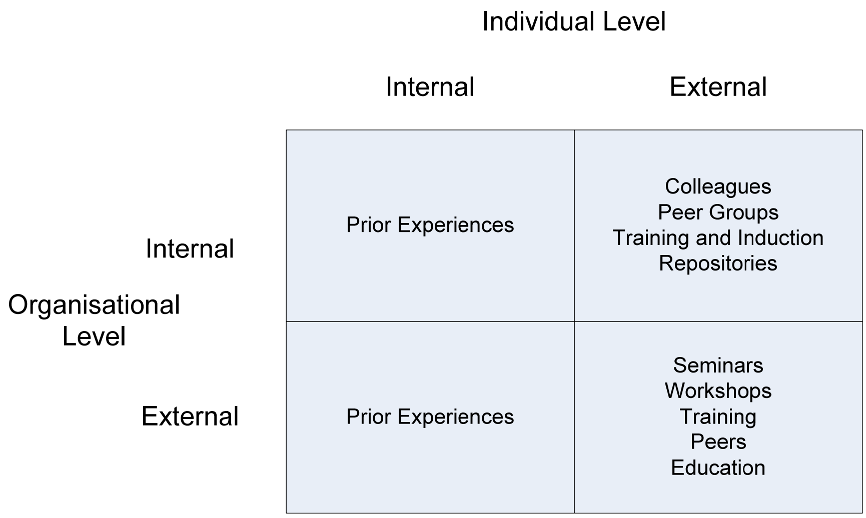

Figure 2: Analysis of sources of tacit knowledge

Overall, it was common among directors of the company to acquire tacit knowledge from external sources (seminars, workshops, training, peers), whilst internal sources (colleagues, peer groups, training, repositories) were widely used by operational level employees to acquire tacit knowledge. However, reliance on prior experience, both internal and external to the company, was prevalent at all different levels as a source of tacit knowledge. In general, new challenges; to overcome weakness in a system or to become familiar with a change in the system, and new experiences; when faced with complex projects or a request from a client; were cited as the main triggers for tacit knowledge generation.

The motivation for employees to generate and acquire tacit knowledge presented some diverse views among different interview respondents. However, the general consensus on this was the ultimate improvement in business performance through enhanced efficiency and effectiveness, in addition to personal development. For operational level employees the motivation to generate and acquire tacit knowledge was mainly driven by the desire to perform their tasks more efficiently. Hence, they highly valued different opinions, advice, points of view, evaluations, experience; mainly from their colleagues, which could improve the performance of their day-to-day activities.

Table 1: A summary of key concepts elicited on the role and importance of tacit knowledge

	Directors'	Managers'	Operational Level Employees'
What? What constitutes tacit knowledge	• Understanding of external markets and business opportunities, focused on external activities	• Ability to manage the team members	• Understanding of work activities, processes, procedures and pressures, mainly focused on internal activities
	Ability to provide thoughts, points of view and advice		
How? How can tacit knowledge be generated and acquired	• External peers, seminars, workshops, training and education as major sources of acquisition	• Training and colleagues as main sources of acquisition	• Internal colleagues, peer groups, training and repositories as major sources of acquisition
	Reliance on prior experience both internal and external to company		
Why? Why should tacit knowledge be generated and acquired	• Drivers mainly focused on enhancing business effectiveness, innovation and growth	• Drivers mainly focused on cost savings and avoiding costs to meet customer requirements efficiently	• Drivers mainly focused on enhancing efficiency in discharging day-to-day activities
	Enhance and broaden understanding of work		

Managers were mainly concerned with meeting customer requirements efficiently by cost savings and cost avoiding, through the exploration of different means of achieving customer requirements. Noticeably, the directors' motivation to generate and acquire tacit knowledge was focused on enhancing effectiveness, innovation and business growth. In that context, they were mainly concerned with finding best practices, new ideas and ways of working, mostly acquired through external sources. Therefore, in general, motivation to generate and acquire tacit knowledge varied from 'effectiveness focused drivers' at senior level to 'efficiency focused drivers' at operational level. However, the personal development; through enhanced and broadened understanding of work, was cited by all levels of respondents as a major benefit from the generation and acquisition of tacit knowledge. Table 1 illustrates the summary of key concepts elicited on the role and importance of tacit knowledge, from different levels of staff.

7. Discussion

The importance of tacit knowledge within the construction industry can be highlighted from two points: due to intrinsic characteristics of the construction industry, and the popularisation of the 'knowledge worker' concept. The unique, complex, relatively low-tech and labour intensive nature of construction projects, and the limited ability to codify construction knowledge are considered as leading features of the industry, which supports tacit knowledge generation and utilisation. The importance of the 'knowledge worker' is highlighted by the fact that industry relies on skills, experience and capabilities of construction employees when delivering the products and services. In the context of construction, examples of tacit knowledge included estimating and tendering skills acquired over time through hands-on experience of preparing bids, understanding the construction process, interaction with clients/customers and project team members in the construction supply chain, as well as understanding tender markets. The importance of tacit knowledge in the construction industry was further highlighted by the interviewees in the pilot study. They believed that employees do fall back on experiences, friendship and collaboration when faced with complex projects or challenging situations, as the use of explicit knowledge or IT in such situations is considered to be minimal. Several interviewees believed that tacit knowledge is the key to the performance of the construction industry due to its intrinsic characteristics, and it has recognised the contribution of tacit knowledge towards innovation and competitiveness. In addition, the interviewees stressed the need to fully explore tacit knowledge within the construction industry, since the industry as a whole has not learned how the 'sticky and messy' knowledge works.

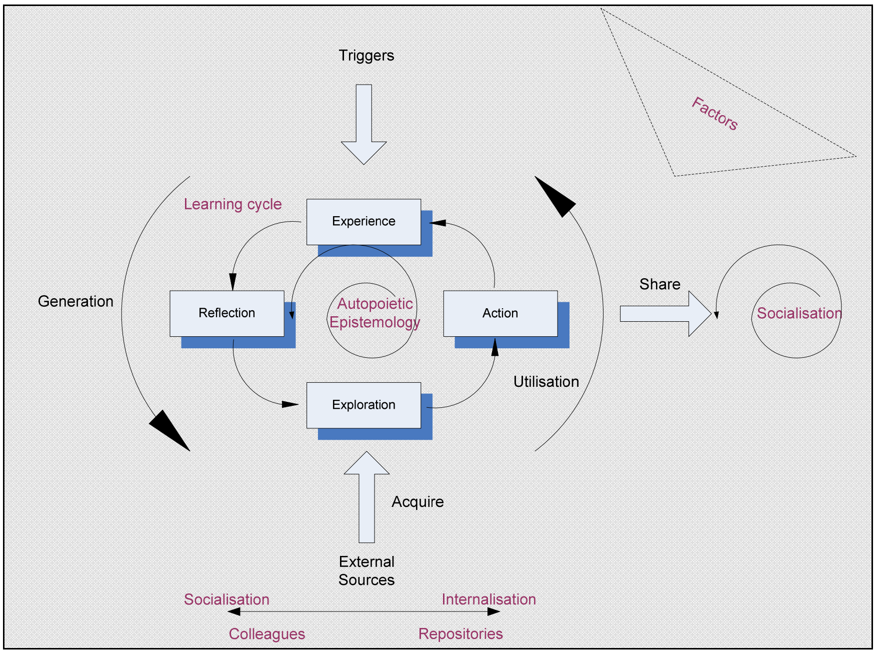

Figure 3: Tacit knowledge generation and utilisation process

The exploratory phase case study findings added rich insights into the different facets of tacit knowledge: 'what' constitutes tacit knowledge; 'how' can tacit knowledge be generated and acquired; and 'why' tacit knowledge should be generated and utilised. In order to articulate the process of tacit knowledge generation and utilisation, the study integrated theories of experiential learning, cognitive science and knowledge creation. The autopoietic epistemology was preferred as the philosophical basis of understanding tacit knowledge generation and utilisation; whilst Kolb's [30] experiential learning model was considered in terms of the stages that followed within the cognitive process of tacit knowledge generation and utilisation. Figure 3 summarises the sources of tacit knowledge generation and acquisition together with the individual cognitive process based on case study findings.

Tacit knowledge has been defined as the unarticulated knowledge that resides in human beings, based on experience and expressed in the form of attitudes, points of view and commitment [3,14,22]. This definition of tacit knowledge was used extensively throughout the study; however, the pilot interview outcomes and case study findings provided richer insights on what tacit knowledge is in an organisational context, hence the following definition is synthesised:

Tacit knowledge constitutes understanding, capabilities, skills and the experiences of individuals; often expressed in human actions in the form of thoughts, points of view, evaluations and advice; generated and acquired through past experiences, individuals, and repositories; utilised for the benefit of individual and organisational development.

8. Conclusion

Due to the intrinsic characteristics of the construction industry, tacit knowledge of the workers and their social interactions has gained increasing importance within the industry. As the industry is very much centred on tacit knowledge and experience of construction workers, it is biased towards the process-based view of knowledge. Hence, the process-based solutions, enhancing personalisation strategies and interactions between construction workers to generate and share tacit knowledge, would be much more relevant to overcome KM problems in construction organisations. Understanding what tacit knowledge is, its generation and utilisation are central to its effective management. Accordingly, this paper explored and discussed the nature and importance of tacit knowledge in the construction industry, based on a doctoral study which investigated the process of tacit knowledge management in a construction organisation.

Abstract

It has been suggested that the contracting organizations can capitalize on experienced based learning, thus performance change is not simply incidental. There are good reasons to hypothesize that learning plays a part in performance improvement. The lack of reported studies in this regard prompted this study. Learning curves are used in this study to demonstrate the effect of contracting organizations' learning on performance. This involves fitting of longitudinal performance data with a number of well-established learning curve models. Data on performance was provided by a major public housing provider in Hong Kong. Applying the Least Square Curve Fitting Analysis, it was found that the collected performance data fit well with the 3-parameter hyperbolic model. It was found that some contracting organizations in the sample displayed performance deterioration over time until reaching the asymptotic performance level. This is in line with the underlying learning theory of the 3-parameter hyperbolic model.

Keywords: learning effect, contracting organizations, performance

1. Introduction

Competition in today's construction engineering sector is no longer inter-firm but among supply chains formed by networks of organizations [1]. Within these networks, the main contractor is responsible in converting the design into practical reality [2]. His ability to deliver the project directly affects the client's satisfaction and value of the facilities. This ability is an invaluable competitive advantage to compete in the fierce construction market [2]. In this connection, a vast amount of studies pinpointed the importance of enabling a main contractor to attain continuous improvement [3].

nevertheless, several industry reviews reported the declining quality of contractors' performance in terms of the lowering productivity, profitability, as well as deteriorating relationships with other organizations within the supply chain [4-5]. Worse still, main contractors are often considered as inflexible and slow to respond to clients' changing demands. Such a trend is believed to be continuing [6]. In addressing such problems several studies have pinpointed that contractor's practices should be changed from perpetuating obsolete procedures to continuously imbibing knowledge from both the internal and external environments for more efficient and effective ways of working [7-8]. The significance of integrating learning as part of the contractors' daily routines has previously been addressed in a number of studies [6, 9-10].

Researchers have long advocated the positive effect of learning on contractors' performance [11-12]. For example, based on a review of literature, Thomas et al. [13] pinpointed that a contractor can capitalize on the lessons learnt from experience. Everett and Farghal [14] extended the work of Thomas et al. [13] and suggested that increase in productivity is possible if a contractor can learn from repetitive operations – a phenomenon often described as learning effect. Based on interviews, Franco et al. [11] revealed that the improved performance in construction project is related to contractors' learning from the performance feedback. Supported by views obtained of construction practitioners in Hong Kong, Wong and Cheung [12] demonstrated empirically the effect of performance improvement is contingent on contracting organizations' practice of and engagement in learning.

Whilst many of these studies were based on reviews of literatures and the perceptive views of the practitioners, there seems to be a general agreement among researchers that performance change of contractors is not incidental [7-8]. To certain extent, it can be an outcome of a subtle learning process, notwithstanding that little attention has been paid on addressing what exactly the contractors have been learning [7-8]. Nevertheless, such proposition has yet been backed with sufficient empirical evidences [15]. Moreover, it is understandable that there are a variety of ways by which performance improvement can be achieved [16]. For example, performance of contractors may be improved by their productivity gain during the course of construction, the management capability of their project manager, as well as their ability to manipulate project monitoring outcomes [6, 14]. In this perspective, it seems unreasonable for researchers to advocate that performance change is exclusively a product of learning. As such, evidences of the effect of learning on performance change remained obscure and want of quantitative research.

2. The Research Objectives

This paper reports a study which seeks to demonstrate the development and application of a quantitative approach to make learning effect, if any, observable by fitting longitudinal performance data with well established learning curve models. The longitudinal performance data required for accomplishing the above research objective were obtained from real project data from Performance Assessment Scoring System (PASS), a system implemented by the Housing Department of the Hong Kong Government to gauge performance .Their fitness with some classical learning curve models was analyzed by the least square curve fitting analysis methodology (LSCFA hereafter) [14, 17-21]. The analysis may help to deepen the understanding of the relationship between the performance and learning of the contractors. Furthermore, this provides an objective and quantitative means for the researchers to explore the possible learning dimensions that may affect the contractors' performance change.

3. Research Methodology

LSCFA was employed to analyze whether the effect of contractors' learning can be tracked by the use of longitudinal performance data [21]. Indeed, this method has been employed to identify the learning effect of organizations in a number of previous studies [13, 17-21]. Table 1 lists five theoretical learning curve models that are recognized as appropriate for the demonstration of learning effects of organizations in construction and other engineering fields. The mathematical formulae and brief descriptions of these theoretical learning curve models are also presented.

LSCFA can be described as an evaluation of fitness of a learning curve model to describe the change patterns of the performance data longitudinally across the project span [17]. The evaluation can be described by Eq. 1.

$y = f(x,\theta) + \varepsilon$ - (Eq. 1)

Where

- x = the performance data set throughout a specified period of time
- θ = the parameter(s) of the theoretical model
- ε = the error term
- y = respective values agreeing with the theoretical model throughout the specified period of time

The fitness of the learning curve model for describing the performance change can be identified by the residual errors (ε) (i.e. the difference between the values of parameters x and y throughout a specified period of time) [21]. The lower the ε value, the more 'effective' is the theoretical model in describing the change in performance data [21]. The ε value determined by the LSCFA is presented as the means-squared error (MSE) value. The equation for computing the MSE value is presented as follows:

$$\text{MSE} = \frac{\sum_{j=1}^{N} (x_j - y_j)^2}{N}$$

Where

- N = Number of contractors' performance data
- yj = Respective value agreeing with the learning curve model at the jth quarter
- xj = Contractors' performance data at the jth quarter

Table 1: Learning curve models appropriate to demonstrate the learning effects

Learning curve model	Form	Definition of the parameters	Use	References
Log-linear (negative slope)	$Y=AX^{-B}$	Y= the average cost (or time) required to produce x units; A= the cost (or time) of the first production unit; X=the amount of the production units; B=the slope of the logarithmic curve	To express the learning effect by decreasing average cost (or time) of production over cumulative period	Thomas *et al.* [13], Everett and Farghal [14, 17-18]. Farghal and Everett [19]
(positive slope)	$y = ax^{b}$	y = the productivity (or the cumulative performance score) after x cycles of work, a= Productivity (performance score)of the first cycle of work x= cycles of work b= The learning rate	To express the learning effect by the performance improvements over time	Emir [22], Blancett [23]
3-parameter Exponential	$y= k(1-e^{-(x+p)/r})$	y = the work performance k = an estimate of the maximum performance level that is projected after all improvement has taken place x = the cumulative time p = an estimate of the accumulated prior experience r = time required to reach the performance level equal to k / 2	To express learning as a process to replace incorrect responses by correct ones (considering the effect of the learners' prior experience to the performance)	Uzumeria and Nembhard [20], Mazur and Hastie [24]

2-parameter Exponential	$y = k(1-e^{-x/r})$	Ditto	Ditto (without considering the effect of the learners' prior experience to the performance)	Ditto
3-parameter hyperbolic	$y = k((x + p) / (x + p + r))$	y = the work performance k = an estimate of the maximum performance level that is projected after all improvement has taken place x = the cumulative time p = an estimate of the accumulated prior experience r = time required to reach the performance level equal to k / 2	To express learning as a process 'by which correct response tendencies increase steadily with practice and compete with the incorrect tendencies, which are constant' (considering the effect of the learners' prior experience to the performance)	Ditto
2-parameter hyperbolic	$y = k(x / (x + r))$	Ditto	Ditto (without considering the effect of the learners' prior experience to the performance)	Ditto

*Remark: Popular models like the Stanford-B Model, the DeJong Model and the S-curve Model are also derived from the Log-linear learning curve model to describe some particular learning scenarios in the manufacturing and automotive industries. They are not specifically introduced in this connection.

In this study, the LSCFA determines the MSE values when a contractors' performance data set is fitted to the various types of learning curve model. Nembhard and Uzumeri [20] used the following criteria in evaluating the effectiveness of the learning curve models in their studies:

(1) Testing the 'Efficiency' by comparing the mean MSE values (i.e. averaging the MSE values of the entire data sets) of the learning curve models. The lower mean MSE value represents the better fit of the data sets to that particular model.

(2) Testing the 'Stability' by comparing the degree of variation of the standard deviations of the mean MSE values. It is because a particular learning curve model may fit well with some data sets but not others. Yet, 'a stable model will not be overly dependent on some specific learning episodes to obtain good model fit' [21]. The lower standard deviation of the mean MSE values represents the better fit of the data sets to that particular model [21, 25]

Generally, the methodology employed in this study follows the approach which has been adopted by Nembhard and Uzumeri [21]. Nevertheless, in order to demonstrate the fitness of the learning curve models to describe the data sets, their respective percentage error values are measured by the following equation:

$$\text{Percentage error} = \frac{\sqrt{\text{MSE}}}{\text{Max. scoring of the assessment scale}} * 100\%$$

4. Programming Tool For The Lscfa

In this study, MATLAB 6.1 is used as a programming tool. Indeed, MATLAB has long been recognized as an effective tool to conduct least square curve fitting analyses [26]. The 'polyfit' and the 'lsqcurvefit' functions of MATLAB are adopted to determine the fitness of the contractors' performance data to various learning curve models. Furthermore, 2–dimensional plots that illustrate the fitness of the learning curve models to describe the tested data in a graphical format are generated [26].

5. Data Collection

The success of this study depends very much on the availability of longitudinal performance data. Nevertheless, such data is not easy to obtain as it is not a standard practice to keep such data in construction. Examining the monitoring practices of the private sector projects in Hong Kong, contractors' performance assessment is usually conducted by the architect and/or the project manager. Nonetheless, comprehensive monitoring systems for regular tracking and recording of contractor's performance are rarely installed in the construction industry. In the public sector, for accountability purposes, more formalized and elaborate monitoring systems have been implemented for gauging contractors' performance throughout the construction stage. Among these developed systems, the Performance Assessment Scoring System (PASS) has been identified as one of the most comprehensive systems [27]. This system has been designed to keep track of contractors' performances during the course of construction. PASS has been used in over one hundred public housing projects since early 90's. The research team is grateful for the support rendered by the Hong Kong Housing Department (HKHD) in providing valuable contractors' performance data captured from PASS for this study. The Hong Kong Housing Authority (HKHA) is the executive arm of the HKHD that is responsible for providing public housing to the needy. In Hong Kong, there is a strong demand for public housing. As such the HKHA, as the sole provider, is the largest building client in Hong Kong. The collection of PASS data that records contractors' project performance during the course of construction is a unique and rare wealth of data for the kind of study reported in this paper.

In essence, PASS presents the monitoring results in terms of the contractor's performance score (described as PASS score hereafter) in a project. The system aims to provide a more 'objective' basis for gauging and monitoring the contractors' performances on the public construction engineering projects. PASS scores are performance records that comprise monthly Works Assessment scores and quarterly General Assessment scores. The relative weighting between Works and General Assessments is 70% and 30%. It has been suggested that performance records with remarks by the management team can highlight the causes of underperformance and thus help improvement with contractors taking appropriate actions [7-8]. As such, contractors in each project monitored under PASS would be notified by the PASS Control Unit of the HKHD about their quarterly PASS scores regularly. This ensures that contractors are provided with monitoring results in a standardized format. The composition of PASS score is shown in Figure 1.

In this study, the PASS scores of 38 public housing projects were examined. Each of the data sets contain at least 8 quarterly (i.e. 2 years) PASS scores. These data were then fit to several established learning curve models.

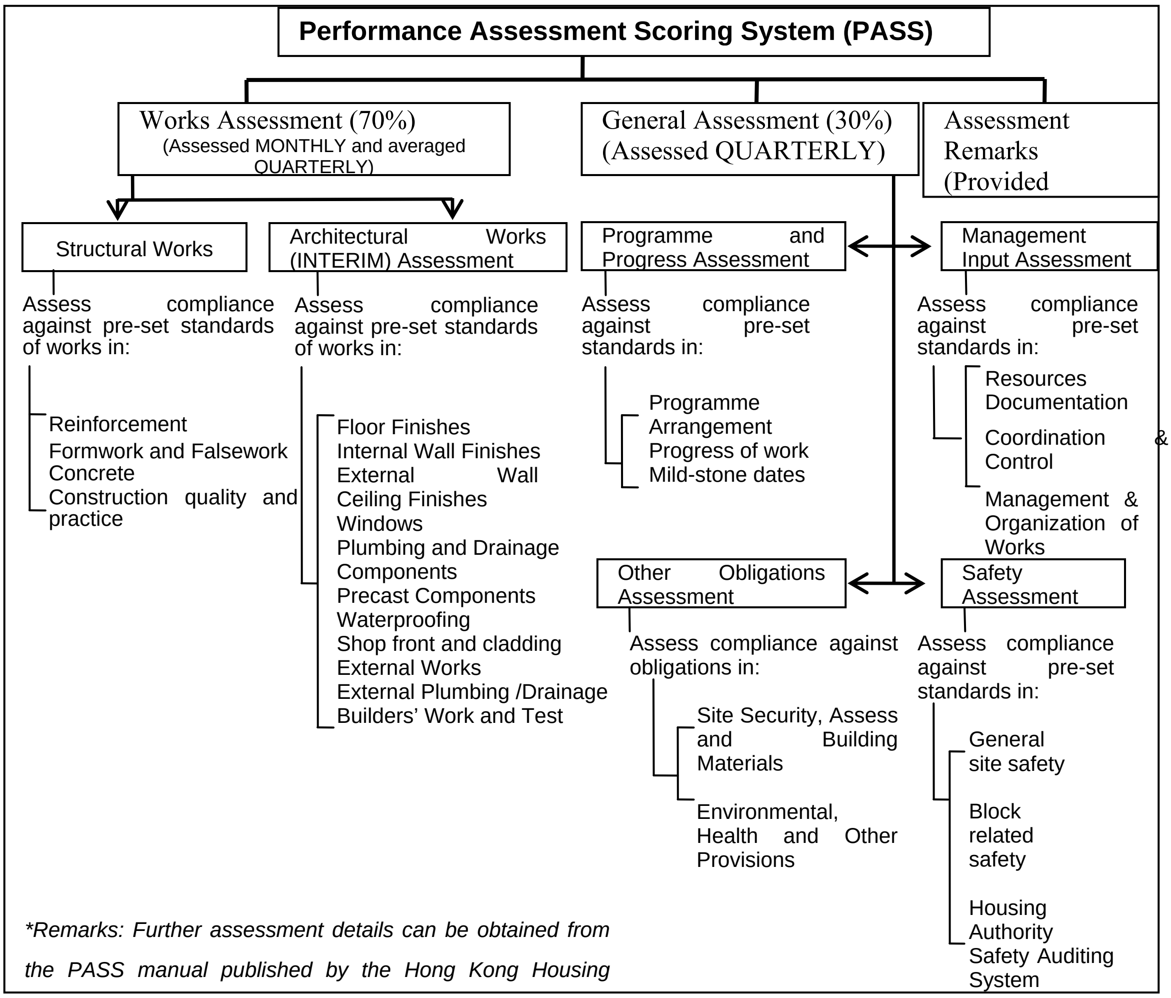

Figure 1: Composition of PASS

6. Results and Discussions

6.1 Collecting the analyzed results – an illustrative example

The results of the LSCFA of the learning curve models are presented in this section. The efficiency, stability and percentage errors of the models are also discussed. The results of fitting the PASS scores of one of the 38 tested projects to the various learning curve models (described as Project P1 hereafter) are detailed to illustrate the working involved. The outputs of the least square curve fitting analyses of Project P1 are shown in Figure 2. 'loglinearmse' represents the MSE value when fitting the log linear learning curve model to the contractor's performance data of Project P1. c values (Figure 2 refers) are the estimated values of the parameters of the log linear learning curve model calculated by the MATLAB 'lsqcurvefit' function. They are presented according to their sequence of appearance in their respective learning curve equations. The mathematical equation of the log linear learning curve model is:

$y= ax^b$

Where

- y= the cumulative performance score after x cycles of work
- a= Performance score of the first cycle of work
- x= the cumulative performance score after x cycles of work
- b= the learning rate

As shown in Figure 2, the first c value (79.5992) in the output refers to the estimated Performance score of the first cycle of work (i.e. parameter ‘a’) and the second c value (0.5414) refers to the learning rate of the contractor With reference to the outputs of Project P1 (Figure 2 refers), the contractors’ learning rate is higher than 0. This suggests that the respective contractor performed positive learning and improved his performance throughout the project [21]. In addition, the lowest MSE value is found when fitting the contractor’s performance data to the 3-parameter hyperbolic model. In other words, the organizational learning pattern as presented by this learning curve model appears to be the most appropriate, among others, in describing the OL patterns of the contractor of Project P1. The fitting results are also illustrated in Figure 3, the 3-parameter hyperbolic curve is also found to give a good fit for the performance scores.

The same set of procedures was applied to each of the 38 projects with PASS scores. The ‘Efficiency’ and ‘Stability’ of the learning curve models used for fitting are reported in the next section.

```
>> P1_PS

 c = 79.5992                    0.5414

loglinearmse =  2.0529e+004

c =     84.8922    0.0842

hyperbolic2mse =    9.2702
```

Figure 2: Outputs of LSCFA of Project P1

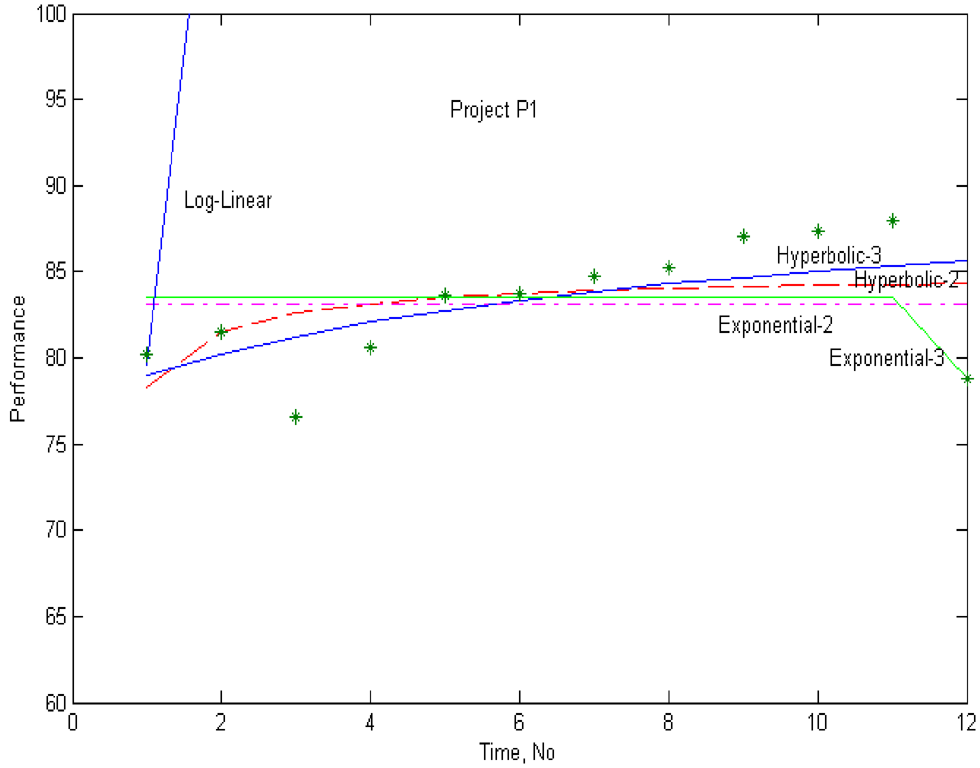

Figure 3 -: PASS scores of Project P1 fitted to various theoretical learning curve models

6.2 Efficiency and Stability of fitting contractors' PASS scores to different learning curves

The views expressed in this section are solely those of the authors and do not represent the view of the HKHA or HKHD. The results of the LSCFA indicate that the data sets fit well to most of the earning curve models (Table 2 refers). Among these, 3-parameter hyperbolic model was found the most efficient and stable model (Mean MSE= 9.2033, Standard deviation of MSE= 6.3725) [20-21]. In this connection, it is suggested that the learning pattern underlying the LSCFA is a good description of the learning element involved.

Furthermore, satisfactory results were also found while fitting the same set of data to the 2-parameter hyperbolic model (Mean MSE= 10.8758, Standard deviation of MSE= 8.3876), 2-parameter exponential (Mean MSE=13.4929, Standard deviation of MSE= 9.3311) and 3-parameter exponential (Mean MSE=12.5082, Standard deviation of MSE= 7.7335) models. Nevertheless, a relatively unsatisfactory result was found when data sets were fitted against the log-linear model (Mean MSE= 22392.3392, Standard deviation of MSE= 49402.8666).

In search for an explanation, the underlying bases of learning of the models are examined. The log linear learning curve model assumes a linear relationship between performance and time (i.e. the PASS scores are assumed to improve continuously with the same learning rate throughout the project) [21].

Nevertheless, in reviewing the data sets, it was found that contractors' performance change often flattened at the later part of the project. Such performance change pattern matches with the assumptions of the hyperbolic and exponential models. Organizations with these learning patterns would improve or deteriorate over time until reaching the asymptotic performance level [14, 17-18].

The fitness of the PASS scores to be explained by the exponential and hyperbolic learning curve models in this study suggests that contractors' performance change is not incidental but has a learning element [6, 12]. Furthermore, the 3-parameter hyperbolic model is identified as a comparatively 'efficient' and 'stable' learning curve model in describing the PASS scores. Nembhard and Uzumeri [21] emphasized that the theoretical bases and assumptions of the best-fit learning curve model may be instrumental for a search of possible factors which characterized the patterns of performance change of the contractors. Further investigations on the performance change patterns of the HKHA contractors in terms of the project characteristics and the estimated output parameter values of the 3-parameter hyperbolic model are recommended.

7. The Concluding Remarks

Whilst studies were based on the perceptive views of the practitioners, findings from previous studies typically suggested that learning may have positive effect on contractors' performance. The study reported in this paper employed the LSCFA to track the effect of learning from the performance data of contractors during the course of construction. PASS scores from 38 HKHA projects were fitted to five well-established learning curve models. The findings of this study highlight some interesting patterns displayed by contractors who were subjected to regular performance assessment. PASS scores effectively fit the exponential and hyperbolic learning curve models. This indicates that performance change of a contractor may have a learning element. This study paves the path for further exploration on the possible learning dimensions that may affect performance change of the contractors.

EDUCATION

Resourcing programmes in the built environment

Allan Ashworth
Centre for Education in the Built Environment University of Salford

Abstract

This paper is based upon a survey carried out for the UK Heads of Department group, CHOBE (Council of Heads of Built Environment Departments). Its membership represents approximately 45 departments in the UK that offer programmes in construction, property and surveying. The survey was aimed at finding out the perceptions of these heads of department on a range of topics that influence the resourcing of these departments. The survey asked questions about staffing, students, curricula, research, accreditation and assessment. Respondents were also asked to identify the three most important issues facing these disciplines at the beginning of the twenty-first century. It was not surprising that recruitment and retention of appropriately skilled and knowledgeable staff were identified as the most common and important issues facing these disciplines. This was followed closely by links with industry and industry engagement. Whilst there were some differences in opinion expressed between those departments that are research-led compared with those that concentrate more on the delivery of programmes, such differences were not in some cases distinctive.

Keywords: Departments, Education, Resourcing, Staffing, Students,

1. Introduction

Within the United Kingdom the heads of subject disciplines are encouraged to form associations with other similar heads to discuss current trends, share best practices and examine issues facing their schools or departments. Historically Surveying Departments and Building (Construction) Departments were managed as separate entities, especially in the new universities. This was the pattern of their formation during the early 1970s and different Heads Groups represented these disciplines.

During the 1990s, with the creation of the new universities in 1992, university vice-chancellors began an ongoing process of reorganisation of provision across all departments. In some institutions the number of Faculty's were reduced and the smaller departments were amalgamated with others to form more coherent academic subject areas. It was not surprising therefore that the existing departments of surveying and building were merged to create new and larger departments of the built environment, since much of their work had common elements. In 2004, the former Heads of Department of Surveying and the former Council of Professors of Building agreed to merge their respective bodies to become the Council of Heads of Department of the Built Environment (CHOBE). Whilst its title is broader than its practice, it was a title that was chosen as being aspirational. At the present time CHOBE represents the disciplines of Construction, Property and Surveying and has links with a number of chartered professional bodies.

CHOBE represents some 45 departments in the UK. Its vision is to support and represent with a voice of influence those with strategic responsibility for the development and delivery of graduate and postgraduate education and research within these disciplines.

In support of the vision CHOBE aims to provide:

- Networking opportunities for Respondents to share and inform each other in respect of knowledge and good practice.
- A means of mutual support at individual and institutional level.
- A forum in which to discuss and solve problems of mutual concern,
- The opportunity to foster relationships to achieve educational and research aims.
- Representation on professional bodies and other organizations in order to strengthen knowledge of the disciplines and their contribution to the economy and to lobby on behalf of our members; and
- The primary point of *consultation* by external stakeholders for education in our sector

There are proposals to allow similar departments overseas to become affiliate members of CHOBE, to help in sharing good practice, trends and issues associated with managing the range of provision.

2. CHOBE Heads of Department Survey

In 2007, the Executive Group of CHOBE decided to initiate a survey amongst its constituent members about their perceptions on a range of topics that influence the resourcing of its schools or departments. Twenty-two of the departments responded to the survey and their findings are discussed below.

2.1 Staffing

By far the greatest discussion point amongst UK heads of department is academic staff. Refer also to the *Other Concerns* towards the end of this paper. At the present time there is a difficulty of recruiting staff with the appropriate qualifications and experience who closely match the programme provision and curriculum content and the necessary underpinning research needs. Sometimes teaching and research staff compatibility remain at odds with each other.

In the present economic climate, industry and commerce are seen by most as being much more attractive than the work of an academic; at least measured on the basis of salary and other financial packages. This has probably always have been the case, but the gap is now perceived to be much wider. Also the majority of undergraduate students' aims and expectations are for a good, long-term career in practice. Current evidence in the UK indicates a dwindling ability to attract UK nationals to academic positions in construction, property or surveying. This is also often coupled with applicants from overseas having better academic qualifications.

The first question in the survey was about the age profile of departments. Figure 1 shows the age distribution of the 22 departments for their full-time academic staff. Columns 24 and 25 represent the average data from this sample. Column 24 represents the average of all departments and column 25 the average of the six departments with the highest age profile.

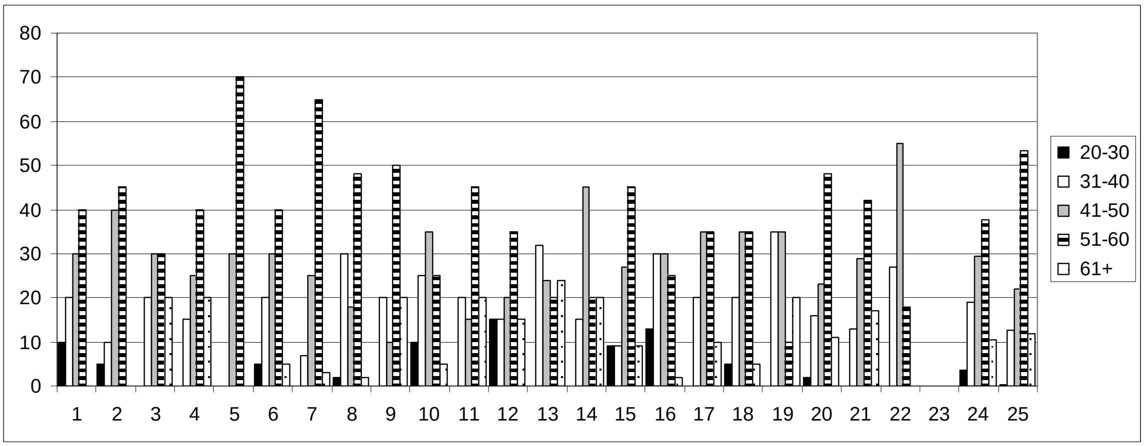

Figure 1- Age distribution of staff with in 22 departments

In twelve of these departments, over half (55%) of the departments, there was no academic staff employed who were under 30 years of age. On average only 3% of the academic staff were less 30 years of age. At the other end of the age spectrum almost half (48%) the staff were over 50 years of age. Ten per cent were aged over 60 years of age. In the early 1990s, a newspaper report commented that to teach architecture properly required maturity. At that time it was stated that that the average age of architectural academic was 48 years, but wasn't this just too mature when

at that same time staff were being offered redundancy packages by the age of 50. Coincidentally the average age of lecturers in CHOBE departments is now of a similar age, but most of these will now be expected to work in to their early 60s.

Figure 2 illustrates the percentages of academic staff in departments over the age of 50 years. Column 24 represents the average for all departments and column 25 represents the six departments having the highest age profile.

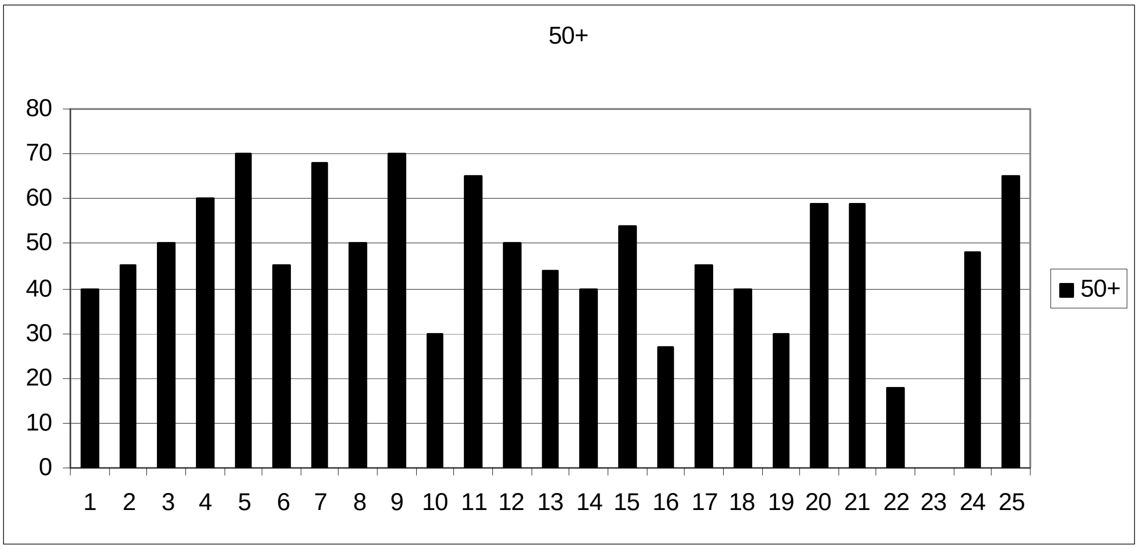

Figure 2- Percentage of staff within departments over 50 years of age

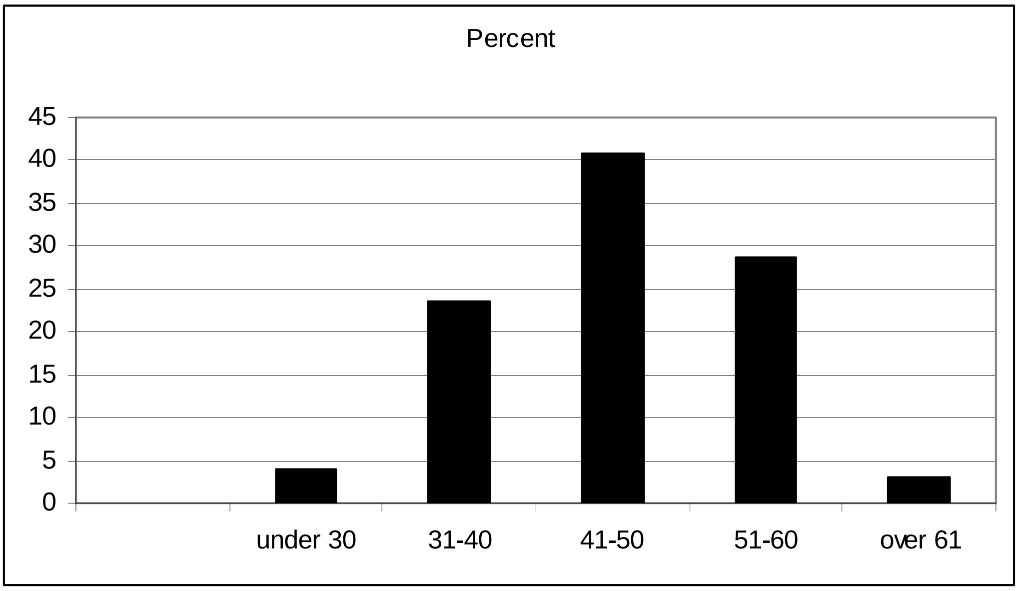

Figure 3- Example of a former polytechnic academic staff age profile (Source: HMI 1989)

Twenty-five years ago a Report (HMI, 1992) stated that the average age of full-time built environment lecturers in the former polytechnics was 45. In 1989 a report on the then English polytechnics (HMI, 1989) showed an age profile for comparison with that of CHOBE departments in 2007 (figure 3).

Table 2 compares the 1989 HMI data with the 2007 CHOBE data. It can be observed that CHOBE data indicates comparably fewer younger academic staff. Staff under 40 years of age are 27% and 22% respectively. Today there are three times more staff over 60 years of age than in 1989 (3 and 10%).

Table 1- Comparison of HMI (1989) with CHOBE departments (2007)

	HMI (1989)	CHOBE (2007)
Under 30	4	3
31-40	23	19
41-50	41	38
51-60	29	30
Over 61	3	10

The question of course may be asked whether the age profile of academic staff matters? Is it preferable to have a department with a spread of ages or a department with predominantly young staff? Also is it a comparable profile to that of industry or commerce? Ellis and Wood (2006) have shown a similar profile to those who are employed in industry and commerce. The profile matters in terms of succession planning and the generation and development of new ideas. There also comes a time in everyone's career when they peak in terms of workload and indeed stamina.

Thirty-five years ago, in the early 1970s, was an expansion period for UK higher education. Departments recruited heavily to match the changes in their provision and in the author's own experience there were a significant number of staff then under the age of thirty. This was significantly higher than the 3% who are now in this age group. Also a great many of these academic staff are now in their late 50s and early 60s and are due to retire or already have done so.

Figure 4 gives some indication of the difficulties in recruiting staff in the different core subject disciplines. This is not to discount the very valid contribution made by other subject disciplines on these programmes. Some of the disciplines are not represented in all departments and this may have the effect of distorting the figures marginally. The subject disciplines that recorded the greatest difficulties in terms of their recruitment were building surveyors (with 82% of departments reporting difficulties) quantity surveyors (73%) general practice surveyors (55%) and construction managers (50%).

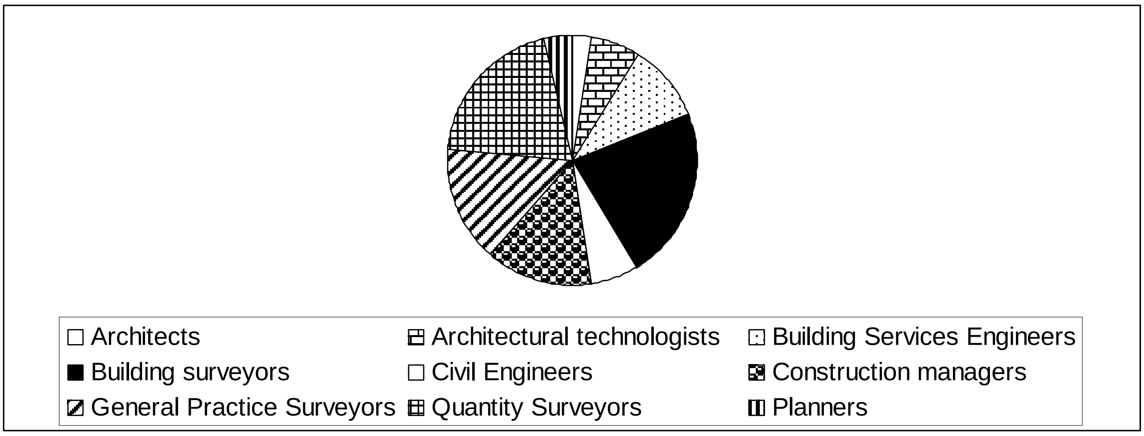

Figure 4- Difficulty recruiting staff

2.2 Staffing qualifications and experience

Compared with 40 years ago there has been a marked shift in academic staff and qualifications and experience. Forty years ago you it would have been unusual to have found anyone teaching these vocational programmes without prior and *related* experience of working in industry or commerce. The vast majority would also have relied exclusively on their professional qualifications as means of evidence of their capabilities. It was not until the late 1970s that undergraduate degrees became the norm rather than the exception. Four questions were asked of respondents about the importance of qualifications and experience when appointing new staff today. The responses to these are shown in table 2.

Table 2- Importance of staff qualifications and experience (percentages)

	Highly Important	Important	Neutral	Unimportant	Unimportant Highly
Professional qualifications	45	50	0	0	5
Work experience	27	68	0	5	0
Higher degrees	32	59	9	0	0
Research capability	27	4	53	3	5

These indicate a high degree of agreement amongst respondents for first three of the questions. The vast majority still continue to recognise the importance of chartered professional qualifications and relevant experience of industry and commerce when appointing new academic staff. Departments do have different criteria and this will to some extent be dependent upon their existing staff complement and the need to balance this with the criteria when actually appointing new staff. There is also some general agreement about the importance of staff now having higher degrees. This will become much more important in the future when perhaps half of the population will have acquired an undergraduate degree and something more will be required to distinguish between prospective applicants.

Where a significant difference was identified was in research capability. One respondent stated that this depends not just on an existing track record, but also the potential for future performance in research. The research-led university departments, of which there are relatively few in these subject areas, naturally rated this characteristic highly. For some, this would also be considered to be the highest of these four characteristics. However, somewhat surprisingly, over half of all the respondents felt no more than neutral about this aspect and overall only a quarter of the replies rated it as highly important. This raises significant questions about the interface between teaching and research.

2.3 Students

Historically most of those who joined the construction and property industries forty years ago would have done so through some form of part-time study, either at a college or through what is now described as distance learning. The 1970s changed much of this, firstly by introducing undergraduate degree programmes and secondly, until at least until the early 1980s, these were only available on either a full-time or sandwich basis. Undergraduate degrees by part-time study only came in to existence with the demise of external examinations provided by the professional bodies in the mid-1980s.

The shift of undergraduate students from full-time or sandwich modes of study to part-time is most noticeable amongst quantity surveying students. Almost 40% of respondents stated this. The percentage increases to over 50% in those departments that offer this discipline. There is a noticeable shift amongst other subjects such as building surveying and construction management although this is not quite so distinctive. Respondents generally did not record much, if any, of shift from part-time to full-time. This to a large extent reflects the good state of commerce and industry with the opportunities to students to learn and earn at the same time.

In terms of postgraduate education there has been an increase in programmes in most of the surveying subject disciplines in many universities. Construction management Masters' programmes have been available since the late 1960s. Conversion masters' programmes are now popular with many students. They are also much sought after by the larger employers. Some employers have stated that they now typically recruit 40% of their new staff from such programmes.

Figure 5 indicates the percentage of students entering undergraduate degrees in construction, property and surveying with qualifications other than GCE Advanced Level qualifications. The UK Government is keen to widen the access to students to all programmes and to increase participation rates in higher education. By 2010, Government expects that over 50% of the cohort will be taking this opportunity. It is unlikely that there are many programmes in this discipline that recruit entirely from students with GCE Advanced Level qualifications. Figure 5 indicates that somewhere between 10-25% of students will have other qualifications which will include further education level 3 qualifications and mature students. This percentage is higher for students on construction management programmes and lower for those general practice surveying programmes. Differences will also exist between programmes that are full-time or part-time and across the different institutions.

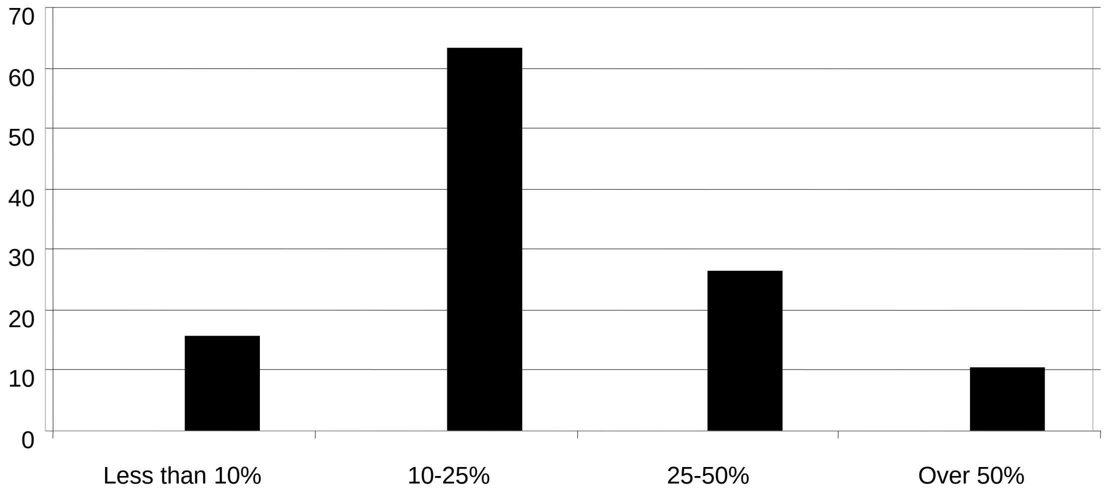

Figure 5- Non-standard student entry qualifications

2.4 Curricula

The curricula for these programmes continues to evolve through changes in practice and new knowledge derived from research. Comparison with the curricula in the past shows that programme leaders are dynamic in the evolution of their programmes through their periodic review. Departments' responses to Leitch (2006) indicate that they anticipate making only minor changes to comply with the Report's expectations. Most feel that they are already doing what Leitch expects of them in terms of the employability of graduates. This is currently very high, with students often being offered more than one job. These programmes do not within the current economic climate envisage any unemployment even for the weaker students. Respondents felt that curricula would continue to change. Subject knowledge and skills would be enhanced, replaced or removed from the curricula. An examination of the curricula over the past 30 years confirms this to be the case in the past.

Respondents stated that employers already influence the programme design through employers' liaison groups, their contribution to delivery of programmes and as external examiners. A majority felt assured that they could easily satisfy any expectations or requirements of the various sectors skills councils. There is likely to be an increasingly emphasis on flexible delivery and the recognition of work based learning and the assessment of in-house training, especially amongst the larger companies. There could be pressure to focus programmes to a greater extent on the immediate needs of employers. This might allow learners to select the elements of learning in which they are interested and combine this with credit from work-based learning towards qualifications. However, other employers are more interested in the intellectual strengths of their new employees and are less focused on the detailed knowledge base. This latter view has been expressed by some of the larger employers.

The curricula is determined largely through a combination of professional body requirements and expectations, industry practices because of the vocational nature of the subject and, the academic staff who deliver it. There are tensions in just what knowledge and skills should be developed. Universities have consistently argued that their main focus should be education and mind training. Professional training should be more properly and easily be provided through work placements, work based learning and training programmes in practice.

One respondent suggested that universities should be able to develop the curricula that they feel offers students the best opportunities. The interference, especially by professional bodies, was considered to be unnecessary and a hang up from the time when they controlled external professional examinations.

2.5 Research and consultancy

The Research Assessment Exercise (RAE) has been a common feature of UK academia since the early 1990s. Its purpose is to reward departments, both financially and through a rating, for the research that has been carried out over a previous four year period. In the past this assessment has been based on citations and has for the past three RAEs been based on a peer group assessment of research outputs. Evidence indicates that over the past few years, a greater proportion of the funding has been allocated to fewer departments generally across all disciplines. One of the aims of Government in the late 1980s was to create teaching only universities and research-led universities. Whilst this policy has not yet been achieved in practice, the RAE mechanism has gone some way towards achieving this result. It has recently been announced that the principles of the RAE in 2012 is likely to be on citations.

Given this background to the two survey questions about research and consultancy the respondents’ comments are perhaps not entirely surprising, although these more than any of the other questions resulted in comments being added by the respondents. Those departments that aspire to being more research intensive also expressed different views to others who felt that applied research was a key direction for them. One respondent questioned the ability or desire of graduates from these undergraduate programmes to effectively undertake research that would be funded either by government, industry or commerce. It was suggested by some that most the students leaving these programmes had no interest at all in research.

However, over half of the respondents thought that the RAE had beneficial effects on both teaching and increasing scholarship within departments. A quarter thought it was unhelpful to their departments and the remainder that it was not really applicable to them at the present time. More specifically respondents were divided almost equally three ways, on whether it was a positive feature, unhelpful or not applicable to their circumstances at the present time.

The attitude to consultancy or updating and links to industry and practice were more positive. All the respondents thought that practice and industry were important in the context of ongoing staff development. Those who were especially research active claimed that they worked closely with industry and that this offered benefits all round. Almost 80% suggested that a good and current understanding of industry and practice was of major importance to their departments, with the remaining 20% indicating that it was of minor importance. None indicated that it was not a priority for them.

2.6 Programme Accreditation

The accreditation of programmes in property, surveying and construction in the UK is important. Without this many programmes would fail to recruit students, since becoming a member of a professional body is a long-term goal of many students. This importance is emphasised if we examine the growth in membership of the chartered professional bodies. The RICS, for example has increased its members to in excess of 130,000 today, from just over 90,000 ten years ago and less than 60,000 25 years ago. Other UK construction and property professional bodies have also gown but perhaps not at the same rate.

The survey asked respondents three questions about accreditation. These were about the prescriptive nature of professional bodies, the possibility of common frameworks across the different professional bodies and the continued importance of accreditation.

It needs to be recognised that the different professional bodies each have different and in some cases distinct requirements regarding the programmes that they accredit. Some are highly prescriptive about curriculum content or in meeting the specified core competencies of the professional that they produce. Others rely more heavily on a final external assessment prior to awarding an individual membership status. Some are prescriptive about threshold requirements in respect of, for example, the entry qualifications of students joining programmes or the research capabilities of the academics who teach on the accredited programmes. Overwhelmingly, some 77% of respondents were neutral about the level of prescription. Some added comments that referred to the different professional bodies. In some cases universities would like a greater freedom but recognised the importance of all programmes that were accredited met certain standards. About one-fifth (18%) of respondents would prefer less prescription to be applied.

The introduction of common frameworks for the accreditation of programmes or even joint visits would help to reduce an academic's preparation and time commitment to accreditation. However, there was no general agreement for this as shown in table 3. Perhaps there was a concern that the most stringent rules would be applied! Respondents reacted very differently to the three questions in Question 16 with no overall pattern emerging. Joint visits which would reduce the need for multiple visits were not considered to be important by 82% of the respondents.

Table 3- Professional accreditation

Q16. Should the professional bodies be encouraged to develop a common framework of course accreditation?			
	Important	Neutral	Unimportant
Common framework	45%	45%	10%
Joint visit	18%	41%	41%
Extended accreditation periods	41%	50%	9%

Extending the accreditation period for programmes although considered by 41% of the respondents to be important half of them were unequivocal and a further 9% thought that this was unimportant.

Table 4 - Accreditation of undergraduate programmes

Q17. How important is it that professional bodies continue to accredit undergraduate level programmes?			
	Important	Neutral	Unimportant
Short term	82	13	5
Long term	59	36	5

As stated earlier the accreditation of programmes is important for the continued health of a programme. Without accreditation and, especially in times of recession, programmes will fail to attract sufficient students to make them viable. It was not surprising therefore to find that 82% of respondents thought that the continued accreditation of undergraduate programmes was important. The fact that 50% of 18 year olds are now studying in higher education may cause professional bodies to review the accreditation of undergraduate programmes at some point and concentrate on postgraduate programmes only, remains a distinct possibility in the future. This is partially recognised by these respondents where a shift in their views is shown in table 4.

2.7 Assessment

There was a distinct feeling amongst half of the respondents that assessments under some form of controlled conditions would be increased in the future. This was possibly due as much to the problems of plagiarism than to any real shift because of educational reasons. It is felt by some that staff are finding that with the considerable increase in student recruitment, the marking of course assignments in their current form is becoming unmanageable. A majority of the respondents (64%) felt that there would be no shift either way with unseen student assessments. However, approximately 45% of respondents indicated that there was likely to be an increase in continuous assessments.

Sixty percent of respondents thought that work based learning should be more formally assessed. Respondents with high numbers of students on part-time programmes were more likely to consider that some of the assessment might be carried out through work based learning. Respondents from those departments that had relatively few students on part-time programmes recognised that unless some form of work based learning was introduced on a full-time programme this would not be possible. Also those respondents who were more representative of property were more likely to feel neutral about this question.

2.8 Other Concerns

Respondents were asked to identify the three most important issues facing the disciplines of construction property and surveying education. The four most identified issues are listed in table 5. The numbers indicate how often this issue was raised amongst the 22 respondents.

Table 5- Major issues identified by respondents affecting construction, property and surveying education

Staffing (18)
• Recruiting the right calibre (experience and research) of staff
• Maintaining quality academic teams
• Difficulty in recruiting staff with strong research records
• Succession Planning re academic staff
Commerce and Industry (11)
• Work based learning
• Engagement with industry and practice
• The skills gap agenda
• Training v education
Students (7)
• Demographic Trends 2010 - 2020
• Attitudes and expectations between full-time and part-time students
• Enhancing the student experience
• Increasing the number of female students on these programmes
Research (5)
• Integration of research with practice.
• Importance of research-led teaching materials
• Difficulty of creating and developing research active staff
• Post-RAE research strategy

By far the greatest issue revolved around staff; the key resource. Most departments faced the same issues of recruiting staff who had work experience and who wanted to both teach and undertake research. Some departments are considering enhancing salaries in order to entice staff in to an academic career. This has been tried, with some success, in other subject areas. Retaining staff was less of an issue although maintaining academic teams in the future is of concern. Ellis and Wood (2006) commented in their report, *The future of surveying education in universities*, that half of all academics under the age of 45 were considering leaving their academic positions.

The second most important issue that was raised by respondents was the links between universities and practice. Whether teaching-led or research-led this was considered to be an important issue since such links provide relevance to programmes and students and to the research focus. Student matters, was the next consensus issue with a range of issues that included the different attitudes and expectations between full-time and part-time students. Research and the difficulty, for example, of both creating and developing research active staff was a concern of a number of respondents. Other issues included the following:

- The cyclical nature of education.

- Recognition within universities about the importance of construction, property and surveying.
- The tensions between education and training and producing students who were fit for purpose.
- Competition from other professions.
- The belief that architecture and civil engineering had higher profiles within universities and clearer objectives in practice.
- The recognition that these programmes straggle technology and business yet do not fit easily in to either.

3. Conclusions

There are of course many other questions that could have been asked of respondents of department in managing their departments in today's educational climate. Reading the foregoing could represent a view that all is doom and gloom, yet this is far from the truth. Whereas ten years ago many such departments were under threat of closure and some did cease to exist, today the picture is very different where such departments represent a net gain to universities. But there are warning signs that departments need to address. Some of these have been identified above from this survey of Heads.

Abstract

Surveys carried out in recent years in higher education have shown staff suffering from high levels of stress with many finding their workloads unmanageable. This paper reports findings on workload allocation (WLA) practices in higher education based on sixty-two interviews across seven UK universities, two overseas universities and two other knowledge-intensive organisations.

The focus is on the social aspects of the process through cross-case analyses of: the role of the Head of Department/School (HoD/S) and issues of equity and transparency. The complex dynamics between these factors is revealed using a cognitive mapping technique, which highlights that, in addition to technical issues, consultation is pivotal. This has consequences to both the WLA process itself and underlying aspects such as trust and equity.

The paper concludes with a set of connected recommendations. The dynamic, interactive approach proposed should help to facilitate a collegial response to enhance WLA, anchored on the basis of a *Socio-Temporal Contract*, where work is not viewed in just the one dimension of time, but rather as part of a richer network of relationships that require attention.

Keywords: Higher education**,** Workload allocation, Consultation, Equity, Socio-temporal contract.

1. Background

The challenges facing the HE sector have been much commented on [1-3] with many pressures within it, not only from resource issues [4], but from factors such as the move to a mass market, tuition fee increases, and pressures from quality review systems. This presents a challenge for leaders and the style of leadership appropriate to various contexts has been widely discussed [5, 6]. It has also been recognised that special problems exist for leaders at the level of the HoD/S, because of a dual identity as manager and colleague [7, 8]. Various surveys have also been done on academic staff, both in this country [9] and in Australia [10, 11], whose HE sector has parallels with the UK. These surveys, although large, had fairly poor response rates of around

25%. Although this raises questions on representativeness, the findings make interesting reading. For example the Kinman and Jones survey [12] found that 69% agreed or strongly agreed with the statement 'I find my work stressful'. Further strain indicators showed that 50% of the sample had borderline levels of psychological distress (p27). However, interestingly, the psychological well being measures used (Goldberg D, 1981,) showed surprisingly low correlations (0.12) with the average number of hours worked in term time (p63). Most pertinent to this study was that in answer to an open question on improvements to minimise work related stress one of the most commonly mentioned items was 'the need for a managed allocation of workloads and transparency in workload planning' (p47).

The study by Winefield et al [5] also explored the area of strain and looked to factors such as the balance between demands and control at work, [13] and models that look at mismatches between worker's ability and job demands [14]. This individual response, or interpretation, of environmental stressors is felt by many to be pivotal [10, 15-19]. It might explain the complex and often unexpected relations between stressors and outcomes, and the problem of identifying the actual source of a strain. The findings of these surveys go some way to show the complex issues at play in relation to work strains and job satisfaction for academics.

Burgess [20] has carried out one of the few studies on workload planning in higher education looking at three establishments. The study concluded on three key criteria for systems: equity, transparency and the alignment of staff with strategic goals of the institution. These findings together with the survey results suggest the importance of the social aspects of workload allocation, for example on communication and trust. Much work has been done on these mechanisms, such as how information flows affect commitment. Thornhill and colleagues [21] look at how this commitment is also affected by a range of other factors such as personal characteristics, role characteristics-including aspects such as role conflict and autonomy, and also to expectations in terms of fairness over decisions and leadership styles. Thornhill's study looks at the relationship between the nature and style of communication and reports a significant, but not causal relationship with staff commitment. Another related study [22] looks at what commitment is focused around, for example agents or values, and describes how this dynamic may have a part in reinforcing social arrangements. However an interesting area in workload allocation might be to look at when the foundations for commitment diverge, for example divergence between commitment to an agent, such as a Head of Department/School, and to a value such as equity. Situations can, and do, occur when a WLA model is not seen to be completely fair, but commitment to a HoD/S makes staff disinclined to object. Trust and expectations of behaviour are at the heart of these issues [12, 23] and are a vital aspect of the HoD/S and staff dynamic. These studies reveal the complexity that will lie behind workload allocation processes, which have to operate beyond the merely technical aspects of allocating work.

2. Methodology

Out of the initial literature synthesis a loose framework of issues emerged surrounding the subject of workload allocation, but as this particular field was relatively undeveloped the approach had to be one of theory building rather than testing. Having reviewed the various alternative ways of analysing qualitative material Grounded Theory [24] was chosen as being appropriate methodology to such a complex social issue, founded on multiple perspectives of a real world with an emphasis on theory building. It involves inductively building up theory through comparisons of the same event or process, but in different situations, with findings emerging progressively through the various analyses. Within this a case study framework seemed the most fitting way to capture the interaction between university and department/school level rather than interviewing discreet individuals, and with interviews the best method to capture the rich material. In order to strengthen the research approach it was felt that it would be helpful to compare these practical findings with related theoretical works as described in Soft Systems theory [25]. Further to create a focus in the study, in line with Checkland's theories [25], it was useful to identify the particular *Weltanschauung*, or world view. This could be individual staff members, university leaders, heads of departments or schools (HoD/S), union representatives and so on. As the study was involved with the interfaces between individuals, departments and university the most appropriate perspective seemed to be HoD/S.

3. Fieldwork and Analysis

To maximise the robustness of the findings, the research design stressed achieving triangulation from a rich variety of sources [26]. So the universities themselves were not selected randomly, rather they were chosen to give a broad picture across the sector, so that size, geographical location and type of university grouping were taken into account, using the groupings as set out in the UUK 'Patterns of Higher Education Institutions in the UK: Third report' [27].

Further to help to get a broad view of the process the interviews were designed to cover a range of staff at each university. In each, two lecturers and their respective HoD/Ss were interviewed as well as a senior University staff member, and representatives from Personnel and the union body. A semi-structured questionnaire was used as a prompt rather than as a directive tool. Ethical procedures were followed throughout: in the interviews, their recording, and storage and use of material.

The general procedures set out by Strauss and Corbin [15] provided a guide to help with the coding of the documents using NVivo software. This involved the comparing of phenomena leading to groupings under general category names (open coding). After completion of the coding, case analyses for each university were written, covering the main phenomena, such as allocation methods and equity. Following on from this a cross case analysis (axial coding) was carried out looking at these phenomena, in all the cases. Then, building from this a framework was developed of the contexts, actions and consequences (C/A/C) pertaining to phenomena. This helped with the final phase of Selective coding in which narratives are constructed about the central phenomenon. In this case the core focus on workload allocation had been clear from the start and, drawing from the C/A/C framework described above, Decision Explorer software [21] was used to develop cognitive maps to help show the major relationships between the various categories around this focus.

An earlier paper [4] has concentrated on the more technical aspects of the findings. In summary three main approaches to workload allocation were identified: *informal models* relying on the HoD/S to share out work taking into account preferences, specialisms and competence issues, *partial models* that put only some aspects of the work into a model, and *comprehensive models* that included all the main work types, of research teaching and administration, in their models. The focus here will be on the social aspect including: Head of Department and the consultation process; issues of equity and transparency; and the individual response, using cognitive maps to illustrate their relationship. Finally a longitudinal case study was carried out to see the how perceptions changed a few years after a new model had been implemented.

4. Findings

4.1 Head of Department and Consultation

HoD/S did feel workloads were high and felt that WLA models were needed to help achieve equity. Yet there was also a feeling that not only did HoD/S themselves need the discretion to make adjustments, but ultimately staff had to make their own assessment of work priorities. Most HoD/S felt that they had been consultative over the introduction of, or amendment to, WLA models, discussing aspects such as weightings for roles (cases 1a, 1b, 2b, 3b, 4a, 4b, 5a, 5b, 6a, 6b, 7a, 8), although this process was not always successful. Even when there was consultation HoD/S noted how difficult it was to know all the issues, with size of department an important element here. However where staff had become actively involved in the overall process their awareness of the complexities of the problem of WLA had made them more supportive. Often HoD/S had inherited a model and continued to run it without too many problems (cases 1a, 2b, 3a, 8a, 8b), but there was often resistance to any changes to the existing system. Indeed the introduction of new WLA models was often greeted with suspicion.

Heads discussed their role in mentoring staff, encouraging and at times challenging those who were not fully engaged. They also frequently discussed the issue of personalities, often this was in relation to staff who were motivated and almost overstretching themselves (cases 1a, 7b). Although HoD/S stressed how hard it was to find time to fine-tune the allocations to individuals, and some delegated this aspect. The importance of this local monitoring was highlighted in one of the universities studies that ran a ‘Well Being’ survey every year, which revealed large variations in stress levels. Not only did academic staff have significantly higher stress levels than other staff groups, but also that these levels varied between faculties, so that some faculties had double the average rating of others.

Staff interviewed seemed to generally have good relations with their Head of department and quite high levels of trust appeared to be operating, although feelings on the system used were often less positive. Honesty and openness were appreciated, but there were a few instances of staff feeling unsure of the plans of their HoD/S (cases 1b, 2a, 3a), and others did suggest that communication of plans was sluggish (3a, 4a, 7b). Where staff had had anxieties and concerns over their work, the reassurance given by HoD/S had done a lot to mitigate the stress of the situation. There was, reportedly, a degree of conflict between a small minority of staff and their

HoD/S in a few academic units, often focused on problems surrounding workload allocation, sometimes in relation to contracts of employment (cases 3b, 8b), or the details of the model, such as marking allocations.

4.2 Issues of Transparency and Equity

Although many saw transparent systems as means to reduce tensions and to see the contribution of others, as with many things this could be seen from other angles. Some saw a danger of transparency, particularly if the model was detailed, as it could encourage staff to bicker over the details through divisive comparisons (cases 2, 5 and 8). The definition of a transparent system was also open to interpretation and there was a range between systems that named individuals and listed all their duties, to approaches involving just a summary document of the range of duties. Another aspect that emerged was that, even where decisions were transparent, the criteria for arriving at them was less so, for example why particular individuals got certain roles and how weightings for tasks were decided upon.

There was generally a belief that things were handled fairly within schools and departments, however this was somewhat hazier where systems were less transparent. The Head was pivotal to perceptions of trust and equity, rather than the WLA model itself. Further there was quite a lot of discussion about staff who tried to do the minimum and those efficient, amenable and diligent members that always picked up any extra tasks, each HoD/S had at least one such colleague. Work associated with research was mentioned frequently as the aspect that accounted for the most diversity in loads. In teaching, marking and assessment were also areas frequently highlighted as being potential problem areas in relation to equity, because of differences in class sizes and so on. Additionally most staff seen felt that there was an unwelcome rise in the amount of administrative work that they had to do.

4.3 Relationships between factors

As described in the methodology section case study data and *the context actions, consequences framework* were used to create cognitive maps. These led to an understanding of how the various categories interacted and built to a broader picture of the mechanisms and relationships at play. A range of different maps were produced, for example a complex one showing the entire set of relationships and another type of map that identified a main perspective or W*eltanschauung* for the analysis [25]. In this paper the HoD/S view was chosen as this seemed to be central to the process. See Figure 1 below.

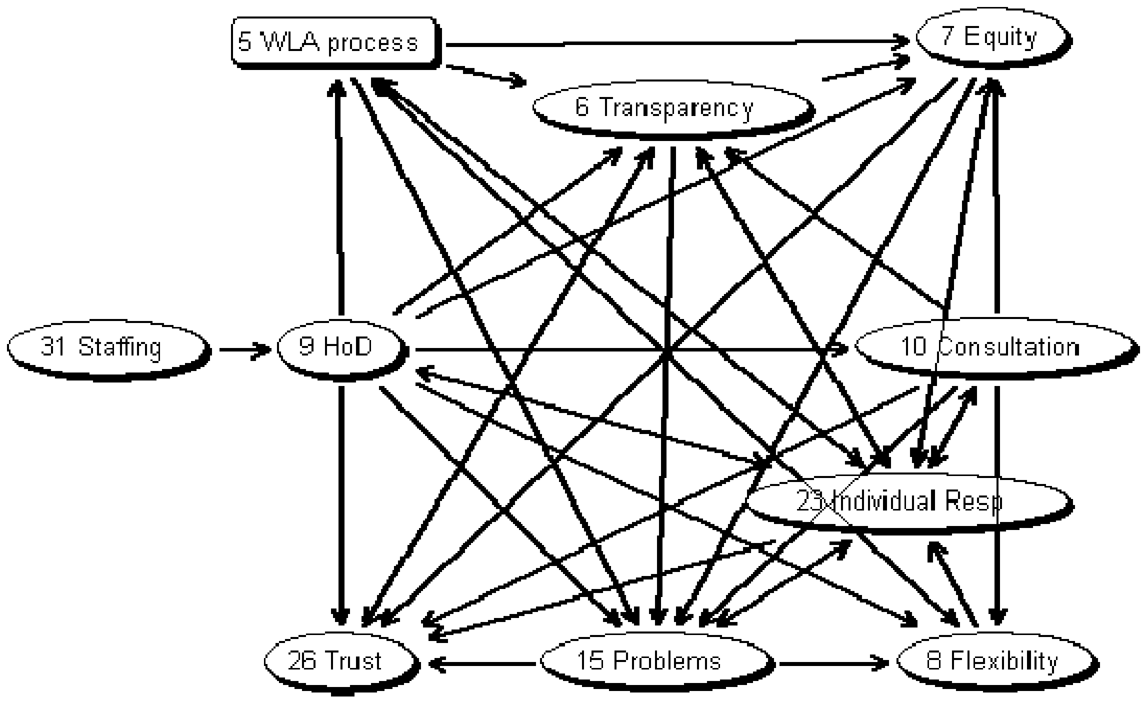

Figure 1: "HoD/S" View (excluding organisational factors)

This map shows factors involved such as Trust, Equity, Flexibility, Consultation and Staffing. However the university Organisational factors and Systems nodes that connect to just about everything have been hidden from this view in order to see the more direct influences more clearly. The broad split is between 'hard' factors, such as the calculation and allocation of workloads, and 'soft' factors, such as transparency and equity. Staffing is a contextual factor for the HoD/S, but the node Consultation, driven by the HoD/S can be seen to impact on many of the other nodes: WLA Process, Trust, Equity, Transparency, Flexibility and Problems and the central Individual Response. However the Trust node also follows as a consequence from HoD/S, Equity and Transparency nodes, but without a direct connection from WLA process itself, suggesting the importance of these 'soft' mediating elements within the process. The frequency with which these elements are connected with reciprocal links illustrates the dynamic interrelationships, where past actions and their consequences create the conditions for future exercises mediated particularly through the absence or otherwise of trust.

So the map, taking the perspective of the HoD/S, reveals consultation to be pivotal, with consequences to both the WLA process and factors such as trust and equity. This finding was then reviewed using data from the case studies. Perceptions on equity and trust surrounding the HoD/S allocations were evaluated in relation to the consultation process involved in the development of a WLA model and also and the fine tuning of allocations to individuals. A summary table show these findings below.

Table 1: Social Aspects of Model Development within Academic Units Against Perceptions on Equity and Trust, by Technical Model Groupings

Group	Case	Developing model (unit level)	Fine tuning to Individual	Perceptions on Equity	Perceptions on Trust
Informal Model	2a	Negative	Negative	Neutral	Neutral
	3b	Negative	Neutral	Negative	Neutral
	6b	Neutral	Positive	Positive	Positive
	7a	Neutral	Positive	Positive	Positive
	7b	Negative	Neutral	Negative	Neutral
Partial Model	1a	Positive	Positive	Positive	Positive
	1b	Positive	Neutral	Neutral	Neutral
	3a	Negative	Neutral	Neutral	Neutral
	4b	Positive	Positive	Positive	Positive
Comprehensive Model	2b	Positive	Positive	Positive	Positive
	4a	Neutral	Positive	Positive	Positive
	5a	Positive	Positive	Neutral	Neutral
	5b	Positive	Positive	Neutral	Neutral
	6a	Positive	Neutral	Positive	Positive
	8a	Neutral	Positive	Positive	Positive
	8b	Neutral	Neutral	Neutral	Positive

It must be noted that the findings do not indicate any absolute values and work off comparative, subjective assessments of the researcher, looking across all the data. Neutral responses were often non-committal responses made due to a felt lack of evidence, for example on the loads of others in relation to equity.

- The actual type of technical model alone used seems to be relatively independent of beliefs on equity, as all three model types had cases showing positive perceptions on equity and trust at unit level, although only the informal model had any negative perceptions.

- A fairly consistent relationship operates between perceptions on equity and those on trust at academic unit level.

- However a far more complicated relationship appears to be operating beyond the technical aspects that involve perceptions about the HoD/S and areas such as fine tuning or individualising the allocation, that is the, social aspects. So for example where fine-tuning to individuals has been positively addressed this almost invariably leads to positive perceptions on equity and trust. Notably within the Informal model neutral or negative responses are more random and reflect the absence of any objective measures for individuals.

- The comprehensive and partial models did have higher positive perceptions of equity than the informal model with 57% and 50% respectively, compared to 40% positive response in the informal cases. These tendencies might be related to more inclusive social procedures (see above), suggesting that these HoD/S have not relied alone on the technical aspects of their model, and perhaps that its development had facilitated the social process and the ongoing more transparent process. However as many of these systems were fairly recent the permanence of this effect will need to be assessed.

- The notable exception to this general trend is case 5 where in both cases perceptions on equity were lower than might be anticipated from the fine tuning and development processes, this was due to perceptions generally that online teaching methods were causing problems that were not being addressed. This issue alerted us to the potential for deterioration in the process as a consequence of some contextual change, and the need to test this out looking from a longitudinal perspective.

- A longitudinal case study was carried out and this revealed that the consultation and fine-tuning process had been neglected in the years after the model had been developed and that this had had some adverse effects on perceptions on equity.

5. Conclusions

Despite the variety in practices there was broad agreement on ideal principles in relation to these methods, for example on equity and transparency. The findings suggest, irrespective of the technical model used, that consultation processes play a large part in forming perceptions on equity, which seem to have a strong relationship with the trust operating.

Moving from the current position and informed by the analyses reported in this paper a set of connected recommendations will now be put forward.

5.1 University level

Universities often had a policy on workload allocation that called for equity and transparency in the systems, but guidance needs to given at a more practical level to overcome the potential problems in choices between aspects such as quality and equity, and the problem, frequently seen, of overloading competent and more cooperative staff.

A framework for workload allocation might assist HoD/S in the development of their model, but training and advice for Heads is required on how to customise the framework model to their department through consultation processes.

5.2 Academic Unit Level

As shown from the cognitive mapping in Figure 1, consultation should be central to the development, and use, of whatever system is used to allocate work, as can be seen from the related outcomes in the areas of equity, trust and transparency. Case evidence has shown that where radical changes are being made this process benefits from an approach that incorporates a pilot study, with feedback and modifications. Such a double loop process seems to facilitate staff engagement with the process, and reassure those staff resistant to change.

Further this process need not be seen as monolithic, as individual consultation should also be done between staff and HoD/Ss, or their representative, so that using judgement and discretion the overall model can be fine tuned to optimise equity within it. However if the HoD/S does delegate this aspect to another, such as subject group leader, the HoD/S will need to review workloads over all the areas to ensure that equity is operating across the spread of work engaged in.

A danger with a comprehensive model seems to be overdependence on the technical aspect and less emphasis on the consultation and review aspects. A model might be perfectly equitable, but staff need to have some idea of how decisions are made and what impact their representations have had to their overall allocation. This longitudinal case highlights the importance of the fine tuning aspect, but interestingly the benefits possibly derived from the initial act of collectively creating a model can be lost if those social dimensions are neglected and there is not an ongoing, collective, dynamic ownership of the system. Such monitoring might pick up disquiet for example brought on by contextual changes, such as a move to more online teaching, that alter perceptions on equity.

Through these processes consideration could be given beyond just the technical model and the overall balancing of work to aspects such as how the work arrives, patterns and distribution of work. For example case studies showed that workload peaks caused stressful conditions for staff that some HoD/S had actively managed by working with central university. This sort of understanding could form the basis of a *Socio-Temporal Contract*, where work is not viewed in just the one dimension of time, but rather as part of a richer network of relationships that require attention. This of course draws on the notion of psychological contracts, an idea with a long history starting with Agyris [28], carrying notions of organisations and their staff negotiating a "social as well as an economic exchange" (p114). The specific idea here draws from Vischer [29] where the analogous "social-spatial contract" is introduced, highlighting the social complexities of managing work-spaces for staff.

In relation to workloads the "temporal" aspect expresses the more subjective experience of time. For example teaching contact hours are not just objective measures, but are informed by other aspects such as whether the teaching material is new or repeat, how the contact hours are distributed through the week and the diversity of tasks involved. This type of approach with a broad understanding of what is fair and reasonable built up across the department/school (the "socio" part) and supported by a consensually agreed model could assist in delivering allocations that are perceived as fair and are effective in practice.

Abstract

Awareness of climate change and adaptations of building stock play a key role in the UK government's environmental agenda. While some European countries and countries like Japan move forward by bringing their sustainability agenda to the public sector, the UK seems to be slow in embracing these ideas and long term sustainability in improved products and processes for better performance, efficiency and innovative application of renewable technology is yet to come. While funding remains a major constraint research show that a number of detrimental issues including; organisation, risk, mind sets of the stakeholders, planning constraints, reluctance to accept change and the unexploited markets are major contributing factors. Most of these barriers can be overcome with research, development and information and knowledge transfer techniques. Educating all stakeholders can act as an accelerator for innovation. This paper examines innovation in the built environment and how research and education can stimulate this process. It explores drivers and barriers for innovation and how research and education in construction, design, engineering and project management can enhance this process. It presents and discusses lessons learnt from two action research projects in relation to innovation.

Keywords: Research, Education, Innovation, Built Environment, Accelerators of Innovation

1. Background

The current UK government believes that climate change is the greatest long-term challenge facing the world today [1] and has led the way with innovative policies, such as the Climate Change Levy and agreements, Renewable Obligation and Energy Efficiency Commitment. In its new climate change programme, the government set itself many targets that are to be achieved in each sector. In the timely 'Climate Change Review', Stern states that the first essential element of climate change policy is carbon pricing, followed by technology policy, which is vital to bring forward the range of low-carbon and high-efficiency technologies that will be needed to make significant cuts in emissions. Policies to remove the barriers to behavioural change are stated as the third critical element. Also, 'research and development, demonstration and market support policies can all help to drive innovation and motivate a response by the private sector’ [2].

All stakeholders need to be committed to this process and provide as much flexibility as possible to achieve these targets. Many professional expertise and skills are needed. Planners, Designers, Surveyors, Architects, Civil, Mechanical and other specialist Engineers and consultants, specialist builders, workers, need to collaborate and participate in this process establishing a knowledge and skills base from which organisations can benefit and stimulate innovative procurement processes in delivering the quality standards that are expected. Alongside companies that are already taking action to cut their emissions, and those that are developing innovative low-carbon products and services, professional and educational institutions need to be aware of the challenges that are facing them in enhancing the knowledge and skills. Long-term investments are needed in terms of research, training, continuing professional development programmes, incentives, etc. Many new professions and specialities are emerging as a response to the increased corporate property and asset management programmes. Environmental management and planning is now considered as a new field of professional expertise [3]. Energy consultants are in high demand. These aspects raise the questions of formal training in higher education, for new type of professionals.

Innovation in the current context has to incorporate issues of social, environmental and economic sustainability, where quality of life issues are given a high priority. Developing a culture of innovation in organisations and industry appears to be vital in triggering innovation. The main driving forces are the ideas of stakeholders; customers, management, marketing personnel and production personnel, as they focus on problem fixing and developing new ideas. The lack of proper qualifications, training, access to cutting edge knowledge and technology, fear of taking risks, the culture and mind sets of the particular organisation could all be contributing factors. For an organisation to be competitive specialist skills, consultancy services and professional expertise are needed. The thinking has to move away from the traditional box and consider whole life values rather than short term demands, profits and balancing books. This new way of thinking can be stimulated by research and development within the organisation or externally, exposure to innovative technology and projects, promoting best practice and specialist training. While some European countries and countries like Japan move forward by bringing their sustainability agenda to the public sector, up until recently the UK seems to have been slow in embracing these ideas. A number of reviews of the construction industry provided waves of re-structuring and re-inventing, but long-term sustainability in improved products and processes for better performance, efficiency and innovative application of renewable and low carbon technology serving the built environment is yet to come. While funding remains a major constraint there are many other issues that directly or indirectly influence this process [4].

Research related to the construction industry tend to be multi-disciplinary, long term and challenging. In most cases they are disseminated through refereed journals and ‘these may not be the most appropriate forms of output either for improving knowledge through academic discourse or for dissemination to industry’ [5]. Traditionally universities provided education and skills to students as well as carry out research within particular disciplines. A well defined peer review process established quality and clarity and a clear demarcation of public and private was established. Private consultants and other organizations provided knowledge to private commercial organizations and the government. In the current context, the distinctions between public and private boundaries are distorted. Universities are involved in consultancy, and industry has become a significant participant in scientific research and training. Thus, education & professional institutions and research organisations need to allow for diversity, new ideas, disciplines and forms of knowledge. The need and the rise of new fields of study put pressure on the education and professional system to be flexible and innovative to respond to new opportunities and developments. The intention of this paper is to examine some key issues that are important in accelerating innovation in the built environment and how research and education can stimulate this process. It briefly looks at the process of innovation, explores drivers and barriers for innovation and how research and education in construction, design, engineering and project management can enhance this process. The paper summarises lessons learnt from two Engineering and Physical Sciences Research Council (EPSRC) funded research projects to illustrate factors that promote or hinder innovation. The discussion examines the accelerators of innovation in relation to education and research, including the importance of educating all stake holders, the role of the professional and research organisations and the crucial role played by the correct mode of dissemination of the research. The role played by the government in focusing attention on new opportunities for innovation, and an organisations capability in absorbing research into practice are also discussed.

2. The Innovation process

Innovation process is defined by experts as ‘the successful exploitation of new ideas’ [6] which results in ‘enhanced performance and delivers objectively new or improved services to the user’ [7]. Recent authors have stated that ‘innovation is not a discreet or entity, but a socially mediated process that results from, and contributes to, a range of systemic relationships and interdependencies’ and ‘from organizational, managerial and individual practices and decisions’ [6]. Their view of innovation is as a socially constructed and not technologically determined process, noting by way of introduction that ‘innovation is, and will remain, a socially determined and hence unpredictable process’ and concluding that ‘technological change requires associated social, organizational and managerial changes’. There is also a consensus that innovation is risky, requires significant investment and is often resisted within firms [8]. Innovation is often categorised according to whether it involves the development of a new product- by a new or established technique- or the introduction of new processes for producing an established product [9]. While many people associate innovation with major technological or organisational advances, the vast majority of successful innovations result from a stream of small incremental changes which may individually have only limited effects on consumer behaviour [10].

2.1 Innovation in the built environment

Innovations in the built environment are often a complex blend of government, business, and market and consumer decisions. The main rationale for innovation in the built environment is economic benefits related to cost reduction and quality improvements. Other rationales include tackling environmental and structural problems and achieving public policy objectives. The rationale for government support of innovation in the housing industry focuses on the social and economic importance of housing. It acknowledges the value of innovation and the social benefits to be obtained from improved industry performance and the need for government funding in order to offset the industry's characteristic under-investment in innovation activities. As evident from the results in Case Study One, government support can be crucial for innovative projects to sustain their investment in a competitive housing market. Consumers also rely on the government for protection against failures in the system. Given the problems facing building innovations (risk, invisibility, uncertainty, cost of failure and correction, 'trialability', and difficulty in establishing relative advantage in the short term) consumers probably expect government and building officials to be conservative in their acceptance of innovations. Reducing risk may be as important to homebuyers as cost savings. If so, time-honoured technologies and processes will not be abandoned without ample evidence that their replacements will perform as expected. This socio-cultural fear of change and risk is deep rooted, difficult to change and forms a major barrier in bringing innovation to the housing sector. Information sharing and responsive communications can contribute in combating these fears.

Innovative processes can be easily adopted in new construction and the complex problem lies with the existing built environment. The UK has a fairly mature building stock which must be taken into account if a significant change in environmental performance is to be achieved. New buildings only add between 1-5 % of the total building stock each year [11]. Intelligent application of advanced 'smart' facade technology in conjunction with innovative environmental systems can result in significant energy savings and – at the same time – improvement of indoor comfort. Case Study examples from Research Project 2 illustrate that very little innovative environment technologies are implemented in the refurbishment of the existing housing stock. While initiatives such as 'Decent Homes Programme' [12] is intended to improve the environmental performance of dwellings, they sometimes achieve the opposite results, as housing authorities treat these schemes as vehicles for obtaining more funding rather than achieving sustainable dwellings. Research shows that when there are opportunities to employ new and innovative technologies in refurbishment, housing authorities implement basic or out-of-date technology to update their stock due to tight budgets and fear of risk [13].

There is a need for more government investment and research, alongside commitment from industry to provide a driving force for a future renewable technology markets. This would lead to augmented markets which in turn increase the demand and the supply in mass production, bringing the costs down. In Photovoltaic technology, 'Britain is losing out to countries that have created a large market, by introducing market stimulation measures and low manufacture costs' [14]. The lack of market demand is one of the major factors preventing the growth of PV, and subsequent employment, in the UK on a larger scale [15]. Many countries including Germany, Japan, the Netherlands, Norway and the USA have initiated programmes of government investment, in collaboration with industry, which have lead to thousands of solar electric homes being built around the world. These increased markets offset the high costs, which has led to employment opportunities in the PV field, as well as associated professions. Germany has established themselves as world leaders through extensive research, development and technological developments [16]. UK does not currently have a suitably large market to display its expertise in PV technology or the financial incentives to develop this market further.

3. Lessons from two research projects

3.1 Monitoring an innovation programme to examine Egan compliance in social housing in UK- (2001-2004)

Project one monitored a consortium of Register Social Landlords (RSLs) established to provide innovative high quality housing designed and procured in line with the principles set out in the Egan Agenda (1998). A strategic partnering arrangement was set up with a single contractor who developed an award winning modern pre-fabricated timber frame housing system. It was an opportunity to monitor and record the performance of 28 housing development projects and the roles played by a complex team network. As the RSLs agreed to procure 2000 new house units over a four year period (2001-2005), the research project exploited the opportunity to study a major innovation programme and identify what key lessons could be learnt. The main aim of the research was to set, monitor and compare the Key Performance Indicators (KPIs) and map the cause and effect relationships within the change programme. The selected contractor was the subject of several takeover bids by rivals and experienced a number of problems with both, the supply of the timber frame housing system and site personnel, which compromised the quality of construction and resulted in a high turnover of site-based operatives. This, together with other problems (outlined below) meant that the volume of demand initially forecasted never materialised. The details of the research methodology, data and analysis are beyond the realm of this paper and are published [20]. A brief summary is presented here.

The research methodology was based on case study monitoring and action research and a range of questionnaire surveys, detailed interviews with key project personnel, examination of site meeting notes and general feedback reviews were undertaken to identify good and bad practices associated with each project.

Key Lessons learnt from the initiative:

- All parties needed to be fully committed to the innovation programme;
- The level of demand required to sustain the contractor's performance should be ensured and risk management processes needed to be in place prior to commencing the project;
- Innovative procurement processes require a change in mindset at all levels within the organisations. Effective mechanisms should be put in place to ensure that everyone understands the joint goals and know their part in the overall process;

- Training was identified as an essential ingredient in this process. The lack of familiarity with the innovative approach illustrated the need for formal training for all project managers, prior to commencement of new projects. There was also the need for support systems in terms of knowledge and information to be in place for frontline staff;
- Communication and co-ordination, which lead to continuous improvement of services and products, emerged as some of the key drivers of the process; and
- Even though the government encourages initiatives, such as that monitored in the research study, there is little flexibility in support systems to assist in sustaining them.

A major drawback of the project was that, a continuous improvement process which would feed information from the site and different stakeholders who were involved with the project, was never implemented. The innovative timber frame system needed more research and development input to reduce the defects and the associated costs.

3.2 Stakeholder consultation for Sustainable Urban Environments Project (SUE_IDCOP, 2004-2007)

The SUE-IDCOP programme is responsible for providing the fundamental knowledge to underpin the improved sustainability of existing buildings. The overarching aim is to find ways to improve the performance of existing building envelopes which reduce the consumption of non-renewable resources over the whole building life-cycle in a way that is economically viable and socially acceptable. There are many innovative environment technologies that are readily available in the market. Case study examples here in UK and extensively throughout Europe show that these technologies can be used effectively and economically in new build housing. In UK, there is very little evidence of their use in routine maintenance and refurbishment. The current data on refurbishment illustrate that very basic building technology, sometimes unsustainable, is used to upgrade the dwellings. As part of the ongoing research, a number of stakeholder consultations were undertaken. Here, results from a pilot study done with 6 major housing associations to identify barriers in promoting innovative environment technologies in refurbishment are presented.

The aim was to identify and review the barriers that stakeholders face in promoting innovative environment technologies in social housing refurbishment. The consultation was carried out in relation to three sectors in the procurement of social housing; management, development and the maintenance sectors. It was considered under the following criteria: Energy peformance, Water performance, Waste management, Durability and Flexibility (Whole life performance), Health and well-being of tenants (Quality of life issues).

The results illustrated that:

- Value for money is a major governing factor and the benefits should outweigh the costs incurred. The RSLs work on a tight budget and unless it is proven that the benefits outweigh the capital cost, none of the new technologies are considered for implementation. The capital costs of most of these technologies are significantly higher than the available budgets and the potential cost savings in utility bills. The tangible benefits of employing renewable technologies are usually long-term and do not result in quick savings.

- The technology should be proven and fully demonstrated.
- There are quite a lot of products and systems in the market but very little information about their long-term performance, durability and ways in which they can directly reduce cost. More information about whole life performance and cost savings is needed and should be made available to the RSLs.
- Confidence levels in the new products are low due to high costs in demonstration projects and occupants and organisations are reluctant to take the risks.

All the above factors illustrate that there is a demand for more information, effective communication and research and development. Informing and educating tenants and organisations about the long term benefits and whole life cost value seem crucial in implementing innovative technologies. Research and development is essential to bring the cost down and increase market potential.

4. Factors that affect innovation

Factors that affect the implementation of innovative technologies define the context in which the industry operates. 'Three sets of factors that affect innovation and are controllable constitute elements to develop strategies to foster more innovation in housing. They are referred to as innovation accelerators, innovation barriers and contingent factors (factors which can foster or impede innovation, depending on how they are managed or implemented)' [19)]. The first major reason for innovation is economic benefit which can be reflected in increased profit, increased market share and business growth. Another reason for innovation is remedying problems which results in better performance and related economic benefits. A third reason is to achieve public policy objectives, such as energy conservation. The public policy rationale for energy conservation may well be environmental preservation; the private sector rationale may be reducing operating costs of homes or businesses and making profits by marketing improved products. The housing consortium monitored in research project 1, was set up to achieve a 'better performance at an affordable cost using factory production techniques' as was advocated in the Egan agenda (20)

Organisations and their structure have a major influence in the innovation process. Visionaries who have corporate influence can drive innovation and influence the market growth, but will need support from other organisations in stabilising the process and creating the demand that is needed to establish the market. Project 1 was set up solely by a visionary who wanted to achieve real change in the social housing sector. But as the lessons from this experience show, the organisational structure and the support which was needed to facilitate such an initiative was not present. The commitment of all parties, a changed mindset at all levels and better communications between all levels were crucial requirements to make the initiative a success.

The construction industry has a serious shortage of skilled labour and a skilled workforce is critical to an organisation's ability to innovate. Training and education are essential in the development of a skilled workforce. In Project 1, the contractor experienced many problems due to his inability to retain skilled workers. The lack of demand for the houses (mainly due to rival takeovers) slowed down the factory production and affected the retention of staff, which in turn affected the quality of the product. Poor quality products resulted in losing the trust and confidence of the consortium members and reduced the demand that was originally envisaged [4].

Risk is one of the main barriers to innovation. Innovators face many types of risk, including performance failure, market rejection, delayed or non-approval by regulatory authorities, rejection by trades/labour and liability. All of these risks have an associated potential financial loss, and the trend is towards increasing risk, particularly risk of liability. Results from the stakeholder consultations showed that many housing organisations are reluctant to implement innovative technologies due to fear of taking risks, and consider implementing only basic technology in their refurbishment programmes.

Financing innovation has always been a key problem. Small and medium companies find it hard to invest in research and development and hence break into new markets due to financial constraints. Research Project 1 shows that, in some instances, there are considerable upfront capital costs, but increased consumer demand and a greater market share will contribute to recover these costs. In Project 2, the housing associations were reluctant to spend the initial capital cost required, without having guarantees that they will be recovered within a limited time. Developers are also wary of implementing new technologies because of fears about consumer preferences. Consumer demand affects the supply and market investors and stock market analysts become concerned about investment in new techniques or products which may be regarded as risky. Project 1 showed that without sufficient demand, a new initiative cannot sustain itself. Lack of consumer demand, coupled with the inflexibility of building regulations and regulation administrators, are commonly regarded as detrimental factors for innovation.

The construction industry is heavily regulated by national and local regulations governing land use and planning, infrastructure and buildings. Literature reviews, experiences from the industry and research, indicate that regulations are a major barrier for innovation. In particular, factors such as lack of mandate to accommodate or foster innovation at the local level, and lack of empathy by local building officials to accommodate innovations, are detrimental to the process. It is the availability of incentives that promote innovation. These incentives could be of various forms, such as tax or VAT refunds, and targeted funding and support. Some incentives, such as compensation to offset costs of training trades on how to incorporate innovations may also be useful [4].

5. Accelerating innovation

5.1 Educating all stakeholders

Professional expertise and skills play a crucial role in supporting the Governments agenda to combat climate change and promote sustainable development. The requirements of the EU Energy Performance of Buildings Directive (EUPD) creates a large demand for; professionals who had specialist training in energy performances and sustainable construction techniques including the installation and maintenance of renewable energy alternatives, professionals who are aware and trained in new legislative practices and higher standards. With the establishment of the ‘The Higher Education Partnership for Sustainability’ [21] the government explores some of the key elements of good practice in integrating sustainability issues into the provision of all courses in the higher education sector. Based on existing good practice, it provides useful tools to help course designers identify and prioritise sustainability elements in any existing or new courses. The South East England Development Agency (SEEDA) is also working collaboratively with the region's businesses and universities to promote knowledge transfer, innovation and training. The lessons learnt from project one emphasized the need for training and information sharing in facilitating innovation process. New communication technologies can assist in co-ordinating this information.

The social systems surrounding construction, especially housing production, resist change. This could be due to inflexible mindsets, socio-cultural values, or simply fear of change or taking risks. In order to achieve the full benefit of innovative technology, the user has to be familiar with its use. Educating the occupier is crucial to overcome these setbacks. Research carried out by Sustainable Homes (2003) showed that, given the right information and control, tenants are happy to implement new environment technologies in their dwellings. Savings in utility bills can be a major incentive in this process.

5.2 The role of professional institutions

Employment patterns and the role of professional institutions play an important part both in retarding the development and uptake of new ideas. They often see themselves as guardians of ‘the discipline’, and resist radical change [5]. In the construction sector, many employees, especially engineers, architects and planners etc. are members of professional associations, who usually have their own publications which inform the members about new debates, methods of practice, new technologies, regulations and government policies. They also can play a key role in developing Continuing Professional Development (CPD) courses and activities which keep their members up to date with new developments of technology, research and knowledge. The traditional role of construction professionals as ‘knowledgeable experts’ may require augmenting with additional interdisciplinary skills to enable participation in teams of specialists [22]. The practice of ‘Expert advisers’ providing discipline-based knowledge at certain times is being challenged by new ways of organizing processes in which systems integrators and ‘knowledgeable team players’ are required.

5.3 The role of research funding organizations

The main funders of academic research aim to create new knowledge; educate and train people; and promote public trust, confidence and understanding of science and technology. But little is done about how this research could be put into practice and stimulate industry to maximise the benefits. The objective of the UK’s EPSRC, which is the main funder of construction related academic research, is to generate new knowledge that helps to improve and underpin industrial competitiveness and the quality of life, in collaboration with research users of all types which include design, engineering and construction organizations, client and user organizations, professional and trade associations, and government and nongovernmental agencies.

5.4 Dissemination of research

Dissemination is a key factor in benefiting from any research and development activity. Construction academics may not have the skills or resources to carry out the dissemination, technology transfer and delivery of results once research has been completed. This in turn influences the expectations of funders and industrialists and the capability to absorb and implement new ideas within the industry. In order to obtain the maximum benefit of research a complex feedback and learning processes has to take place through development and implementation. According to Gann 'the steps taken between research and impact are not usually sequential in nature, particularly in construction. Moreover, the experience of collaborative research projects indicates that interactive and iterative processes involving researchers and practitioners can produce valuable and implementable results before research is completed. Nevertheless, some research projects may not result in benefit for many years, whereas others may never result in measurable success – such is the nature of research' [5]. Publications can play an important role in knowledge formation and diffusion but may not be the best mode in certain types of construction research. CPD courses, workshops, conferences and seminars also facilitate the dissemination process. Currently there are many construction industry related forums that promote the sharing of knowledge and information with the patronage of the government or as independent bodies.

5.5 The government's role

Governments can enhance or slow innovation processes. Despite governments advocating innovation, there is little support to sustain the growth of innovation. Advocates for adoption of building innovations have to change building codes to enable builders and consumers to adopt any favored innovation. Government incentives in terms of tax benefits and funding can facilitate the innovation process. Clear government targets and patronage can make the construction sector embrace innovative strategies into practice. New innovative procurement methods and contractual reforms have to be introduced to achieve the targets set. Initiatives such as Partnering (PPC 2000), Private Public Partnerships (PPP) and Private Finance Initiatives (PFI) contractual agreements were introduced as a result of Latham [23] and Egan [17] reviews.

Current policy in the UK identifies the experienced client as the main institutional leader in stimulating construction innovation, yet doubts remain regarding a clients' ability to play this role. Nam and Tatum [24] show that a client needs to be technically competent in order to understand innovative proposals from systems integrators, and hence take the risk of innovating. The analysis of complex systems industries also suggests that more attention needs to be given to the two other elements of the innovation superstructure: the regulatory environment on the one hand, and the professional bodies, research establishments and universities on the other. 'It is the way in which the professional institutions carried out their brokering role that sometimes slowed the innovation process, and it was this brokering that provided the basis for the new regulations' [25].

The UK Government is committed to expanding its supporting programme for renewable energy technologies including research, development, demonstration and dissemination. The main hurdle preventing large-scale manufactures of photovoltaic panels in the UK is the current market, or lack of it. The understanding and potential of photovoltaic technology is improving, but further research and development is required to achieve cost reductions. It is important that strong partnerships are established between industry and government. Increasing environmental concerns and the need to achieve emission reduction targets should help the technology to become further established as a marketable and economically viable product [15].

5.6 Organisational capability to innovate

Cohen and Levinthal [26] argue that industrial research and development (R&D) not only generate new information but also improve the ability of firms to absorb knowledge developed outside the firm. The type of staff employed provides an indication of a firm's capability to develop, manage and utilize new technical knowledge. Other issues are equally important such as; organizational structure and culture, the nature of internal and external communications, coordination and feedback mechanisms, the ability to codify knowledge and the type and use of information and communications technologies [27].

Companies associated with fast-moving science and technology sectors usually invest more intensively in R&D than most construction organizations. By other industries' standards investment by government and construction firms in R&D is very low, particularly in the UK; this is not the case in some other countries such as France, Japan or Scandinavia [5]. It follows, from Cohen and Levinthal's argument, that lack of internal R&D capability in construction indicates that many firms are unlikely to have the capability to absorb the results of academic research, or work published in journal articles. Technological progress across the sector is therefore likely to be slow. When faced with the prospects of technological change, the majority of construction firms are recipients of innovation first exploited in other sectors, or by a few construction market leaders. Even when a firm has the technical competence to absorb new ideas, it may not have the internal structure, systems and cultural attributes necessary to capitalize on research results.

6. Conclusions

Awareness of climate change and adaptations of buildings form a key role in the current environmental agenda. Promotion of renewable energy and innovative environment technologies are essential to meet the targets set by the government. Government support mechanisms in terms of resources, incentives, providing opportunities and access for local and international markets, training and information sharing mechanisms all can foster innovation. The drivers of innovation are economic benefits, performance improvements, environmental upgrading, research, development and information and knowledge transfer techniques and access to markets. While the implementation of innovative technologies can be accelerated with the right government-lead incentives like subsidies, tax benefits, availability of resources and information; the removal of barriers will be equally if not more effective: less strict regulations or reduced financial risk. Risk is one of the main barriers to innovation. Organisations can control risk by researching innovative technologies to reduce the number of unknowns about them, establishing quality control measures to reduce product deficiencies and training staff to increase their competencies.

The accelerators of innovation are education, research, development and information and knowledge transfer techniques. Educating all stakeholders, including the occupants of the built environments, are essential in this process. There is a significant role for the universities and professional institutions to play, acting as repositories of knowledge and as an essential part of the knowledge production system. Together with research organisations they need to allow for diversity and allow for sources of new ideas, disciplines and forms of knowledge.

Government has a key part to play as a sponsor of higher education, academic research and as a facilitator in bringing academic research and industrial practitioner communities together in collaborative research projects. In the current context, interactions between academic researchers and industrial practitioners appear to be increasing. New models of collaborative research have emerged partly sponsored by the public sector and promoted by professional institutions. Management of research, correct mode of dissemination and implementation are important components in the process of absorbing research results into practice. Continuous improvement processes are important in feeding back knowledge from one project to the next. Technology transfer could take place through closer interactions between researchers and practitioners using new technology. Firms need professionally qualified personnel who work in technically challenging and specialist areas to absorb and act upon the results of academic research in the UK. They also need the internal technical support infrastructure which assists in learning between projects and which can improve their internal business processes by developing feedback and learning mechanisms. Current development in technology provide new opportunities in providing virtual environments in which mistakes can be made and rectified before implementation takes place on real projects. They could also provide new environments for learning and training. Communications in terms of intranets, internet, hotlines, and knowledge sharing databases all facilitate this process and support the dissemination of good practices and feedback on implementation of new ideas.

Abstract

The process of finding solutions to the research problem does not follow a clear sequential approach, but often takes unexpected turns due to the uncertainties of the research process and its outcomes. However, appropriate research design would be able to identify any problems and pitfalls that the researcher may come across during the process. In this regard, consideration of the research philosophy pertaining to the study helps a researcher in choosing the appropriate approach for a study. Not only the philosophical stance, but also the research problem under investigation and its underling circumstances influence the selection of a research approach. Accordingly, this paper discusses the factors that drive the selection of a case study as the research approach with particular reference to the use of single case study to undertake an in-depth inquiry regarding the impact of performance measurement towards construction research and development. Further, this paper discusses the incorporation of multi-phase, multi-perspective and multi-method approaches within the single case study to build valid theory.

Keywords: Interpretivism, Single case study, Performance measurement**,** Research approach, Research and development

1. Background

Research and development (R&D) activities play an important role within the construction industry by developing advanced and new construction materials, processes and management methodologies to successfully address its stakeholder needs. Further, R&D activities help to enhance the effectiveness and efficiency of construction processes and address resource constraints and sustainable goals [1, 2]. Moreover, R&D activities facilitate the exploration and creation of new knowledge and capabilities within organisations to help them compete successfully in the marketplace [3]. Hence, prioritising R&D activities, creating longer term R&D

programmes and increasing investment on R&D activities have been identified as vital factors for the growth of the construction industry ([4, 5]).

Due to rising costs, time and other resource constraints, much attention is paid on identifying the actual contributions from construction R&D activities, justifying and showing the accountability of resources spent, and ensuring outputs are aligned with expected goals. The inadequacy of mechanisms to evaluate the successfulness of R&D activities and the effective usage of funds has negatively affected these activities in construction (see [6, 7]). R&D has also become more complex, as it involves many stakeholders and has a wide range of interrelated activities [8]. Lack of communication and coordination between stakeholders and lack of clear objectives to address their requirements are evident within construction R&D. Consequently, these issues have lowered the investments for construction R&D and resulted in producing research results with low applicability.

It was revealed that, to address the issues within construction R&D, effective control and monitoring mechanisms are needed [7]. Thus, this study suggests the implementation of Performance Measurement (PM) within the construction R&D function to enhance its success (see [7]). The utilisation of PM systems within the construction R&D function would generate benefits including: evaluating the success of R&D activities; identifying the future improvement areas and required support for such activities; the proper allocation of resources, and improved communication, coordination and direction of employees towards common goals [7, 9]. Through the literature, it was identified that the concept of PM within construction R&D is not adequately exploited. Therefore, this study intends to address this gap with particular reference to its PM application. Accordingly, the aim of the study is to explore the influence and impact of performance measurement on the construction R&D function. To achieve this aim, following research questions are formulated:

- what is the importance of R&D to the construction industry?
- what is the current position of construction R&D function?
- what are the critical success factors of construction R&D function?
- how is the performance of construction R&D function measured?
- how can PM influence the performance improvement of construction R&D function?

This paper discusses the research methodology adopted for this study with particular reference to the use of single case study as the research approach. The paper first presents the philosophical stance pertaining to the study. Secondly, the selection of case studies as the research approach and rationale behind the use of single case study is presented. Next, the paper examines the phases and methods used during the single case study to build theory.

2. The research methodological design

The main intention of any research is to add value to the accumulated knowledge through the means of identifying, investigating and producing solutions to an unsolved problem [10]. The process of finding solutions to the research problem is “not a clear cut sequence of procedures followed by a neat pattern, but a messy interaction between the conceptual and empirical world" (Bechhofer, [11] cited in [12]). Booth et al [13] also agree with this view stating that "research follows a crooked path, taking unexpected turns, even looping back itself". Even though the research process is uncertain and risky, the appropriate research design would minimise the possibilities of any failure by identifying and forecasting problems and pitfalls that the researcher may come across. In addition, research design looks into the philosophical aspects of the research which in turn helps to identify the overall research strategy (collection, analysis and interpretation of data to draw up conclusions); evaluate various research methods and identify their limitations; increase the compatibility of research approaches and research techniques.

To design the research methodology logically and systematically, the researcher used Kagioglu et al's [14] hierarchical model. This model nests the research philosophy, approach and techniques (Figure 1) where the outer ring "guides and energises the inner research approaches and research techniques" [14]. Adherence to the nested model ensured the chosen research philosophy, approach, and techniques are compatible with each other and as a whole cater for the requirements of this study.

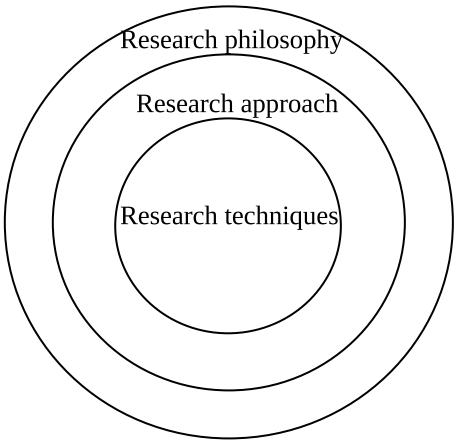

Figure 1: Nested approach [14]

Following sections further describe the research philosophy and research approach pertaining to this study in detail.

2.1 Research philosophy

Gill and Johnson [12] stipulate that there is no one best approach to research but rather a compromise between the options based on the philosophical understanding or basic beliefs about the world. Agreeing with this view, Easterby-Smith et al [15] also recognises research philosophies as the base for effective research design and argues that failure to adhere to philosophical issues can affect the quality of the research negatively. There are two main research philosophies - Positivism and Interpretivism - which can be placed at the two extreme ends of a research continuum [15]. Three assumptions can be identified within these philosophical stances i.e. Ontology, Epistemology and Axiology. Ontology seeks to identify the nature of the reality; Epistemology shows how we acquire and accept knowledge about the world; and Axiology indicates the nature of the values the researcher placed on the study [15, 16]. The following section evaluates how positivism and interpretivism is characterised with the ontological, epistemological and axiological assumptions.

2.1.1 Positivism

Positivism takes the ontological assumption of reality as having a pre determined nature and structure. This is known as “realism” [17] or “objectivism” [18]. Further, the positivist lies on the epistemological assumption that the properties of reality needs to be measured through objective measures rather than interfering subjectively through sensation, reflection or intuition [15]. Moreover, the positivist believes that the process of research is value free in terms of the axiological assumption [16, 18]. Thus, the researcher would detach from the research environment and takes the role of an independent observer without interfering with the research environment and would not allow the values and bias to distort the research results. In addition, the positivist uses deductive method i.e. abstracting a concept prior to testing it through empirical evidence [12, 15, 16].

2.1.2 Interpretivism

The Positivistic approach which was originally used to study the natural science was criticised when applied within the social science as the latter deals with human behaviours. It is argued that humans cannot be treated as objects and theories that lead into definite laws due to the fact that humans are influenced by feelings and perceptions. Thus, conversely to positivistic studies, interpretivism is based on the ontological assumption that the external world does not have a pre determined nature or structure but is created by the perceptions and consequences of humans. This is known as “idealism” [19] or “subjectivism” [18]. Further, interpretivist lies with the epistemological assumption that the properties of reality can be measured through subjective measures by examining the perceptions of people [15, 16]. Thus, rather than searching for casual explanations or for external factors, interpretivist admire the different views that people place on their experiences. This makes the researcher more closely interactive with the research environment unlike in the positivist studies. Due to this close interaction, the interpretivist believes that the research is value laden, thus choice of what to study and how to study is determined by human beliefs and interests [15, 16]. Further, the interpretivist generates ideas and theories inductively by getting rich data from the study itself.

Interpretivism can be identified as the most appropriate research philosophy for this study due to a number of reasons. To achieve the aim the study the reseacher was required to identify different views of the people regarding the importance, success factors and suitable performance measures related to R&D within the construction sector. Hence, the study valued and encouraged the free flow of ideas, opinions and perceptions of the people, and based on their experience within the research environment thus, considers the human interaction as the main driver of the study. Hence, the study takes the ontological assumption of ‘reality is not pre determined, but socially constructed’ and the epistemological assumption of ‘the knowledge is gathered by examining the views of the people’. In terms of the axiology, the study takes the value laden stance as it is believed that the researcher would add value to the study. The characteristics of positivism and interpretivism based on ontology, epistemology and axiology and the philosophical stance pertaining to this study (shown with a red circle) are illustrated in Figure 2.

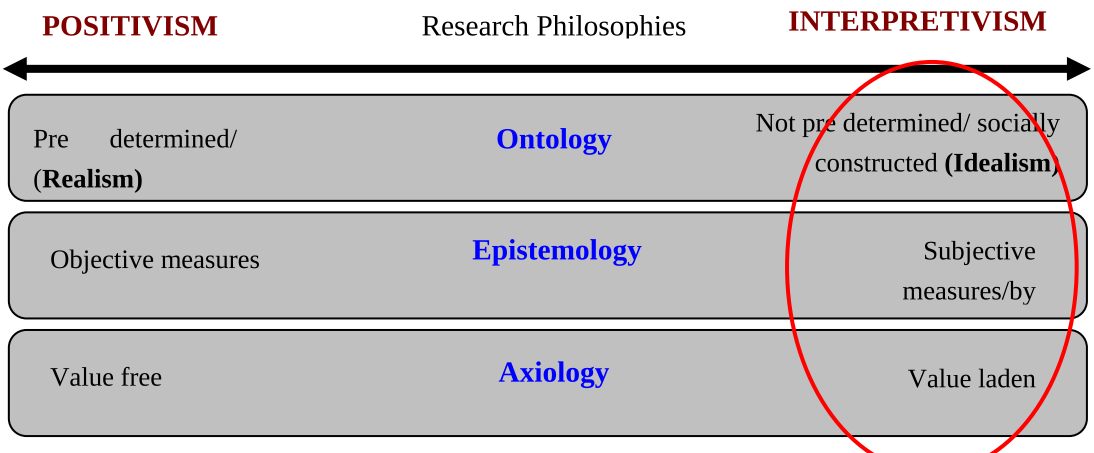

Figure 2: The philosophical stance pertaining to the study against the research philosophical continuum

Having identified the philosophical stance, the next section looks into the research approach governing to this study.

2.2 The research approach

There are number of research approaches where ones research can be based upon, such as experiments, surveys, case studies, action research, and ethnographical studies. Since the parameters are controlled and simplified with hypothesis, experiments are mostly associated with the deductive approach. Similar to experiments, surveys are also related to deductive approach [18]. Collins and Hussey [16] describe case studies as "an extensive examination of a single phenomenon". Unlike the experiments which separate the phenomena from their context, case studies are carried out within the rich, real-world context which the phenomena occurs [20-22]. As oppose to experiments and surveys, ethnographical studies are rooted within the inductive method. In the ethnographical research, the researcher uses the socially acquired and shared knowledge to understand and interpret the human activities [16]. Thus, this approach is suitable to investigate the characteristics of people, their societies and customs. Action research is based on the assumption that the social world is changing constantly and the researcher and the research are also part of the change [16]. Therefore, the researcher will become a part of the environment under study whilst trying to solve practical problems [23-25] and influence the attitudes and behaviours of the participants [26].

From the above discussion, it is evident that research approaches tend to favour deductive or inductive method based on the way they build theory. From the discussions in Section 2.1.1 and 2.1.2 it was revealed that the interpretivist prefers inductive method whilst positivist prefers deductive method. Therefore, by considering these views it can be claimed that the research approaches are likely to be harmonised well with a particular research philosophy than the *other, thus the selection of the research approach needs to reflect the philosophical stance of the study. Accordingly, the researcher plots the research approaches against the philosophical continuum (see Figure 3).*

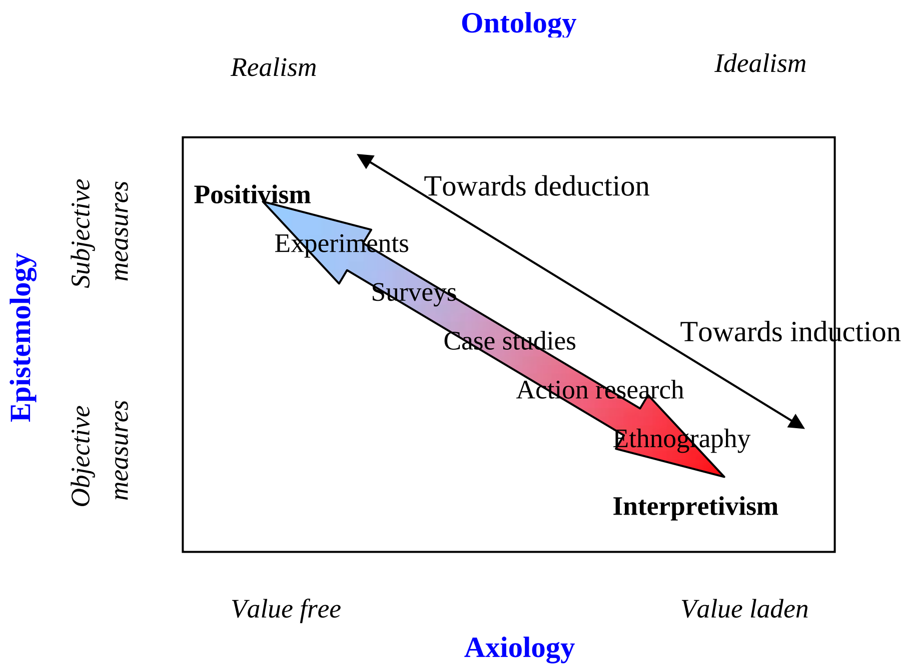

Figure 3: Research approaches within the philosophical continuum

Having developed the relationship between the research approach and philosophy, the following section justifies the use of case study for this study.

2.2.1 Case studies as the research approach

According to figure 3, experiments and surveys are more towards positivism while case studies, action research and ethnography are more towards interpretivism. Since this study takes the interpretivism stance with regard to the philosophy, the use of experiments and surveys are unjustifiable. Accordingly the researcher has to make a choice between ethnography, action research, and case studies. The research under consideration does not intend to influence or change the attitudes or procedures of the participants or the environment as in action research. Further, it does not intend to study behavioural patterns or psychology of the participants as in ethnographical studies. Hence, the case study approach is preferred for this study to explore the PM applications within construction R&D over action research and ethnography.

In addition to the philosophical stance, the research questions posed in a study influence the selection of a research approach. Yin [21] stipulates that "how" and "why" type of explanatory questions favour the use of case studies whilst "what" type of questions support exploratory research. This study consisted of "what" and "how" type of questions (see Section 1) thus, by using the case study research approach, much insight can be obtained firstly by exploring and secondly by explaining the phenomenon under investigation.

Moreover, based on the degree of focus on the contemporary events as opposed to historical events, a researcher can decide a suitable research approach. As Yin [21] states, case studies are more suitable to study contemporary events. Since this study considers a contemporary phenomenon, i.e. the impact of PM towards construction R&D, the selection of case studies can be further justified.

The above section provided three rationales for the selection of case studies; firstly considering the philosophical stance coupled with the requirements of the study, secondly based on the research questions posed and thirdly due to the contemporary nature of the study. The section below further justifies the selection of case study research approach by providing the added benefits of case studies and elaborates on the design aspects of the case study for this study.

2.3 Case study design

The unit of analysis and scope of this study (see Section 2.3.2) requires the consideration of multiple perspectives from different categories of people involved in the construction R&D function. Furthermore, to find solutions to the research questions given in Section 1, and the exploratory and explanatory nature of the study, multiple data collection techniques were needed to cater for the varying purposes of the study. Thus, it became an advantage for this study to choose a research approach that assists an in-depth analysis by incorporating multiple methods. As Zonabend [27] asserts case studies are carried out in a way that incorporates the views of the "actors" of the case under consideration. Further, Gerring [28] stipulates that "one of the primary virtues of the case study method is the depth of analysis it offers" and the use of multiple sources of evidence for data collection [18, 21]. Thus, by using the case study research approach, the study gains the depth of inquiry as well as the utilisation of multi-methods as required.

Despite the advantages discussed above, case studies are criticised for biasness, use of incomplete evidence and for being time consuming and expensive [10]. Yet it can be argued that, if not properly designed the biasness can be included in surveys and experiments. Although case studies are considered as time consuming and expensive, careful design can minimise time and budget. In addition, case studies have a number of advantages which can offset their inherent drawbacks. As mentioned above, case study research approach embraces variety of evidence such as document reviews, interviews, and observations [10, 18] which is considered as a strength that increases the richness of the collected data whilst creating the prospects for data triangulation.

Having chosen case studies as the research approach based on the philosophical stance, research requirements, research questions, contemporary nature, and by considering the added benefits, the next section explains the compromise made between the use of single and multiple case studies.

2.3.1 Single vs. multiple case studies

As stipulated by Yin [21], case studies can be broadly divided into multiple and single and then depending on the number of unit of analysis, embedded (more than one unit of analysis) and holistic (one unit of analysis). A single case study approach is suitable when it investigates critical, unique, representative, revelatory or a longitudinal study [21]. A critical case can be used to challenge, confirm or extend a theory whilst the unique case represents a rare situation. As opposed to a unique case, a representative case captures a common situation or a "typical" project, thus, studying one case is sufficient to get an understanding about other situations. A revelatory case can be used to study a phenomenon that was inaccessible earlier. From a longitudinal case, the phenomenon will be studied over a time period observing how certain conditions have been changed with time. The study under consideration falls under the critical case as it sought to develop and refine a theory on the impact of PM towards construction R&D. The researcher argues that to develop a valid theory, it is critical or important to apply it to the existing situation and refine it. Thus, by taking the critical view, the abstracted concepts will be applied to the existing situation (i.e. the R&D function) and refine it.

Furthermore, this study takes a longitudinal approach as the phenomenon under consideration i.e. PM within construction R&D function is a dynamic process. One of the objectives of the study is to develop a Performance Measurement System (PMS) that could be used to identify the impact and influence of PM on the construction R&D function. To identify the actual impact of PM on the function, the PMS developed through the study needs to be tested on a R&D project, over a time period. Nevertheless, when considering the scope of a PhD, testing the PMS on a R&D project is not practical due to their life span. This is considered as a limitation of this study. As an alternative, it is expected to present the developed PMS to a group of experts through a workshop during the theory refinement stage of the case study, and thereby to assess the impact and influence the PMS could provide to R&D function. With such practical limitations a similar refinement and identification of the impact of key performance indicator's (KPI) on a Knowledge Management environment was done by Pathirage et al [29]. In his study, a structured survey was used during the refinement stage to get the views regarding the impact of KPIs. Accordingly, by taking the longitudinal view, this study explored the current situation within construction R&D function, designed and proposed solutions to enhance the effectiveness of R&D activities and finally obtain the views of expertise on the anticipated benefits of the use of PMS.

The third rationale for the selection of single case study is based on the depth of coverage from this study. Generally speaking, by using multiple case studies, a researcher can increase the breadth of a study. However, the single case study provides the opportunity to explore the phenomenon in detail. Though single case studies are often criticised for not generalising conclusions, many authors argue that the number does not matter as long as the case study addresses its stipulated objectives [21, 30, 31]. Consequently, if it is designed and conducted appropriately, even a single case study would be able to contribute to the knowledge rather than a poorly designed multiple cases. By taking forward this argument, the researcher also believes that what matters is not the quantity of case studies (because the quantity cannot substantiate the quality of the research work), but designing the case study to suit its scenario governed by the aim of the study. Since this study expects the continuous development and refinement of theory the researcher needs to carry out an in depth study by making a compromise between the breadth and depth. The depth of coverage using multiple data collection methods, multiple perspectives and at three different instances is further discussed in Section 2.4.

In brief, the study chose the single case study approach due to the criticality of the theory development and refinement of the phenomenon, the longitudinal view of the study and the depth of inquiry. The next section looks in to the unit of analysis pertaining to this study.

2.3.2 The unit of analysis

As asserted by Miles and Huberman [32], the unit of analysis of a study is a "phenomenon of some sort of occurring in a bounded context". According to Collins and Hussey [16] it is the focal point where the variables, phenomena and the research problem referred to and about which the data is collected and analysed. Because of its importance, Miles and Huberman [32] identify the unit of analysis as the "heart" of the study. Remenyi et al [10] states that the decision of the unit of analysis is governed by the research questions of the study. The unit of analysis of a case study can range from an individual, group of people, to a process or relationship (see [10, 21]). It is advisable to establish the unit of analysis similar to a previous study by considering the literature in the subject area rather than establishing it arbitrarily [10, 21]. Accordingly, by considering the research questions posed for the study (see Section 1) and by considering the previous literature (see [33]) *R&D function* was selected as the unit of analysis of the study. R&D function was defined as the "set of activities necessary to effectively and efficiently initiate, co-ordinate and accomplish the product and process development activities of a company" [34]. Therefore, by fixing the unit of analysis at the R&D function, this study takes the single-holistic case study nature.

Having identified the unit of analysis, the researcher fixed the boundary of the study. Definition of the boundary helps the researcher to identify the scope of the study, for example to determine the limits of the data collection [21]. Construction R&D activities can take the form of academic research, industrial research and collaborative research between academia and industry. It was identified from the literature and expert interviews that collaborative research yields number of benefits [35, 36]. Thus, the unit of analysis was extended outwards to represent multiple organisations namely the universities and construction organisations which fall under the scope of the study. Accordingly the data was gathered from the individuals (academics and industrial partners) employed in those multiple organisations regarding the R&D function.

2.4 The case study process

As discussed in Section 2.3.1, the single case study approach was selected for this study. Accordingly, the researcher explored and understood the PM concept within the construction R&D function, without controlling the variables but rather taking into account the variables applicable and studying the inter relationships between R&D and PM. As noted by Strauss and

Glaser [37], theory building requires the on going comparison of data and theory. Adding to that, Lynham [38] asserts continuous refinement between theory and practice is also needed for the effective theory building. This section describes the case study process used for the theory building and refinement with particular reference to the stages and objectives of the case study.

As mentioned in Section 2.2, the deductive method starts by conceptualising the phenomenon followed by empirical observation to test it whilst inductive method starts with empirical observation to develop theory. Further, it was noted that the positivism research takes a deductive method whereas the interpretivism takes the inductive method. However, it was justified that the research under question take the interpretivist stance in terms of the philosophy (see Section 2.1). Therefore, should this study use a purely inductive method and generate the theory from the data itself? Eisenhardt and Graebner [20] provide much insight to answer this question by stating that case study research starts with a deductive approach and moves on to an inductive approach to build theory. The importance of having an initial definition of the research question prior to starting theory building was highlighted, otherwise the researcher can become overwhelmed by the amount of data gathered. Similarly Yin [21] asserts the need of pre establishing a theory or conceptualising the phenomenon prior to data collection and analysis process. Accordingly, before starting the case study approach, the researcher conceptualised the PM in construction R&D function by deriving research questions through a comprehensive literature review and expert opinion. Thereafter, during the case study design and preparatory stage (refer Figure 4), a suitable case study was selected and the data collection protocols were prepared and piloted. With this background, the researcher started the actual data collection within the case study. The case study took multi-phase approach that consisted of three stages of data collection (refer Figure 4).

The first stage took on an exploratory nature by investigating the current status of construction R&D, application and need of PM within R&D, and exploring the success factors of construction R&D in general. For this semi structured interviews were carried out. The second and third stages also took an explanatory nature. Accordingly, during the second stage, the critical success factors of construction R&D function was established by administering a questionnaire survey. The data from the first and second stage lead to the development of the PMS to identify the impact of PM towards construction R&D. During the third stage, it is expected to refine the theory developed through the case study and to suggest solutions for effective PM within the construction R&D function.

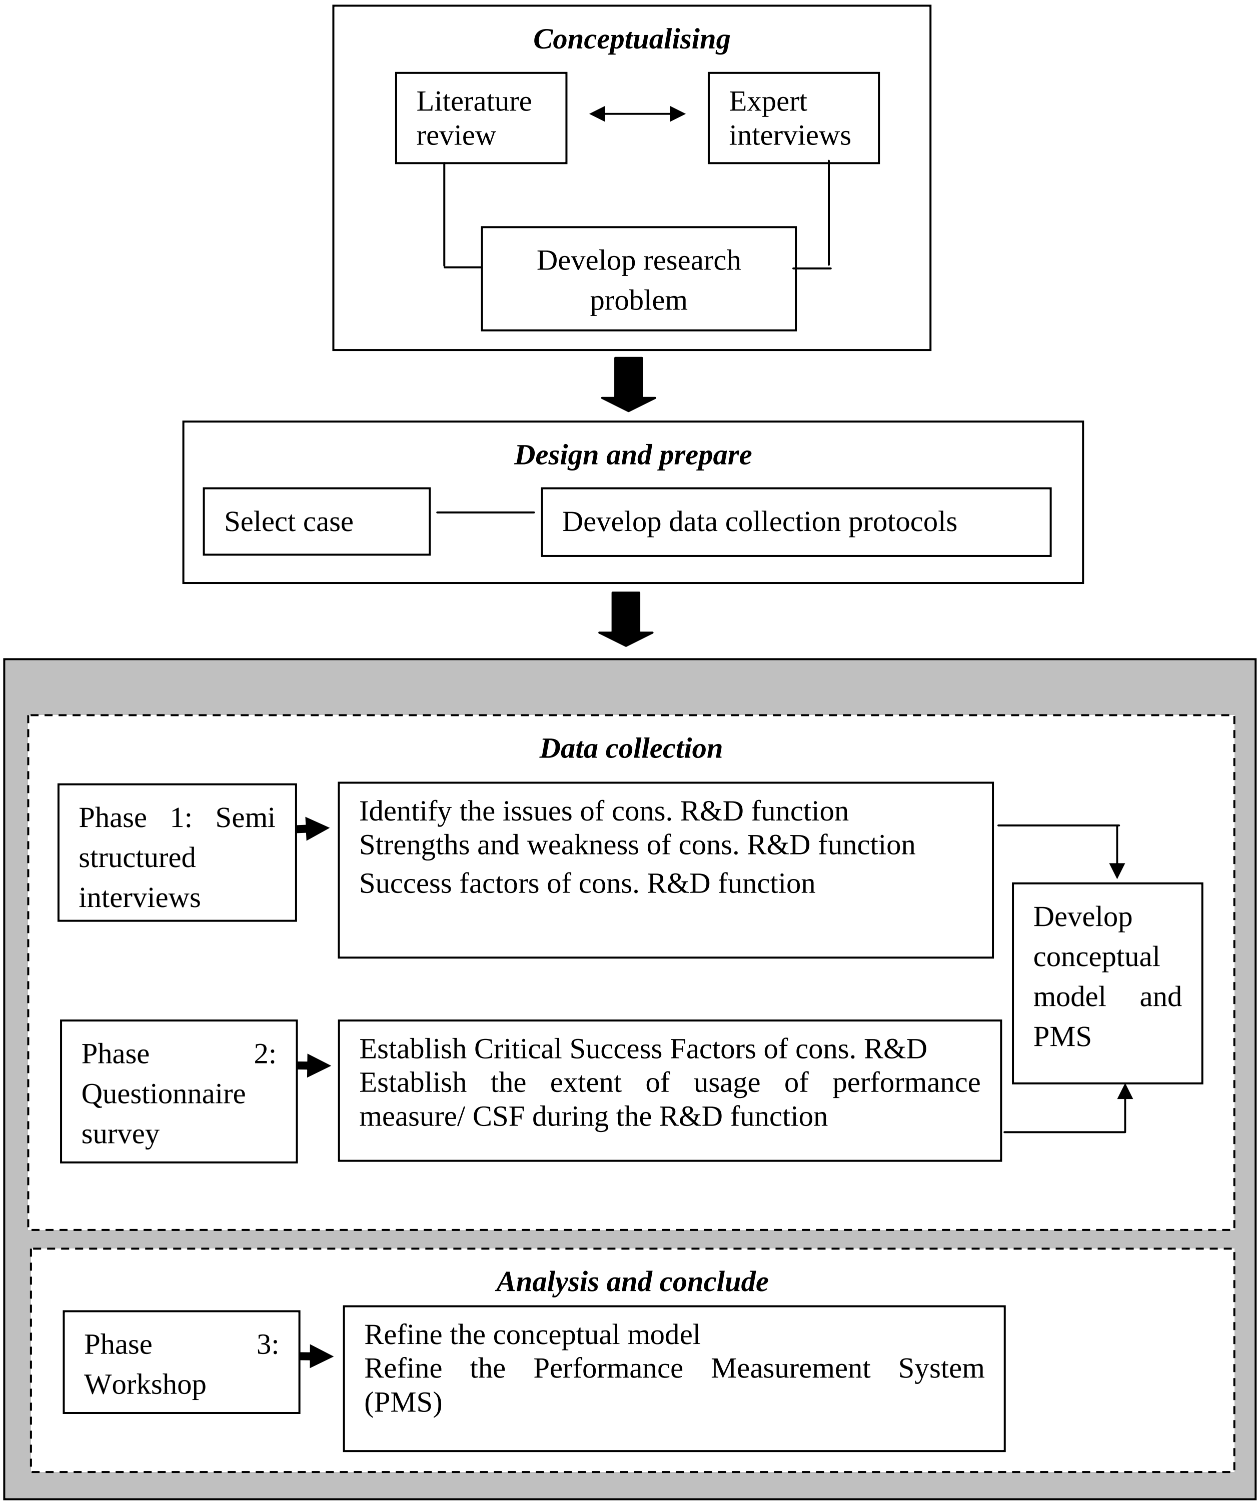

Figure 4: The single case study research approach

During the case process, the researcher adheres to a number of characteristics to enhance the completeness, validity and reliability of the study (refer table 1)

Table 1: Characteristics of an exemplary case (adopted from [10])

Character	Description	How it is addressed
Significant	Case study is of interest to the relevant stakeholders	Through the literature and expert opinion, the need for PM within R&D function was established. Further, paucity of research in this area created the need of further research.
Complete	Clear definition of research problem, identification of boundaries of the case study	Establish the research problem through a comprehensive literature review and refinement of the same through expert opinion. Through the research questions the study gained the focus and identified the areas to be explored. Identification of unit of analysis and scope of the case study ensured the proper establishment of a boundary.
Consider alternative perspectives	Collecting the relevant evidence from different perspective and triangulation of evidence	The evidence was gathered from principle investigators, researchers and industrial partners to corroborate the same issues. Triangulation of evidence in terms of source, methodology.
Display sufficient evidence	Present compelling and convincing evidence	Through the data analysis, the initial research questions and thereby the aim and objectives of the study was addressed. Creating links between the literature and empirical evidence, consideration of the different perspectives to corroborate the evidence.
Composed in an engaged manner	Ensuring the validity and reliability of the study	Number of good practices was adopted to ensure the reliability and validity of the study (member checking, preparation of interview guidelines, tape recording the interviews, piloting the survey etc.).

In brief, it can be summarised that the initial concepts abstracted through the literature review and expert opinions were empirically observed, validated and will be refined by employing a multi-phase single case study approach, by considering multiple perspectives and by using multiple methods for data collection.

3. Conclusions

The paper explored the use of single case study research approach to evaluate the impact of PM towards construction R&D function. It was revealed that the proper understanding of the philosophical issues followed by a clear definition and design of research strategy are essential elements in developing successful research. Through the use of single case study, the paper emphasised that what matters is not the number of cases, but the appropriate design and selection of methods to investigate the research in question. Therefore, it can be concluded that the application of single case study to investigate the impact of PM in construction R&D function by incorporating multi-phase, multi-perspective and multi-method approaches will enable us to build up a *valid theory* due to the continuous comparison of empirical data with the study's initial concepts (propositions) and the refinement of the developed theory within the same case study.

Abstract

Education globalisation is a reality today. Students from different countries can participate in exchange programmes in universities worldwide. However, this makes sense only if students understand the language of instruction. For large and industrialised nations there is no problem, they teach in their native language and there are always foreign students who can understand the course content. Developing countries and small nations face a more complicated situation: they can choose to teach in an internationally recognised language or in their native language. Both solutions have their advantages and disadvantages and in both cases a large number of students pursue their university education in a foreign language. The research is intended to examine whether language proficiency represents a significant disadvantage for engineering students who do not learn in their mother-tongue. This paper describes research into the performance of Russian-speaking civil engineering students relative to their Estonian-speaking counterparts at the Tallinn University of Technology. Results over eight years for a course taught in the Estonian language are compared to determine whether any trends in the relative performance of students from the two main language-cultural groups and also genders are perceptible. In addition, comparison is made with students' results for a course taught in English in the 2006/7 academic year to provide an indication of the effect of Estonian language knowledge on course results.

Keywords: Engineering education; education globalisation, influence of language; influence of gender

1. Introduction

1.1 The Wider Research Context

In today's globalised market for higher education, students have the possibility of studying at universities in almost any country worldwide. However, this makes sense only if they understand the language of instruction. For large and industrialised nations the choice of language of instruction at universities is obvious - they teach in their official state languages (English, Russian, French, German, Chinese, etc.) and there are always foreign students who can understand the course content. Developing countries and small nations, on the other hand, face a more complicated situation: they can choose to teach in an internationally recognised language (as universities in Sri Lanka do), in their native language (as in Estonia) or some combination of the two. In all cases, issues relating to language proficiency amongst students and institutional capacities to provide suitably qualified staff and course material in all requisite subject areas to teach in the elected language (or languages) arise.

While a considerable body of literature examines the role of language-cultural groups in education in Estonia generally, to the authors' knowledge this is the first time that an attempt has been made to compare the advantages and disadvantages deriving from language-cultural group membership in the education of engineers in Estonia. As such it represents original research.

1.2 Historical Background to the Linguistic Environment in Estonia's Universities

Largely as a consequence of Soviet era settlement of ethnic Russians, Ukrainians and Belorussians in Estonia, a Russian-speaking minority comprises approximately 30% of Estonia's population. Throughout the Soviet era, education was provided separately in both Estonian and Russian languages, the majority of schools being either monolingual Russian or monolingual Estonian schools. At university-level, students were taught separately in Estonian and Russian groups with both groups following the same programme but each in their native language.

Since the restoration of independence in 1991, one of the most significant government policy changes in Estonia has been the adoption of Estonian as the only official state language. In order to integrate the Russian-speaking minority, the Estonian Government has elaborated a State Programme for Integration [10]. Among the comprehensive measures planned are different methods for the teaching of Estonian language. However, most schools remain as either Estonian schools or Russian schools and a considerable proportion of Russian-speaking children complete secondary school with limited Estonian-language proficiency. As the language of instruction at state-funded universities is mainly Estonian, this constitutes a potential disadvantage in pursuing further academic studies (Leino et al [9]; Brown [4]).

With an Estonian-speaking population in the order of only 1 million people, it is debatable whether it is possible to provide universities with high quality professors in all the necessary fields. Consequently, universities are faced with a choice between two working language directions for the future:

- to maintain the requirement that academic staff be able to teach in Estonian and thereby effectively preclude foreign staff with the risk that quality might be compromised; or,
- to drop the demand for teaching in Estonian and thus increase the pool of eligible academics. However, this involves risks associated with the quality of engineering knowledge transfer if students are not fluent in the language of instruction and the negative effects that this will have on Estonian engineering and scientific language.

> Having avoided it during 50 years of Soviet occupation, voluntarily accepting the demise of Estonian language through changing the language of instruction in universities at a time of national independence would be unthinkable.

There is a need to find a reasonable compromise to this problem by deciding which disciplines, at what levels, etc. might be taught in other languages in such a way so as to complement the core, Estonian language, university courses. The current study's investigation into the influence of language of instruction on course results offers empirical input to this debate by providing insight into the effectiveness of knowledge transfer where issues of language proficiency exist.

1.3 Languages of Instruction in the Faculty of Civil Engineering at Tallinn University of Technology

Tallinn University of Technology (TUT) was founded in 1918 as an engineering college and it was granted university status in 1936. Today TUT is one of the largest public universities in Estonia and has over 10,000 students. In the Faculty of Civil Engineering there are approximately 800 students. The faculty currently offers Master of Science in Engineering and PhD study programmes with nominal study durations of 5 years and 4 years respectively. At TUT civil engineering students are taught separately in Estonian and Russian for the first two years during which time non-Estonian-speaking students can take the Estonian language course offered by the university. Starting from the third year the language of instruction is primarily Estonian. From this point, Russian-speaking students are taught in a combined group with their Estonian-speaking counterparts in the Estonian language.

Since Estonia's accession to the European Union in 2004, the effects of education globalisation have begun to be felt. With increasing international mobility of both students and staff, the university hosts more foreign professors, lecturers and students and, as a consequence, the use of English at TUT is growing. As more courses taught in foreign languages (particularly English) are developed, Estonian-speaking and Russian-speaking students are increasingly being called upon to undertake some of their studies in a foreign language (refer to Altbach [2] on the predominance of English as an international academic language).

2. Problem Definition

In this way, language issues are central to TUT's ability to successfully maintain the quality of technical education and thus fulfil its national obligations to develop and transfer knowledge as well as to compete in the global market for education and research. Two specific language-related questions arise from recent developments and anticipated future trends:

- How has the change to Estonian language tuition affected students whose home-language is not Estonian – particularly the large minority of Russian-speakers?
- How might the increasing tendency to provide modules in English or other foreign languages impact on the performance of students?

3. Basis of Research Approach

The importance of proficiency in the language of tuition and testing has been investigated by many researchers covering a variety of taught subjects, e.g. Cuevas [5], and, unsurprisingly, an inadequate understanding of the language of instruction is found to be a major source of underachievement. Similarly, a considerable collection of factors have been variously found to be correlated with academic performance including:

- Alfan, E. and Othman, M.N. [1]: secondary school academic performance, admission qualifications, gender, attendance (full-time / part-time), linguistic capacity, ethnicity, culture, age;
- Eskew, R.K. and Faley, R.H. [6]: academic aptitude, past performance; effort / motivation, previous experience of subject matter, exposure to more generally related subject matter areas;

Some have considered these in the context of ethnic groups, e.g. Hofman, A. and van den Berg, M. [7], – ethnic specific differences: prior education, financial considerations (minorities need to earn more to afford university), effort.

The influence of language of instruction has been widely investigated at the level of primary and secondary schools in Estonia. Leino *et al* [9], based on empirical studies, stated that young non-Estonians put greater emphasis on their acquiring education and obtained better results than the local Estonian majority. The same authors also found that differences exist in students' performance at schools in Estonia between both the Estonian and Russian language-cultural groups as well as on the basis of gender so that the subgroups may be ranked by school results achieved as follows (from best to worst): (1) Girls whose language of instruction is Russian; (2) Girls whose language of instruction is Estonian; (3) Boys whose language of instruction is Russian; (4) Boys whose language of instruction is Estonian.

R. Kallas [8] has observed the performance of students of non-Estonian origin learning in Estonian secondary schools and indicated that there is no significant difference in their results by nationality.

In this paper an attempt has been made to compare the advantages / disadvantages deriving from language-cultural group membership in civil engineering education at university level.

4. Methodology

The research described here is essentially a comparative before and after study. It compares the performance of two populations of undergraduate students one of which is Estonian-speaking and the other Russian-speaking. The results obtained by these students in a Building Technology course are compared:

- for the years when the two groups received separate instruction in Estonian and Russian languages, i.e. before the change to all students receiving the course in Estonian; and,

- for some years after the change to all students being taught the course in Estonian.

Since it is a comparison, the influence of factors such as prior education, past performance, age, previous experience, culture and financial considerations are assumed to be insignificant in that they are considered to remain relatively constant. The effect of gender, however, must be taken into account as the changing proportions of males and females within the language-cultural groups may affect differences in course results between the groups given that gender differences in academic performance have already been observed at school level (Leino *et al* [9]).

For the years 1999 to 2006 inclusive, the results for all students participating in the Building Technology course were collated. The student group for each year was disaggregated by language-cultural group membership and by gender into four sub-groups: (1) Estonian-speaking females; (2) Estonian-speaking males; (3) Russian-speaking females and (4) Russian-speaking males. The course results obtained by students in each sub-group were compared in order to determine:

- whether the course results achieved by Estonian-speaking students in each year are significantly better than those achieved by Russian-speaking students; and,
- whether the course results obtained by Estonian-speaking males differ significantly from those obtained by Estonian-speaking females and whether the results obtained by Russian-speaking males differ from those obtained by Russian-speaking females.

In addition, comparison was made between students' results in the Building Technology course (taught in Estonian) and those in the Project Management in Construction course (taught in English).

5. Description of the Study Group and Results

5.1 The Building Technology Course 1999-2006

The course of Building Technology is taught during 2 semesters in the third year of engineering studies. It involves 120 academic hours of lectures and a course project. Students must pass 8 tests, 2 written exams and defend their course project, which involves considerable independent work. In return, they receive 6.5 credit points (3 for the first exam, 2.5 for the second and 1.0 for the course project).

In the years 1999 and 2000, Estonian and Russian students were taught in separate groups in their respective languages. Since 2001, the separate groups have been united and the language of instruction is Estonian. For the 8 years from 1999 to 2006, total student participation in the course varied from 44 to 130 with the proportions of Estonian-speaking and Russian-speaking students varying from 55% - 72% and 28% - 45% respectively. Between 16% and 27% of participating students were female.

5.2 The Project Management in Construction Course 2006

In 2006, for the first time, a course previously offered in Estonian language was delivered in English. The course, Project Management in Construction (60 academic hours and 2.5 credit points), was taught to fourth year civil engineering students. Students' performance was assessed by means of a coursework project and a written exam. A total of 74 students participated in the course of whom 55% were Estonian-speaking and 45% Russian-speaking. 38% of participating students were female.

5.3 Results

For the Building Technology and the Project Management in Construction courses, the student participation rates and average results achieved for the years under consideration are tabulated in Table 1 and Table 2 respectively.

Table 1: Student Participation in the Building Technology and Project Management Courses

Student Subgroup	Number of participating students							
	1999	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
a) Building Technology Course								
Estonian-speaking Females	16	4	11	8	6	14	9	11
Estonian-speaking Males	71	60	30	26	18	48	57	49
Russian-speaking Females	15	12	5	4	4	12	13	17
Russian-speaking Males	28	25	14	9	16	21	29	32
Total	**130**	**101**	**60**	**47**	**44**	**95**	**108**	**109**
b) Project Management in Construction Course								
Estonian-speaking Females	-	-	-	-	-	-	-	**15**
Estonian-speaking Males	-	-	-	-	-	-	-	**26**
Russian-speaking Females	-	-	-	-	-	-	-	**13**
Russian-speaking Males	-	-	-	-	-	-	-	**20**
Total								**74**

Table 2: Average Results obtained for the Courses

Student Subgroup	Average results, %							
	1999	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
a) Building Technology Course								
Estonian-speaking Females	78.6	81.3	88.7	59.1	69.3	84.9	71.8	76.6
Estonian-speaking Males	71.3	83.4	83.3	79.3	77.0	78.0	78.2	74.8
Russian-speaking Females	77.2	86.8	82.8	72.8	66.0	58.6	68.8	57.5
Russian-speaking Males	72.5	79.5	69.6	60.1	66.8	58.3	64.5	61.6
b) Project Management in Construction Course								
Estonian-speaking Females	-	-	-	-	-	-	-	74.2
Estonian-speaking Males	-	-	-	-	-	-	-	76.1
Russian-speaking Females	-	-	-	-	-	-	-	65.4
Russian-speaking Males	-	-	-	-	-	-	-	57.8

6. Analysis and Interpretation of Results

By analysing the results obtained by individual students comprising each language-cultural and gender subgroup, the statistical significance of the relationships under investigation were tested.

6.1 Do Russian-speaking Students Perform Worse than their Estonian-speaking Counterparts?

The research hypothesis may be framed as follows: The change from instruction in separate languages to instruction in Estonian negatively affected the performance of Russian-speaking students. A corresponding null hypothesis enables the testing of our hypothesis:

- Null Hypothesis 1: (For each year) Estonian-speaking students did not perform significantly better than Russian-speaking students,

An unpaired, one-tailed Student's $t-$test was applied. The values of p calculated show the probability of these results assuming the null hypothesis. The results of this analysis are shown in Table 3 below.

Table **3***: Probability of the Observed Results assuming Null Hypothesis 1*

Student's $t-$test (unpaired, 1-tailed)	**Test results**							
	1999	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
a) Building Technology Course								
Degrees of freedom	128	99	58	45	42	93	106	107
Probability, p (assuming null hypothesis)	0.356	0.357	0.015	0.056	0.051	1E-06	8E-05	2E-06
b) Project Management in Construction Course								
Degrees of freedom	-	-	-	-	-	-	-	72
Probability, p (assuming null hypothesis)	-	-	-	-	-	-	-	1E-05

Assuming an alpha level of p =0.05, we may reject the null hypothesis at values of p <0.05. In the years 1999 and 2000, prior to the change from separate tuition in Russian and Estonian to all students being taught in Estonian, Estonian-speaking students did not perform significantly better than Russian-speaking students. Whereas, in the years 2001, 2004, 2005 and 2006 the null hypothesis may certainly be rejected, the values of p yielded for the years 2002 and 2003 (0.056 and 0.051 respectively) are marginal. However, it should be noted that these results are influenced by the lower number of students participating in the Building Technology course in these two years and, in consideration of this, the better performance of Estonian-speaking students in these years may be interpreted as being significant.

Thus, Estonian-speaking students performed significantly better in all years after the change to Estonian language tuition only (2001-2006) and we may accept our research hypothesis that the change from instruction in separate languages to instruction in Estonian negatively affected the performance of Russian-speaking students. This is clearly visible from a plot of the average course results achieved by the two language cultural groups as shown below in Figure 1.

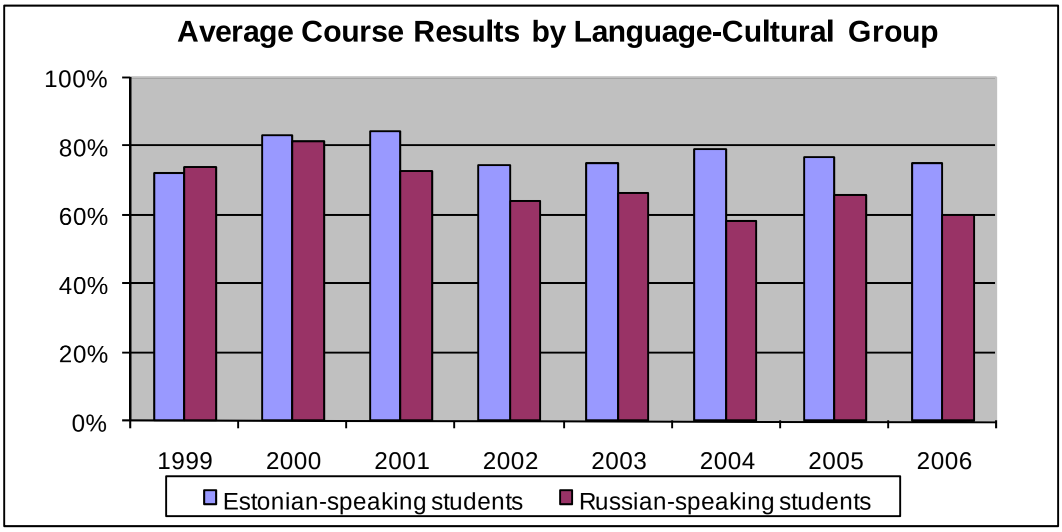

*Figure **1**: Average Course Results by Language-Cultural Group*

In the years 1999 and 2000, when the Building Technology course was taught in two separate languages, the average results obtained by the Russian-speaking students were similar to those of the Estonian-speaking students. In the years 2001 through 2006, when all students were taught in Estonian, a noticeable gap is apparent between the average results of the two groups.

A further illustration of the effect of the change on Russian-speaking students may be seen from a plot comparing the proportion of students in each of the two language-cultural groups who achieved ’good’ grades (i.e. grades of 4 and 5 in the TUT grading system, corresponding to results of > 80%) as shown in Figure 2 below.

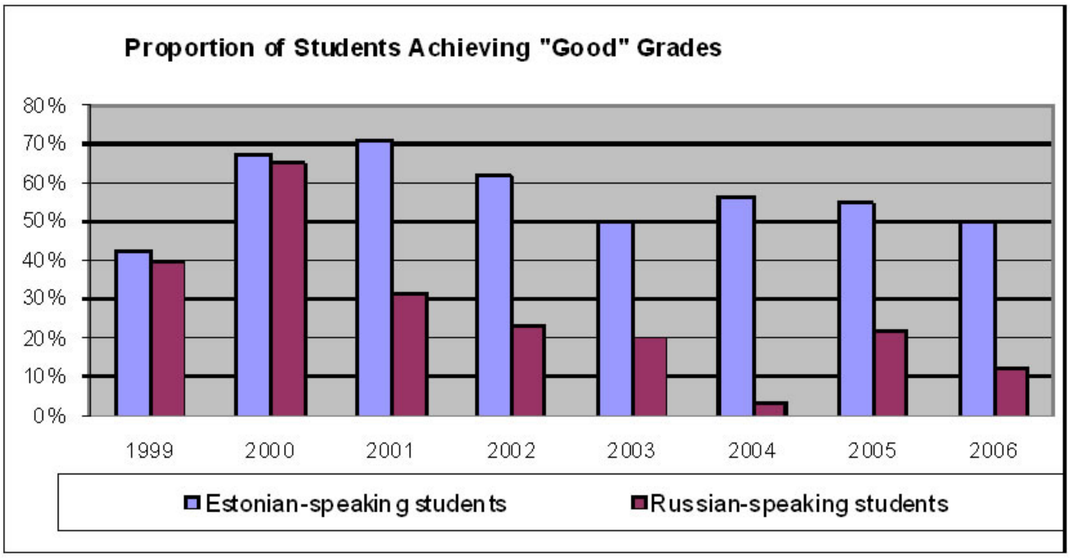

Figure **2**: *Proportion of Students Achieving "Good" Grades*

The same analysis of results achieved by the two language-cultural groups in the Project Management in Construction course (which was conducted in English) reveals that Estonian-speaking students performed significantly better than their Russian-speaking counterparts. This may indicate a similar gap between the groups in both Estonian language and English language proficiency but could as well be influenced by other factors. In contrast to the results for the Building Technology course which allow for comparison before and after the change in the language of tuition, the Project Management in Construction course results are available for only 2006 when instruction in English started. Beyond serving to confirm that a performance gap between Russian-speaking and Estonian-speaking students exists in other courses besides the Building Technology course, they do not provide additional insight into the nature of this gap.

6.2 Is there Evidence of a Gender Difference in Student Outcomes?

Since a difference in the performance of Estonian-speaking and Russian-speaking students (following the change to Estonian language tuition) has already been established, the existence or otherwise of significant gender differences in performance must be investigated within the language-cultural groups rather than considering the entire student group.

Research Hypothesis: Within the Russian-speaking and Estonian-speaking groups, differences between course results obtained by males and females exist.

- Null Hypothesis 2: (For each year) Estonian-speaking males did not perform significantly differently to Estonian-speaking females.
- Null Hypothesis 3: (For each year) Russian-speaking males did not perform significantly differently to Russian-speaking females.

An unpaired, two-tailed Student's $t-$test was applied. The values of p calculated show the probability of these results assuming the null hypothesis. The results of this analysis are shown in Table 4 below.

Table **4***: Probability of the Observed Results assuming Null Hypotheses 2 & 3*

Student's $t-$test (unpaired, 2-tailed)	**Test results**							
	1999	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
a) Building Technology Course								
Degrees of freedom	85	62	39	32	22	60	65	58
Probability, p (null hypothesis 2)	0.218	0.737	0.082	0.067	0.600	0.062	0.101	0.695
Degrees of freedom	41	35	17	11	18	31	40	47
Probability, p (null hypothesis 3)	0.486	0.264	0.159	0.253	0.913	0.968	0.463	0.487
b) Project Management in Construction Course								
Degrees of freedom	-	-	-	-	-	-	-	39
Probability, p (null hypothesis 2)	-	-	-	-	-	-	-	0.450
Degrees of freedom	-	-	-	-	-	-	-	31
Probability, p (null hypothesis 3)	-	-	-	-	-	-	-	0.165

Assuming an alpha level of p =0.05 again, in no year within the study may either null hypothesis 2 or 3 be rejected as all calculated p values exceed this threshold. Thus, there is no evidence of statistically significant differences between the course results obtained by males and females in either language-cultural group. This may well be influenced by the small sample sizes.

6.3 Has the Performance Difference between Estonian-speaking and Russian-speaking students Increased over Time (since 2001)?

Having established that there is a significant gap in performance since 2001 between the Russian-speaking and Estonian-speaking students and that this appears to be independent of gender differences, it is important to determine whether this gap is stable, narrowing or widening. Figure 3, below, plots the difference in results (how much better Estonian-speaking students have performed, expressed as a percentage of the Russian-speaking students' average results) for the Building Technology course against time.

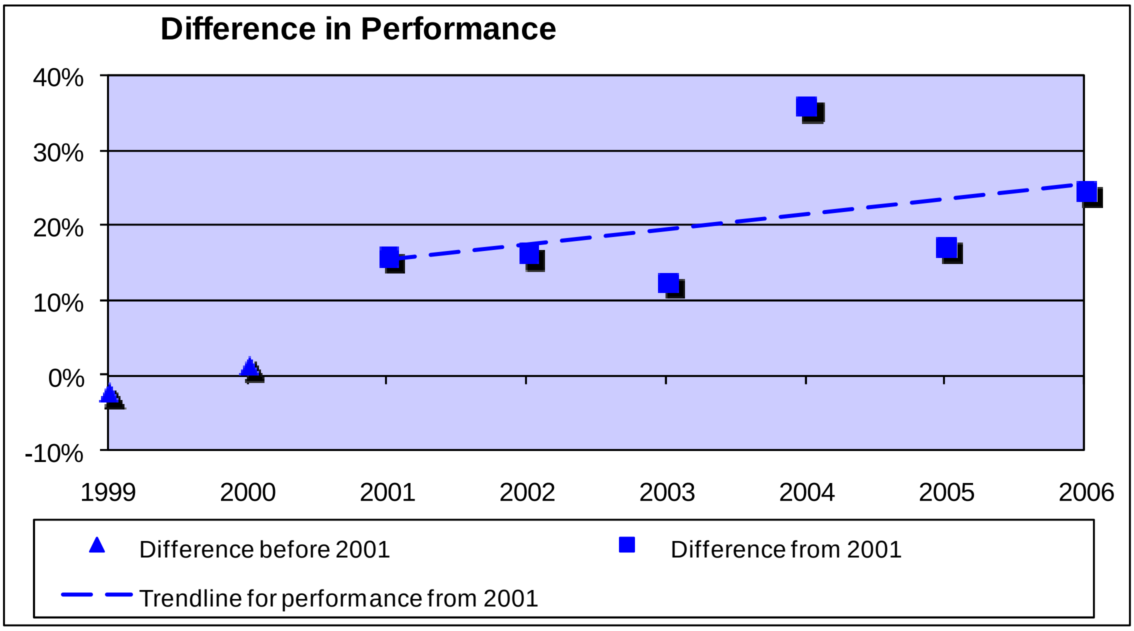

*Figure **3**: Difference in Performance*

A linear trendline superimposed on the performance differences calculated for the years 2001 to 2006 would indicate that the performance difference has tended to increase over time. It is also evident that the performance differences between the groups which were negligible in 1999 (-2%) and 2000 (1.6%) are considerable from 2001 (the average results of the Estonian-speaking group having ranged between 12.7% and 36.2% better than the average results of Russian-speaking students). Interestingly, the performance difference calculated for the Project Management course results in 2006 is 24.1%, very similar to that shown below for the Building Technology course in the same year.

7. Conclusions

This research represents an initial and very limited investigation, but it does highlight the sensitivity of the language problem by showing that students' performances are dependant on their proficiency in the language of instruction:

- The difference in the results achieved by Russian-speaking students and those achieved by Estonian-speaking students since separate language tuition was stopped and the Building Technology course was taught in only the Estonian language indicates that the Russian-speaking students' Estonian language skills are insufficient and considerably compromise their course results. A direct relationship between language proficiency and course outcomes is apparent.
- As observed with the Project Management in Construction course, opting to teach in a foreign, international language may yield similarly large gaps between language-cultural groups' performances. In contrast to the case of the Building Technology course where at least the Estonian-speaking group's results were not adversely affected by the language proficiency factor, all students' results in the Project Management in Construction course may have been adversely affected by the choice of English as the language of instruction.

It follows that decisions concerning the language of tuition at universities have a profound effect on knowledge transfer to students and, ultimately, on national development.

8. Recommendations

The considerable magnitude of the performance gap observed and the possibility that it may be increasing is concerning not just from a narrow, effectiveness of university tuition point of view, but potentially for its wider socio-economic and political implications. It is therefore recommended that a further, wider investigation establish whether or not these performance differences are apparent in other courses taught within the Faculty of Civil Engineering and to define more precisely the factors influencing the differences with a view to proposing practical measures to close the gap. Additional factors affecting performance may include the extent of students' employment, lecture attendance rates, etc which need further investigation.

In the wider, international context, where both students and professors are increasingly mobile, questions are raised in terms of the effectiveness of learning in foreign languages – to what extent are engineering students throughout the world having their learning experience compromised by inadequate language skills? The influence of language of instruction must be given thorough consideration.

- It is important to ensure that students obtain solid fundamental knowledge and, therefore, that instruction in basic and core modules of the civil engineering curriculum should preferably be maintained in students' native languages. Where this is not possible, targeted language support should be provided. Similar was suggested also by Briguglio [3] in strategies for overcoming linguistic difficulties.
- At a higher level of education (Master, PhD) the need for knowledge of foreign languages is obvious and engaging international professors is highly recommended. The same applies to elective courses within the civil engineering curriculum. However, lecturers instructing in foreign language must give consideration to students' knowledge of the language of instruction.

A Change in Perspective For Construction Management Education

Sidney Newton,
Faculty of the Built Environment, The University of New South Wales
(email: s.newton@unsw.edu.au)

Abstract

Competency-based training has become synonymous with training per se. It has had a particular and major impact on vocational education and training, and it is unsurprising that professional associations have moved to adopt competency-based accreditation of study programs in construction management. However, this paper will argue that the nature of university education, the constraints on course structure, the traditions of teaching, etc. collectively militate against effective competency-based educational models. At the same time, there are significant questions being raised against the promotion of competencies as an effective measure of professional education. Educational providers, legislators, and professional associations each tend to disagree about what competence means and what the nature of expertise actually is.

This paper will draw on the emerging concepts of transformative learning, to propose perhaps a more radical response to what appears to be an ongoing (and ultimately losing) battle to condense construction management programs further and further. The conceptual framework it presents will range across reflective and deliberate practice, situated learning, disciplined awareness, and the ontological structure of disclosure. In essence it calls for a displacement of competency and knowledge as the primary drivers of vocational degree programs in construction management. Instead it argues for a more psychosocial approach to learning, where content is replaced with process as the driver of learning. The psychosocial approach privileges a case-in-point approach to learning. It moves the focus of education away from the individual learner gaining a discrete body of abstract knowledge, acquired and subsequently applied in practice. It treats learning as an interpretive process in which understanding is related to action contexts, and not to prescribed conceptual structures.

Keywords: Education, Transformative Learning, Competency-Based Training, Case-in-Point

1. The growing domination of competency-based training

1.1 What is competency-based training?

There remains a significant difference of opinion, within the literature, on a range of issues relating to competency-based training: how best to define and distinguish competency itself; what might constitute a competency-based training model; and how competency-based assessment and accreditation might most effectively be implemented [1]. According to the U.S. Department of Education, a competency is defined as the "combination of skills, abilities, and knowledge needed to perform a specific task" [2]. There is clearly an emphasis on the combination of theoretical knowledge with practical experience. This emphasis is one of the most consistent elements found in how competency is defined more generally. It is an important common emphasis, however. It makes it explicitly clear that competency is fundamentally about the assessment of the capacity for a person to perform certain professional tasks, in given situations, in a particular way [3].

In this sense, the relevance of competency-based training to professional practice (and vocational training more generally) is undeniable: professional competence is inevitably benchmarked against a particular set of specific competencies. The concern of this paper is not, therefore, in regard to the nature of professional competence and how it may or may not be constituted. Rather, this paper takes issue with the use of those professional competencies, so identified, as the basis for the accreditation of professional, higher-educational degree programs in construction management. In other words, the issue here is about the relevance of a competency-based training model for vocational higher education degrees in construction management.

1.2 The background to competency-based training

The emergence of competency-based training (CBT) has been driven largely by industry, specifically by the response of industry to broader-level skill shortages. It has long been realised that the operation of any business or undertaking (existing or proposed) can be broken down into particular resource requirements. The human resource component of those requirements can be identified quite directly in terms of particular competencies. It matters little if it is the strategic plan for an entire business, the performance of a particular department, project, team or even an individual. Given a particular set of performance targets, a comprehensive list of the competencies required to satisfy such targets can also be made explicit. These requirements can then be compared with a survey of the scope and depth of existing competencies within the organisation, department, project, team or individual. It is then possible for a mapping of the capacity/capability gaps, between what is required and what is available, to be generated. Almost surgically, some might argue, training interventions can be identified and targeted to provide all of those, and only those, competencies required of particular individuals: no unnecessary training, no wasted resources, and everything driven directly by business objectives. Of course that places a lot of emphasis, and responsibility, on identifying the required competencies correctly. But as a driver of human resource recruitment and training, CBT has been a major growth area in recent years.

CBT has been a revolution for workplace training – but it has been an industrial revolution. In seeking to divide professional practice into discrete, specialised and contained tasks, where no resources are to be wasted on learning anything other than those particular discrete, specialised and contained tasks, CBT has become reductionist and prescriptive [4]. Any such reductionist approach fails fundamentally to address the needs of professional practice, which is something entirely more holistic in nature [5]. Thus CBT, initially at least, tended to hit a wall with professional practice. In response, the concept of CBT has undergone a series of significant evolutions and improvements. These improvements have included a better alignment of training tasks with the development from novice to expert: different levels of competency have been introduced to stage the learning of particular competencies. CBT has also been improved by including a broader mix of competency types, to more explicitly include attitudes and values as learning outcomes. This expansion of CBT began to introduce new problems of how to measure the different levels and more subjective considerations with reasonable fidelity. Questions relating to the effective and consistent assessment of such an extended and more complex CBT framework are beginning to emerge, making CBT assessment of increasing concern [6].

1.3 The assessment of competency-based training

Assessment within a more complex competency framework is not a simple problem. Notwithstanding that such competencies have first to be identified correctly, effective assessment demands that common, clear and explicit standards have to be agreed and established. Along with such standards must be specified the valid and reliable evidence required to demonstrate when and how each competency has/is to be satisfied. All of this information then constitutes the common assessment framework that each teacher and assessor must understand and interpret in an agreed manner. Throw into this already complex mix the fact that learning situations vary, assessment can involve a range of different methods (from observation through to personal reflection) and the fact that assessment is inevitably judgement-based, and the potential for inequity is clear. Of course such frameworks have been developed successfully, even at a national level, in particular contexts. The question and issue remains, however, whether effective frameworks can be developed for a higher education context where the significance of implicit cognitive processes is more acute [7, 8].

The difficulties exposed in assessment of competencies, are then reflected in the difficulties faced by the teachers of those competencies. To be properly prepared to teach professional practice competencies it can be argued that the educators need, to a substantial degree, to be an expert practitioner themselves [9, 10]. It is an increasingly rare case that an effective academic researcher will also have the breadth of professional expertise needed to teach or assess the complex of professional competencies. This is perhaps more particularly the case in construction than other market sectors, where the separation of research and practice has always been apparent. It is certainly the case where the competencies required are those relevant to anticipating and responding to unexpected events and the disruptive challenges of natural and man-made disasters.

According to Sullivan[11], the following characteristics are essential elements for an effective assessment framework to operate:

- Competencies are carefully selected
- Supporting theory is integrated with skill practice. Essential knowledge is learned to support the performance of skills

- Detailed training materials are keyed to the competencies to be achieved and are designed to support the acquisition of knowledge and skills
- Methods of instruction involve mastery learning, the premise that all participants can master the required knowledge or skill, provided sufficient time and appropriate training methods are used
- Participants' knowledge and skills are assessed as they enter the program and those with satisfactory knowledge and skills may bypass training or competencies already attained
- Learning should be self-paced
- Flexible training approaches including large group methods, small group activities and individual study are essential components
- A variety of support materials including print, audiovisual and simulations (models) keyed to the skills being mastered are used
- Satisfactory completion of training is based on achievement of all specified competencies

These characteristics describe a process for the development of effective competency-based accreditation. It is not clear whether it is possible to take only a selection of these characteristics and still constitute a competency-based approach. In fact examples where a complete implementation of this list has been achieved are rare across the spectrum of educational settings. In professional degree education and accreditation settings, the full list would appear increasingly unattainable.

1.4 The accreditation of competency-based training

In Australia, the Australian Institute of Quantity Surveyors (AIQS), the Australian Institute of Building Surveyors (AIBS) and the Australian Institute of Building (AIB) collectively publish their joint system for the assessment of courses and accreditation qualifications – The Cooperative Accreditation Agreement for Education Providers: Handbook for Users [12]. The Cooperative Accreditation Agreement (CAA) is thus a joint initiative for the professional accreditation of higher education programs in construction management and related professional disciplines. It is specific to Australia, but mirrors the accreditation processes applied in other countries and in professional disciplines more generally. The following is a summary of the CAA, as presented in the handbook.

The CAA system constitutes a broad-ranging process through which a particular higher educational provider can seek to have a program of study accredited as meeting the academic requirements for membership of a participating professional body. There is a difference between an initial accreditation and an ongoing accreditation process, but this difference is insignificant in the context of this paper. Essentially, the accreditation process involves two (2) phases.

In Phase 1, the education provider submits program documentation detailing the nature and scope of the program of study, and how the program meets the requirements of the professional body. This documentation would include: general information on the academic institution and school; broad descriptors of the title, length of study and industry experience requirements of the program; data on number of students in the program, graduating and entering; comments on the facilities and funding available to the program; a listing of all full-time and part-time staff, their roles, staff/student ratios, teaching quality calculations, etc.; and a matrix that describes how graduate competencies and benchmarks as required by the professional associations are met by the program. The documentation is then reviewed by two external examiners, one a practitioner nominated by the professional body and one academic nominated by the educational provider. The documentation, the external examiners review and the educational providers' response to the external examiners review are then considered at an initial CAA meeting. If satisfactory then accreditation is awarded for a period of time (typically 5 years) and the CAA moves to Phase 2.

In Phase 2, there is an annual review by the external examiners that is to include compliance data on the threshold standards set by the professional body. This report is then considered at an annual CAA meeting, along with the educational providers' annual response, comments from representatives of the accrediting professional body and any other relevant items.

There is a range of assessment criteria listed in each CAA that is common to all professional bodies. The substantive, and only, difference between the assessment criteria specified by each professional body is in the compliance threshold of specific competencies/benchmarks set by each professional body. For example, the AIBS lists in excess of 100 discrete competencies that all graduates of an accredited program are required to satisfy.

A number of concerns have been raised with regard to the overall CAA approach and requirements, but this paper takes particular issue with the use of competency-based benchmarks as the basis of a professional accreditation process for graduate education.

1.5 The implications of a competency-based training approach

Competency-based training (CBT) has revolutionised vocational training, and now features prominently in workplace training and across the school and TAFE education sectors [13]. The adoption of a competency-based accreditation process by various professional bodies might be assumed to be a simple extension of that revolution in training and education. However, the vocational degree context is very different to workplace and diploma-level studies.

One of the most apparent consequences of a CBT accreditation process in construction management higher education has been the relentless increase in the range and scope of competencies being identified. Program amalgamations have combined what were traditionally separate disciplines into the same program of study. In Australia almost all quantity surveying and building degrees have now been amalgamated in this way. The combined competencies for both quantity surveying and building professional accreditations then have to be contained within a single program. More and more content is being included in/imposed upon the same program structures.

At the same time, teaching traditions have tended to focus on lecture-based presentation and delivery of the content. Changing pressures of larger class-sizes, reduced contact time, lower staff-student ratios, etc. each make it more and more difficult to support competency-based training and assessment. Anecdotal evidence suggests that the construction industry is tending to favour more generic graduate attributes over specialist competencies, especially as graduates increasingly fail to satisfy the traditional expectations for specialist competencies. This trend is likely only to be accentuated by generation X and Y graduates, who tend to avoid the longer duration required for effective CBT.

A crisis appears to be developing around CBT in the higher education context. In very broad terms, industry is not satisfied with the levels of competency that Universities currently produce, academic staff do not have the same depth of industry experience as their predecessors, degree programs are already packed with content and do not have the space to accommodate a full suite of professional competencies, and today's students are tending to be motivated to learn only that particular mix of competencies tailored to their individual career aspirations. The strong growth in demand for education is in terms of the graduate attributes associated with dealing professionally with disruptive challenges: problem solving, team work, ethics, creativity, resilience, leadership, etc. These have a very different focus to the bulk of competencies listed by professional associations, and are exceptionally difficult to contain in a competency-based approach to learning. Another approach is called for.

2. The emergence of transformative learning

2.1 What is transformative learning?

The notion of transformative learning, originally proposed by Mezirow [14], seeks to address the process of change involved when students move from a schooling context to a working context. It is particularly focussed on the more fundamental, personal aspects of this change: moving beyond the learning of facts and information; to learning/identifying the framework of personal values and attitudes within which facts and information are interpreted; to challenging and changing the personal worldviews, value frameworks and 'habits of mind' that drive and constitute our (learning) behaviour [15]. Under the traditional rubric of transformative learning there are two schools of thought: (i) the rationalists who focus on an explicit process of critical reflection and discourse, deconstructing experiences in a prescriptive process of self-examination, adjustment and reintegration [16]; (ii) the psycho-socialists who focus on extrarational sources or prompts that are more intuitively/emotionally based, and involve the development of sensitivities and presencing over critical reflection [17]. Since the initial dichotomy, various versions and hybrids of the two schools have emerged.

This paper focuses on an interpretation and application of transformative learning that offers a different orientation to teaching and learning again, from the more generic personal transformation of the approach in general. The particular interpretation adopted here is intended to address the learning requirements of construction management, specifically in terms of how students engage (directly) with (and in) the socio-cultural aspects of construction management practice. These socio-cultural practices are the shared routines, sensibilities, vocabulary, styles, artefacts, procedures, etc. that the people who constitute a particular professional group have developed over time [18]: what Schön [9] refers to as the 'language, media and repertoire' of a particular professional practice. These learning requirements are often considered in terms of 'communities of practice' (CoP) or 'situated learning' responses [19]. For CoP and situated learning responses, the operational context is the actual working environment itself. The focus on transformative learning provides for an effective teaching responses to occur within a classroom setting, and is therefore likely to be more practicable than the CoP or situated learning approaches in many instances.

2.2 What does transformative learning offer?

In contrast to a CBT approach, where the emphasis is on particular competency outcomes, transformative learning puts the emphasis on changing the framework that drives and interprets our learning. Students often enter higher education with a view of learning based on authority and achievement. Authority is deemed to include the teaching staff who determine what and how the content will be taught and learned. The authority offers such qualities as knowledge, predictability, safety, answers and power. Students tend to expect and welcome the authority as this mirrors the context in which they successfully learned at school. Authority provides a robust comfort zone for the new learning context. Achievement in learning is gauged by the grades and equivalent performance measures applied to the study program. Grades provide a hugely important driver for an increasingly achievement-focussed generation of students. Authority and achievement complement each other, because each reinforces the others need: to maximise achievement, students expect an authority to deliver 'comfortable' learning.

Transformative learning in this context moves to break the dependency on authority and achievement. It does this in order to transition students into a learning context more like the working environment they will face on graduation. It would appear that the working environment today is far less structured, less dependent on contained specialist knowledge and more complex than previously. Transformative learning offers the possibility of challenging an existing mindset/expectation around authority and achievement, to better enable a student to understand and deal with the working environment they will face. This personal reorientation is particularly important for a rapidly changing working context. It equips students with the concepts and understanding to appreciate the need for transformational change, what is required to achieve transformational change, and how to promote transformational change in others and in organisations. Thus, transformational change provides the essential tools for students to become effective change agents.

In addition to these broad outcomes, transformational learning also offers a more direct alternative to competency-based training. There is no argument here against the need for a range of competencies to be taught and learned within a higher educational context. It is the unilateral emphasis and focus on CBT, promoted by the professional accreditation bodies, that is being called into question. Rather than a comprehensive (and therefore large) set of required competencies, this paper calls for more focus on what are typically referred to as 'graduate attributes'. Mezirow [20] argues that transformative learning leads to students having improved self-knowledge, who are more mindful, autonomous, reflective, able to deal with change, creative, socially responsible, ethical, etc. These are commonly cited as the graduate attributes higher education programs typically seek to develop in their graduates. With the force and imperative imposed by professional accreditation, such graduate attributes are increasingly given only lip-service. Transformational learning puts the focus directly back onto such graduate attributes as explicit outcomes from the learning experience.

2.3 How is transformative learning taught?

It is notoriously difficult to teach personal transformation, particularly in the context of an undergraduate degree program at University. It is certainly so when operating within the paradigm of teaching that presumes learning to involve knowledge transfer, and to revolve around a process of reading, lecture, expert presentation, formal discussion, note-taking, exams, etc. Teaching based on knowledge transfer is very different to teaching based on the preparation of students to exercise the judgement and skill needed to bring that knowledge to application in practice. It is different again to teaching based on the promotion of self-awareness and the capacity to operate effectively in the face of an adaptive challenge. The role considered for transformative learning in this paper is with regard to this latter teaching ambition.

How might teaching based on the promotion of self-awareness and the capacity to operate effectively in the face of an adaptive challenge be taught to a reasonable large, undergraduate class? A particular approach currently being applied and explored by the author is a technique that uses the classroom as a case-in-point. Case-in-point teaching is an approach to teaching developed by Ronald Heifetz and his colleagues at the Kennedy School, Harvard University [21]. It essentially draws from the expectations, situations, feelings, dynamics, behaviour and discussions that occur within the classroom setting, as an immediate experiential reference point for discussions and reflections on transformative learning [22]. The author has recently taught a project management course to 160 first year construction management undergraduate students using this case-in-point approach, to surprising good effect.

Case-in-point essentially follows the U-Process developed by Senge and Kahane, where three phases are required for transformation: a sensing phase, where the emphasis is on acknowledging and recognising the impact of our mindsets on what we do; a letting-go phase, where habits, blind-spots and historical presumptions are identified so as to be suspended; and a presencing phase, where an expanded sense of self (through reflection) is realised [23]. It involves a process of naming, where particular terms/metaphors are introduced as a shorthand vocabulary to refer to elements of the sensing, letting-go and presencing phases of transformation. For example, the notion of a balcony and the dance floor is used to discuss the different perspectives provided on a situation when a person is (on the dance floor) actively involved in the moment, actions and discussions. Contrast that to the more reflective (balcony) perspective where relationships and dynamics are more apparent. Naming and discussing such issues not only builds an effective lexicon for conversations, but acts to sensitise the student to particular roles, characteristics and possibilities.

Case-in-point articulates a rich assortment of terms, each introduced in response to some immediate experience. It has generally been applied to the teaching of leadership, precisely the adaptive leadership needed when responding to complex and uncertain situations, such as those following a catastrophic event. However, the nature of the transformation required to learn how to practice adaptive leadership, is fundamentally no different to that required to improve self-knowledge, become more mindful, autonomous, reflective, able to deal with change, creative, socially responsible, ethical, etc. In other words, here is a teaching process that does emphasise graduate attributes. Less dependence on professional competencies would free space in the programs to include more explicit case-in-point teaching, and thereby more effectively promote graduate attributes.

3. In conclusion

Competency-based training has become synonymous with training per se. It has had a particular and major impact on vocational education and training, and it is unsurprising that professional associations have moved to adopt competency-based accreditation of study programs in construction management. However, the nature of university education, the constraints on course structure, the traditions of teaching, etc. collectively militate against effective competency-based educational models. At the same time, there are significant questions being raised against the promotion of competencies as an effective measure of professional education. Educational providers, legislators, and professional associations each tend to disagree about what competence means and what the nature of expertise actually is.

This paper has proposed an alternative emphasis away from competency-based training, towards a more transformative learning. Transformative learning is presented as a psychosocial approach to learning, where content is replaced with process as the driver of learning. The psychosocial moves the focus of education away from the individual learner gaining a discrete body of abstract knowledge, acquired and subsequently applied in practice. It treats learning as an interpretive process in which understanding is related to action contexts, and not to prescribed conceptual structures.

A particular method of teaching transformative learning has been described. The case-in-point method mixes a naming and framing of particular situational features with a sensing, letting-go and presencing approach. Where this is generally applied to teaching adaptive leadership, it is beginning to be applied also to more direct teaching of particular graduate attributes. It is the broad contention of this paper that teaching a full spectrum of professional competencies (in construction management, for example) is untenable in the current University context. A substantially scaled-down set of such competencies, complemented by more explicit teaching of graduate attributes, would appear a more attractive proposition in the current market context.

Abstract

'Lean' is a newly addressed concept for construction industry, the core of this concept is segregating construction activities into Conversion Activities and Flow Activities, arguing that making conversion activities more efficient whilst improvement of non value-adding activities - i.e. reducing or eliminating them – should primarily be focused.. In addition to processes, Lean concepts can be adopted to professionals' activities in construction industry- i.e.Quantity Surveyor. Effectiveness and efficiency of their functions are essential for a profitable process with overcoming all inconveniences and difficulties that may arise. 'Lean' can be considered as a method of overcoming aforementioned situations. This study explores the acceptability of Lean Concept in functions of Quantity Surveyor in the Sri Lankan context, through an expert opinion survey using Delphi Method. The research finds that Sri Lankan Quantity Surveyors accept the core principles of 'Lean' and concludes that 'Lean' is an acceptable concept within the Sri Lankan Quantity Surveyors and recommended as a methodology to be adopted for the Sri Lankan context. The needing of examining the Feasibility and the Suitability of the Lean concepts is suggested before implementing, while providing base for 'Suitability Test'. Several requirements and organisation related procedures are also proposed for successful implementation of Lean Concepts for the Sri Lankan Quantity Surveyors.

Keywords: Contracting Quantity Surveyor, Flow Activities, Lean Concepts, Sri Lankan construction industry

1. Background

Construction sector encompasses a wide spectrum of activities including provision of professional and technical. While providing them, construction industry is still renowned for its chronic problems such as low productivity, insufficient quality, time over-runs, and poor safety, which hinder customer delivered value.

Among the professionals who are involved in the construction process, to perform, to avoid above issues and provide a good quality service, Quantity Surveyor plays a major role. The Quantity Surveyors is one of the major characters of the construction team, a financial consultant [1] who is keeping accounts and controlling of all costs. The Royal Institute of Charted Surveyors (1991) defines the role of the Quantity Surveyor as "ensuring that the resources of the construction industry are utilised to the best advantage of society by providing financial management for projects and a cost consultancy services to the client and designer during whole construction process." Duties of a Quantity Surveyor depend on factors such as nature of the project; organization context; and, procurement system adopted. However, the traditional role of the Quantity Surveyor was typically organised around the production of Bill of Quantities and final accounts [2]. In addition, [3] describes QS in a different way; as an amalgam of several other disciplines such as economics, law, accountancy, management, information technology and construction technology. In sum, the traditional services of the quantity surveyor were considered to be largely reactive, but necessary important which was mainly a technical back office operation has expanded his services to various paths [4] such as Real Estate Management, Contract Management, Project Management, Facilities Management, Risk Management, Value Management, Claims Management.

Through QS work, various problematic circumstances such as low productivity, insufficient quality, poor coordination and high expenses [5] can associated with the Quantity Surveyor, same as for any other construction professional. Thus, there is a need to apply some methodology to increase their productivity and efficiency in functions.

In the beginning of the 1990's, the new production philosophy, which is known by several names(world class manufacturing, lean productivity, new production system) evolved in the European Construction Industry and in United States, adapting from Japanese manufacturing principles of Lean thinking; Lean Concepts, to provide solutions for such chronic problems arise in construction industry. The core of it is in the observation that there are two aspects in all production systems: Conversions and Flows. Conversion activities produce tangible outputs whilst flow activities bind such conversion activities together during the delivery process of the outputs. Although all activities expend cost and consume time, only conversion activities add value to the material or piece of information being transformed into an output, thus, the aim is to reduce or eliminate non value-adding flow activities and to make conversion activities more efficient [6].

In addition to processes, Lean concepts can be adopted to professionals' activities in construction industry. According to traditional thinking consideration is paid only for the conversion activities and ignores flows. Many tools and techniques have been devised for implementation of Lean thinking in amplifying the performance of the professionals such as quality assurance, computerized integration of design and procurement and electronic data interchange and they can be implemented for the profession of Quantity Surveying also. According to [5], application of the Lean principles can be done several stages. Through such an application, cost and time reductions can be achieved; and hence productivity improvements can be achieved in number of circumstances which incorporates the benefits of competitive advantage.

Considering the current status of Construction Industry in Sri Lanka, this concept seems productive and effective, timely and appropriate at the outset. Still, since any type of an application may need to be customised to better suit the local setting, the acceptability of Lean Concepts to role of the Quantity Surveyors in Sri Lankan context, too, is indecisive. Therefore, the essentials of this new philosophy should be explored in the domestic environment in order to test its acceptability to Sri Lanka, before the application. Thus, it seems necessary first to be clear on a main area of focus in Lean Concepts - such as the prevalence of non value-adding activities in the profession of Quantity Surveying in Sri Lankan construction processes and the awareness of such concepts amongst both consultant's and contractor's Quantity Surveyors in order to examine its relevance to the Sri Lankan context.

2. Acceptability of Lean Concepts to QS

For any process or activity, proper systematic implementation is essential to achieve maximum usage of the implementing concept. In adopting the Lean principles for the Quantity Surveying profession, proper consideration should be given, to gain the benefits and evaluation of the concept because it is important to check the adoptability to a particular organization, environment or a role. "Strategic Option Evaluation Tests" presented by Johnson and Scholes (1997) can be used to check the application of Lean for the profession of Quantity Surveying since it consist of three tests which are helpful in evaluating a strategic option. These are Suitability Test, Acceptability Test and Feasibility Test. Both Suitability and Feasibility Tests have been intentionally omitted from this study since they are more related to process and organisation context and results is hard to generalise for the whole Quantity Surveying population they cannot be accomplished through the scope of this study.

2.1 Acceptability

According to the Strategic Option Evaluation Tests, the Test of Acceptability considers whether the strategic option will gain crucial support from the people who involve in it or whether it will lead to opposition or criticism. According to general management theorists to check the acceptability of a philosophy, acceptability of its principles must be checked among involving people. Therefore, principles of 'Lean' and methodologies to attain the concept will be explored in the remaining part of this section.

2.1.1 Principles of 'Lean'

As stated above the core principles of 'Lean' should be analysed to check the acceptability and the core principles of Lean Concepts are elimination or minimising of non value-adding flow activities and making conversion activities more efficient. In addition to those core principles, According to [5] and [7], there are few other principles in 'Lean' related to construction professionals. They become the benefits gained by the involving professionals, as mentioned below.

- Increase output value through systematic consideration of customer requirements
- Reduce variability
- Reduce cycle times
- Build continuous improvement into the process
- Simplify by minimizing the number of steps, parts and linkages
- Increase output flexibility

- Increase process transparency
- Focus control on the complete process
- Balance flow improvement with conversion improvement
- Benchmark

Thus, if the construction professionals are to accept Lean philosophies, they also should believe in these principles, as mentioned above. For example, if a Quantity Surveyor is to accept major principles of 'Lean', he also should accept that only conversion activities add value and thus non value-adding flow activities should be eliminated whilst making conversion activities more efficient in all his activities and it gains benefits. Only if they are convinced and open to believe its benefits in implementation, they support in establishing Lean principles for their duties. If the Quantity Surveyors feel that application of Lean concepts may cause inconvenience to them, with the prevailing workload, they may hesitate to accept this philosophy. Since this application creates changes for the prevailing workflow or process, an extra attention and effort are needed for the procedure, this may creates less-responsive among Quantity Surveyors about them.

3. Selection of research approach for testing the acceptability

In this research process such opinion survey will be conducted for few functions of a Quantity Surviving role, which are mostly used in Sri Lankan Construction industry. According to [4], functions of a contracting Quantity Surveyor, can be identified according to their relative importance; pricing of Bill of Quantities, Interim valuations, Variation accounts, Cash Flow preparation and Final accounts are the five functions which are most common in Sri Lankan context. Above mentioned decomposition of activities can be done for them and then the acceptability of Lean principles can be tested by identifying flows and conversions included in them.

Since, this is an initial study on acceptability of Lean Concepts in Sri Lankan Quantity Surveying; it is needed to pay attention to a broader perspective rather than to in-depth analysis. Thus, considering all these facts it was decided to undertake an Opinion Survey based on the Delphi Method to check the acceptability of Lean Concepts for the Quantity Surveying, in the Sri Lankan context.

Since the M1 and M2 are considered as main contractors who carry out the major construction work in Sri Lanka while adopting profession of Quantity Surveying, expert panel from the Quantity Surveyors of M1 and M2 contractors was selected. Among all Quantity Surveyors involving in post contracting activities in the industry, managerial level Quantity Surveyors of the organizations were selected because since this 'Lean' is a managerial concept which can be successfully achievable with the level of experience through the industry. With the idea that, there may be many types of flow wastes in the functions of Quantity Surveying, but due to the fact that there may be flows either hidden or not given much attention, only well experienced personnel will observe and identify the most amount of them, it was decided to choose twenty five (25) Quantity Surveyors who are currently involving in managing post contract activities, with high level of experience.

4. Delphi Method

As required by the Delphi Method , the mode of data collection was through questionnaires, and, were distributed in three rounds. Data collection steps were as follows.

STEP 1: The Delphi Round One Questionnaires will be distributed amongst the panel members, with the aim of identifying flows and conversions of the selected functions of Quantity Surveying.

STEP 2: As the second step, the Delphi Round Two Questionnaires were distributed to the survey sample, presenting the identified flows and conversions from the First Round. The participants were asked to provide their opinion on these identified flow activities, whether they can be eliminated or minimized, or not while make opinions on the given statements about the lean principles.

5. Data Analysis and Discussion

5.1.1 Identification of Conversion and Flow activities

In the First Round, the participants were asked to identify the Conversion and Flow activities separately, they had experienced in the Sri Lankan construction industry, out of given sets of sub activities, decomposed from the selected major five activities (see Figure 1) and to mention the additional types of activities they had experienced. After analysing the collected data from the First Round of the survey, the results were taken to the second round to check the opinions regarding the elimination and minimisation of flow activities. Out of the total results obtained from the Delphi Round One, the flow activities, which obtained less than fifty percent (50%) opinion, have been excluded as per the analysis criteria. When analysing the second round results, flow activities, which scored more than fifty percent (50%), as ‘can be minimised or eliminated’ were only selected in modifying the models of the selected functions of a Quantity Surveyor. The results obtained through the analysis can be presented according to the selected activities as follows.

(A) Pricing Bills of Quantities

All other sub activities relate to both flow and conversion activities, according to the opinions of the panel. Flow activities hold 86.96% of total activities, while emphasising that most of the sub activities were flows which consume time and cost, without adding value to the total process. Only ‘get site visit investigation report’ and ‘use pre-bid meeting records’ scored more than 75% of flow wastes which cannot be minimised, according to the results of the second round. Out of all fourteen (14) flow activities mentioned in the round two, eight are more than 50% saying that they can be minimised or eliminated. It emphasises that although they believe there is a huge set of flow activities, they may have the problematic mentality on whether they can be minimised or eliminated in the real practice as illustrated in theories. Pricing Bills of Quantities is a critical activity of a contracting organisation, which decides the profit and the survival of the organisation in the industry. Quantity Surveyor is the responsible person in this task to perform it accurately, holding a great risk. Therefore, it is amply palpable that above mentioned flows- ‘get site visit investigation report’ ‘use pre-bid meeting records’ and also ‘Getting prices from suppliers’ hold a high percentage as ‘cannot be minimised or eliminate’, when considering the importance of information receiving from that steps.

All five functions were checked and analysed using decompositions of sub activities (see Figure 1) and activities, which can be minimised or eliminated, are presented in shaded boxes (see Figure 1). All the activities can be presented as this and figures of other activities are not been presented due to space limitations.

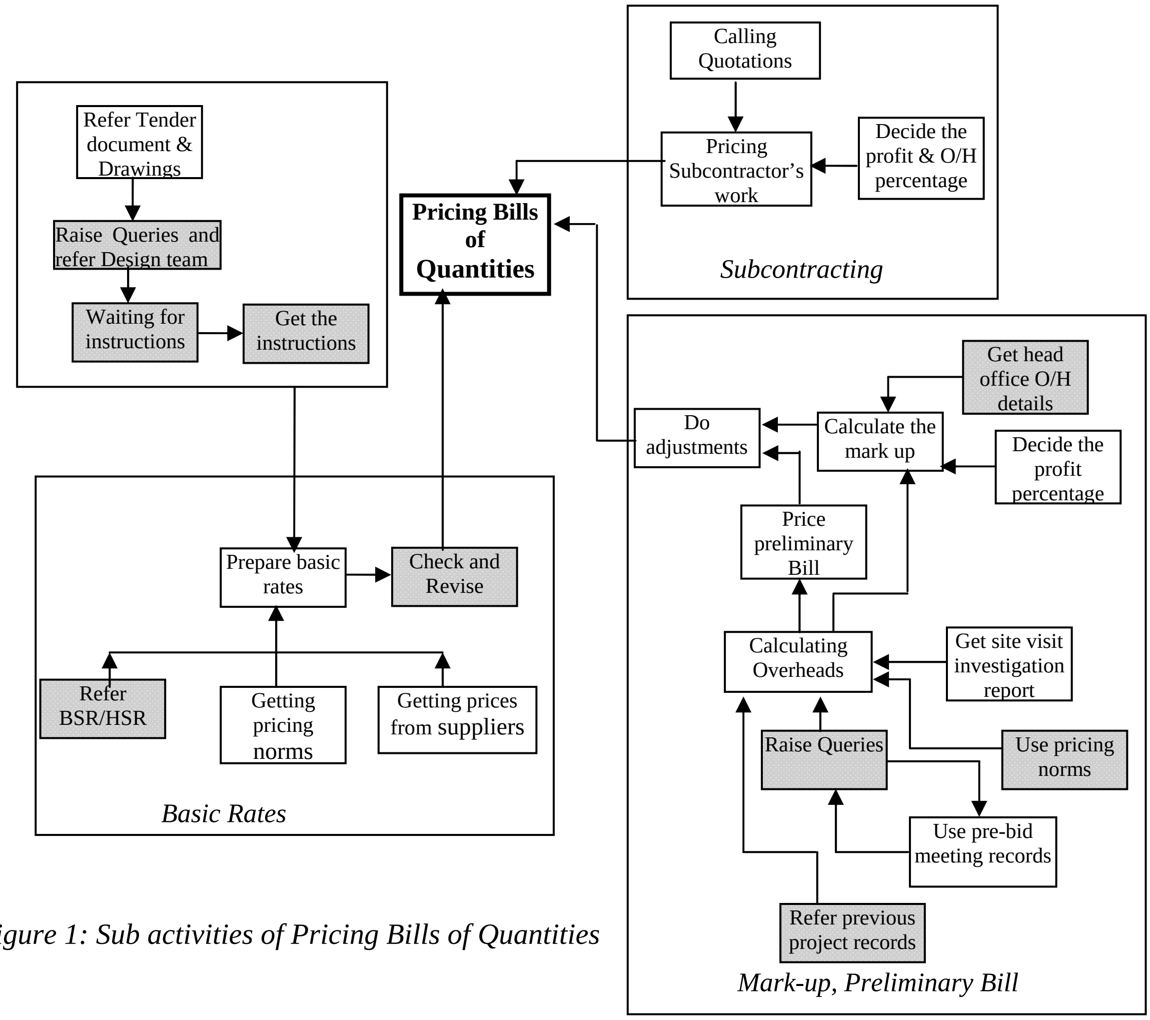

Figure 1: Sub activities of Pricing Bills of Quantities

(B) Interim valuation

In the function of Interim Valuation, only the ‘preparation of interim application’ acts as a pure conversion activity, as selected by the experts, resulting of 91.67% of activities as flows. Only ‘Joint measurements’, ‘Obtain items and rates from BOQ’ and ‘refer previous valuations’ obtained more than 50% out of all responses of the panel, which emphasizes that the most of the sub activities of the function act as conversions throughout the interim valuation process. Joint measurement is the only flow activity which gained higher percentage as ‘cannot be minimized or eliminated’ type, according to the second round results of the opinion survey. Other two activities can be eliminated or minimised according to the responses of the panel.

(C)Preparation of cash flow

Preparation of cash flow bears the highest percentage of 92.86% as flow activities, which leads to conclude that it, is the least significant out of given five functions, among the contracting Quantity Surveyors. There are five (5) flow activities which scored more than 75% in the first round while only ‘Raise Queries gained more than 80% while others hold between 50%-65%. The results mentioned above, provides evidence to confirm the thought that most Sri Lankan contractors are not practicing standardize or proper cash-flow forecasting or controlling method.

(D)Pricing Variations

Pricing Variations, twelve (12) sub activities were presented and three (3) were selected as fully conversion activities with 100% of total while six (6) sub activities obtained 80% as flow activities which can be considered as high amount. In pricing variations, ‘Submit the Quotation for Engineer’s approval’ is only activity which depict less tendency to be minimised or eliminated, while all others scored more than 50% as flows that can be minimised. As this holds the least percentage of flow activities; the panel has considered that most of the sub activities of the function are significant. There is a propensity to arise variations in any project and pricing is important from the view of both client and contractor.

(E)Final Accounts

When considering Preparation of Final Accounts, out of seven activities, only two activities scored more than 50%. It allows concluding that most of the sub activities in the final accounts are conversion activities, according to the opinions of the panel members. When considering second round results, both flow activities can be minimised or eliminated with a percentage ranged from 65%-70%. It is also a significant function of a Quantity Surveyor since it is the point that both client and the contractor view the total financial involvement of the product- leads to Quantity Surveyor to feel more on his responsibility than adopting new concepts.

Even though the Quantity Surveyors participated in the study were quite experienced and in managerial level of contracting organisations, they also had mentioned a considerable percentage of flow activities as ‘cannot be minimised or eliminated’. The main reason for this might probably be the fact that a concept such as Lean Concepts, which pays attention to flow wastes, has not been applied in the Sri Lankan construction industry so far. If there had been such a concept, the whole workforce including Quantity Surveyors throughout the organisation, would have had knowledge and practice to some extent, regarding minimising of flow activities. Since these different professionals and other parties such as clients, statutory authorities and suppliers have different roles to play in the construction setting, Quantity Surveyor needs to deal with them in fulfilling his/her tasks. Thus minimising or eliminating identified flow activities would cause changes to the procedure and influence other involving parties, which would lead to explicit problems. Also this procedure may incur additional resources such as time and other physical resources and new implementation may interrupt the existing process of the Quantity Surveyor including other organisational activities. If there would not be such barriers, there seems to be a demand for such a concept to be applied in the Sri Lankan construction industry in order to eliminate the earlier mentioned non value-adding flow activities.

Thus, it is very logical to argue that these non value-adding flow wastes should be a critical factor causing such cost and time overruns. Therefore, these flow activities seem to be a major weakness in contracting Quantity Surveying, also with the overall Quantity Surveying profession in the Sri Lankan construction industry.

From the above analysis of results from Delphi Round One and Two Questionnaires, it seems apparent that these non value-adding flow activities are a major weakness in contracting Quantity Surveying profession in Sri Lankan construction industry.

Thus, there needs to be a necessity for some methodology which can eliminate or minimise these non value-adding activities from the functional processes of the Quantity Surveying. Since Lean Concepts is a concept, that aims to eliminate or minimise non value-adding flow activities, it can be argued that Lean Concepts is appropriate in applying to renovate the processes of contracting Quantity surveyors in Sri Lankan context.

From the above discussion, it is quite evident that Lean Concepts is suitable to apply in the Sri Lankan context. Thus, it is then necessary to test how 'acceptable' this concept is, in the Sri Lankan context.

Before understand the 'applicability' of the Lean principles, it is needed to understand that there is a need of such theory, for the functions of Quantity Surveyors. With above opinion survey, panel members clearly understood about the flows and conversions in their functions and 'need of Lean concept' for their functions, to gain a more effective and efficient work procedure.

5.1.2 Acceptability of Lean Principles

In order to test the acceptability of Lean Concepts, through the Part 'B' of Delphi Round Two Questionnaire, the participants were asked to mark their opinion regarding twenty (20) statements which were compiled based on core principles of Lean Concepts.

Table 1: Results of checking the acceptability of principles of 'Lean'

No.	Statement	Mean	St.Dev
Principle 1	**'Conversions add value for the process'**		

01	All of earlier mentioned main functions of a Quantity Surveyor add value to the final output for the client	4.80	0.50
02	A majority of functions of a contacting Quantity Surveyor in the concepts industry are add value to the final output for the	4.64	0.64
03	Any Quantity Surveying function consist both value adding and non value adding activities	4.48	0.77
08	Conversion activities should be improved to gain an efficient and effective process	3.28	0.74
<u>Principle 2</u>	**<u>'Flow activities, which are non value-adding, should be eliminated'</u>**		
04	Most of the sub activities of main functions add no value to the final product of the client	3.48	0.87
05	Non value adding activities consumes both time and cost but adds no value to the process	4.24	0.60
06	The amount of value adding activities is less when considering the sub activities of single function of Quantity Surveying	3.88	0.73
07	The amount of conversion activities (value adding activities) are less inside all contracting Quantity Surveying functions	4.52	0.77
09	Flow (non value adding) activities should be minimised or eliminated to gain an efficient and effective process.	4.64	0.64
<u>Principle 3</u>	**<u>'To increase output value, systematic consideration of customer requirements is essential'</u>**		
10	The prime intention should be adding value to the client in every activity in the process	4.72	0.61
11	Systematic consideration of customer requirements should be given to increase output value of the functions	4.52	0.71
20	With these improvements, Quantity Surveyor can gain benefits through his/her functional processes which assist in achieving	4.68	0.56
<u>Principle 4</u>	**<u>'Reduce variability'</u>**		
12	These improvements reduce the variations which can be arise through the process	3.80	0.96
<u>Principle 5</u>	**<u>'Reduce cycle time'</u>**		
13	These improvements reduce the time of a particular process	3.80	0.87
14	Improvements should be continuous through whole process of the functions	4.64	0.57
<u>Principle 6</u>	**<u>'Minimise the number of steps'</u>**		
15	These improvements help to minimise the number of steps in a function of a Quantity Surveyor	4.04	0.79

Principle 7	**‘Increase process transparency’**		
16	These improvements help to create error free functions for the contracting Quantity Surveyor	3.76	0.97
17	These improvements increase the sharing and communicating information in functions for the contracting Quantity Surveyor	4.36	0.57
Principle 8	**‘Control and balance of the process’**		
18	When improving the functions, total procedure of the work should be considered well.	4.65	0.63
19	Both conversions and flows should be improved simultaneously	3.68	0.99

The results showed that the Mean values for the eight principles are approximately around 4.00 with Standard Deviation values lesser than 1, which can be considered as a less deviation. Inline with the earlier interpretations of Mean and Standard Deviation, the above results show that all the eight factors gain values over the centre limit of 3.00, even after the deviations are considered. This implies that there is consensus amongst the participants that they ‘Agree’ to these principles. Therefore, it is reasonable to argue that the experts accept that ‘Conversions add value for the process’, ‘Flow activities, which are non value-adding, should be eliminated’– which are the statements two core principles of Lean Concepts. Among all the statements, Principle 3 statements gained the highest mean value, depicting that most of the members believe in positive side of the statement. It is true that there should be a systematic procedure to adopt any concept successfully, for a particular process and this general truth apply for the Lean Principles as well. Further it can be argued from the results of lowest mean value of the Principle 4 above, ‘Reduce Variability’-that the experts believe that there would be a level of accomplishment on it, but only up to a marginal extent. Panel members may have the mentality that the adopting new methods of Continuous Improvement would occur some deviations to their normal procedure of the functions. Although, Lean Principles emphasises that Continuous Improvements will reduce the propensity of varying the work throughout the procedure, above stated mentality of the practitioners may had lead to comparatively low response on it. Therefore it seems that whilst the experts themselves accept the Lean principles, they believe that the other practitioners too would accept the ideology of Lean Concepts. This emphasises the importance of teamwork and coordination between the Quantity Surveyor and other involving professionals, for a successful completion of tasks. So this improvement should not be focused only to Quantity Surveying profession and should relate to involving other professionals in an organisation.

Since reliability and validity of the results must be checked, ‘Reliability Analysis’ in the SPSS 10.0 software is used to measure the reliability of the data obtained through the research while the Rotated Component Matrix of the Factor Analysis in the SPSS 10.0 software was used to

check the validity. Thus, according to the above discussed results of the Factor Analysis, the twenty (20) statements in the Part ‘B’ of Delphi Round Two Questionnaire seem to be valid. This implies that the intended idea of testing the acceptability of Lean Concepts in the Sri

Lankan context is conveyed through these twenty statements. According to the Reliability Analysis, since the Cronchbach's Alpha value of the data exceeds 0.70, it is clearly evident that the data obtained for Factors are reliable.

6. Conclusions

'Lean' is a new philosophy for the construction industry which was adapted from the manufacturing industry which depicts the concept that there are two activities in any process- Conversions and Flows. This concept argues that whilst making conversion activities more efficient, improvement of non value-adding activities - i.e. reducing or eliminating them – should primarily be focused [6].

From the obtained results of the first part, it can be clearly identified that all selected activities of Quantity Surveying are considered as conversion activities, when taking them as a whole. But each of them is a combination of sub activities-identified as conversions and flows. In accordance with the data analysis, major portion of the main activities are flow activities which obtained more than eighty five percent (75%) of total sub activities (see Figure 2), means that major share of Quantity Surveying activities consume time and other expenses without adding a worth for the process.

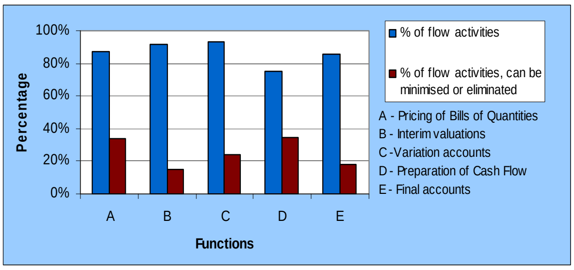

Figure 2: Proportion of Flow Activities of selected functions of a Quantity Surveyor

These results suggest that almost all participants in the panel have a common understanding that there are frequent flow activities throughout the provided functions of a contracting Quantity Surveyor in the Sri Lankan construction industry. This leads to conclude that all Quantity Surveying functions consist both flow and conversion activities.

Also it was disclosed that most of the flow activities can be minimised or eliminated and the awareness amongst the Quantity Surveyors regarding these non value-adding flow activities is considerable. This fact also support that 'Lean' is a suitable concept for the Quantity Surveyors since it becomes easy to adopt it with the awareness of component in it.

This research discovered that Lean Concepts are acceptable for implementing in functions of contracting Quantity Surveyors in Sri Lanka. To accomplish this in Sri Lanka, individual quantity Surveyor and the involving organisation should check its feasibility and suitability for the working procedure within the particular firm. In order to check whether it is feasible to implement the concept of Lean Concepts within the particular organisation, the company should ensure that, there is top management commitment to the implementation; there should be resources provided to the Quantity Surveyors and also company policies and regulations should facilitate this concept.

Also it is recommended that the Quantity Surveyor as the cost expert in the industry should try to quantify these wastes and should try to cost them. As a result he/she would be able to draw the attention of all the management and other employees of the company to take necessary actions to prevent these flow wastes. A cultural change to Quantity Surveyor and other involving parties is essential to minimise the problematic effects arising through the application of the 'Lean Concepts'.

Abstract

Transferring new knowledge created through research into teaching is a primary task in any higher education institution. Recently in UK, this area has gained a wider attention with the growing emphasis on student learning approaches, quality assurance procedures and research funding mechanisms. The link between research and teaching is not automatic. Thus, it needs to be formally created in higher education departments in order to achieve a productive relationship and to manage research activities of university staff with their teaching duties. The research study on which this paper is based on, aims to develop a framework to enable transfer of research knowledge into teaching. This study is different from previous approaches in that it looks into the research and teaching link as a two-way knowledge transfer process in the light of growing knowledge management viewpoints. The framework which is developed through an exploratory case study is validated through five further case studies in different disciplines. Thus, the final framework that is described in this paper can be considered by a higher education institution in creating a formal research to teaching transfer process.

Keywords: Higher Education, Knowledge Transfer, Learning, Research, Teaching

1. Background

Research studies that have explored the relationship between research and teaching had revealed different outcomes. The quantitative studies, which have considered different outcomes to measure research and teaching, have generally concluded that there is no relationship between university staff research and teaching [1]. The qualitative studies, which have considered actor perspectives, for example, staff, student and researchers' views, have concluded that a symbiosis relationship exists between university staff research and teaching [2, 3]. Badley [4] synthesises different interpretations of R&T relationship into five types, 'an impending divorce'; 'a martial relationship'; 'a holy alliance; 'a scholarly relationship'; and, 'a really useful link'. In an impending divorce, separate institutions exist for research and teaching. In a martial relationship, research is viewed as the male partner and teaching as the female partner. In a holy alliance view, research is seen as a generator of uncertainty; and, teaching need to address this uncertainty. In a scholarly relationship, research and teaching are separate but overlapping scholarly activities. Badley [4] further adds a ‘really useful link’ by seeing R&T in an interactive relationship.

According to Jenkins [2], an effective way to link research and teaching is managing staff research to benefit student learning, which will benefit both students and staff; and, also, will improve knowledge development and learning within universities. However, as most studies confirm, research and teaching are loosely coupled activities, which may not have a necessary or an automatic link; and, therefore, it is necessary to create this link to achieve a productive relationship [5]. Recent studies address this issue and introduce different strategies to create a beneficial relationship rather than the problematic one that naturally exists.

As Jenkin and Zetter [5] argue, it is the academic departments who should develop this effective link depending on whether the department is teaching-biased or research-biased. Research-biased departments can create the link to benefit teaching from their research activities. Previous work shows that in research-biased departments, students are unaware of the high quality research discovered within these departments due to poor transfer mechanisms [6]. Thus, these departments can help students to appreciate the value of research within the department by creating a flow from research into teaching. Transferring research into teaching in research-biased departments is, therefore, seen as an important task that needs prompt attention.

Research has also found that the R&T link is dependent on different disciplines [7]. ‘Linking Research & Teaching’ [8] is a national project that has broadly studied the R&T link in a variety of disciplines such as geography, biosciences, law, health science and hospitality disciplines. An associated project, namely LINK: Good Practice Resources Database [9] explores the R&T link specifically in the built environment sector. In addition, the work of Fawcett et al [10] on nursing; and, the work of Cech [11] and Sears and Wood [12] on bioscience provide useful insights into this link. Planet [13] is a special issue that focuses on R&T link in geography, earth and environmental fields. However, these research studies fail to appreciate useful insights from the extant knowledge transfer and learning literature. By identifying this gap, an attempt is made to bring in knowledge management perspectives to this transfer process and develop a better understanding on the phenomenon.

2. Knowledge Transfer Perspective

Some pedagogical researchers have identified the importance of knowledge management perspectives on university research and teaching. For example, Jenkins [2] states that knowledge economy demands academics to be creative and gain ability to create; find; and, synthesise new knowledge. Scott [14] state, “in a ‘knowledge society’ all students –certainly all graduates – have to be researchers. Not only are they engaged in production of knowledge; they must also be educated to cope with risks and uncertainties generated by the advance of science.” Scott [15], further, laments that in the knowledge society research and teaching are no more separable activities; and, the impact of the knowledge society has been to make research and teaching even more transgressive. Brew [16] puts across knowledge-based views with respect to research and teaching link. Accordingly, research and teaching are seen as activities where individuals and groups negotiate meanings and build knowledge within a social context. Brew [16] brings in the concept of academic community of practice where academic departments, disciplines, sub-specialisms, a university as a whole, or networks of professionals interact through face-to-face settings to disseminate research knowledge.

More insights can be gained by viewing research into teaching as a knowledge transfer process. According to Sexton and Barrett [17], knowledge transfer is viewed as the movement of knowledge via some channel from one individual or firm to another. In this context, this means movement of research knowledge (be it research findings, skills or processes) from researchers (be they academics, researchers or practitioners) to students (be they undergraduates or postgraduates) through teaching and other mediums such as seminars, workshops, conferences and project-based work.

Szulanski [18] identifies the difficulty of a knowledge transfer process in six ways. First, strength of relationship between the staff (staff research) and students influences the effectiveness of the transfer. Such relationships can be strengthened by creating positive attitudes among students toward staff research though awareness. Second, direct transfer of research findings to students is inappropriate as this can create ambiguity. In order to overcome this difficulty, research output of projects can be re-constructed to suit the student audience. Rowland [19] describes this as 'talk down to students'; that is devising a simple structure to deliver complex research knowledge to students. Third, absorptive capacity of students differs depending on their prior knowledge [20]. In fact, as Elton [21] argues, a positive R&T link depends on the nature of student' learning experience and the abilities of students (absorptive capacity). Thus, strategies need to take this into account. For example, at level one, students can be given an introduction to the basic research process and at a higher level they can access direct research experience. Fourth, reliability of research results is an important factor in transferring research knowledge into teaching. Lindsay et al [22] explains that research needs to be of interest, relevance and utility to students. This suggests that research results should be tested for their suitability and accuracy before transferring to students. Fifth, Szulanski [18] points out motivation as an influencing factor during knowledge transfer. Not only staff motivation but also student motivation is required in creating this R&T link. This can be created by a cultural change within a department as described in Section 3. Finally, since the transfer does not occur in a vacuum, contextual factors such as organisational context can also have an influence [23]. In sum, to transfer research into teaching effectively, these factors and their impacts need to be considered.

According to Davenport and Prusak [24], effective knowledge transfer does not involve mere transmission but also absorption and use following such a transmission. As such, initiating the R&T link in a department and feeding research knowledge into teaching is insufficient; the transfer needs to ensure that such knowledge is absorbed and used by students after a transmission. Huberman [25] confirms this when he claims that research data penetrates very slowly into the consciousness of the potential user, helped along by discussions and observations. According to him, the dissemination of research knowledge depends on its usefulness to the user and the absorptive capacity of the users. Accordingly, when students are considered as the potential users of such a transfer process, their learning process followed by such a transfer is an essential consideration. As Griffiths [26] emphasises, for an effective transfer and learning, providing students with learning opportunities is insufficient; therefore, it is equally important to evaluate student learning. In fact, learning is the key driving force that links research and teaching [27, 28]. As such, in transferring research knowledge into teaching, different student learning styles need to be addressed.

The literature on learning styles can be grouped into four theories [29, 30, 31]. First, the 'field dependency' theory illustrates that learning can be influenced by the context that the students learn. Second, 'holistic versus sequential' learning theory describes that some students prefer visual approaches whereas some prefer verbal approaches to learning. Third, experiential learning theory (Kolb, 1984 cited in [29]) explains an individual's learning cycle in four aspects: activist, reflector, theorist and pragmatist. This role of experience in learning calls for activities such as project-based work that provide students with first-hand experience. Finally, based on 'surface versus deep' learning theory, it is the deep learning styles that should be encouraged in higher education institutions compared to surface learning. Griffiths [26] describes that inquiry-based learning as a powerful active learning tool, especially in the form of problem-based learning. Schon [32] describes that 'reflection on action' is also needed when students engage in active learning processes. On the whole, these theories on learning, suggest that not everyone can be taught in the same way and the teaching approach need to take these differences into account in evaluating student learning followed by such a knowledge transfer process.

In summary, the educational research has established that R&T link is not automatic and need to be created in each academic department based on the discipline. The knowledge transfer and learning literature values the importance of student perspectives and maintenance of R&T link following an immediate transmission process. With these key findings from the literature, the next sections move to the empirical stage. Accordingly, the research methodology is explained next.

3. Research Methodology

This research selected case study methodology due to the context-specific nature of the phenomenon under study. The case study methodology allows to carryout an in-depth investigation of a complex phenomenon within its real life context. According to Yin [33], "*a case study is an empirical inquiry that investigates a contemporary phenomenon with its real-life context, especially when the boundaries between phenomenon and context are not clearly evident.*" As such, the case study method was considered most suitable for this research. This study was based on multiple case studies, which were of exploratory and explanatory nature.

The case studies were designed by identifying the unit of analysis and a sampling strategy. The unit of analysis considered was academic departments within a university while the study expanded to individual and university levels where appropriate. The sampling strategy was to identify departments that focus on vocational or social science disciplines. Accordingly, study first selected a department on built environment with a high research assessment rating as an exploratory case study. Aim of this exploratory phase was primarily to develop a framework to transfer research into teaching. Subsequently, departments that focus on disciplines such as information technology; sociology; nursing; geography; and, management were selected for detailed case studies. Aim of these case studies was to validate the already developed framework in the identified disciplines. The next section describes the development of the framework.

4. Framework Development

This section explains the development of a framework (see Figure 1) to create research to teaching transfer. The initial framework that was developed through the exploratory study was validated in detailed case study phase. This section describes the final generic framework that is validated by case study participants.

As case study findings identified, many academics favoured introducing formal strategies to facilitate RtoT transfer process. In formalising these strategies within a department, the questions as to 'who should lead?' and 'who should be allocated to maintain the link?' arise. These questions led to recommend assigning a new staff position called 'R&T co-ordinator' with 'R&T team'. By allocating human resources in this way, not only the link can be initiated but also it can be maintained. Therefore, the start-up activity of the framework is assignment of ownership and resources.

To enable RtoT transfer, three activities based on case study findings are identified as necessary. First activity is to review current research and teaching policies in creating the R&T link. The second activity is review of staff recruitment and development strategies at regular intervals; for example, research staff job descriptions can be changed to include teaching duties. Thirdly, to improve the learning environment and to make effective use of advanced technologies, creating and maintaining interactive forums, both physical and virtual, are proposed. The purpose here is to link students, researchers and the academic staff in the department in order to strengthen relationships and provide opportunities to disseminate good practices and research.

The specific RtoT transfer strategies are then considered by integrating various RtoT strategies; some of these were already in practice and some were suggested through case studies. Firstly, a cultural change within departments is proposed in terms of research and teaching practices. At the heart of this change, a week of activities (an 'innovation week') is introduced to offer research awareness and knowledge. This 'innovation week' is introduced at each year of study. For example, in the first year of study, 'innovation week' can be assigned for research awareness activities such as awareness of the research institute and staff research. Similarly, in the second year, this week can be used to give students knowledge on research such as research process, methods and findings. In the third year within this week, research skills can be cultivated in students by offering them research training and experience. This progressive introduction of research activities from lower levels to upper levels enable to feed-forward learning gained at each year. Thus, this innovation week will provide a research environment among students. Furthermore, this week can be effectively utilised to provide opportunities to interact and share knowledge with different groups such as academics, researchers, postgraduate students and, also, relevant industry practitioners.

Most staff believed in project-based learning and problem solving as a path to transfer research to teaching. Thus, an integrated project task is introduced as another RtoT transfer strategy. This is a group exercise that enables students to work collaboratively and gain active research experience. Further, to provide not only new findings within the discipline, but also to give students with first hand research knowledge, separate module called 'research module' is proposed. For undergraduates this module can be introduced at the final level along with their dissertation project whereas for postgraduates this module can be introduced along with their research project. This module is aimed to specifically select current research themes and make students knowledgeable on these. Further the coursework tasks related to this module can specifically focus on giving students some research experience. Finally, based on suggestions offered by interviewees, another RtoT strategy introduced is implementing 'short courses' around staff research activities. Finally, as an outcome activity of this RtoT transfer process, recognising and rewarding RtoT good practices are proposed.

The above-discussed nine activities are integrated into an overall framework that represents 'RtoT transfer process'. These activities are divided into four elements: start-up, process-specific, on-going and outcome (See Figure 01). The start-up and outcome elements act as input and output activities in the RtoT transfer process. The most significant activities related to RtoT transfer process are grouped under the process-specific element, where the real transformation takes place. The four activities under this are shown in a loop to represent the learning cycles within and in between the activities. Three activities, which should take place on a regular basis to enable the RtoT transfer process, are identified under on-going element. This framework is aimed at providing a step-by-step guide for academic departments to transfer its research into teaching.

In validating the framework within case study departments, significant comments were received which were incorporated into this final framework. Most departments agreed that this is a comprehensive framework that covers most of RtoT aspects. However, one case study department, which had strong informal research-based teaching practices, stated that it is important to evaluate the value of such a formal transfer mechanism where natural transfers exist. With respect to separate ownership, academics raised mixed views. Some stated that it will create bureaucracy while some pointed that people will start thinking that it is someone else job. Thus, it is important to emphasise that a separate ownership is assigned purely to facilitate the process and all academics need to effectively take part in RtoT transfer. Anyhow, many saw the importance of assigning an ownership, in particular, to manage administrative work in connection. The 'innovation week' received many positive comments; for example, in healthcare courses its academics expressed that this week would work well with their large student batches. Some mentioned that this week would nicely align with their induction programme in level one. Some academics pointed that this kind of activity needs to be assessed to get good student participation. In recognising and valuing good practices, academics emphasised on valuing innovative teaching methods and staff personal development.

5. Conclusions

The importance of research knowledge transfer into teaching has been identified and debated by many authors with differing viewpoints ranging from the type of the discipline to types of departments. Key areas such as knowledge management and learning have been largely ignored in the search for effective strategies of research knowledge into teaching. This research had developed an understanding on research knowledge transfer into teaching through case studies across several disciplines.

Even though, research-informed teaching is the key to transfer research into teaching, many academics agreed that there should be formal processes to aid natural mechanisms. Such formal mechanisms should not only be implemented in a department but also be properly maintained and evaluated for the success. Further, formal mechanisms should not mislead its members to feel that it is a separate process. Both literature and case studies emphasised that departments should have a research to teaching culture where everyone is actively and effectively involved. Finally, considering knowledge management concepts and views of academics, the transfer should go beyond academic departmental level to a wider community where everyone effectively share and disseminate research knowledge and good teaching practices.

Abstract

Several researchers perceive construction industry as a knowledge based, value creating sector of an economy. There is an emerging importance placed on the Human Resource Management in the construction industry, as one of labour intensive sectors of the economy. The issue of the critical role played by employees in fostering an effective construction business has often been overlooked over the years. Capacity of wealth creation of a company is based on the knowledge and capabilities of its people. Therefore the value addition is done to the organisations by installing such personnel knowledge into knowledge management systems that organisations create and use. This focus of the human resource as a strategic resource central will help organisations to achieve competitive advantage in business environment. It also represents an alternative way in which to understand employee selection and evaluation. Employee selection and evaluation practices can contribute significantly to the organisation gaining a competitive advantage. Hence it is very important to analyse and formulate a suitable set of competencies in a knowledge-centric industry such as construction. This research attempts to construct a simplistic model to help the industry practitioners to rank the suitability of a person for an assigned job based on their competencies. From a literature synthesis and informal discussions with experts, qualification and work experience are selected to form a simplistic model. This paper discusses scaling of selected competencies while highlighting the appropriate methodology for the undertaken research.

Keywords: Employee selection, Human intellectual capital, Qualification, Work experience, Research methodology

1. Background

The UK construction industry is one of the strongest in the world, with output ranked top amongst top global construction industries[1]. The industry contributes to roughly 8% of the national GDP and employs in excess of 1.8 million people[2]. Thus construction in the UK is considered as one of the pillars of the domestic economy, with its capability to deliver the most difficult and innovative projects, matches that of any other construction industry in the world [3]. Nonetheless there is a deep concern that the industry as a whole is underachieving. A considerable amount of attention and effort has been directed in number of disciplines to address the industry's poor performance level. In light of this, it is increasingly being acknowledged that knowledge management can bring about the much needed innovation and improved performance in the UK construction industry [4, 5]. Furthermore several researchers perceive the construction industry as a knowledge based, value creating sectors of the economy [6, 7]. This affirms the transition of the construction industry from an asset-centric to a knowledge-centric business environment.

There is an emerging importance placed on the Human Resource Management in the construction industry, as one of labour intensive sectors of the economy, which is still considered to be an uncharted territory [8] within construction organisations. Nesan & Holt [9] argue that the issue of the critical role that employees play in fostering an effective construction business has often been overlooked over the years. According to Cooke-Davies [10], "it is people who deliver the projects and not processes and systems", which gains increased validity in the context of labour intensive construction industry. Hence it is prerequisite to define more appropriate and realistic employee selection and evaluation for the creation of knowledge-centric construction industry.

2. Importance of Intellectual Capital

Even though commentators tend to use different terminologies to explicate two types of organisational assets, commonly they can be divided into tangible and intangible assets. While tangible assets are referred as traditional or physical assets [11, 12], intangible assets are mostly referred as intellectual capital [13-17]. Despite the differences in the usage of terminology, many researchers believe in the importance of intellectual capital over the traditional tangible assets of an organisation.

According to Petty and Guthrie [17], the commonly held definition of intellectual capital is that offered by Organisation for Economic Co-operation and Development(OECD) which describes intellectual capital as the economic value of two categories of intangible assets of a company, organisational capital and human capital. Organisational capital refers to organisational infrastructure such as software systems, distribution networks, and supply chains. The term human capital corresponds to human resources, consists of education, competencies, values, attitudes and experience components [18]. Various other authors consider intellectual capital as the combination of human capital, structural capital and relationship capital. Interestingly, of these various categorisations of intellectual capital, human capital is regarded as the most valuable asset [19].

The advocates of the human capital approach emphasise that many of the assets that individuals bring to the organisation are intangible, premised in individual, tacit knowledge rather than the more explicit, explicated, formal, routine and standardised knowledge [18, 20, 21]. Capacity of wealth creation of a company is based on the knowledge and capabilities of its people [22]. Therefore the value addition is done to the organisations by installing such personnel knowledge into knowledge management systems that organisations create and use. This focus of the human resource as a strategic resource central will help organisations to achieve competitive advantage in business environment. It also represents an alternative way in which to understand employee selection and evaluation.

The contemporary employee selection and evaluation is a complex decision-making process that has a means that places the right employees in the right jobs at the right time [23]. These are key human resource practices in any organisation which can contribute significantly to the organisation gaining a competitive advantage. Several researchers from the field of knowledge management consider that success of an organisation is formed by the interaction between individuals and several types of knowledge [24, 25]. Organisations frequently spend considerable resources making an effort to engage employees who are well suited to the positions that should be filled. Engaging employees may be subjected to the trial time, but in case of poor or disappointing employees, there are often substantial costs associated with the engaging, training, and firing before realising that an employee is inadequate. Therefore these painstaking decisions can be very significant at the beginning about whom to engage [26].

Individual competency is anything that an employee brings to a job or acquires along the way throughout a carrier that ultimately contributes to the success of entire organisation [27]. This includes relevant skills, knowledge, abilities, formal education and experience gained on the job. As a distinctive concept, a competency goes further to include any other demonstrable personal attribute that improves performance [27]. According to Cardy and Selverajan [28] competency model is considered as the set of competencies associated with a job or role in an organisation. Core of these competency models are built by determining the factors which are used as the basis for assessing the relative value of employee suitability. Criteria of competency models are influenced by strategic vision and mission goals which are again interrelated to organisational culture and leadership. Furthermore external environment and requirements derived from its dynamic nature also influence the selection criteria of a competency model.

Perhaps the dominant model to date is the development on generic competencies. The fundamental assumption behind generic competencies is that a set of characteristics necessary for success across organisational settings can be identified [28]. Hence it is very important to analyse and formulate a suitable set of generic competencies in a knowledge-centric industry such as construction. Perhaps, one way of looking at this is by understanding various ‘human intellectual capital measures’, which represents the areas where personnel knowledge can add value to an organisation to achieve competitive advantage in business environment. Hence, by analysing these ‘human intellectual capital measures’ a generic criteria for employee selection and evaluation can be formulated.

3. Human intellectual capital measures

The research and published literature on measuring and reporting intellectual capital has grown rapidly over the years. The current focus of intellectual capital research work is primarily concerned with the process of creating and managing intellectual capital and understanding of better measurement of intellectual capital. Measurement of intellectual capital is mainly concerned with finding the best metrics to use for the purpose of measuring human intellectual capital. Skandia navigator/ value scheme developed by Edvinsson and Malone [20], the balanced scorecard by Kaplan and Norton [29], Sveiby's intangible assets monitor [30]; intellectual capital rating approach are few of them, currently being used under the intellectual capital measurement domain.

Leif Edvinsson, the chief architect behind Skandia's initiatives developed a dynamic and holistic intellectual capital reporting model, the *Navigator* with five areas of focus: financial, customer, process, renewal and development, and human capital. This new accounting taxonomy identifies the roots of a company's value by measuring hidden dynamic factors that underlie "the visible company of buildings and products" [20]. Here, human capital is considered as the combined knowledge, skill, innovativeness, and ability of the company's individual employees to meet the task at hand, which also includes the company's values, culture, and philosophy. The other important intellectual capital measurement system was proposed by Sveiby [30], which is based on three families of intangible assets: external structure (brands, customer and supplier relations), Internal structure (the organisation: management, legal structure, manual systems, attitudes, R&D and software) and individual competence (education and experience).

Another Intellectual capital measurement model is intellectual capital rating approach, which was developed by Intellectual Capital Sweden to enable firms to manage their intangible assets better and to give companies a practical tool to use when discussing, analysing and measuring intellectual capital [31]. It is originally based on ideas put forth by Sveiby [30] indicating a division in internal, external and market assets. The intellectual capital rating model contains three main areas of intellectual capital; organisational structural capital, human capital and relational structural capital. Once again the core of this intellectual capital model is the human capital. Based on these models various authors looked into different types intellectual capital measures to help organisations to strengthen and improve their competitive advantage by measuring and recuperating intellectual capital. Table 1 provides the list of measures used by various commentators to evaluate employee competence/human capital. This list only provides the concerned factors mentioned the researchers in their research article.

From this analysis is it evident that qualification and work experience are perceived as the most important factors in determining employee competence/human capital. Most of the authors on this area agree with the importance of these two factors and suggested other factors which would also help the organisation in improving its culture and competitive advantage. Few informal communications conducted with academics and industry practitioners suggest the same. Especially the employee selection and evaluation based on qualification and work experience is found to be very common in the practice. However, there is a concern over the class of qualification, decay of 'knowledge from qualification' over the years, relevance of the qualification, relevance of the work experience and relative importance of work experience to qualification. Having these in mind, this research proposes a simplistic model for competency based employee selection and evaluation in the UK construction industry.

4. Development of simplistic model for competency based employee selection and evaluation

Focus of this research is to propose a simplistic model to help the industry practitioners to rank the suitability of a person for an assigned job. As such, research intends to develop a simplistic model based only on easily observable major human intellectual capital measures, qualification and work experience. Furthermore, an additive model is found to be appropriate than a multiplicative model. Multiplicative model will result to zero 'human intellectual capital' without either qualification or work experience. To avoid this, an additive, simplistic model is proposed for this study. However, concerns such as class of qualification, decay of 'knowledge from qualification' over the years, relevance of the qualification, relevance of the work experience and relative importance of work experience to qualification are also incorporated into this model.

$$Y = r_1 dQ + r_2 cE$$

Where, Y = Human intellectual capital

r_1 = Relevance of the qualification

d = Decay of ‘knowledge from qualification’ over the years

Q = Qualification

r_2 = Relevance of the work experience

c = Relative importance/weighting of work experience to qualification

E = Work experience

Here, Y is proposed to be measures in human intellectual capital units, only to assist the ranking of suitable personals. As shown in figure 1, human capital measures are dependent on several organisational characters and decision maker. Especially relevance of the qualification (r_1) and work experience (r_2) are very subjective and they are left for the management/decision maker for a suitable employee selection and evaluation. This research attempts to determine ‘decay of knowledge from qualification over the years’ (d) and ‘relative importance/weighting of work experience to qualification’(c) to help the practitioners with easy and general decision making process. However, it is prerequisite to quantify qualification (Q) and work experience (E) to measure human intellectual capital. Other than the coefficients of work experience, it is easily quantifiable.

4.1 Qualification

Quantifying qualification is very important since qualification is considered as an independent variable in this model. The National Qualifications Framework (NQF) sets out the levels against which a qualification can be recognised in England, Wales and Northern Ireland. This is a widely accepted framework which illustrates the level and category of those qualifications, which have been accredited by the Qualifications and Curriculum Authority (QCA), which enable recognition of candidates' achievements and which facilitate career progression. Here, higher education qualifications are categorised into 5 levels in terms of their minimum amount of required credit at the point at which the qualification is awarded (QCA, 2007). The amount of credit attributed is based upon an estimation of the learning time, which it would take the average learner to achieve the specified learning outcomes. The tariff used to determine the relationship between learning time and credit is averaged at 10 hours (QCA, 2004). Hence, ‘credit requirements for each qualification’ can be considered as directly proportional to the ‘amount of required knowledge acquisition’ which enables scaling of qualifications against credit requirements. Following Table defines the credit requirements for major higher education qualifications of NQF. Details of other qualifications and incorporation of class of qualification are still to be explored in the first phase of the study to quantify qualifications and to scale them against credit definitions.

Table 2: Framework for higher education (FHEQ) qualifications and their credit definitions

Qualifications	FHEQ qualification levels	Credit definitions	Accumulative credit definitions
Doctorate	D	540	900
Masters Degree	M	180	540
Bachelors Degree	H	360	360
Diploma of Higher Education	I	240	240
Certificates of Higher Education	C	120	120

5. Research Methodology

This research is aimed to develop a simplistic model to measure human intellectual capital for employee selection and evaluation. This is largely a model development/theory building attempt by quantitative research methods using primary data gathered from employers' opinion. As discussed above, firstly it is important to quantify qualification (Q) and work experience (E) before estimating decay of knowledge from qualification over the years' (d) and 'relative importance/weighting of work experience to qualification'(c). As such this research is divided into three phases of data collection and analysis to develop this competency based model for employee selection and evaluation.

As shown in Table 3, the exploratory, first phase of the research focuses on quantifying qualification (Q) and work experience (E). Above mentioned guidelines will be assessed with expert opinion gathered from unstructured interviews to form an accepted scale of measurement. This qualitative, rich data is expected to provide guidance to understand the influence of different methods of scaling. The main, second phase of the research will concentrate on estimating d and c which are more quantitative. The details and scaling of qualification (Q) and work experience (E) will also be confirmed in this phase. For this a survey method would be more appropriate to collect quantitative data which would be analysed with regression analysis. In the third phase of the study, case study employer will be asked to rank a list of employees and the ranks will be compared to the ranks achieved from the list created from the usage of the constructed model. Significance of this ranking will be evaluated against 'degrees of freedom' to determine the level of significance, which would help the hypothesis testing in this phase. Since it is a model testing/theory testing phase, case study approach is more appropriate to improve the validity of this model in the UK construction industry.

Table 3: Research Methodology

Phase	Research type	Research method	Research techniques
1	Exploratory research	Expert opinion	Interviews and content analysis
2	Model development	Survey	Questionnaire survey and regression analysis
3	Model testing	Case study	Questionnaire and hypothesis testing

6. Conclusion and further research

Employee selection and evaluation practices can contribute significantly to the organisation gaining a competitive advantage. This research attempts to construct a simplistic model to help the industry practitioners to rank the suitability of a person for an assigned job based on their competencies. Person's qualification and work experience are selected as competencies by literature synthesis and informal interviews to construct this model. With the usage of an additive model and scaling of qualification based on accumulative credits, a simplistic competency based employee selection and evaluation model is formed. However, concerns such as class of qualification, decay of 'knowledge from qualification' over the years, relevance of the qualification, relevance of the work experience and relative importance of work experience to qualification are also incorporated into this model. Appropriate research methods and techniques are selected to build and test this model and to improve its validity for the use of the UK construction industry.

Performance of Mature Entry and Matriculation Entry Students focusing on the National Diploma in Building at the University of Johannesburg, South Africa

Wellington Didibhuku Thwala
Department of Construction Management and Quantity Surveying
(Email: didibhukut@uj.ac.za)

Abstract

Developments in the teaching of the National Diploma in Building students should be geared towards meeting the needs of the construction industry in South Africa. These needs are usually in the form of skills and knowledge required to resolve thorny issues encountered in practice. The lack of capacity in the construction industry needs to be addressed from the basis of ensuring that the education system caters for both mature entry and matriculation entry students. The paper looks at a comparison in performance between mature entry and matriculation (just finish High School) entry students focusing on the National Diploma in Building students at the University of Johannesburg. The paper will make a comparison between those students who work first before enrolling for their first year National Diploma in Building and those who are directly from high school. Cooperative education involves training and systematically developing students through the acquisition of the requisite skills, attitudes, values and knowledge required to adequately perform in their chosen careers. The paper describes the problems and experiences that have been encountered by both mature and matriculation entry students in their three years of study which affects their performance. The paper will then look at the value of prior experience in enabling students to finish their National Diploma in Building within a three year period. The paper closes with some recommendations for the future.

Keywords: Building, Construction, Education, Mature, Matriculation, Skills, South Africa.

1. Introduction

The University of Johannesburg was founded on the proud academic traditions of the former Rand Afrikaans University, Technikon Witwatersrand and two campuses of Vista University. The UJ has approximately 46 000 students, who attends classes on its five campuses, spread over the industrial landscape of Johannesburg. The UJ is focussed on maintaining high academic standards, while boldly embracing change and empowering its students to contribute knowledge and skills to this city and our beautiful country. In South Africa the levels of unemployment and poverty are extremely high and unemployment is one of South Africa's most pressing problems. Acceptable levels of social development, economic growth and a decrease in high crime levels will only be achieved if the 28 per cent unemployment is decreased dramatically. The high unemployment rate can undermine the democracy if it is not reduced. At the same time there is a great need for physical infrastructure in both urban and rural areas. According to the World Bank [1] infrastructure can deliver major benefits in economic growth, poverty alleviation, and environmental sustainability - but only when it provides services that respond to effective demand and does so efficiently. In addition there is a lack of capacity and skills at institutional, community and individual levels.

From a theoretical perspective supported by experience elsewhere in Africa and the world at large, there is a huge role to be played by tertiary institutions in addressing skills development in South Africa. One of the main thrusts of the RDP White Paper remained "to link reconstruction and development: to reduce poverty and create employment through programmes of infrastructure construction and maintenance." The Reconstruction and Development Programme is a programme that seeks to redress the inequities and deprivation caused by the former government's apartheid policies. The programme is founded on six basic principles, linked together which make up the political and economic philosophy that underlies the whole RDP: the use of all available resources in a coherent and purposeful effort that can be sustained into the future; a people driven process; peace and security for all; nation building; reconstruction and development; and democratisation of South Africa [2]. These principles are indicative of a strong emphasis the RDP places on community participation methods.

There is an urgent need to address the skills and unemployment challenges in South Africa. The levels of unemployment have been rising steadily over the years. The unemployment rate is an extremely important indicator of economic and social health. The level of unemployment was 7% in 1980; 18% in 1991 McCutcheon [3]; 15.7% in 1995 Statistics South Africa [4]; 30.2% in 2002; 27.4% in 2003; 25.6% in 2004; and 26.5% in 2005 Labour Force Surveys (LFS) [5]. The unemployment rate rose rapidly over the 1990s, then fell in 2003 and 2004 and rose again in 2005. This is due to the drastic fall of the demand for unskilled labour in the formal sector caused by structural changes in the economy as a result of a decline in the importance of the primary sector.

2. Aim and Objectives of the Study

The study aims to gather and share information on the performance between mature entry and matriculation (just finish High School) entry students focusing on the National Diploma in Building students at the University of Johannesburg. The paper will make a comparison between those students who work first before enrolling for their first year National Diploma in Building and those who are directly from high school. Cooperative education involves training and systematically developing students through the acquisition of the requisite skills, attitudes, values and knowledge required to adequately perform in their chosen careers. The paper describes the problems and experiences that have been encountered by both mature and matriculation entry students in their three years of study which affects their performance. The paper will then look at the value of prior experience in enabling students to finish their National Diploma in Building within a three year period. The paper closes with some recommendations for the future.

3. Methodology

A questionnaire was designed and distributed to 30 students who are currently on the 4th year of study who had worked before embarking on their first year of study. All the 30 students who were given the questionnaire responded to the survey.

4. Skill Development in South Africa

The important note was to recognise the improvement of the work skills of all South Africans, which is critical to grow the national economy. The Skills Development Act (SDA) was promulgated to create the structures and framework for the national development strategy. In terms of the SDA employers are obliged to provide formal structured education to their workers. Furthermore, the act encourages partnership in this effect between government, employers, workers, education and training providers, and beneficiary communities. The trained people are the beneficiaries from the community. According to SDA, the needs of employers, the economy and the communities must dictate which skills development should be developed.

The SDA covers structured, targeted and generic training implying that all training interventions should be planned and managed as projects that is the reason why Group Five has “people at the gate” which is Corporate Social Investment Project. In SDA, employers together with their workers formulate workplace skills plans (WSP) to enable them to realize their employment training targets. All designated employers pay a monthly skills development levy of 1% of their budgeted payrolls to the National Skills Fund (NFS), via South African Revenue services (SARS). Of this amount, the employer can claim back 70% in the form of discretionary grant, provided that they submit WSP and Implementation Report (IR) annually and conduct special training projects.

These levies finance the implementation of the National Skills Development Strategy (NSDS). Construction Education and training Authorities (CETA) receives 10% of the skills levies paid by construction employers for administration costs, NSF receives 20%, and 70% is available to be claimed back by these contributing employers. However, international trends shows that companies need to spend between 4% and 7% in order to be successful in addressing the current shortages and gaps (National Advisory Council on Innovation (NACI) [6]. Furthermore, there appears to be over-reliance of a number of levels in the micro and provincial economy on the SETA’s as being responsible bodies for coordinating the identification of scare skills in South Africa.

5. Education of “Thinkers”: Theory

Preparing young people for the world of work is a current focus for discussion and debate in South Africa and in many other countries. Current questions on the subject ask whether or not young people should be prepared for the working environment and if so how ands why? The education of young people is a central political and economic issue in South Africa. In recent years there has been much debate on the form and content education policy should have. One aspect of the debate has been on whether the education system should specifically prepare young people for the world of work. In order to achieve this there must be a close scrutiny of the curricula and there must be a shift in the balance of subjects with the emphasis being towards the sciences and technologies with less emphasis on art-related subjects. It is believed that in a technologically orientated society such as South Africa, the educational bias should reflect this. Whilst this philosophy might be regarded as sensible, there are those who believe that young people should have a more pluralist education. Such an approach exposes young people to a wider range of options, thus enabling knowledge and expertise to be nurtured equally.

The present word “university” comes from the Latin “universitas litterarum” which means “the whole of sciences” (taught at the university). The important aspect of generality of the university education or the need to educate the students in a broad sense (i.e. not only technical), simultaneously underlining the must for some sort of universal knowledge, based on “thinking”. Creativity depends on the information base and the capacity of unrestricted thinking. The question to ask ourselves does the present method of teaching encourage critical thinking? Teaching theory is the best and most efficient way to teach. There is nothing more practical than a good theory. “A good education system should be based on theory and practice, whereby practice may be viewed as a long-time experiment on full-size scale. The opinion prevails that “theory is one eye, practice the other. Only with both of them together can one truly have three-dimensional construction vision.

There are complaints that students need better understanding and appreciation of how theory applies to situations encountered in practice, and graduates are not prepared for the jobs they face in the present world, being weak in concept and problem-solving tools. Employers must recognise the graduate as an entry level without experience and without definable capabilities latter will emerge during their experiential learning, since “real-world” problems are often complex and “unstructured” and do not lend themselves well to classroom analysis and synthesis of solutions. Some people believe that “work experience has a more role to play than ever before and some believe theory is more important. What is the solution? I believe it should be a combination of both?

6. Examples of Work-Based Tasks

There are numerous ways that universities have endeavoured to prepare their students for the world of work. Many of the suggestions are not new or will they be suited to every course or group of students. Examples will need to be carefully evaluated, adjusted, piloted and honed to reflect the particular ethos of a course, the staff, employers and student needs and abilities. Only when such a process is undertaken can a judgement be made on their validity.

7. Industrial Training Practice

In this model, students are employed for about one year. Training can be undertaken in a single period or be divided into blocks of 3 to 6 months duration. Being exposed to real industrial practices, students se and feel the stresses and pressures of that particular industry. Further, in many instances, students work long hours and are given considerable responsibilities. Whether or not companies should make heavy demands on inexperienced students is a separate debate, but as a preparation for a future career many industries would argue that such experience has unsurpassed benefits. Some companies with international links can also provide excellent training. Such exposes students to a wealth of experiences, both technical and social, and has benefits in developing communication skills in different societies and cultures.

8. Lecturers into Industry

Lecturers must be seconded to industry. Whether for a few days or several weeks, the net effect is that lecturers refamiliarise themselves with industry practices and procedures and gain knowledge. This educational/ industrial experience then comes full circle in that lecturers, having updated their skills, are thus able to impart this to students. The three-way arrangement between industrialists, lecturers and students where there is collaborative integration has mutual advantages. Industrialists must be given chance to teach certain modules. Industry/Education partnership must be encouraged. Visit to industries must be encouraged.

9. Non-Formal Education

Non-formal education became part of the international discourse on education policy in the late 1960s and early 1970s. It can be seen as related to the concepts of recurrent and lifelong learning. Tight [7] suggests that whereas the latter concepts have to do with the extension of education and learning throughout life, non-formal education is about 'acknowledging the importance of education, learning and training which takes place outside recognized educational institutions'. Fordham [8] suggests that in the 1970s, four characteristics came be associated with non-formal education: relevance to the needs of disadvantaged groups; concern with specific categories of person; a focus on clearly defined purposes; and flexibility in organization and methods.

Table 1: Models of normal and non – formal education- Adapted by Fordham 1993 from Simkins 1977: pp12-15

	formal	**non-formal**
purposes	Long-term & general Credential-based	Short-term & specific Non-credential-based
timing	long cycle / preparatory / full-time	short cycle / recurrent / part-time
content	standardized / input centred academic entry requirements determine clientele	individualized / output centred practical clientele determine entry requirements
delivery system	Institution-based, isolated from environment. rigidly structured, teacher-centred and resource intensive	Environment-based, community related. flexible, learner-centred and resource saving
control	external / hierarchical	self-governing / democratic

The purpose of RPL is to relate informal training, life experiences and work experience to a set of clearly defined vocational (workplace) outcomes to open up the candidate's access to wider career and vocational training options, especially to those candidates who have previously been denied access to formal training opportunities.

Table 2: The Benefits and challenges of Recognition of Prior Learning

Role-player:	Benefits of RPL:	Challenges of RPL
EMPLOYER	Existing worker competence can be easily measured against required standards (employable skill standards) Cost-effective identification of further training needs Better qualified workforce increases competitiveness Aid to effective recruitment	The workshops as they are conducted by external assessors are going to be costly for the company. The company will loose a number of production days as the employees will be attending the workshops on different days.
LEARNER	Improves self-esteem and self worth Improves visibility and accessibility of qualifications Provides for recognition of existing skills and knowledge Identifies individual paths to relevant qualifications Improves work motivation and performance Candidate-centred-focuses on individual skills and training needs.	Most of the employees from the previously disadvantaged may have problem with the language as only English and Afrikaans will be used. This may lead to other people not benefiting from the workshops. RPL is self-paced and self-managed so many employees may end up not completing if they are not self discipline.

10. Results of the Survey

Thirty students were selected and each student was given a questionnaire to complete. All the thirty questionnaires were completed and returned. There were twenty seven male and three female students. The age of the students ranges between 22 years and 44 years. Out of the 30 students only 4 were from outside South Africa. 40% of the students came from the Gauteng Province; 20% Limpopo Province; 15% Eastern Cape Province; 7% from Lesotho; 7% from Botswana; and 11% from KwaZulu Natal. The average years of experience in the construction industry before doing the first year in Building is 6 years. More than 80% of the students had worked for the private sector and 20% for the public sector. 50% of the respondents alluded that they work first before going to the University to further their studies after completing High School because they wanted to learn more about the construction industry before choosing the right course; 20% of respondents had no money to further their studies and they had to work first to raise money to pay for the studies. 20% of the respondents were offered a job opportunity immediately after High School completion. 10% of the respondents were encouraged by their parents to enter the construction industry as they were employed by the industry themselves.

90% of the students were employed as Trainee Site Agents and 10% as Trainee Technical Officers. 80% of the students alluded that they were adequately prepared and 20% were very well prepared for their first year. They were exposed to a variety of construction projects; project management skills, site management skills, human resources management; construction skills; communication skills; report writing; team work. The students were also able to make a right choice between construction management and quantity surveying course. All the 30 students alluded that it was easy to complete their studies on record time. The 30 students had not repeated any subjects in their Diploma in Building Programme. 80% of the students believe that all students must work before doing their first year. 20% of the students believe that students should be exposed to the construction industry in their first of study.

80% of the students received good support from their supervisors and 20% of the students received poor support. 80% of the students attributed their support to good communication channels between themselves and their supervisors. The 20% of the students were neglected most of the times and left alone. The supervisors were to busy to give guidance to the students. As a result team members were the one who assisted them in addressing the challenges they faced while undertaking their work. All the students were very positive about the future of the construction industry and the construction profession in South Africa. They believed that more people must be trained in order to improve the construction industry. 90% of the students alluded that their industry exposure made them to understand the construction industry better and they were able to choose construction as their career.

The students who come direct from high school encounter the following that makes them to repeat some subjects: lack of communication skills; lack of computer skills; unable to work in a team; no practical knowledge of the construction industry; lack of skills to write and present report properly; lack of problem solving skills; and unable to relate theory to practice. From the research it can be concluded that prior work experience among Diploma in Building students reduces the failure rate. This also improves the through put rate.

11. Recommendations

- Students who are admitted straight from Matric (High School) must be encouraged to work during university vacation in their first year.
- Potential students who undertake work based learning first must be encouraged to keep a daily log book which will contain details of the work they have performed during their stay in that company. A major benefit of this approach will be the positive development of the potential student’s attitudes towards responsibility and accountability in relation to the project in which he or she is engaged.
- Encouraged more female students to engage in the construction industry
- Each potential student must be assigned a supervisor from the first day they are employed. The supervisor must check and certify the correctness of the record for each task performed.
- The supervisor must have appropriate qualifications and experience and should ideally hold the position of either a registered quantity surveyor, construction or construction

project manager, or a site agent or a construction surveyor. Any other person provided that he or she holds a responsible position in the company being represented, and is actively pursuing continuing professional development in a built environment field of study.

- The learning outcomes must be clearly defined from the beginning when the person is offered an employment opportunity.

12. Conclusion

The paper looked at a comparison in performance between mature entry and matriculation (just finish High School) entry students focusing on the National Diploma in Building students at the University of Johannesburg. The paper made a comparison between those students who work first before enrolling for their first year National Diploma in Building and those who are directly from high school. The research revealed that those who worked first before doing their first year of study all of them completed the Diploma in Building in record time (three years). The high failure rate is caused by lack of knowledge about the construction industry. The foregoing examples provide a range of options available to assist in providing world of work experiences for students in the different disciplines. Academic institutions must be relevant as the industry requirements changes industries must also play a major role in affording graduates an opportunity to learn, as you cannot buy experience.

The relevance of professional institutions to students and early career practitioners in the property and construction industries within Australia

Clive M J Warren,
School of Geography, Planning and Architecture, University of Queensland

Sara J Wilkinson,
Faculty of Architecture, Building and Planning, University of Melbourne
(email saraw@unimelb.edu.au)

Abstract

The role of professional institutions and the transition from student membership to full professional membership among real estate and construction students in Australia is examined. Students' perceptions of professional qualifications and institution membership is explored to show that graduates seek networking and career advancement opportunities over professional training and development opportunities. The expectation of many young practitioners is that they will work outside Australia during their career and this has significant implications for the future policy development of professional bodies. The paper provides a valuable insight into the aspirations of young professionals and goes some way to identifying the reasons for the low level of transition from student membership to full membership of the national and international professional bodies.

Keywords: professional institutions, student membership, real estate and construction education Australia.

1. Background

The property and construction industry has relied heavily on its professional bodies to maintain educational and professional standards among its members and to regulate the profession for the benefit of its members and the public. It is widely recognised that professions fulfil an important role in society and much has been published on these benefits over the years. Grimshaw [1], writing on the facilities management profession, identified a number of underlying characteristics of a profession. He posited the hallmark of a profession to be; 'specific and have a definable knowledge and skills base that has to be acquired and tested; a high degree of self-control of behaviour via codes of ethics; and a recognised social responsibility that gives a primary and selfless orientation to the community interest.' [1;55].

The regulation of ethical standards by professional bodies is recognised as a cornerstone of professional practice and, in many jurisdictions around the world, it is the professional bodies, with their well established codes of ethical practice, that provide a regulatory buffer between the professional in practice and the role of the state in protecting the public. The role of professional codes; ‘is to prevent professionals from exploiting the asymmetrical information that is a part of the professional-client relationship.’(Jamal & Bowie 1995). It is for these reasons that professional bodies have grown in national and international contexts and the import of the quality of membership and the ethical standards which they maintain is essential to their continued success [1, 2].

While the importance of professional body membership has not changed, there is an apparent change in the attitude of young members towards membership. The value for money and the need to belong have been questioned. Wilson [3] examined the role of the accounting professions, highlighting the need for value for money in professional institutions stating: ‘At a more tangible level of services, when the value of their annual subscriptions is questioned members of both bodies are scratching their heads.’ This reluctance to join is echoed in many professions where the benefits of membership are weighed against the financial costs to the individual or the organisation [4]. Yet other research in the USA points to an increasing membership of trade associations by ‘generation x’, with a focus on what they can get out of the membership in terms of career advancement and the benefits of networking that can be achieved [5, 6;11].

There is little research in the property and construction professions with respect to the value of membership to young graduates. As the professional bodies seek to become global organisations the need to attract new members is a quintessential element of the growth strategy. This rapid growth expectation, while being realised among established practitioners, is not being so readily translated into student and early career professionals.

The Royal Institution of Chartered Surveyors (RICS), the largest international professional institution in the property and construction industry, established an office in Australia in 2000 with a stated objective of attracting new members and growing its professional influence within the Asia-Pacific region. It was envisaged that young practitioners would be attracted to the global brand as interest from Universities to accredit courses in both property and construction, was strong. One early strategy to attract young members was to offer free student membership. Not surprisingly this strategy paid off with student membership rising from virtually nil in 1999 to over 3000 by 2007 [7]. While free student membership has grown, the level of conversion to full membership has not been as strong. The reasons for this lower than expected conversion is not clear, although it might be as a result of changing attitudes to professional body membership and perceptions of value for money as has been demonstrated in some other professions.

2. A survey of student attitudes to professional institution membership in Australia

This paper reports on research supported by the RICS Oceania into the perceptions of students and young property and construction practitioners to the professional bodies within Australia. The research, although supported by the RICS, sought to address the full range of professional bodies serving the property and construction sector and was not influenced by any individual professional body.

2.1 Methodology

The research methodology was based on a paper based questionnaire which could be distributed easily among students studying property and construction courses in Australia. A questionnaire survey was compiled by the Universities of Melbourne and Queensland in the early part of 2007. The survey was piloted to industry prior to distribution to selected participants. In order to gain as wide a spectrum of students as possible, the survey was administered to a range of student cohorts in three separate universities. The universities selected to participate were leading course providers in Sydney, Melbourne and Brisbane. The students were drawn from all year groups within the undergraduate program and from postgraduate students undertaking master level study. The survey was administered in the early part of semester one 2007. A total of six hundred and sixty one completed surveys were returned.

The survey comprised three sections: Section one asked the respondent about their age, gender, the course they were studying, the level of the course (undergraduate or postgraduate), the year of study and their intentions to work within Australia and or overseas during their career. This data enabled the researchers to ascertain whether these respondents were aware of, or were likely to join, professional bodies based on their age, gender and year of study. It might be anticipated that professional body awareness and perceived importance would increase with years of study.

The second part of the questionnaire posed questions about the professional bodies. Respondents were asked whether professional body membership was important to them and of which bodies they were currently student members. They were also asked which bodies they intended to join in the future. Also in this section respondents were asked to rank the importance of reasons for joining professional bodies, and were asked about their expectations from professional bodies. This data helps to identify the drivers and expectations potential members and current student members have of professional bodies.

The third section asked more detailed questions identifying a number of built environment professional bodies which operate in Australia. For those in employment, respondents were asked whether employers paid fees. Respondents were also asked to respond to questions about the length and duration of professional training prior to attaining full membership of professional bodies and their views on current fee levels. Finally respondents were able to give any additional comments if they wished.

3. Data analysis and results

3.1 Survey demographic

The respondents to the survey were predominantly aged 21 and under, with 23.4% in the 22-25 year age group, 8% in the 26-34 year age group and only 5.8% being aged over 35. The postgraduate respondents, representing 7% of the sample, were, as would be expected, older than the undergraduate respondents with 43.5% in the 26-34 year age group and 21.7% being over 35.

The gender balance of respondents was 60.5% male to 39.5% female. These figures are deemed to be representative of the gender balance in the built environment courses at the three universities.

The break-up of courses studied at the three universities were; 56.2% of the respondents studying property and 14.9% studying combined courses such as ‘property and construction’ or ‘construction and architecture’. Of the remaining students, 10.4% were studying planning and 8.5% construction courses.

Overwhelmingly the respondents were enrolled on full time courses (91.4%) with only 8.6% studying part time. Similarly 87.6% or 571 respondents were enrolled on undergraduate courses, with 12.3% studying at post graduate level. The largest proportion of the total, 40.8%, were in the first year of study, leaving 59.2% to be in the second or subsequent years of study. The courses attended were three or four year undergraduate ordinary and honours courses or 1.5 year postgraduate masters courses.

3.2 Career Intentions

The respondents were asked to give some indication of their career intentions, particularly if they intended to work outside of Australia as this might have some bearing on the type of professional body the students may orientate towards. The survey revealed that 45.3% intended working solely in Australia for the first two years after graduation. This is a period during which they could, if motivated, complete training for professional body membership. A significant number, 34.5%, did not know whether they would remain in Australia to work in the two years following graduation. The remaining 20% intended working elsewhere within the two years after graduation. Just over a third of these respondents were seeking to work in Europe, closely followed by those seeking to work in Asia. Ten students were looking to work in the Americas with the remaining respondents considering the Middle East and New Zealand. Of those intending to work overseas, 17% did not identify the countries in which they intended to work upon graduation.

In the longer term 74.8% of respondents believed it was probable or certain that they will work overseas during their career. Of the remaining respondents 14.6% did not know whether they would work overseas and only 0.8% of respondents stated that they did not intend to work overseas with 9.8% stating it was not likely that they would. These figures clearly show that many of the graduates from property and construction courses in Australia are contemplating working internationally at some point in their careers with 20% of them intending to go oversees shortly after completing their degrees.

3.3 The importance of professional qualifications

The students' perceptions as to the importance of professional bodies could provide a clear indication of their understanding of the role of professional institutions and the likelihood that they would seek to join one of these organisations. The responses from the surveys were very positive and show clearly that respondents view professional qualifications as being very important to them. 93.8% viewed professional qualifications as being either very important (64%) or of some importance (29.8%). Only 3.3% viewed professional qualifications as being of either no or limited importance and 2.3% did not know.

Student membership of professional institutions was found to be relatively low. Only 35% of students belonged to a professional body with the most, 12.9%, belonging to the Australian Property Institute (API) and 8.3% being members of the RICS. A large proportion, 21.6%, were members of more than one professional body. A total of 429, or 64.9%, of the respondents were not members of any built environment professional body.

Respondents were asked which professional bodies they intended to join when they graduated. The number of responses left blank was relatively high at 31%. This contradicts a previous response in respect of the importance attached to the professional qualifications. Most students intended to join the API, 41%, and 9.2% intended to join the RICS. When duel API / RICS membership was considered the response rate was 34.2%. This result shows that, while there is a clear perception that professional organisation membership is important, a large number of students had not considered which institution they would join. Those that had made a decision tended to favour the local organisation over the international one, a figure which did not reflect the proportion of respondents intending to practice overseas.

The respondents were asked how important it was to them personally to join a professional body. The responses showed that there is less importance attached to gaining professional membership than gaining professional qualifications. It is apparent that there is a gap in knowledge of these respondents in that professional qualification and professional membership are not seen as co-related and mutually beneficial. Joining a professional body was seen as very important by 28.2% and 45.3% saw it as being of some importance. This compares to 93.8% who saw professional qualifications as being very important or of some importance. Only 73.5% saw professional body membership as important.

3.4 Reasons for joining professional institutions

The next section of the questionnaire asked respondents a series of questions about what they perceived as reasons to join, and the benefits of, professional body membership. Respondents were asked to rank each the reasons given on a Likert Scale between one and five, with five being the highest option. The results, shown in Table 1 below, clearly show that the top reason or motivation for joining a professional body was that it is perceived to enhance career prospects. This reason was followed by the apparent access to professional networks and the increasing of career progression (promotion). The next reason for joining a professional body ranked by the respondents was employability, followed by the need to keep abreast of current issues, remuneration, the apparent increase in employability overseas and the improvement of benefits paid by employers. It is a major concern that professional body membership is not perceived as being a benchmark of professional skills and knowledge - this reason being ranked nine out of the ten reasons given. Access to Continuing Professional Development (CPD) was ranked at ten, and last as a reason to join a professional body. These results indicate that students' expectations of the role of professional institutes is not fully aligned with those of the institutes in terms of a professional body membership being a benchmark of a member's professional skills and knowledge and, as such, a means of enhancing work opportunities both within and outside Australia.

Table 1 Reasons for joining a professional body

Reason	**Number of responses**	**Mean**	**Rank**
Enhances my career prospects	632	4.26	1
Provides access to professional networks	629	4.11	2
Increases promotion	626	4.05	3
Increases employability in Australia	626	4.00	4
Will keep me up to date	632	3.98	5
Improves my salary	627	3.91	6
Increases employability outside Australia	622	3.86	7
Improves benefits paid by employers	628	3.74	8
Is a benchmark of professional skills and knowledge	628	3.65	9
Provides access to CPD	624	3.63	10

Respondents were then asked to rank their expectations of professional bodies (again on the Likert Scale between a score of 1 and 5, with five being the highest score). The results are shown in Table 2 below. Networking was the biggest expectation that students had of professional bodies. The clear implication from this is that networking opportunities such as social events, training seminars and CPD activities, present an opportunity to raise the profile of institutions and attract young members. The second expectation ranked was in career development and mentoring opportunities, with students expecting that professional membership will enhance their career progression. These results show a disconnect between career development expectations (ranked 2) and structured training (ranked 5), in that students are perhaps not considering the need to take-up further education and training in order to enhance and develop their careers. It is interesting to note that access to state of the art knowledge was ranked equal second, demonstrating that students have some expectation that the professional bodies will serve them as a source of future knowledge. The enhancement of salary was ranked fourth by the respondents showing that there is not a clear expectation that professional body membership would equate to greater earning capacity, even though career development was ranked second which might be expected to be associated with increased earning capacity.

There is an expectation evident among students that mentoring schemes are provided by the professional institutions to assist their progression to full membership. There is a need for institutions which do not already do so to meet this expectation and develop effective mentoring programs to guide the transition from student membership into full membership.

Table 2 Expectations of professional institutions

Expectations of professional bodies	**Number of responses**	**Mean**	**Rank**
Networking opportunities	632	4.32	1
Career development and mentoring opportunities	631	4.08	2
Access to state of the art knowledge	631	4.08	2
Enhanced salary	629	3.90	4
Structured training	630	3.80	5

3.5 Perceptions of employers' expectations

Respondents were asked whether they thought their employers expected them to join a professional body. The answers to this question revealed a substantial gap in knowledge and understanding about professional bodies among Australian based students. A large number failed to answer the question and this could be attributed to the high number of first year students who are unlikely to work in professional offices at this stage in their studies. Of the 485 who answered, 127, or 26.2%, did not know whether their employer would expect them to join a professional body. The largest percentage, 63.7% (309), stated they thought their employer would not expect them to join a professional body and only 10.1% thought employers would expect them to join. Clearly only a small minority of students see that employers would expect them to become professionally qualified. This data provides an interesting student perspective that can be compared with the actual expectations of employers of graduate property professionals. Further research is required in this area to map industry employer expectations.

A similar picture emerges when students were asked whether they thought employers would pay employees professional body membership fees. A large number failed to respond, 190 or (28.7%), and an even larger number, 201, did not know the answer. 46.7% thought their employers would not pay professional fees, with 7.4% considering that their employers would pay their fees. A similarly cloudy view of whether an employer would pay fees for an employee to be a member of more than one professional body was apparent in the sample. Only 5.6% thought their employer would pay for more than one professional membership and 35.3% thought that their employer would not pay more than one fee. These results show that students entering professional practice do not have an understanding of what might be expected of them in terms of membership of professional bodies, and very few expect that their membership fees would be paid by their employer.

The entry requirements of professional bodies vary but, in general, most currently require a period of structured, ‘on the job’ experience before being granted full membership. The RICS Assessment of Professional Competence (APC) takes a minimum of two years and applicants are required to submit a diary, a critical analysis of a project, a summary of experience and undertake an interview with three RICS members before they are able to join as a full member. When asked about the current RICS APC, 65.5% of respondents (379) felt that it was either too long a time period or too much work. However, 33.7%, (195) thought that it was ‘about right’.

A similar response was achieved when asked about the level of professional bodies’ membership fees. Using examples of several professional bodies current fees, students were asked if the fees were, in their opinion, too high, too low or about right. The results varied from organisation to organisation but broadly fell into categories of one third not knowing and one third each thinking they were too high or about right. Very few students, not surprisingly, thought they were too low. This result could be considered to reflect the lack of detailed knowledge of the professional bodies, as demonstrated above, with a large number of students not in a position to be able to evaluate the appropriateness of the fee level.

4. Conclusions

The results of this survey of student perceptions of professional organisation membership within the built environment profession have provided some valuable insight into student knowledge and attitudes. They will provide a useful resource both for those educating and preparing students for entry to the profession and for those administering the professional institutions. What has emerged form the research is that students do value professional qualifications but that there is a distinct lack of understanding about the role of the professional bodies in their careers.

The level of international outlook for students in their careers, with many expecting to work overseas early in their careers, is encouraging for globalisation of built environment professional practice. This result has implications for the recruitment of students into professional bodies and clearly shows the need for international links between professional bodies and the establishment of global professional recognition. It demonstrates that professional institutions will increasingly need to work on their ability to service members in a global context.

The move by some professional institutions to establish themselves as global profession bodies may go some way to addressing this challenge, although the results of the survey clearly show that, in the Australian context, local institutes are a preferred option over international options. This local preference becomes even more significant when taken within the context of membership fees. If student perceptions are correct, and employers are reluctant to pay more than one professional membership fee, if any, then the growth of international professional bodies is likely to be restricted. There are lessons to be learned in terms of international versus local that should influence institutional policy moving forward.

The area of most significance in terms of why students are not progressing to full membership of professional bodies is demonstrated at a number of levels. While professional qualifications are seen as important by young practitioners, membership of a professional organisation is seen as less important. Membership is perceived as taking too long to achieve, with a complex joining process over two years. It is apparent from the results that student perceptions of the importance of the APC is not in tune with the importance that professional bodies place on this period of practical experience. If student conversion to full membership is to be achieved then some considerable education of the need for, and importance of, this training needs to be undertaken by the institutions. The period of training required by professional bodies needs to be seen to add value both to employers and to young members seeking advancement of their careers. It is also clear that in order to assist potential members to successfully navigate their way to full professional institute membership, the expectation among students that mentoring programs exist needs to become a reality.

The expectations of what membership offers in terms of career advancement and networking opportunities are not necessarily the same priorities that employers might perceive of the membership organisations. The next phase of this research will seek to evaluate major employer groups' perceptions of professional institutions. It will seek to establish perceptions of professional institutions importance in the work environment. It will allow conclusions to be drawn as to the importance of structured training before becoming a full member of an institution and will gauge the willingness of employers to pay professional membership fees and reward employees for seeking to become members of local and international professional institutions.

The message that can be taken from this research is that young professionals entering professional practice are focused on career development and will only seek to link themselves with professional bodies where that membership delivers clear value for money in delivering career goals and opportunities for advancement. This finding echoes those cited at the beginning of this paper pertaining to other professions and the challenges that member professional institutions will face in the future. These results will be useful in guiding the development of professional institutions as they seek to service their membership and increasingly meet the demands of a global membership base.

The relationship between research and teaching in built environment undergraduate education

Gerard Wood,
Research Institute for the Built and Human Environment, University of Salford
(email: g.d.wood@salford.ac.uk)

Abstract

The research-teaching nexus debate is a complex and often contentious one which has received a good deal of attention in the UK in recent years. Based on an international survey of built environment academics and practitioners this study explores the importance and relevance of research to Surveying undergraduate education. A key finding is that although the research process and outcomes can nourish undergraduate studies, they have a much greater impact upon postgraduate provision. There is a consensus amongst those surveyed that (UK) Research Assessment Exercise type research may have only marginal relevance when compared to case study, market-based or professional development type activity. Many respondents believe 'blue sky' research to be of limited use to undergraduate studies.

Keywords: Research teaching nexus, undergraduate education.

1. Background

1.1 Research and research funding

The UK Government currently funds Higher Education Institutions' (HEI) research through a dual support system, providing distinct but related sources of income. Firstly, the four UK Higher Education (HE) funding bodies (the Higher Education Funding Council for England, the Scottish Higher Education Funding Council, the Higher Education Funding Council for Wales and the Department for Employment and Learning Northern Ireland) allocate 'quality-related' (QR) funding on the basis of performance in a periodic Research Assessment Exercise (RAE) in the form of block grants to universities. The most recent RAE was in 2001 and the next in 2008. Secondly, the Research Councils, for example ESRC and EPSRC funded through The Office of Science and Technology (OST), award grants for specific projects or programmes on a competitive basis. The Government is committed to this system and to rewarding excellent research, and the correlation between an HEI's QR and OST income streams is very strong: between 2000 and 2005 the average correlation was 0.98, with no variation across years [1].

Other sources of research funding available to universities include charities (e.g. the The Joseph Rowntree Foundation), industry, the European Union and Government departments. Success in securing significantly sized awards from these sources often relies upon extensive networks and research reputations. According to HM Treasury [1], once again the correlation between institutions' QR income and their total research income is very strong, between 0.97 and 0.99 over the same five year period. Hence, success in the RAE is of crucial importance: not only does it provide the major source of research monies, but the associated profile it affords a university is highly likely to be a key factor in securing other research grants and awards.

Whilst acknowledging that the RAE has led to an increase in the quality of research, the UK Government's White Paper *The future of higher education* [2] clearly argues for a change in strategy. One of the stated aims is to reward research intensive institutions by funding research in larger, more concentrated units – notably through the RAE in 2008. It also confirms that research council grant funding, will follow a similar pattern.

Analysis of Royal Institution of Chartered Surveyors (RICS) statistics indicates that in 2005 approximately 9000 students were registered on accredited UK courses. The distribution of these students across the various RAE research-rated universities is shown in Table 1.

Table 1: Percentage of students on RICS accredited courses

Rating	%
5*	3
5	14
4	9
3a	21
3b	26
2	3
1	0
DNS	24
Total	100

%	percentage of national total (9020) of students on RICS accredited courses
– – – (red)	optimistic equivalent minimum threshold to receive funding RAE 2008
– – – (green)	minimum threshold to receive funding RAE 2001
DNS	did not submit to RAE 2001

The cumulative totals show that 47% of students are currently studying at research funded institutions (i.e. those rated 3a and above). If the threshold is raised to 4 (or the equivalent score under RAE 2008) following RAE 2008 then, all other things being equal, this would drop to 26%. If, as some experts are suggesting, the bar is raised to 5, then only 17% of students would be studying at universities funded by research grants through their relevant HE body. Such a funding regime could create a polarisation of Surveying Schools/Departments which could in turn be reflected in recruitment policies i.e. some (relatively few) universities will seek to develop and recruit research-focussed career academics, whilst others (the majority) require experienced practitioner/teacher staff. So, how important is departmental research activity to undergraduate students and what balance of expertise is actually required for an effective Surveying academic?

1.2 Research and teaching

Dearing's report *Higher Education in the Learning Society* [3] concluded from the evidence received by the National Committee of Inquiry that a total separation of research from teaching in HEIs had little support, stating:

> *There is near-universal rejection of the idea that some institutions of higher education should be 'teaching only' institutions. For the majority of respondents, such an institution would simply not be a 'university' in any legitimate sense of that term.*

In contrast, the Government's White Paper [2] outlines a policy that encourages such a separation. The White Paper cites research by Hattie and Marsh [4] which, it claims, found no relationship between the ratings of both research and teaching. The White Paper goes on to suggest that institutions should play to their diverse strengths. The summary confirms the intention to channel research funding towards the highest achievers, stating that the Government will:

- *encourage and reward research in larger units* . . . [and]
- *invest more in our leading research departments and universities.*

In fact Hattie and Marsh [5] are of the view that the UK White Paper misinterprets and misrepresents their findings. Whilst they do conclude in their 1996 study:

> *. . . that the common belief that teaching and research were inextricably intertwined is an enduring myth. At best teaching and research are loosely coupled;*

their report also adds:

> *The strongest policy claim that derives from this* [study] *is that universities need to set as a mission goal the improvement of the nexus between research and teaching . . . we beseech you to publish and teach effectively.*

Many authors, such as Brown [6], argue strongly that the research-teaching relationship in universities is crucial because it is that which sustains the HE sector's claim for distinctly better resourcing, when compared to Secondary and Further Education (FE). If there are no benefits to teaching, he argues, there is no case for doing research in universities at all. Indeed, the research-teaching nexus debate is a complex and often contentious one, but the notion that links should be developed has received a good deal of attention in recent years. The Higher Education Academy has published substantial and comprehensive reports on teaching-research relations [7] and on institutional strategies to achieve such links [8]. These excellent publications are recommended to readers seeking an in depth consideration.

1.3 Aims of the paper

As part of a much more broadly based research project funded by the RICS Education Trust and the Construction Knowledge Exchange into the future of Surveying education, this paper aims to explore the following questions:

What are the essential criteria for an effective academic in the Surveying field?

What is, or ought to be, the relationship between research and teaching in a Surveying context?

2. Methodology

Phase I comprised a detailed literature review of publications related to the research-teaching nexus. **Phase II** included ten semi-structured interviews with selected Research Directors or Heads of Schools, following which eight regional forums were convened to gather a broader view from academics and practitioners related to the themes of research and teaching in the context of Surveying education. The research study interviewees were drawn from some of the UK's leading Surveying education providers. Student numbers, geographic location and RAE 2001 scores were used to identify the sample. Focus groups were convened throughout the UK. The forums in England were closely aligned with the Construction Knowledge Exchange (CKE) national network and took place in Bristol, Leeds, London, Newcastle, Salford and Wolverhampton. In addition, forums were held in Belfast and Edinburgh. Manifest items, i.e. those which are physically present in the recorded content of interviews and focus groups, are identified to avoid any reliance on latent content, which is according to Robson [9] a matter for inference or interpretation. Hence, direct quotations are used extensively in the presentation of findings, and are indented and italicised in the script for clarity. Attitude statements extracted from interview transcripts, focus group notes and the literature were used to create an item pool from which an on-line questionnaire was devised. The questionnaire was widely promulgated during **Phase III** of the research and over a three-week period 433 respondents, working principally in academia and practice, took part in the survey from all World Regions.

3. Findings and discussion

3.1 Essential criteria for academic staff

The interviews revealed that whether or not an institution is actively pursuing RAE funding does have a significant impact upon their recruitment policy. But from the broader spectrum of participants in the study, there are very different views as to the relative merits of professional experience, teaching expertise and research capability. Whilst many interviewees refer to an 'ideal' profile for a Surveying academic, they all realize that it is largely unattainable.

> *The ideal person is someone with professional qualifications, industrial experience, teaching experience and research experience . . . we very rarely get people who meet those ideals.*
>
> *Ideally I want somebody who has 10 years experience in practice, has a PhD, has a long string of outputs, has experience of teaching, has a good personality and is well organised. You tell me who I can recruit with that for £35K.*

Amongst the whole sample though, the greatest contrast in opinion relates to the importance of professional experience in comparison to research capability. Interestingly, teaching experience is mentioned relatively infrequently. The following quotations are a representative sample of opinions held by staff within post-1992 universities (old polytechnics):

Experience of practice is essential but this is a personal view, not an institutional one.

. . . by and large we want somebody who will show relevant experience in the particular field.

The research record and capabilities of the staff would feature in the desirable rather than the essential list.

I have to say to you, that in the recruitment of staff to those areas, the issue of the research capabilities . . . is but a marginal consideration. The more important thing short term, is the experience and expertise that they can offer . . .

I've just turned down 3 people who have got PhDs – they may have been very clever, they may have lovely PhDs – our students would eat them alive.

Professional experience is essential for undergraduate education.

However, examples of a diametrically opposed view are not uncommon, but not nearly so prevalent. The following quotations illustrate the views of staff within pre-1992 universities:

I'd plump for the research capabilities . . . [they] *are about the long term capabilities of the individuals. The experience* [is about] *the short term and frankly, given the pace of change in the real world, quickly becomes redundant.*

I think the value of a practitioner in a university actually diminishes quite quickly.

We would expect someone who's got a PhD . . . to pick teaching up - whereas somebody with a professional background, they would be difficult to transform into researchers.

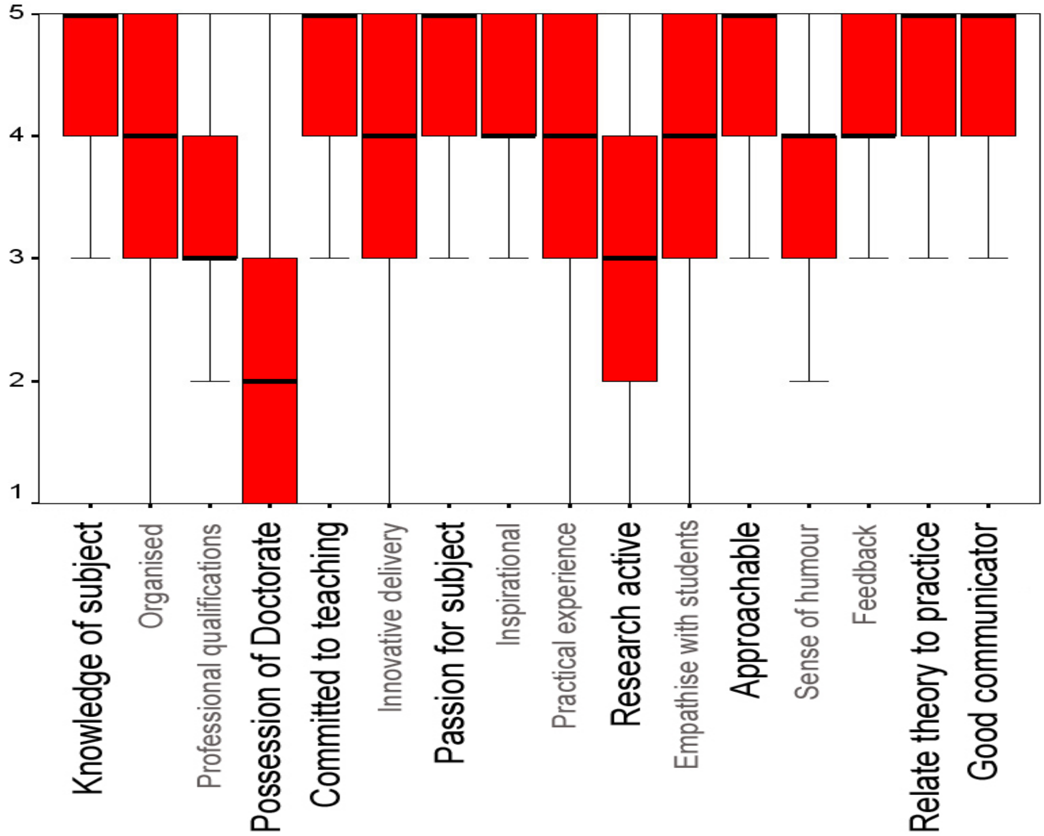
Their background is mainly research; we were quite happy to make that appointment, even though the person had limited professional experience, limited teaching experience.

The University is not interested in professional qualification, that's a bonus . . . it's 99% research profile – doesn't matter how good a teacher you are – doesn't matter what you know professionally in the Chartered Surveying sense.

Professional practice is not relevant.

Your ability to teach any Surveying topic is not a consideration.

The questionnaire results indicate that the majority of the attributes extracted from the literature are rated as either very important or of great importance, although possession of relevant professional qualifications and commitment to research are considered as quite important and the award of a doctorate degree of little importance.



5 = great importance

4 = very important

3 = quite important

2 = little importance

1 = not important

Figure 1: Attributes of an effective lecturer

Notwithstanding the preferences and ratings expressed above, there is a consensus from interviews and forums that, to date at least, performance in research has been the key to achieving promotion as a Surveying academic.

> *There's not necessarily a connection between good quality teaching and individual promotion prospects.*
>
> *It is increasingly difficult for people to progress up unless they have research credentials. Not impossible, but increasingly difficult.*
>
> *If you look back, at who's received promotions over the last 10 years here, you would find it's heavily weighted in favour of research . . . there has been a bias in favour of research, I can't deny it.*

The questionnaire results concur with the qualitative data in this respect: 45% of academic respondents believe that their department ranks research more highly than teaching or management duties when promoting staff.

3.2 Research and teaching

Views expressed at the interviews and forums indicate a broad agreement that there are important links between research and teaching.

> *Research is about knowledge generation, teaching is about knowledge dissemination – they have to be linked.*
>
> *It's an integral process. I think it's invidious to try and separate the two.*

A number of interviewees have a firm belief that research can nourish the curriculum, but that it must be relevant.

> *We've taken a very strong view that the vast majority of our research should be linked to teaching.*
>
> *The expectation is that every member of staff will continuously think of ways by which they can pass their scholarship / research knowledge on in to teaching.*
>
> *Research is important in terms of the way in which we communicate the ethos of research itself to our students, so that's the first reason it's important. The second reason it's important is of course in terms of subject content and choice of subject content.*

Others are more equivocal.

> *Research culture does feed its way through to the undergraduate programmes but it's difficult to show.*

There are clearly very different practices at different universities. Two respondents who have recently completed terms as External Examiners make the following observations.

> *As an External Examiner I see a kind of dislocation between research capability and their teaching material and teaching load.*
>
> *I've just finished – I will not say where – as an External Examiner, where the people who are research active, you just never saw them. They were not involved in the teaching of the students.*

There is also considerable disagreement about the type of research or scholarly activity which might benefit Surveying courses. Many feel that professional development activity is important; others that market based or case study research is most useful. The issue of 'blue sky' or 'discovery' type research is one that seems to generate some of the most fervent opinions. Many participants question its applicability and usefulness, particularly to undergraduate programmes.

> *Professional development for keeping up to date is more important than research that makes discoveries.*
>
> *Pure research that is published in journals* [is not useful], *as opposed to research that informs, embellishes and brings to life good teaching and knowledge transfer.*
>
> *To be honest, a building surveyor couldn't care less about the esoterics of electrical power engineering research, for example, but they are interested in how you put a transformer inside a building.*
>
> *Research that is market information based, that is what we crave. And it can be incorporated* [into the curriculum] *much quicker.*
>
> *RAE type research is always about 'blue sky' and may not be too relevant to practice.*

Some go further.

> *It* [research] *is not that important, not crucial at undergraduate level. Surveyors get educated on the BSc to get the knowledge base.*

Nevertheless, many participants do feel that students benefit from being taught by researchers, that it is of great help particularly when supervising student research projects and dissertations, and cite reputable postgraduate programmes which are largely based around research strengths.

However, the view that research potentially diverts valuable time and attention away from teaching is very commonly held and is repeated many times during both interviews and forums alike.

> *Research diverts attention from teaching, as the saying goes, "teaching ruins a good day".*
>
> *You could argue it takes resources away from teaching and learning and researchers are not fully committed to teaching.*
>
> *The big negative is that some good academics expend by far the majority of their energy on research work and they see teaching as not even a by-product.*
>
> *I think if we are not careful teaching is devalued.*
>
> *Our success in research does mean we've got to face certain tensions, particularly in terms of the teaching / research balance.*

The questionnaire attempts to distil a number of these issues. Respondents generally agree that courses should be delivered in a research-active department and likewise research of direct relevance to the needs of industry, the invention and generation of new ideas and the application of existing knowledge in experimental development should underpin course delivery. Common themes to emerge from an analysis of the positive contributions that research can make to teaching are:

- Enriches the curriculum: currency, context, breadth and relevance
- Promotes staff development: pedagogic, intellectual and vocational
- Provides funding: capital and revenue
- Develops key skills: problem solving, creativity and communication
- Creates a progressive learning environment and school culture
- Promotes innovation: new knowledge and ideas
- Stimulates staff and increases retention
- Encourages collaboration, team-working and internationalisation
- Enhances staff credibility and role model for life long learning

Whilst several questionnaire respondents recorded the view that research has no negative contributions aside from the time taken to pursue such activity, the majority used this opportunity to identify tensions associated with the research-teaching nexus as follows.

- Limits time available for student education and welfare
- Lacks relevance and is overly theoretical
- Distorts course content
- Leads to isolation and preoccupation with personal research
- Devalues teaching
- Takes funding and experienced staff away from teaching
- Polarises teaching and research activity
- Adversely affects (“dulls”) the student experience
- Overloads academic staff

In addition, respondents suggest that an undergraduate curriculum is less likely to reflect staff research interests than a postgraduate programme, and is generally perceived to be of less value to undergraduates than postgraduates. The majority of academics either agree or strongly agree that the pressure to be research active is draining the value placed on teaching and that the synergy between teaching and research is undermined by the fact that they are managed, assessed and funded separately.

4. Conclusions

4.1 Research and research funding

It is evident that some providers of Surveying education are research-led, take pride in this fact and place high value on RAE-type activity when recruiting staff. Others are teaching-led, although it would be erroneous to suggest that no research takes place in these departments - much depends upon the chosen definition of research. Hence the idea of polarisation is perhaps rather simplistic. The evidence here is that there is a research-teaching continuum along which institutions are variously placed and that the pluralism of purpose which this demonstrates is thought to be healthy. As such it should be recognised and applauded. However, it is also widely acknowledged that funding systems over a period of years, and particularly following RAE 2001, have not helped those aspiring to move along the continuum from teaching only, towards research.

In this context, the evidence confirms that there are very different opinions regarding the essential and desirable qualities for a Surveying academic. Unsurprisingly research-led universities favour candidates with research expertise, whereas teaching-led universities are normally more interested in professional experience. What is clear from the open discussions and the questionnaire is that professional experience is considered to be of greater importance for an effective Surveying lecturer. Despite this view, the evidence also suggests that research expertise is the most important criteria in the *promotion* of academic staff confirming Brown's [6] assertion that universities (even the post-1992 institutions) give far greater esteem to research over teaching.

4.2 Research and teaching

The findings of this study suggest that research outcomes and the research process can nourish undergraduate studies, but that they have a much greater impact upon postgraduate provision. Whilst most people accept the value of research in enabling academic staff to keep abreast of the latest developments in industry, the real issue centres on the nature and scope of the research being undertaken. Many people consider RAE type research to have marginal relevance when compared to case study, market-based or professional development type activity. Indeed many participants rail against the notion of 'blue sky' research, believing it to have limited interest or use to undergraduate studies. There is a clear link here to Elzinga's [10] notion of 'epistemic drift' which Chynoweth [11] suggests can occur when the availability of research funding encourages research in some areas to the detriment of that in others. Indeed, Brandon [12] observes that this has already occurred in the Built Environment field with the growth of research in Management at the expense of Technology. At its extreme, this phenomenon can lead to a School/Department which has a top research rating, but where the research subject matter has, at best, only tenuous links to the Surveying knowledge domain. Furthermore, a strong message from the evidence gathered here is that research diverts resources (time, funding, commitment etc.) away from teaching, and that teaching is devalued as a result. This perhaps suggests a need to adopt a broader appreciation of the concept of scholarship, as recommended by Boyer [13], to include the scholarship of discovery research; the scholarship of integration including the writing of textbooks; the scholarship of application and the scholarship of teaching. As he speculates, this may help to break out of the tired old teaching versus research debate.

A QUT Experience in Combining Sustainability Research with Educational Activities and Professional Practice

Jay Yang
Queensland University of Technology, Australia

Abstract

The paper discusses the development and delivery of a university subject on sustainable construction, using related research projects as case studies and learning materials. It exposed students from a variety of disciplines to real life scenarios, to group around project cases, and learn to work with one another in solving sustainable development problems. The problem based learning approach directly responds to the new trends of learning by practising which, in the area of sustainability education, is particularly appropriate because of the need for multi-disciplinary approach to complex issues, and the impetus for research and development to provide timely input for education in this growing discipline with a relatively short history. Collaboration of students from cross-disciplines, the engagement of industry and practitioners, the concept of using project cases and student design competition, and the tangible improvement of students' comprehension of the sustainability phenomenon as a whole, have been the highlights of this Australian experience.

Keywords: sustainability, education, problem based learning, construction research, practice

1. Introduction

Climate change, rising oil prices, increasing energy and resource demands have become issues of priority around the globe and major impacts on everyone's life. Naturally this further raises the high level of concerns over sustainable development and living among our societies. Such awareness is not only reflected through intensified media reports and evolving policies and strategies from governments, but also shown in the level of sustainability coverage in all levels of education as a whole.

In Australia, the educational focus on sustainability coincides with the UNESCO's initiative for a wide-spread global implementation of sustainable education. Nowadays school children of all ages tend to get early lessons on sustainable living through a variety of exercises and projects, ranging from tips of reserving water, to the use of alternative energy to designing model cars. At the university level, many academic disciplines have developed subjects and courses that cover relevant sustainability issues. For planning, design, engineering, and construction education, the need to respond to this global challenge is particularly strong, as graduates from these disciplines work on the front end of the issue, directly on projects with sustainability deliverables.

Despite of the flurry of activities on sustainability curriculum development by many disciplines from Business schools to Science departments, existing trends of these subjects tend to tends to be restricted to the elaboration of sustainability principles, environmental management concepts, and methods and systems of assessing performances, while professional disciplines home in on the specific technological innovations. Few had the opportunity to allow students to "put the ideas altogether" as they will undoubtedly be accustomed to do in the real world of professional practice after they graduate [1]. This requires that we not only teach students 'what" as the technical know-now, but also the 'why' to encourage them think and act in the appropriate way for the rest of their life.

The need to introduce real-life experiences to classrooms in order to promote "deep learning", was also emphasized by a number of earlier research [2][3][4]. It will be much easier for students to relate to and leave with better impressions when their course work study is integrated with the learning of practice under supervision.

This paper discusses the importance of the shifting sustainability foci and how they will impose on sustainability curriculum development in higher education. An example of an integrated approach to combining research, learning, and practical experiences at an Australian university was introduced as a better way for students to learn to practice sustainable design, engineering and construction.

2. The Impetus of Enriching Sustainability Curriculum

There are many interests in the introduction and enrichment of the sustainability agenda into university education. Resource depletion and climate changes are driving the society towards unprecedented awareness of the sustainable issues. Under the pressure of clients and other stakeholders, our industries and businesses are changing the game and are responding to the sustainability challenge with new strategies, processes and products. To do so, they will require a new breed of young professionals to have not only the technical knowledge but also the passion about developing green solutions to design, engineering and construction works, through the promotion of their own belief and self discipline [1] [4] [5]. In June 2006, the Queensland University of Technology conducted an industry survey on graduate capabilities in the fields of engineering and the built environments. The results show that sustainability knowledge has consistently ranked very high by all involved disciplines, as considered by a wide range of practitioners.

Universities will therefore have the obligation to ensure that the students, our future professionals, understand not only the specific technological advancement but also the holistic sustainability practices that occur on a much more complex scale. This application aspect will need to be taught in an integrated manner so that students will become confident in working with peers from other areas as a team, listen and responds to other professional views as they would have to after graduation, and become active practitioners of sustainability. It has been argued that the challenge of sustainability education is essentially to 'learn by practising what is preached' and to shift intensions from impact mitigation to regeneration [6].

Linking research with teaching has been promoted as the way of fast tracking from education to practice [7]. While it is easier said than done, the area of sustainability in the built environments presents three main advantages, compared with many traditional and long established disciplines. First, there are many aspects in sustainability, in terms of social, economical, environmental and institutional dimensions, to explore and associate with through various disciplines. For example, investigating the attitudes towards and the social impacts of sustainable housing is as valid as the design of systems to improve indoor air quality and workplace health of office buildings. And these can be covered from science to engineering, health to law, and management to education perspectives, all current ingredients of high education. Secondly the relatively short history of sustainability education means that lecturers and students are all striving to access appropriate teaching and learning materials. There are virtually few “set routines” to follow but perhaps the associated “reluctance” to change. Thirdly, in parallel to the evolution of sustainability bottom lines and the philosophies of environmental evaluation, there are continuing technological advances being made to deal with specific areas, using individual products and practices. There are enormous information and knowledge out there to be tapped into, to supplement general sustainability courses and subjects through topical coverage of “hot spots” and teaching foci. These arguments highlight the need for multi-disciplinary approach to the subject matters with consistent knowledge update and course materials management. An integrated and multidisciplinary teaching and learning environment linking with research and opportunities of practice will be the new paradigm (Figure 1).

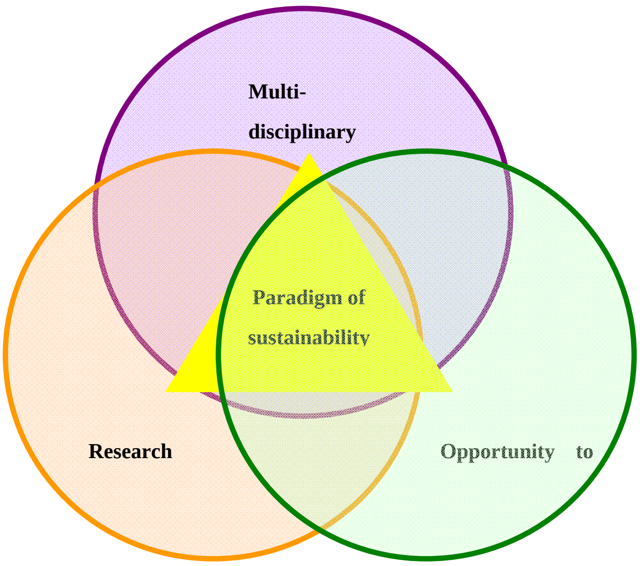

Figure 1 Integrated approaches to sustainability education

3. QUT's Living Laboratory Approach

3.1 Background

The Faculty of Built Environment and Engineering at the Queensland University of Technology, Australia, has a unique organisational structure. It contains almost all of the disciplines involved in developing buildings, infrastructure and other built assets and engineering facilities. For example, there are courses in architecture, interior design, urban planning, property, surveying, construction management, as well as structural, mechanical and electrical engineering. The Faculty also hosts two Corporative Research Centres (CRC) that conduct a large number of industry sponsored real life research projects. Researchers in these projects are also lecturing staff of the university. This presents added opportunities to experiment the integral approaches discussed above in a *living laboratory* setting for teaching, research and showcasing technological advances. The following sections detail one example of applying this philosophy in developing and delivering a subject on sustainable construction.

3.2 Curriculum development

The subject of *Smart and Sustainable Construction* was developed as a final year elective, open to students from a range of related disciplines. The first two years of running this subject saw over 60 students enrolled and completed successfully. They represented eights disciplinary areas of construction, civil engineering, electronic engineering, property, quantity surveying, interior design, landscape architecture, and architecture design.

The subject is based on the study of sustainable development of commercial and residential projects and concentrates on problem solving at a multi-disciplinary level. Case study materials and students' project cases were supplied from relevant CRC and other research projects. The syllabus is project-based and student-centred, with students from different disciplines forming groups to undertake project work according to the chronological order and lifecycles of realistic project development cases. The specific areas of study covered in this unit included:

- Sustainability and its impact to construction and engineering development
- Flexible design considerations
- Innovative building techniques and processes
- Smart engineering services
- Environmental, legislative and social context of sustainable development
- Appropriate techniques for project performance evaluation

This subject utilised real life research project as source for study materials to aid teaching and integrated assessment works. Students formed groups made up of various disciplines to undertake assessments. For example as part of the assessment during one semester, they delivered three major technical reports, and made a presentation based on the evaluation of the project development, should it follow their recommendations and plans. On a continuing basis, project cases were developed and updated with examples such as Sustainable housing development utilizing specific site characteristics; Multi-storey office building refitting project in CBD areas, Urban village development with mixed uses and facilities, Resort and marina development with environmental impact assessment, innovative construction methods, and economic justifications.

3.3 Student competition and research projects

Findings from major research projects that deal with housing and office building refit were used as lecturing materials extensively in this subject. Ways of bridging the gap between research work and scenarios of teaching and assessment were explored. For example, research on integrated sustainable housing development with end result of a demonstration home was used in 2005 offering of this unit as a case study for student assignments as well as the scenario and theme for a student design competition.

With the support of the research industry partners, a student competition on the architectural, engineering and construction aspects of a sustainable demonstration home was held. Research team members of this research project, who were also lecturing staff of different disciplines, provided instruction to nine groups of students who made entries in the competition. Students were able to see the current industry foci on matters related to their disciplines and be part of the problem solving process. Other stakeholders had the opportunity to contribute to education and promote their trades and businesses to potential employees and partners.

At the start of the semester, students were given specific briefings about the challenges faced by housing developers involved, and had the opportunity to investigate matters further by speaking to planning and construction authorities in the local governments. Field observations were organised for students to gain first information about site characteristics (Figure 2).

Figure 2 Field trip and site investigation

After two rounds of judging which involved university lecturers, developers, and practising architects and engineering consultants, three winning designs were selected. They covered architectural design of the home, building methods, and lighting systems:

(a) Interior lighting using solar powered LED **-** to integrate high efficiency LEDs powered by photovoltaic (PV) cells with intelligent control for interior home lighting.

(b) Alternative building system for sloping site – to improve architectural designs from a sustainable construction point of view, using most economical building systems including modular framing for specific site conditions encountered.

(c) Sustainable housing design with local characteristics – to achieve utopian harmony with the natural environment, new sustainable materials and technologies, and high level of comfort and ambience with the modern lifestyles suited for the local topography and subtropical conditions. With focuses on passive design, energy efficiency and social issues, the design dealt with water and aspect; wind, privacy and land formation; soil, vegetation and access; and subdivision context and neighbourhood (Figure 3).

Figure 3 Student design (architectural) with professional enhancement

There winning designs were then enhanced through student involved consultancy practice between the consultants and the developers. Students were also invited to participate in the design practice of the consultants as part of work experience. This produced final documentation for building approval. Students were very pleased to see their own input in the final products.

3.4 Stakeholder engagement

Students were informed of the subject and competition through “promotional” efforts such as posters and staff recommendation. They responded well to the new subject and came from a wide range of disciplines with a high degree of specialised expertise in the field. As all students were senior and have a degree of maturity towards their fields of study, their willingness to contribute and to share responsibilities has been the driver for the successful learning process. A number of opportunities were created throughout the semesters to allow students “mingle” with each other. This included discussion groups, assignment teams, debating challenge, allocated tasks for presentation, etc. But according to students who took this subject, it was the problem based learning and the student competition that motivated all.

With a motto of "university for the real world", QUT is particularly active in bringing back the practitioners to the classrooms. This subject has 13 weeks of lecture programmes which enlisted teaching and learning support of two architects, two civil engineers, one electrical and one mechanical engineer for the development and delivery. It also involved a builder and the developer who discussed with students and presented real life experiences on specific site problems, demographics of clients, and local regulations or applicable building codes.

The practitioners were able to observe how students learn and develop skills. Through this process and following the completion of the subjects, the builder and one of the architects offered employment opportunities to students. Students learned from life experiences of the practitioners and the practitioners had the opportunity to hand-pick promising young professionals of tomorrow.

Higher degree research students (PhD and Master by research) were also involved. As part of the research team, they not only participated in research development that had bearings on case study materials for the classroom, but also provided tutorials during the subject delivery as most of them have industry experiences. Through classroom questions and feedback, these research students pick up practical issues that may warrant further exploration in the research projects.

4. Evaluating the Educational Approach

Through theories and practical components, students gained real life experiences of "how and where" to start dealing with sustainability issues on hand. The intangible benefits included the development of competence, working with multi-disciplinary teams and for some students, employment opportunities. But how have students improved their overall understanding, and more importantly, the philosophical approach, to the challenges ahead of their lives? To partly answer these questions, and to provide feedback for the curriculum development, a student survey was conducted through reflective learning exercises during tutorial sessions.

The survey consists of a total of 16 questions in four categories of Awareness, Lifestyles, Professional engagement, and Technical knowledge, which were drawn together through references to media exposure, course contents coverage, and general lifestyles in the local environment. Examples of these questions include:

(a) *Compared to agricultural and industrial use of water, our daily lifestyle does not cause problems to water resources because the level of consumption is minimal;*
(b) *Design is the specific phase in project development where the triple bottom lines (economical, environmental and social) of sustainability should be incorporated.*

The survey was conducted twice over the semester: in Week 2, when students first started this unit; and in Week 13, after subject completion. To ensure validity and reliability, the same question was asked in a different way or in a different context, and the order and grouping have been changed for the second survey. Each question needs to be rated from *Strongly disagree*, to *Strongly agree* according to a scale of 1 to 5. Depending on the nature of the question, and the most appropriate answers may be at either end of the scale. Where applicable, students are also invited to elaborate on and justify their ranking.

Table 1- Table 1 Students' ranking of survey questions

	Week 2 ratings					Week 2	Deviation from		Week 13 ratings					Week 13	Deviation from	Improvement	%
	1	2	3	4	5	average	best score		1	2	3	4	5	average	best score	or regression	
Q1		4	2	8	10	4.00	1.00				2	6	14	4.55	0.45	0.55	54.55%
Q2	1	4	14	4	1	3.00	2.00		1	3	5	10	3	3.50	1.50	0.50	25.00%
Q3	3	7	12	2		2.54	1.54		8	8	2	4		2.09	1.09	0.45	29.24%
Q4	3	5	13	3		2.67	1.67		3	7	5	7	0	2.73	1.73	-0.06	-3.64%
Q5	11	12		1		1.63	0.63		10	12	0	0		1.55	0.55	0.08	12.73%
Q6	2	6	4	10	2	3.17	1.83			5	10	7		3.09	1.91	-0.08	-4.13%
Q7	3	12	1	7	1	2.63	1.63		8	11	1	2		1.86	0.86	0.76	46.85%
Q8	3	8	1	10	2	3.00	2.00			5	5	11	1	3.36	1.64	0.36	18.18%
Q9				13	11	4.46	0.54				2	12	8	4.27	0.73	-0.19	-34.27%
Q10		1	3	14	6	4.04	0.96		1	1	5	6	9	3.95	1.05	-0.09	-9.09%
Q11		5	2	12	5	3.71	1.29				2	6	14	4.55	0.45	0.84	64.81%
Q12	2	7	11	4		2.71	1.71		5	6	7	4		2.45	1.45	0.25	14.86%
Q13			2	13	9	4.29	0.71				2	13	7	4.23	0.77	-0.06	-9.09%
Q14	1	3	8	12		3.29	1.71			1	1	7	13	4.45	0.55	1.16	68.07%
Q15		6	7	9	2	3.29	1.71				2	7	13	4.50	0.50	1.21	70.73%
Q16	5	12	3	4		2.25	1.25		8	9	5			1.86	0.86	0.39	30.91%
			Note: 24 students provided valid responces in Week2 and 22 did so in Week 13. Total enrolment is 28.														

Table 1 shows students rating of the questions over one semester of study. The improvement or regression on the first round of rating was indicated. It is evident that students have shown improved understanding and consciousness of sustainability, reflected by improved rating on the responses to the majority of questions. Detailed analysis shows that the improvement has been far more significant than the regression, which only occurred in four of the questions in smaller percentages.While not intended for scientific measurement of learning outcome, the survey served the purpose of gauging the attitudinal change of students over the course of the subject, particularly by exposing and involving them in sustainability subject with real life examples, team work and opportunities for "hand on" experiences. A separate exercise, which asked students to complete the ecological footprint quiz by the Earth Day Network (EDN) (http://www.earthday.net) also showed improved the level of awareness and general attitudes towards sustainability.

5. Conclusion

The rising level of sustainability awareness and concerns in our society demands changes in the way industries and businesses operate. This in turn requires universities to prepare our students with the knowledge and skills to take on the sustainability challenge technically and mentally. Traditional classroom teaching has the danger of turning students to be technical experts in a topical area, while still not believing in the general philosophy. We will need to promoting students own belief and self-discipline, and the ability of taking on complex problems of sustainability by teaming up with other professionals. New curriculum development needs to introduce the theory of sustainability in a more tangible and practical way by combining disciplinary specialties together, as required in real life practices. The learning by practising approach, as demonstrated in a case of subject design and delivery in this paper, will present such potential. The engagement of stakeholders in high education, from the industries to researchers, and from professionals to academics and students, will provide more opportunities for a win-win situation for the "sustainable" education of sustainability.

SECTION V

CAPACITY BUILDING

An assessment of municipal development and program management

Adnan Enshassi,
Department of Civil Engineering, IUG, Gaza Strip, Palestine
(email:enshassi@iugaza.edu.ps)
Said El-Ghandour,
Project Manager, SMDM Project, (Selghandour@mail.com)

Abstract

Palestinian local government has been amongst the most committed bodies responsible for the provision of services that have a direct impact on the quality of life of Palestinians. Palestinian local government has been resilient, thus for at least, in responding to increasing demands for municipal services, such as water provision and distribution, wastewater collection and treatment, solid waste collection, transportation and disposal, and construction and maintenance, among other. However, service levels have been, and remain, to a large extent, to be unacceptable, three municipalities in the Gaza Middle Area enjoyed high profile funding from Danish International Development Assistance (DANIDA) in order to improve the level of environmental infrastructure and services, and through this, to build the managerial and administrative capacity of the municipal councils. The objective of this paper is to evaluate some of large scale infrastructure projects and small scale projects that are implemented in Gaza Middle Area. The general finding of this paper indicates that infrastructure services and capacity building have improved. Some recommendations are suggested.

Keywords: Local government, development, infrastructure services, management.

1. Introduction

As result of almost 30 years of administration neglect and under investment, the physical infrastructure in the Gaza and West Bank is severely deteriorated. Thus, since 1994 priority for investment has been given to the renovation and extension of physical infrastructure (Water. sewerage, roads). The major part of international development assistance has been invested in trunk infrastructure with emphasis on the principal urban centers. But attention must now be turned to upgrading the infrastructure and service delivery of smaller municipalities and strengthening their capacity to plan and manage the improvement of infrastructure and services in a sustainable manner. The new municipalities of the Gaza middle Area in particular need for support. Eighty percent of their populations are refugees and major part of their development has been refugee camps since 1948.

Palestinian municipalities bear the greatest responsibilities concerning the delivery of services that affect citizens' lives, services which include water, wastewater, solid waste management, building licensing, local roads, public health and environmental protection among others. The newly appointed municipal councils have a very limited income and virtually no funds for development. They are faced with some of the worst standards of infrastructure and services delivery in Gaza, and the populations, particularly the lowest-income groups, women's, children and the elderly are exposed to immediate health hazards in their living environment. Municipalities in the Palestinian context lacked of well-established service delivery functions. Such municipal performance has an impact on how the public views the effectiveness and efficiency of government in general, in addition to municipal performance's direct and more visible impact on the quality of life of the residents.

In pursuing municipal functions, and given the absence of large national government and regulatory bodies for extensive periods of time, Palestinian municipalities have grown more organically than systematically and structurally in an attempt to fulfill the requirements of a very demanding public. This is especially true for the municipalities of Gaza Middle Areas, municipalities that are also relatively newly-established and whose residents are even more demanding. This is because three of the four municipalities (Breij, Maghazi and Nusseirat) embrace refugee camps, and because of the associated municipal services deficit backlog and other related socio-economic and political difficulties. The upside of this organic organizational growth has been well demonstrated municipal resilience in service delivery modes in response to intensive changes in the political environment. The downside has been however, a lower consistency, hence a lower quality of service, and municipal management's inability to exercise effective and systematic control over service delivery, control being the undisputed prerequisite to municipal service improvement.

2. Background

According to the current administrative divisions, the Palestinian territory was divided into two geographic regions. These are the West Bank and Gaza Strip. The West Bank was divided into nine governorates and two districts (Jenin, Tulkarm, Qalqiliya, Nablus, Ramallah & AL-Bereh, Jerusalem, Jericho, Betlehem, Hebron, Tubas, and Salfit districts), while Gaza Strip was divided into 5 governorates (North Gaza, Gaza, Middle area, Khan Yunis, and Rafah). The Gaza Strip is bounded by the Mediterranean Sea from the northwest, by AL-Naqab Desert from east and south and by Egypt from the southwest. The Gaza Strip has an area of only 365 km^2 with a total population of 1.1 million. Its length about 45 km, the width is 6 km in the north with maximum 12 km at south [1, 2].

Gaza middle area consists of 4 municipalities: Breij, Maghazi, Nusseirat and Zawayda. The four municipalities serve 125,887 people, distributed over 26,325 donums under municipal jurisdiction. Population density ranges between 1.5 persons/donums, the lowest in Zawayda municipality, to 7 persons/donum in Maghazi Municipality. In the four municipalities combined, there are 186 municipal employees, of whom there are roughly 32% contracted and daily laborers. Details of the general employment situation in the four municipalities as well as other general data are provided in table 1.

Table 1- General information on four Gaza Middle Area Municipalities

Item \ Municipality		Breij	Maghazi	Nusseirat	Zawayda
General	Date of establishment of municipality	1997	1996	1996	1997
Demographic Variables	Year 2002 projected population (capita)	37609	21278	55000	12000
	Area (Donums)	5570	3055	9800	7900
	Population density (Persons/Donums)	6.8	7.0	5.6	1.5
	Population density (persons/km^2)	6752	6965	5612	1519
Municipal Manpower	Total number of municipal executive staff, including Mayor	36	27	94	29
	Number of municipal staff/1000 residents	1.0	1.3	1.7	2.4

3. Socio-economic context

The most notable feature of the Palestinian economy, and that the Gaza Strip in particular, is its almost complete dependence on Israel. Most goods produced in the occupied Palestinian territories are sold to or through Israel and around 90% of all import come from or through Israel. In 1993, more than 25% of the Palestinian labour force was employed in Israel, primarily as day labour. In the Gaza Strip, where a proportionately higher percentage of the labour force works in Israel, income from the Israeli labour market constituted 43% of GNP. In this context, repeated Israel border closures, trade restrictions, and policy of replacing Palestinian with foreign workers during the past five years have had a visibly disruptive effect. Per capita GNP in the Gaza Strip, for example, has (measured in 1995 USD) average of USD 1,911 in 1992, to USD 1,127 in 1997, and has been accompanied by a significant increase in unemployment and poverty.

Refugees living in camps, constituting the poorest segment of the population and the most dependent upon the Israeli labour market, have been the hardest hit by theses restrictions. In spite of the on-going international aid programmes and the opening of new investment opportunities as a result of the peace Agreement, the Palestinian economy continues to experience severe strains. Unemployment continues to rise and the living conditions continue to decline. Unemployment in Palestinian areas estimated by the World Bank to be 25% in 1996 was more recently estimated by Palestinian sources to be than 40% as a result of repeated recent border closures [3]. While both the West Bank and Gaza Strip suffered the same obstacles to economic and urban development during the occupation, the overcrowding and high rate of population growth in Gaza Strip in addition to the high percentage of refugees (c. 80% of the population) makes the economic conditions in Gaza far more severe than those of the West Bank [4].

4. Prior and on-going assistance to the municipal sector

Broadly, international aid to the municipal sector falls into three categories: capital projects for upgrading physical infrastructure, assistance to institutional capacity building, short-term income generating activities. More than 90% of aid funds to municipal development have been invested in the first category, though most aid programmes embrace two of these categories, and some include all three [5, 6].

4.1 Capital projects for upgrading physical infrastructure

Capital projects have been dominated by the water and drainage sector. The World Bank through the various components of the Municipal Infrastructure and Development Programme (MIDP), has disbursed/committed some US $35.6 million. A further $25 million is earmarked for Gaza Water supply and sanitation management project to which the European Investment Bank is lending $40 million. The European Union Municipal Infrastructure Project has committed Ecu 25 million to water and sewerage in Gaza, and Japan $50 million as part of a $200 million grant to Khan Yunis water and sewage treatment. Germany has contributed some DM 600 million p.a. to upgrading sewerage systems, mainly in the West Bank and has committed $75 million to a central sewage treatment plant for Gaza City and the Gaza Middle Area. Sweden has committed $25 million to water sewerage and drainage in Jabalya and USAID is funding a $7.2 million storm water drainage project in Gaza City. The Danish contribution to infrastructure development has been a DKK120 million input to the IBRD Emergency Rehabilitation Project for water supply and drainage in Gaza and inter-urban roads in the West Bank.

4.2 Assistance to institutional capacity building

Institutional capacity building in the municipal sector has received less attention. The World Bank local Government Reform and Capacity Building Programme ($7.1 million) is operating in Gaza and Rafah as well as three municipalities in the West Bank and has earmarked funds for institutional reform in the Ministries of local Government, Planning and International co-operation, and finance. Norway has provided substantial support to upgrading the physical planning capacity of the Ministry of Planning and International co-operation. The Netherlands has assisted the establishment of the Association of Palestinian Local Authorities (APLA) and is likely to assist with the establishment of an Institute of Public Administration for training local government officers. And the German Infrastructure upgrading programme includes a significant technical and management training component.

4.3 Short-term income generation activities

Income generation through insistence on labour-intensive methods of implementing infrastructure projects is becoming common amongst donors. However, these only provide short-term job opportunities. There have not been any significant suitable employment generation programmes in the municipal sector. The IBRD Holst Fund Employment Generation Programme (EPG) was an emergency income generating programme that of provided direct grant aid to small projects with an 80% labours content. The IDA Community Development Project provides short-term employment through labour intensive infrastructure projects in some 250 small municipalities and villages. The Swedish Jabalya water and waste project has an explicit employment component to its objectives with the intention of creating more sustainable jobs in public works programs.

5. Municipal projects assessment

The Support to Municipal Development and Management in the Gaza Middle Area (SMDM) project started in 1999 funding from Danish government covering three municipalities in Gaza Middle Area. Implementation of the projects in Gaza is constrained by conflict between Palestinians and Israelis which has led to severe economic decline both in terms of living standards and in terms of the solvency of the municipal administration. The project will support the municipalities in provide improved infrastructure services through labour intensive construction methods and at the same time increase their technical and management capacity to do so.

A project Steering Committee (PSC) which composed of representative of all the municipalities Mayors, Ministry of local Government, Ministry of Financial, Danish Representative Office and Project Manager will be responsible to guide the overall work of the project and will approved all project activities. All individual project activities particularly the infrastructure and services improvement sub projects will be implemented by the three municipalities individually. In day to day activities the Project Manager (PM) with coordination with the Danida Chief Technical Advisor (CTA) will work very closely regarding both the forward planning and the progress monitoring of the project detailed activity and disbursements.

Sixteen projects were studied by means of reviewing project documentation and meeting with key personnel like program manager, mayors and technical staff responsible for implementing the projects (see Table 2). The population of covered area is approximately 96,000. Nearly all residents are refugees or related to refugees of the 1948 war. It has been found that little evidence of program-wide planning of infrastructure in Gaza Middle area. However, program-wide planning was not viewed as being critical to the success of the program by the donor. Project selection is well organized but not as obvious as it might be.

The project selection process consists of the individual municipalities creating lists of projects to be carried out and then prioritized them in order of perceived need. The mayor then prepares a written proposal for presentation to the higher Project Steering Committee (PSC) for funding approval. Once the project is approved oversight and funds are transferred to the local agency for implementation. There is an active financial audit function exercised by the cognizant Palestinian Authority agencies. In particular the Ministry of Local Government and the Ministry of Finance conduct joint financial audits. An interesting point is that the funds are transferred directly to the local municipalities by DANIDA rather than through the national ministries. This ensures that the money actually gets spent on the intended projects.

Concerning supervisory consultant selection procedure, it was noticed that this process consists of advertising in the official newspapers giving the project information, a statement of necessary qualifications, the method of tendering for the work and the date for tender. The proposals are evaluated based on experience, the staff proposed, financial proposal and the technical proposal. Following this evaluation the winner is announced and a contract signed. The management by consultants of the individual projects is limited to using inspection forms, daily reports, site instructions and weekly reports. The procedure for defining projects was as follows: the individual municipalities developed a list of urgent projects to improve the refugee camps' situation. The lists were raised to the steering committee for approval. Each project was also presented to the steering committee for approval prior to implementation.

With regard to projects designed by the technical department of the Municipalities, it has been observed that neither the design calculations nor the design criteria were documented in the projects’ file. Drawings aren’t fully detailed, some existing facilities aren’t presented on the drawings and structural details are sometimes omitted. Missing technical specifications, missing pages in the technical specification and discrepancies between the table of contents and the document content were found. Some specifications referred contractors to international specifications, which the contractor has no access to. These issues push SMDM project management technical team to assist the technical department of the Municipalities through providing local consultant service to assist them in the projects design.

The contractor selection procedure is clear, organized and follows the local regulations for all projects. In most situations the lowest bidder was the successful bidder. Some contractors were not selected because they didn’t satisfy the general specification requirements. It has been observed that the price for supervisory consultant services within the time frame of the contract is fair provided that a professional representative of the consultant’s office is assigned to the job. However, delays occurred on all projects due to a number of factors that resulted in a cost increase. One of these factors was the experience level of the supervisory consultant representative and Gaza main borders closure which affecting lacking of construction materials and unstable prices cost.

Concerning project’s health and safety requirements and the implementation of these requirements, a complete section about health and safety was included in the general specification. The contractor was ordered to follow the health and safety regulations on all the projects. It is noticed that there are many letters from the municipality engineer and the consultant to contractors to follow the health and safety regulations. These are particularly related to the wearing of shoes and safety helmets. Given the number of letters sent to some contractors it is evident that compliance with health and safety regulations needs to be strengthened. In one case, there is a letter from a laborer to the municipality when he described an accident that occurred to him. The contractor didn’t provide compensation. This accident wasn’t registered in the daily or monthly reports or in the accident log. While direct evidence is lacking, it is apparent that there may be a problem with adherence to health and safety regulations despite attempts by the municipalities and consultants to enforce safe building practices.

The quality of the finished work is appropriate for the invested cost when compared to other projects in the Gaza Strip. The overall functional quality appears to be adequate for the purpose intended. For the projects there is submitted document from the contractor requesting approval for project activities and invoices payment. For some daily reports the consultant requested the contractor to take approval for using the projects materials and to be tested in independent laboratory before using in the site.

Normally the consultant requests the independent laboratory to collect the samples for testing. Results from the laboratory were discussed by the lab technician or the consultant although some results are less or approximately equal to the required strength or quality which in most cases was rejected by the consultant.

Some problems were occurred which led to disputes, change orders or claims. The early large projects all had relatively large sums of money paid for change orders and claims. In addition to that a time extension was granted to one of the contractors which relieved him from penalties. The reasons for change orders and claims were traced and found to be as following:

- Substandard design had resulted in introducing major changes which should have been taken into consideration at the design stage. The rush to get projects ready for construction may have led to substandard design.
- The quantity of work listed in the bill of quantities in the contract documents was not surveyed properly at the early stages of the projects. Accordingly, some items exceeded anticipated contract quantities by 25% and resulted in unit rates being revised upward.
- On some occasions the consultant evaluation for claims was unjustified. Examples of that are increasing the unit rate of some items by 100%. Instead of, per contract specifications, a reduction in the unit rate to be agreed in case of the quantity of work exceeds 25% of contract quantity.
- A time extension was granted to a contractor in the absence of entitlement demonstrated on an up-dated time schedule. The consultant's evaluation for some claims was not supportable. For example, holidays and rain days were considered to be an approved delay when they should not have been.
- Time extensions were granted to the contractor for shortage of materials in absence of a material supply schedule and without assessing whether the shortage was a result of the contractor's planning or to border closures.

6. Conclusion

The living conditions in the neighborhoods affected by the projects have been improved substantially. There is considerable evidence that the people living in the project areas have received a substantial benefit in the form of improved quality of life. Therefore, the selections have merit. However, program-wide planning could be improved. There is a need for a master plan treating the entire service area as one entity to assist the municipal leaders in developing projects.

SMDM project is the only one which explicitly target the Gaza middle area municipalities. It is also the only project in this region which activities implemented directly by the municipality administration. Its emphasis is on civic participation through highlight on local committee's needs and participations. DANIDA through providing the Technical Assistance Team consisting of national and international advisers and consultants which assist and support the municipalities in their implementation of the project activities and play a strong role in advising and increasing the capacity building of the municipalities staff during SMDM project period reflected positively in their performance. The procedure used for selecting supervisory consultant is to some extend sound.

More training of the municipal staff is required to strengthen their ability to provide oversight of the consultants and, indirectly, to the contractors. Guidance should be provided to the top management and councils members of the municipalities encouraging them to support their professional staff in dealing with the consultants and contractors. Guidelines should be established specifying documents that should be made available in Arabic and English. More attention needs to be directed toward maintaining complete construction records, log books, letter files and written directions among the municipal engineers, consultants, and contractors.

The health and safety written requirements are realistic and reasonable. However, compliance with health and safety statutes and regulations could be improved. There is considerable evidence of violations witnessed by the municipal engineers and consultants that were not corrected by the contractors involved. This indicates a pattern of violations. The site quality control needs improvement. Documentation of proper quality control procedures and standards is acceptable. Evidence of follow through on correction orders is sufficient.

There were design flaws, some outside the ability of the individual municipality and consultant to avoid. As experience was gained, design issues became less of a problem indicating that as experience is gained, better designs can result. Although not of a magnitude to cause severe difficulties, bills of quantities were improved and properly surveyed, time extensions granted with ordinarily acceptable reasonable cause but in some cases cost analysis was missing. There is evidence of claims being approved with sufficient documentation to justify the claims. There are also indications of positive changes in managing construction problems and claims on later projects.

Abstract

Through a case study analysis, this paper discusses the essential elements of successful university-industry partnerships in the context of the integration of the scholarships of teaching, research and application. This scholarly integration is advocated as the modern paradigm of real-world laboratory activity termed the “living laboratory”. The paper further examines the application of the concepts of experimentation, engagement and regeneration as critical measures for evaluating successful university-industry partnerships. University-industry partnerships play an increasingly important role in the current climate of universities being held increasingly accountable for the benefits of their scholarship to be transferred to the wider community and to demonstrate measurable impacts.

Keywords: Industry collaboration, Industry-University partnerships, Living laboratory

1. Background

1.1 An overview of industry-university partnerships

Universities are increasingly accountable for the benefits of their scholarship to be transferred to the wider community and to demonstrate measurable impacts. A recent call in the UK higher education environment for “business-facing” Universities has been followed by a debate on the prospect of UK research council funding being more fully determined by innovation potential rather than simply based on research quality. In Australia, the forthcoming Research Quality Framework is scheduled, at the time of writing of this paper, to be the first such exercise to have a separate “impact” rating alongside one for “quality”. It is in this context that collaborative university-industry partnerships play an increasingly crucial role.

The benefits of industry-university partnerships are illustrated in the data given in Table 1 below. It is based on a sample size of 8,172 ranging from small to large scale businesses.

Table 1- Data from the Community Innovation Survey for UK 2003 [1]

Businesses undertaking innovation	Increased goods & services	Increased market share	Improved quality	Reduced costs
No university partner	42%	40%	46%	33%
University partner	82%	81%	85%	65%

It is important to differentiate types of university-industry partnerships that can be established. At one end of the spectrum is a consultancy where a single academic provides a service. Other than being a revenue generator, this type of activity has limited flow-on benefits to the individual/s or the academic institution. Publicly-funded academic research in partnership with an industry sponsor, which entails the creation of new knowledge falls at the other end of the spectrum. Such a partnership may involve only a single, or a limited number of individuals. A recently emerging form of partnership entails a more collaborative and deep-seated involvement where both organisations work as one to gain benefits to meet their respective organisational goals. Such partnerships evolve and mature over time and are primarily influenced by the level of trust and commitment held by both parties and the outcomes they generate.

1.2 The essential elements for Industry-University partnerships

The role of the modern professoriate has been the subject of study by Boyer [2]. He makes the strong argument for the work of the academic community to extend beyond scholarship involved in pure research (the scholarship of discovery) or in student learning (the scholarship of teaching). He elaborates on the scholarship of application, linking knowledge to applied problem solving, and the scholarship of integration where research, teaching and applied work is brought together in common scholarly environments. It is this integration that we advocate as the modern paradigm of a real-world laboratory which we have labelled as a “living laboratory”. The following are proposed as the essential elements or critical success factors, of a living laboratory for the sustainability of a university-industry partnership.

1. A common fit between the two organisations, at a strategic level. For example, the corporate vision and strategic goals should enable the formation of a shared and common bond clearly demonstrating the feasibility of working together to enhance its achievement. This would also mean the accommodation of organisation specific characteristics such as understanding the nature of academic research and in the case of the industry partner, the need to safeguard shareholder value.

2. The two organisations subscribe to the common shared goal of ensuring mutual benefits to each other within a “win-win” framework. The primary challenge is to identify and clearly articulate the specific beneficial role for each organisation in the context of the partnership. This in essence would form the vision for the partnership and has to be endorsed and supported at the highest levels of the two organisations.

3. Though the engagement is at a whole of organisation level, it needs “champions” or “partnership guardians”, essentially a small group sharing the common passion of

"making the partnership work" and understanding its strategic goals. It is not realistic to expect every key member of both organisations to understand the nature of the partnership or to have the patience to abide by its stipulated protocols.

One could argue that there are a set of KPIs that evolve and mature for a living laboratory, which might equate to the partnership moving through phases of experimentation, engagement and regeneration. In the experimentation phase, the KPIs might equate to the number, value and spread of projects. Engagement might be measured by the number of repeat projects, the diversity of source of participants from within partner organisations, and the extent to which the link goes more than one person deep. Regeneration implies structural or organisational adjustment around the partnership and can be measured by shared employment of staff, opening up the networks of the two organisations, and the establishment of shared business ventures and facilities. These concepts of experimentation, engagement and regeneration lie at the heart of the QUT Blueprint for its future [3]. This paper examines these critical success factors and measures of a successful university-industry partnership, through a case study analysis.

2. Case study of an exemplar partnership

2.1 The partners

The case study involves the collaborative research partnership between Queensland University of Technology (QUT) and Brisbane Airport Corporation (BAC). QUT is one of Australia's largest universities, with a student population of over 40,000. QUT prides itself as being a university for the "real world" with a focus on applied research and a commitment to transferring the benefits of its scholarship to the wider community. The University seeks to develop strategic partnerships with research, industry and community organisations. QUT's vision for the future, as encapsulated in its Blueprint [3], is to:

- provide outstanding learning environments and programs that lead to excellent outcomes for its graduates;
- undertake high-impact research and development in selected areas, to the highest international standards, reinforcing the University's applied emphasis; and
- strengthen and extend the University's strategic partnerships with professional and broader communities to reflect both its academic ambitions and civic responsibility.

BAC is a privatised airport operator responsible for the development and management of the Brisbane Airport. It is Australia's fastest growing airport and now receives the second largest number of overseas visitors into Australia. To meet the growing demand, BAC is undertaking an ambitious infrastructure development program worth A$2.2 billion over the next seven years including a new runway, major terminal expansions and road upgrades in addition to significant commercial developments. Already more than 130 businesses and nearly 16,000 people work on the Airport. This is forecast to exceed 40,000 people by 2025. BAC's vision for the future, as documented in its strategic plan [4] is:

- to transform Brisbane Airport from a city airport to an “Airport City”;
- to develop as a premier gateway airport and a major inter-modal transport hub;
- to promote and develop Brisbane Airport’s role as a major economic engine for the South East Queensland region;
- to grow and develop by balancing economic benefit and environmental impact.

Evaluating the profiles of the two organisations, the following are clearly evident:

- overlap in the perceived social and community responsibilities;
- the desire to achieve excellence in core activities with clear long-term goals;
- BAC has a wider agenda than merely aviation which in turn provides the platform for developing linkages across a broad cross-section of QUT’s areas of academic expertise.

2.2 The underlying concepts

The BAC-QUT Partnership was formalised through a Memorandum of Cooperation in 2000. However, such agreements are only a statement of intent and are often not legally binding. Consequently, the delivery of the envisaged benefits rests solely on those directly responsible for the day-to-day management of the Partnership. They have the responsibility for developing the vision, long-term strategy, management structure and the maintenance of goodwill which are the key defining factors for any partnership.

Since the signing of the Memorandum, the relationship has grown significantly. This is demonstrated by both organisations being increasingly integral to each other’s business. QUT plays a key part in the development and planning processes of BAC with the Airport entering a critical period of growth and development. BAC provides a living, breathing research environment for QUT to enhance its research and development expertise.

The growth and consolidation of the Partnership is underpinned by the innovative concept where QUT has become the “R & D arm” of BAC, and BAC the “living laboratory” for QUT. This concept was developed on a shared vision of mutual benefits to ensure a whole of organisation involvement. For BAC to achieve its vision of the best Airport City in the world and a model for other international airports, it needs to develop best practice management based on extensive research. For BAC, it is not feasible to undertake research encompassing the diversity of disciplines relevant to the operation of an international airport and building of an Airport City. BAC has “outsourced” this responsibility to QUT.

QUT has a primary focus on real world research relevant to society. However, the problems of society cannot be neatly packaged and are not mono-disciplinary. They require the expertise of a diversity of disciplines to work together. Hence, QUT requires a supportive environment where multidisciplinary research, solving real problems will help to push the boundaries of knowledge. Consequently, QUT considers the Brisbane Airport as its living laboratory where it can strengthen its leadership position in the delivery of real world research outcomes, through the integration of the scholarships of teaching, discovery and application [2]. In this supportive environment, academic researchers have the opportunity to create knowledge and witness its translation into application. Together BAC and QUT aim to create an environment with resulting outcomes extending beyond the confines of the Brisbane Airport.

2.3 Partnership management

The management framework for the Partnership is illustrated in Figure 1 below. It encompasses a Steering Committee for the day-to-day management of the Partnership, with overview and guidance provided by a Strategic Advisory Committee. In order to further strengthen the engagement between the two organisations, BAC has appointed Prof. Ashantha Goonetilleke as the Chair in Airport Innovation. He is based at the BAC to further develop research activities and to provide counsel to BAC on appropriate research and technical support.

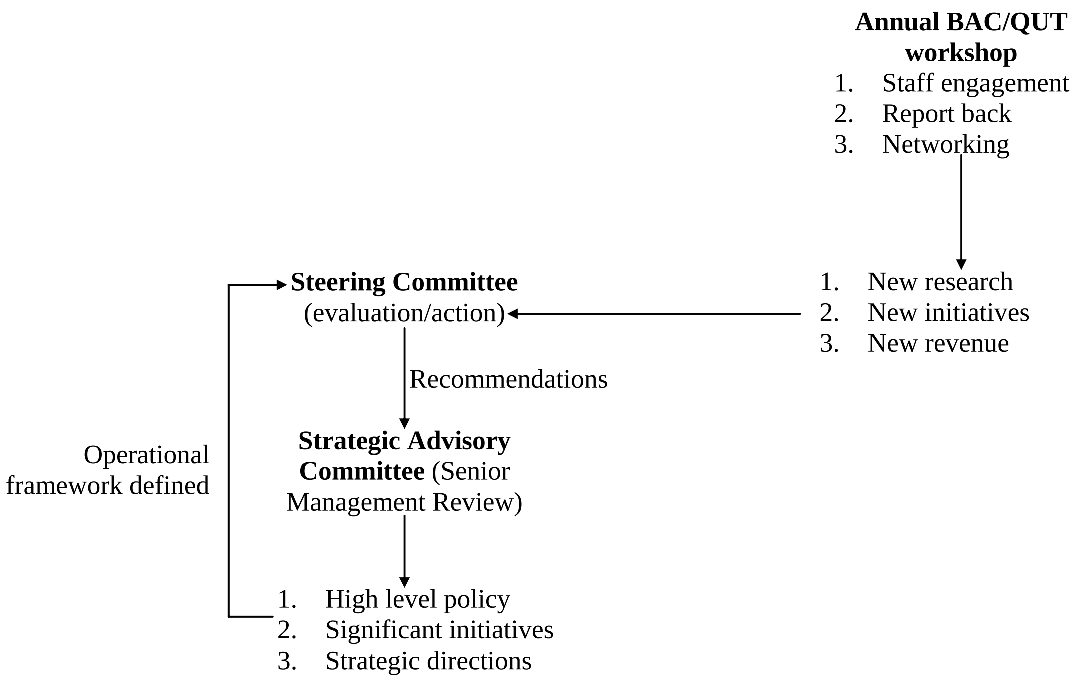

Figure 1- Management framework for the Partnership

For all practical purposes, functioning as a BAC employee, Prof. Goonetilleke performs a varied role. Firstly, he provides technical advice in his own area of expertise, which is water engineering. Secondly, he functions as a technical advisor, providing independent counsel on a range of issues, review of technical documentation and assisting in the drafting of consultancy briefs. Thirdly, he acts as the “relationship manager” for the Partnership liaising between the two organisations, assisting in the development of research projects and facilitating the formation of research teams within QUT and, progress monitoring.

The Steering Committee consists of two senior BAC Executives and Prof. Goonetilleke plus a QUT senior staff member. As shown in Figure 2 below, the Steering Committee is the single point of contact between BAC and QUT. It acts as the bridge between the two organisations to facilitate the delivery of applied research and training to meet BAC needs and the formation of collaborative partnerships between QUT and BAC staff for undertaking research projects. The projects undertaken satisfy the criteria that QUT has strong interest and expertise, and the projects are of strategic value and advance best practice at the Brisbane Airport. BAC engages in these projects either through direct funding or through leveraged funding through QUT.

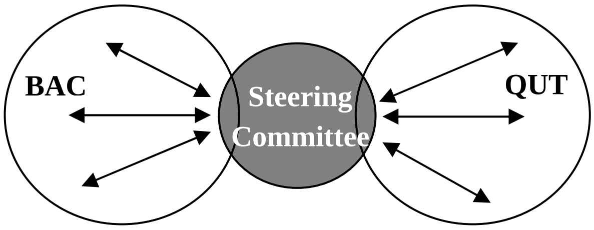

Figure 2 - Role of the Steering Committee

To fulfil its mission, the Steering Committee operates in three different ways defined as:

1. Bringing people together – acting as the intermediary
2. Building the relationship – providing the forum
3. Maintaining the relationship – being the minder

The Steering Committee reports to the Strategic Advisory Committee which consists of the Steering Committee members, two QUT Executive Deans and the Director of Finance and Resource Planning and three additional BAC Executives. The purpose of this committee is to oversee and to provide guidance to the Steering Committee. Its key responsibilities include:

- developing a strategic approach to resources and develop a framework that ensures effective collaboration and targeted successful outcomes for the partners;
- undertaking a twice-yearly senior management review, providing the opportunity for the Steering Committee to discuss their activities and to seek strategic guidance and support;
- providing opportunities for selected research, teaching and learning and other engagement teams to present the outcomes of their programs;
- developing a coordinated approach for promotion of partnership activities, to audiences within the two organisations, and other key influencers and wider communities;
- consider recommendations on appropriate policy and directions for the Partnership to be taken forward to the Chief Executives of the two organisations;

Partnership management as outlined above encompasses a number of layers of responsibility. Additionally, a crucial factor in the success has been the strong support extended by the senior management. At QUT, the Vice Chancellor and other senior staff have been regularly engaged in activities. At BAC, the CEO and the General Manger Operations have been strong champions. This top-down approach has led to the incorporation of innovation into BAC performance plans and in turn has driven them to seek further opportunities for collaboration.

2.4 Achievements to-date and cultural impact

Primary objectives of the Partnership as articulated in the Memorandum of Cooperation are:

Objective 1 Undertaking collaborative research projects

The Partnership has been successful in undertaking collaborative research projects amounting to $4.0M. Since commencement, the number and value of projects has grown exponentially as illustrated in Figure 3 below. In 2006, the Partnership received national recognition with the award for Outstanding Achievement in Collaboration in Research and Development presented by the Business Higher Education Round Table of Australia [5].

Considering the gradient of the graph in Figure 3, it is evident that there was a notable increase in the engagement commencing 2002. This coincides with the formation of the Steering Committee. The next significant change was in 2005 with a further increase in engagement. The embedding of a QUT academic at BAC commenced in 2004. It could well be that the presence of an academic helped in the stimulation of research. The average value of projects being undertaken has increased appreciably. Additionally, the Partnership has generated the following large multilateral projects involving a number of additional industry partners:

- “The Airport Metropolis: Managing the Interfaces” study, brings together fourteen organisations including five national and international universities, three airports, three government departments, a port corporation, a city council, and a rail operator. This four year project valued at over $1.5M investigates the conflicts at the interface between a modern airport city and the surrounding urban area.

- “Airports of the Future: Secure, Efficient and User Friendly Smart Space” is a large $6M research project currently under development seeking Federal Government funding. It has twenty three stakeholders including capital city and regional airports and regulatory and border security agencies. The project proposes the creation of “smart spaces” within airports integrating information as a complex integrated system.

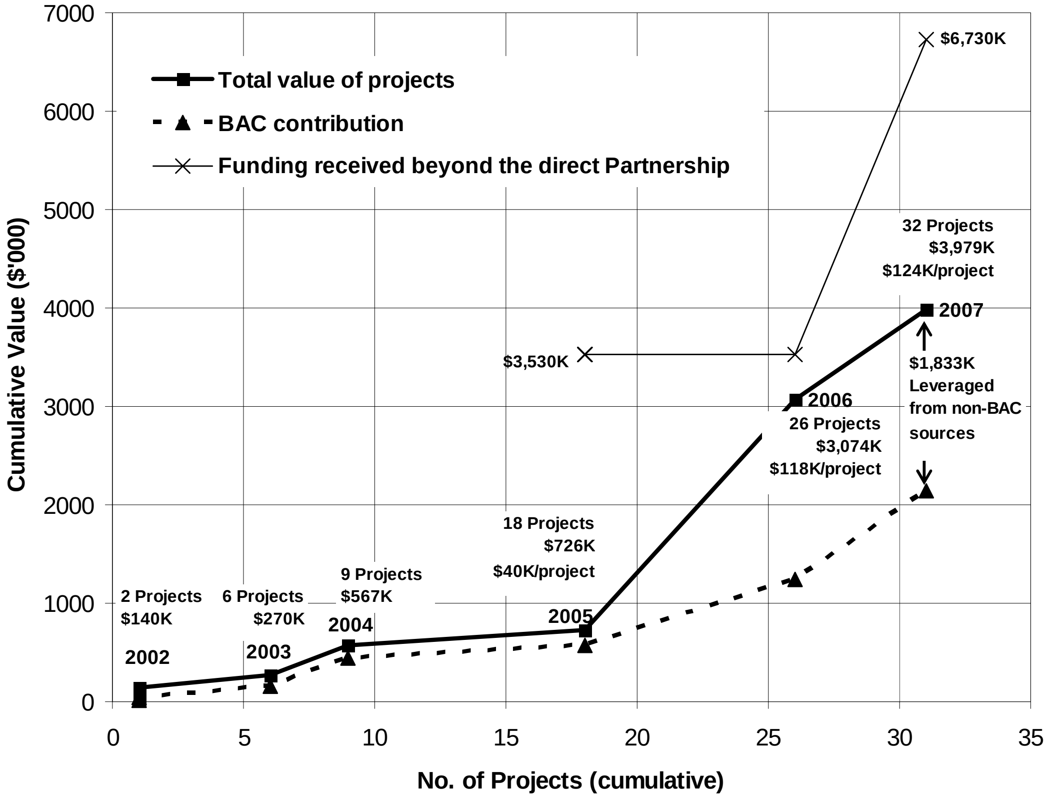

Figure 3- Progression of the Partnership

Objective 2 Wide engagement leading to whole organisation involvement

All the different divisions in BAC have been involved in the commissioning and collaboration in research projects as illustrated in Figure 4 below. In the case of QUT, researchers from seven of the nine faculties have been engaged in conducting research as shown in Figure 5 below. The total number of researchers engaged is over fifty including nine early career researchers.

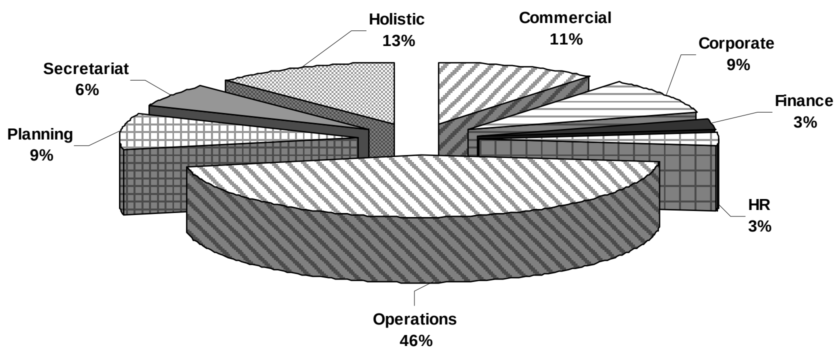

Figure 4 - Share of projects (by # only) commissioned by the various BAC divisions

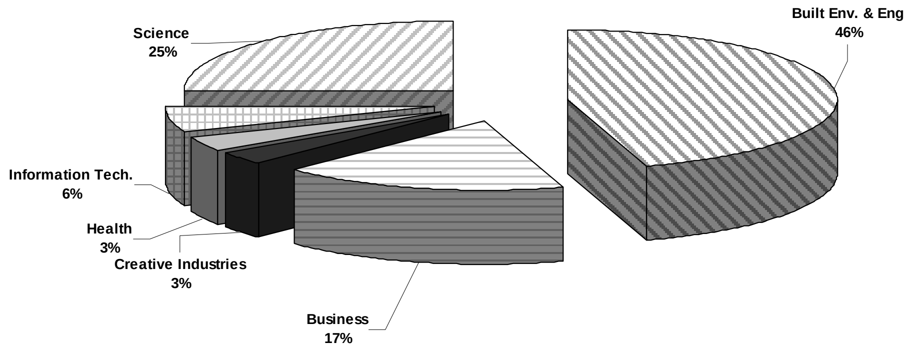

Figure 5 - Share of projects(by # only) undertaken by the different QUT Faculties

Objective 3 Undergraduate and postgraduate student engagement

The Partnership has created significant potential for postgraduate study in the form of data access, opportunities for case study analysis and funding for scholarships. To-date this has benefited four doctoral and three masters students. Undergraduate students too have benefited from the Partnership including:

- Opportunities for work experience for engineering undergraduates to meet the stipulations imposed by the Engineers Australia for graduate engineers.
- Sponsorship of the Faculty of Built Environment and Engineering Dean's Scholars Program. The Program offers high achieving students the opportunity to complete a Bachelor and Master of Engineering degree with financial support.
- Sponsorship of QUT Motorsport Program. As part of the annual Formula SAE Competition, undergraduate students undertake the design, construction and racing of a 610cc Formula race car.

Objective 4 Leveraging research funding from other sources

As illustrated in Figure 3 above, a significant part of the research funding has been leveraged from sources other than BAC. This highlights the fact that the funding received from BAC has played the key role in providing the platform for leverage additional resources from other industry partners and research funding agencies. The partnership has also become a platform for other collaborative research in the aviation sector space with award of funding from the State Government's Smart State Research Facilities Fund of a $3.53M grant for Unmanned Aerial Vehicles (UAV) research and the more recent $3.2M award of a Smart Skies research grant in collaboration with the Commonwealth Scientific and Industrial Research Organisation and Boeing for testing the commercial development of UAV technology for civil infrastructure related applications in Australia.

Objective 5 Collaborations across the industry and internationally

The Partnership has provided the platform for developing a collaborative network with a diverse range of stakeholders in the aviation sector (see also Objective 1). This has resulted in:

- Collaborations with other airports and regulatory and border security agencies across Australia who have joined the various research projects initiated by the Partnership thus enabling QUT to establish a leadership position in aviation related research.
- Collaborations with national and international universities for undertaking aviation related research, thus ensuring that a project's scope is not constrained by the limitations of in-house expertise.

Objective 6 Direct impact on the operational management

The scientific and technical support provided by QUT will lead to changes in the operational management of the Brisbane Airport in key targeted areas. As examples:

- The study on grassland management developed an ecological strategy to reduce bird visitations to the Brisbane Airport. Large scale trials undertaken have shown an 80% reduction in birds which in turn will lead to a corresponding reduction in bird strikes. Furthermore, by keeping the grass to the specified height, it reduces mowing costs by around $60,000/year.
- Assisting in the implementation of strategies on water efficiencies and the introduction of water reuse has enabled BAC to effect a saving of 40% on potable water consumption amounting to a saving of over $0.6M per year.

As discussed above, over the past six years the quantity and scope of research projects undertaken has increased significantly, highlighting both organisations' co-dependence on each other. As the relationship evolved, each organisation has had to become familiar with each other's business, corporate culture, commercial drivers and future goals, whilst developing mutual trust and understanding. A true marker of the strength of the relationship between QUT and BAC is the freedom with which they share highly confidential information. For example, BAC allowing QUT to explore sensitive airport issues such as safety and security is a testament to the trust they have in QUT.

The partnership represents a significant change in the culture of both organisations. BAC has opened up its development, planning and operational process to the rigours of academic assessment and advice, which has led to an organisational culture that is more technically rigorous and conscious of ecological sustainability. QUT has adopted a far more sophisticated approach to collaboration across its faculties to bring a "whole of university" approach to the Partnership. The traditional silos of expertise that generally exist in academia have given way to a more transdisciplinary approach to research, with collaborative involvement from many areas of science, technology, business and humanities.

2.5 Plans for the future

QUT and BAC view the Partnership as a best practice model for universities and industry working together. The Partnership has moved beyond a mere collaboration between two organisations and provides leadership to other airports for developing solutions to critical issues. QUT strives to emulate it as an exemplar for all of its other collaborative relationships.

It has been recognised that the intellectual property originating from the various research projects undertaken is unique and can make a significant contribution to the aviation sector in general. Consequently, the potential for the commercialisation of this intellectual property is being actively investigated. Furthermore, this unique approach to collaboration goes beyond mere R & D. QUT hopes to establish education as an "industry" at the Airport. An initiative currently being investigated is to deliver executive education programmes and niche courses to the Airport Community, later to be expanded to encompass the northern suburbs.

3. Conclusions

In terms of critical success factors for an effective academic partnership, the case of the BAC/QUT Partnership demonstrates a clear strategic alignment and a focus on shared goals between the two organisations. The partnership is based on a model of organised partnership management that embraces a number of champions from the two organisations. The partnership has received recognition and gained national awards for the success of the collaboration. The measures of performance demonstrated in the collaboration are evidence that the framework for measurement of experimentation, engagement and regeneration does offer a maturity model for an evolving partnership and its benefits as summarised in Table 2 below.

This case study does illustrate and demonstrate emerging principles of how to develop and evaluate collaborative partnerships between Industry and Universities. The framework that emerges would be applicable to other partnerships and would potentially offer a more robust way of designing and evaluating such collaboration if applied to partnerships in a wider set of contexts. The analysis in the case study offers a number of implications for individual academics, university support environments, and public policy.

There is an increasing likelihood of involvement in such partnerships becoming a focus for academics with its implications for their training, recruitment and promotion. The way that departmental/school, faculty and university-wide support is best organised for such partnerships to be encouraged, supported and migrated to higher levels of maturity poses many challenges and questions. As described in the introduction to this paper, the growth and success of such collaborative partnerships is both encouraged by and further stimulates the policy changes in research council funding, research selectivity, and third stream funding that is such a focus of policy development in the sector at present.

Table 2 - Evaluation of Collaborative Partnership Maturity Development

Performance Measure	Presence in Case Study
Experimentation	
• Number of projects	Increasing in early stage and then stable
• Scale of projects	Significant recent increases
• Range and diversity of projects	Initial broadening and subsequent focus
Engagement	
• Repeat project involvement	Repeat of partners, investigators, and external funders
• Multiple engagement of the two partner organisations	Initial increase and then stability in partner breadth of involvement
• Multiple engagement of many partner representatives	Expanded and then formalised expansion
Regeneration	
• Shared engagement of staff	Formalised 3-year funded chair agreement
• Shared business unit and facility development	Co-investment in third party business and facility development
• Opening of relationship to respective business networks of each partner organisation	Significant recent expansion of research to competitor airports and universities

Changing Training Needs arising from the Introduction of Off-site Construction Techniques

Louis Gunnigan, Department of Construction Management and Technology, Dublin Institute of Technology (louis.gunnigan@dit.ie)
John McDonagh, Department of Construction Management and Technology, Dublin Institute of Technology (johnmcdonagh13@gmail.com)

Abstract

The objective of this paper is to examine the changes in training needs arising from the increase of off-site construction in the Republic of Ireland. The methodology employed was a case study using a participant observation research technique. For a period of three weeks, the researcher observed the construction of residential housing, constructed using off-site techniques. From the practices observed and from interviews with the operatives on-site, an account of the differences in skills required between those employed in traditional construction and off-site construction was compiled. Each of the different trades involved in traditional construction was addressed and a comprehensive list of the skills training gaps was compiled. The paper examines the implications of the existence of these gaps in training and makes recommendations for corrective action to be taken by the relevant education and training policy makers.

Keywords: Off-Site Construction, Traditional Construction, Training

1. Background

In the relatively short period of time between the early 1990s and the present day, Ireland has changed from having an economic situation which obliged many of its people to emigrate and seek employment abroad (often to the construction sites of Britain and elsewhere) to its current state of full employment (Central Statistics Office, 2006a). This unprecedented (and largely unexpected) increase in prosperity has brought about dramatic changes. Whereas in the past emigration was a necessary safety valve now it is the reverse with thousands of returned Irish emigrants and new immigrants finding jobs here each year. Most sectors of the economy have benefited but perhaps the most visible and dramatic growth can be seen in the construction sector. This is not surprising since the higher levels of employment, increase in population, lower interest rates etc. would inevitably give rise to an unprecedented demand for housing.

Housing output in Ireland has grown at a phenomenal pace, increasing by 400% between 2002 and 2006. By the end of 2006, Ireland’s per-capita housing construction output was higher than anywhere else in Europe. In 2005, for example, Ireland’s output was 19 units per 1000 of the population compared to 4 units per 1000 in the UK. This figure increased to 20 units per 1000 in 2006 (Department of Environment Heritage and Local Government, 2006). The Irish house building sector in 2005 with an output of 81,000 units accounted for 16% of GDP and employed

12.2% of the total workforce (Davy, 2005). In turn, this accounted for approximately for 50% of the output of the Irish construction industry. By the end of 2005 it was estimated that total housing stock in the Republic of Ireland amounted to 1.69 million dwelling units in the State in 2005 with 30% of these units having been built in the past 10 years (Central Statistics Office, 2006b). This equates to 400 houses per 1000 persons, which is approaching the EU average of 450 units per 1000 of the population (DKM, 2005). This level of construction output would not have been possible without the assistance of many thousands of recent immigrants. One in every ten workers employed in the industry in 2005 was a foreign national (DKM, 2005).

2. Off-site versus On-site construction

Until relatively recent times the vast majority of Irish homes were built in the traditional masonry way using the traditional skills of bricklayers, block layers etc. With the traditional method, all load-bearing inner skin walls and load-bearing partition walls are constructed in concrete blockwork. Non load-bearing walls are constructed either in blockwork or timber studwork. Services such as wiring and plumbing are fixed to or chased into the blockwork and covered by the plasterers. The block laying, brick laying and plastering work is usually referred to as the “wet trades” and the electrical and plumbing work as the “follow-on trades” (Allen and Thallon, 2006).

A two storey masonry house for example, is constructed by bricklayers building up both the load-bearing outer and inner walls, one course at a time. The builders fix the insulation inside the cavity between the two leafs of the external walls and they may also fix the window and door frames as they progress upwards. Carpenters are called in to place the floor joists, though sometimes the floor consists of pre-cast concrete floor panels crane lifted into the site. The bricklayers then build the walls up to roof level at which point they hand over again to the carpenters who build the framework for the roof, making way for subsequent felting and tiling.

About two thirds of the work on a traditionally built house involves skilled craftwork, making it very labour intensive and this was one of the external drivers pushing the industry towards greater use of off-site. In Ireland up to recently most residential buildings were built in the traditional way.

In its broadest sense, off-site construction embraces most contemporary construction techniques. Even the traditional bricks and blocks can be regarded as prefabricated components in simplest form (Gibb, 1999). At the other end of the spectrum, whole buildings can now be prefabricated and pre-assembled remote from their final destination and installed in place ready for use with only the minimum of on-site work needed. In all cases, off-site construction invariably involves three stages - factory prefabrication, transportation to site and site assembly. This means that part of the construction that would previously have been done on-site is now moved to a facility away from the site. The percentage of the work done off-site can vary between two extremes reflecting situations where most of the work can be done off-site by factory personnel and situations where most of the work is still done on-site by the traditional craftspeople.

A further part of this research established that approximately 50% of all housing completions in Ireland currently employ off-site construction methods – a large portion of which use timber framed construction as its primary construction method. This makes timber frame construction the off-site market leader in the low-rise residential sector and therefore the primary target of this research.

3. The aim of the research

The aim of the research was to establish the type of off-site systems being used, the extent of that use, the pace at which they are growing and the problems which arise especially at the (on-site) point of assembly and the human resource implications where skilled labour is concerned. This paper is produced as part of that research. The specific objective of this paper is to examine the changes in training needs arising from the increase of off-site construction in the Republic of Ireland.

4. Research Strategy

Following a significant amount of exploratory research using secondary sources, on-site participant observation was established as the most appropriate method of studying the precise issues that were arising in the increasing use of off-site construction methods. Using this approach, the tradespeople would be observed to establish:

- Their input to the process and stage of construction;
- The nature of the work being completed;
- How the work being done compared to what traditionally had been done;
- Any specific technical or organisational problems that may arise.

5. Refining and Testing the Research Method

The research method was initially tested by through conducting a number of interviews and carrying out a series of site visits to off-site facilities (factory pre-fabrication and pre-assembly) and on-site (assembly and erection) operations. This established the issues to be investigated and these were further through an initial week of participation observation on a small site where a single timber framed house was being erected. This process highlighted the issues that would be confronted in the gathering of information and the level to which the researcher could realistically expect to get involved in the project. It also highlighted the following construction related issues that might be expected to occur during the primary research:

1. Systems delivered with inaccurate dimensions (an off-site problem) which resulted in panels not fitting together;
2. Poor system erection (an on-site problem) which resulted in the system not being assembled properly;
3. Poor system servicing (an on-site problem) which resulted in the system being damaged by follow-on trades.

These issues would then be investigated to establish the changes in training needs that were emerging in the move to off-site construction methods.

The preliminary findings had certain implications for the principal research method chosen and lead to the following conclusions:

- All three problem areas identified would manifest themselves at the on-site stage and therefore could best be investigated at an on-site location. (Problem no.1 is an off-site issue but it is on-site that its effects will be seen and experienced);
- A timber-frame construction project was chosen as the most appropriate on-site location as this system has the biggest market share in the off-site low-rise residential sector in Ireland;
- Participant observation was confirmed as the most appropriate research method because it would enable the researcher to work side-by-side with and observe the craftsmen involved in the erection and assembly of the systems. It would also allow for checking of the dimensional accuracy of the systems components being delivered to the site.

6. Site Selection Process

A participant observation study naturally imposes some constraints with regard to location and duration. In order to make the optimum use of the time available (four working weeks) a timber framed housing project consisting of 104 houses was chosen. Phase 1 of this project was already completed and occupied before the observation commenced. However, Phase 2 had several houses at different stages of construction and thereby provided an ideal opportunity for observation, both of the phases of construction and of the role of all of the different trades in the construction process.

The study was conducted over a four week period from 14th Nov to 12th December 2005 and, with the approval of the contractor’s site management team, the researcher engaged in all of the construction tasks associated with timber frame delivery, erection, roofing, servicing and cladding. In this way an opportunity was provided to work closely with all of the craftspeople involved, thereby enabling the recording first hand of observations by means of photographs and diary.

7. Data Collection

The following data collection methods were employed:

- Note-taking - notes were made on a regular basis on the construction site or later in the day. These notes were based on observations and conversations with other workers and often consisted of short phrases or simple keywords to act as subsequent reminders or reference points;
- Visual records - Over one hundred photographs mostly for purposes of record as an aide memoire but some of which could also be used in the presentation of results;

- Data-gathering interviews - informal interviews with site foremen and other construction personnel on specific issues.

During the course of the intensive four-week observation study the researcher participated fully in all of the on-site construction activities of a timber-frame construction project based on off-site methods. This provided a first hand opportunity to see and experience many of the practical day-to-day issues that arise on-site.

The on-site erection of a timber frame house includes the following steps:

1. Site preparation;
2. Scaffolding;
3. Crane/ lifting equipment;
4. Arrival and unloading of the trailer;
5. Erection of ground floor walls (external panels);
6. Erection of ground floor walls (internal panels);
7. Positioning of first floor panels;
8. Erection of first floor walls (external panels);
9. Erection of first floor walls (internal panels);
10. Erection of the roof.

At the outset of the study period the researcher was assigned to work with the erection crew consisting of four carpenters - two fully qualified and two apprentices. This provided the opportunity to develop an insight of the perspectives of an experienced crew member from those of an apprentice.

The entire timber frame kit took ten working days to construct. Although the structure of the house up to roofing stage was completed in the first two days it took a further eight days to complete. In the period of the participant observation all of the craft areas involved in the building and servicing of a timber frame house were observed.

8. Data Analysis

The trades involved in the building process observed during the four week on-site research period. This was then compared to the standard tasks undertaken by these trades in traditional brick and block building to establish the changes in tasks undertaken when the timber frame construction process is used. Table 1 lists these changes.

Table 1 - Tradespeople involved in constructing a traditionally built house compared to a timber frame house

Tasks performed	Traditionally Built House	Timber-Framed House

Internal plastering	*Plasterers*	*Plasterers*
Painting and decorating	*Decorators*	*Decorators*

The extent of changes observed allows each of the trades to be categorised as follows:

- Significantly affected, where trades are being asked to take on additional tasks;
- Moderately affected, where trades are being asked to work in a different manner;
- Not affected.

The traditional trades which most significantly affected are carpenters and masonry workers. Table 2 shows how the tasks are divided up between these two crafts depending on whether the dwelling is being traditionally built or timber-frame built. This illustrates that the tasks required in constructing a traditionally built house the tasks are more or less divided equally between masonry workers and carpenters. A timber-framed house on the other hand relies more heavily on the work of the carpenters. This additional work being undertaken by the carpenters on timber frame raises the need for specific system erection training. Carpenters are expected to assemble the new timber frame systems. Ideally this should require special training to ensure the system is properly assembled. Since the timber frame components are the main structural elements of the building it is essential that they be assembled correctly. Improper assembly can obviously impact negatively not only on the structural stability of the building but also on its thermal performance ability. If for example the panels are not tightly fitted together this will leave air gaps affecting the heat retention capability of the building. These problems can be avoided if the building is properly erected by a trained timber frame erection crew.

The impact on masonry workers is more a question of workload reduction rather than any significant change in the type of work they are required to do.

Table 2- Significantly affected trades

Tasks Performed	Traditionally Built House	Timber Framed House

Felt and battening	*Carpenters*	*Carpenters*
Cladding	*Masonry*	*Masonry*

The training of timber frame erection crews for proper system assembly is being addressed by the Irish Timber Frame Manufacturers Association in conjunction with FÁS (the national training agency). At the moment however there is no government recognised training programme operating in Ireland. The majority of timber frame manufacturers provide a list of certified erection crews but these crews are not endorsed by government certification standards.

It became clear from the direct and participant observation studies at various sites that the majority of the carpenters were trained in all the traditional carpentry skills and for the most part were coping adequately with new demands of timber frame construction. The fact remains however that they were not formally trained to recognised standards in timber frame erection and assembly techniques and the need for such training should not be underestimated. The additional skills needed could be acquired in a relatively short time but they are essential if the quality and structural integrity of the building is to be guaranteed. Additional health and safety training is also needed to ensure the crafts involved recognise the particular hazards of the system of construction, an issue that is now even more relevant with the recent change in building regulations that allows timber frame construction for buildings up to four storeys high.

The tradespeople who are moderately affected are listed in table 3 below. Crafts people in this category are the same for both systems. In this case they do essentially the same jobs but under different conditions.

Table 3- Moderately affected trades

Tasks Performed	Traditionally Built House	Timber-Framed House
Electrical work	*Electrician*	*Electrician*
Plumbing work	*Plumber*	*Plumber*
Insulation insertion	*Insulation crew*	*Insulation crew*
Plasterboard attachment	*Plasterboard crew*	*Plasterboard crew*
External door and window installation	*Installation crew*	*Installation crew*

For example, electricians and plumbers are required to service the building in a similar way for both systems but chasing through concrete is more difficult and time consuming while timber, though easier to penetrate, requires greater care. Similar considerations apply to the installation of doors and windows, the placement of insulation and attachment of plasterboard. The difference in the nature of the tasks here derives from the difference between fixing to concrete and fixing to timber.

The electricians and plumbers have to chase their service lines through the walls of both types of buildings. Chasing through a concrete building is a slower and dirtier job. Timber on the other hand is easier to chase, not only because of the open spaces between the vertical studs, but also because timber is easier to drill through. However, as timber frame is a structural skeleton, only certain parts of the beams can be drilled. The position of the drilled hole, its diameter size and the number of holes in one area are crucial if the structural performance of the timber beam is not to be compromised. Since the majority of electricians and plumbers are accustomed to working on traditionally built dwellings some additional training is required if they are to install services in timber frame houses.

During informal interviews with the senior electricians and plumbers on-site it became clear that best practice guidelines were both known and understood. It was clear from observation however that proper procedures for drilling were not always adhered to as the drilling or chasing was almost invariably carried out by an apprentice rather than a fully qualified tradesperson. A number of examples were found of multiple holes have been drilled for piping and/or electrical cables in a single beam, many so close to the edge of the beam that the structural integrity of the beam was compromised. In all cases observed, further investigation established that the drilling and chasing work had been done by the apprentices who could not yet be expected to be fully familiar with best practise procedures.

The other tasks that are moderately affected by the shift towards timber frame involve insulation insertion, plasterboard attachment and external door and window installation. The trades affected are merely required to attach the various add-ons to a different material i.e. to timber instead of to concrete. From observation and informal interviews it became clear that these trades found it easier to install in a timber frame compared to a concrete building. It became apparent that sometimes window and door openings from the timber frame kit were delivered either in the wrong size or in the wrong place. This is an off-site problem where the system is delivered with inaccurate dimensions or, as sometimes happens, with openings that were not supposed to be there.

The tradespeople who are not affected are listed in table 4 below. The tasks for these trades are the same for both systems because the working environment in which the jobs are done is essentially the same. These tradespeople confirmed that their jobs were not affected to any significant degree by the shift from traditional to timber frame.

Table 4 - Non affected trades

Tasks Performed	**Traditionally Built House**	**Timber-Framed House**
Roof tiling	*Roofers*	*Roofers*
Internal plastering	*Plasterers*	*Plasterers*
Painting and decorating	*Decorators*	*Decorators*

Having identified the trades involved in constructing and servicing both systems (traditional brick and block and timber-framed) and the skills which they are bringing to the different tasks it is appropriate at this point to look again at the potential problem areas identified for investigation in the exploratory research in section 5 above.

1. Systems delivered with inaccurate dimensions (an off-site problem), which resulted in panels not fitting together.

No delivery of systems elements with inaccurate dimensions was recorded during the participant observation period. However, the fact that this sometimes did occur was raised by those who participated in the informal interviews on site and confirmation was given that such panels were generally sent back to the factory to be altered prior to redelivery to site.

2. Poor system erection (an on-site problem), which resulted in the system not being assembled properly.

Again the observation study did not identify any major problems affecting the quality of the work carried out by the erection crews. The carpenters were the group most significantly affected by the shift from traditional to timber-framed construction in that they were engaged in many phases of the work (timber-frame erection and assembly) - phases which traditionally would have been mostly carried out by masonry workers. The tasks however were essentially those requiring woodworking skills and in the circumstances the carpenters were coping reasonably well. There is still however a significant issue in relation to additional carpenter training and the need for some form of certification to ensure that proper procedures are followed.

It is therefore important, that the regulatory authorities and the relevant training organisations become more proactive in this area. Apart from the new skills required by the timber frame system, the add-on training must also embrace health and safety procedures not only for the erection crews but for other site workers as well.

3. Poor system servicing (an on-site problem) which resulted in the system being damaged by follow-on trades.

This is a serious issue in that it can potentially affect the structural stability of the building. Plumbers and electricians, though themselves only moderately affected by the shift from traditional to timber-frame, are sometimes responsible for poor system servicing. This mostly arises when untrained personnel (i.e. apprentices) are allowed to undertake the drilling work for the service lines. The holes if not drilled in the proper locations can seriously impact on structural stability. Poor workmanship in this area can go undetected until the consequences become apparent perhaps years later. A similar training to that envisaged for the erection crews is recommended whereby the follow-on tradespeople can also be certified thus ensuring the maintenance of proper servicing standards.

9. Conclusion and Recommendations

In analysing the findings of the study the crafts or trades involved were divided into three categories depending on the degree to which they were being impacted upon by the new system of construction in which they were engaged. The categories were formed on the basis of whether the trades were significantly affected, moderately affected or nor affected at all.

The trades most affected were the carpenters and the masonry workers. The impact on the masonry workers was more a question of a reduction of workload rather than any significant change in the tasks they were required to do. Not surprisingly the carpenters were involved in many phases of the timber frame construction whereas in a traditionally constructed house the load-bearing walls of the building would have been the responsibility of the masonry workers. Though the carpenters were trained in traditional woodworking techniques they were not necessarily accustomed to erecting and assembling vital load-bearing parts of the building. Ideally this requires special training to ensure that the timber frame system is correctly assembled. The additional skills needed could be acquired in a relatively short time and there is evidence that the regulatory authorities and the responsible training organisations need to be more proactive in this area.

Most of the follow-on trades such as electricians, plumbers, insulation and plasterboard crews were in the moderately affected category. These were doing essentially the same jobs as they would have done in traditionally built houses but under different conditions. The difference in the nature of the tasks derived from the difference between fixing to concrete and fixing to timber. Where plumbers and electricians are concerned, drilling through timber-frame components requires appropriate training if the quality of the finished building is not to be impaired. Follow-on trades such as roof tiling, internal plastering, painting and decorating were not affected because the working environment in which these jobs were done was essentially the same for both systems.

Because the off-site systems used in residential construction in Ireland are at the less advanced end of the market, approximately half of the work still remains to be done on-site. Heavy reliance on the traditional on-site skills to complete this half of the work can give rise to poor system erection, assembly and servicing. These are all issues that could be addressed by further training.

It is estimated that off-site systems as currently practised in Ireland will continue to grow in the future and that there will also be a gradual move from open panel systems to more advanced forms such as closed panel systems and to a lesser extent pods. Such a move would have further implications for the various building trades changing the very nature and location of some of these jobs. A further shift of construction work away from building site to factory could lead to a breakdown of some of the traditional crafts, such as plumbing and electrics, into simpler tasks which would be done by specially trained factory personnel. These factory-trained technicians would in effect be replacing some of the traditional tasks as we know them. These and other issues arising from this study will hopefully provide useful points of departure for further investigation.

Abstract

The paper aims to report the findings of research into factors contributing to or impeding the training and recruitment of personnel within the South African construction industry. The research uses a postal survey questionnaire technique for primary data collection from a sample of consultants and contractors within the Western Cape region of South Africa. Literature review is used to identify relevant practices, which are then incorporated into the design of the survey instrument. Survey response data is subjected to descriptive statistical analysis and subsequently discriminant analysis based on organisational size. Lack of training was reported by both the consultants and contractors as impacting skills shortage. Lack of financial incentives to train construction workers and quality of training ranked as the most next impacting influences on skills shortages according to the contractors. On the other hand, skills leakage and lack of training were the most influential factors on skills shortages according to the consultants. Interesting, both contractors and consultants ranked the effects of higher education as the least influencing factor. This paper argues that development and introduction of aggressive campaigns to positively promote careers in the construction industry including the provision of more attractive bursaries at high school and higher education levels are necessary. This will lead to a development and introduction of more meaningful financial incentives and funding arrangements to train and retrain construction human capital at all levels. This paper contributes to the contingency theory by investigating the impacts of organisation size on recruitment and training aspects.

Keywords: Antecedents, Analysis of Variance, Training, Construction Industry, South Africa

1. Background

This section provides a general overview of the legislative framework and government policy that inherently affect the shortage of construction skills within the two sub-sectors. In particular it addresses the following questions: What impact would the current legislation and/ or policies have on skills development in the two sub sectors (specifically, management, consulting professions, skilled, and unskilled?). To what extent, if at all, could problems and/ or possible gaps in current legislation and / or policies impact on skills development in this specific context?.

1.1 Legislation and government policy

Construction in South Africa occurs in and is impacted by a legislative framework that includes the need to comply with, for example:

- The Constitution of the Republic of South Africa
- The Skills Development Act, No 97 of 1998

The objective of the project was to produce a status report on the skills base within the construction industry, benchmarked internationally against future skills needs and priorities. The National Skills Development Strategy's vision is underpinned by the following guiding principles:

- Developing a culture of high quality lifelong learning
- Fostering skills development in the formal economy for productivity and employment growth
- Stimulating and supporting skills development in small business
- Promoting skills development for employability and sustainable livelihoods through social development initiatives
- Assisting new entrants into employment

In addition, the Implementation Strategy of the NSDS, the Sector Skills Plan of the CETA and Companies' Workplace Skills Plans collectively aims to:

- Increase the level of investment in training and education
- Improve the impact of the training and education that is undertaken
- Ensure that training, education and qualifications are properly structured and quality assured

This section takes a general overview of the legislation and government policy that inherently affect the shortage of construction skills within the three sub sectors. In particular it addresses the following questions: What impact would current legislation and/or policies have on skills development in the three sub sectors (specifically, management, consulting professions, skilled, semi-skilled, and unskilled)? To what extent, if at all, could problems/possible gaps in current legislation and /or policies impact on skills development in this specific context? The approach adopted is similar to that of NACI [1].

1.2 Skills Development Act (Act No 97 of 1998)

Recognizing that the importance of the working skills of all South African is critical to grow the economy, the Skills Development Act (SDA) was promulgated to create structures and framework for national skills development strategy. In terms of the SDA employers are obliged to provide formal structured education and training to their workers. Furthermore, it encourages partnerships in the effort between government, employers, workers, education and training providers, and beneficiary communities. According to the SDA, the needs of employers, the economy and communities must dictate which skills should be developed. It covers structured, targeted and generic training - implying that all training interventions should be planned and managed as projects. Employers together with their workers formulate workplace skills plans (WSPs) to enable them realize their employment and training targets.

2. International Review

Although The SA Construction Industry Status Report of 2004 acknowledge that Skills enhancement in the construction industry faces a very particular challenge since the construction sector employs the fourth highest number of persons having no formal education. To this effect, the second phase report reviewed international literature to examine international experiences relative to skills development. To this end several countries were investigated; *inter alia,* the United Kingdom, Scotland, China (Hong Kong), Ireland, Israel and Australia. However it's beyond the scope of this paper to present the majority of the literature review, however similar trends and challenges confronted the construction industries in each of the countries reviewed. For example within the UK context, Agapiou, Price and McCaffer [2] examined the construction industry in the UK. They recognized the increasing failure of the industry to attract new recruits for several reasons. Further, while offering competitive attractive remuneration packages, the industry was renowned for its poor image and failure to offer a sustainable career structure. Considering the loss over time especially during times and economic downturn when high numbers of skilled workers leave the industry and fail to return when work becomes available again, it is unlikely that these skills will be replaced from the ranks of the unemployed only (Holt et al, [3]). Within the Hong Kong context, Chan and Chiang [4] argue that factors such as technological advances and increased specialization have changed construction methods and consequently the need for new construction skills. In order to establish the equilibrium between supply and demand for construction skills the Works Bureau of Hong Kong needed the development of a manpower-planning tool that would assist the development of the construction industry and assist in maintaining the balance of labour and supply. Elsewhere, studies have been done to forecast construction labour requirements, for example in Israel for the period of 1991 through 2000 as a basis for planning decisions involving recruitment of new workers, initiation of training programs and investment in labour saving technologies (Rosenfield and Warszawski, [5]). The study sought to estimate the demand for workers in major construction skills for the period 1991 through 2000, assessing the existing supply of such workers, and compare demand and supply for skill, derive conclusions and offer recommendations. Training issues have been addressed within the African context with a number of Least Developed Countries (LCDs) showing diligence in mounting training programmes tailored to their needs

(Zeffane and Rugimbana, [6]). According to Visagie [7], there are also some challenges facing small, medium, and micro enterprises (SMMEs) in South Africa such as access to training. Other authors argue that organisations which fail to have a coherent training strategy finds itself "dependent on the external labour market, and hence in a position where it is unable to regard labour as anything than a cost" (Ashton and Felstead [8]). Within the Sub Saharan countries such as Mozambique, there is agreement that training and development, and recruitment and retention are part of the key practice areas of people management. According to Storey [9], despite this acknowledgment, however few firms make use of no training whatsoever. More, whilst unstructured, informal ad hoc and ongoing training probably represents the most feasible option given adverse external circumstances. Webster and Wood [10] also conducted a study which aimed to explore the nature of contemporary HRM practice in Mozambique and found that the failure of HRM techniques to diffuse across the economy, despite heightened external pressures, highlighted organizational inertia, including the continued reliance of many firms on low-paid and low skilled workers, and on autocratic paternalism. Robertson [11] explored the role of training and skilled labour in the success of SMEs in developing economies and found that the effects of increased trade and international dispersion of manufacturing activities on the demand for skills to be widely known. More so, the study concluded education and skills occurred in many types and on many levels, as such emphasis could be put on improving access to primary, secondary, or tertiary education; on training workers for semi-skilled or highly skilled jobs (or no providing very little training at all). A study conducted within the West Yorkshire (UK) construction sector by ECOTEC Research and Consulting Limited [12] for the CITB-Construction Skills

Identified a lack of staff time for training, or a lack of time to supervise training and significant barriers in additional to time related issues. It is evident from the literature review that no matter the country or the models used, the experiences are generally similar. The following trends were observed:

- A general lack of training and the quality thereof; the large number of self-employed; the perception that the construction industry is not a sustainable career choice; there is a grater emphasis on multi-skills in terms in terms of technical skills as well as the need for soft skills; as there is a large number of self-employment and small subcontractors, the amount of time available for training is significantly reduced; the forecasting models used are data sensitive; and the forecasting of future demands and supply can be a indicative tool for planning purposes

Therefore, in order to achieve these objectives of investigating and determining the antecedents to training and training practices within the South African Construction industry, the views of 40 Contractors and 24 Consultants were surveyed within the Western Cape Province. The findings of the survey are reported using descriptive statistics. The following section reports on the research methodology that the researchers then conducted which forms the basis of this paper.

3. Research Methodology

To investigate the factors contributing to or impeding (thus termed antecedents) the training and recruitment of personnel within the South African Construction Industry, the following research methodology was employed in the study.

3.1 Research Aims and Objectives

The main objectives of this research was to determine the skills base of CETA's two sub sectors; identify the skills gap within the sector with special reference to its SMME segment and benchmarking the research internationally against future skills needs and priorities. Finally to aligning findings with the National Skills Development Strategy (NSDS) objectives. The project specifically targeted the following sectors within the construction industry:

- Construction (Building and Civil Engineering Contractors)
- Built Environment professionals (Architects, Quantity Surveys, Civil Engineers, etc.)

3.2 Sample

A mixture of regional and local contractors in the Western Cape Province was interviewed. The original plan was to conduct a qualitative approach based on interviews. The original sample data planned is shown in Table 1.This study issued 90 questionnaires to randomly selected organisations. As evidenced from Table 1, there were difficulties encountered in engaging the contracting sector relative to participation in the study. This is despite allowing for the several measures. The respondents were informed that it would be on an "Interview Basis", those unable to make time to the interview were called and faxed the questionnaire. Another option explored was that of "Telephone Interview" with the last resort being the self completion of the questionnaire. Despite all the measures undertaken, only the Contracting Sector didn't achieve the desired sample as shown in Table 1. The final responses as a percentage of the total number (66) received

Table 1.0: Original Sample versus Response Rate

Sub Sector	Original Sample Planned	Total Responses Received	Response Rate
Contractors	66	40	61%
Consulting Professions	24	24	100%
Total	90	64	71%

A mixture of national, regional and local contractors and consultants were interviewed. Table 2.0 shows the frequency of the respondents by the number of employees

Table 2.0: Frequency of Respondents by Number of Employees

Number of Employees	Contractors (N=40)		Consultants (N=24)	
	No	**Frequency (%)**	**No**	**Frequency (%)**
< 10	5	12.5	5	20.8
> 10 < 50	13	32.5	10	41.7
> 50 < 100	11	27.5	7	29.2
> 100 < 250	7	17.5	2	8.4
> 250	4	10	-	-
Total	40	100	24	100

Table 2 shows that 41.7(%) of the consultants interviewed employed between 11 and 50 workers and 29.2% between 50 and 100 workers. On average the respondents had been in business for 34 years. The majority responded "yes" when asked if they were registered. Registration was however interpreted differently and a variety of organisations were mentioned.

3.3 Measurement Instrument

The Survey instrument used in this study comprised of 6 sections and dealt with the following; The first part (demographics) sought information pertaining to primary participation, geographical location, years of establishment, type of work, profile of labour, turnover, distribution of labour (by gender, disability and age), and distribution of skills profile by number. Section two dealt with skills shortage and development and the output and issues sought were criticality of shortages and impact of skills shortage. The third section was designed to measure the levels of importance and agreement of 21 recruitment and recruitment practices. Each item or practice was measured from a range of (1) representing very low importance or agreement to (5) very high importance or agreement. Thus (3) represented indifference, i.e. neither low nor high importance. Training practices were examined in section four and the issues sought were the constraints and barriers measured on a 5 likert scale with (1) representing totally disagree to (5) totally agree, thus (3) represented indifference, i.e. neither agree nor disagree. This comprised 23 items.

3.4 Reliability and Validity of the Measurement Instrument(s)

According to Sureshchandar et al. [13], a critical aspect in the evolution of a fundamental theory in any management concept is the development of good measures to obtain valid and reliable estimates of the constructs of interest. The instrument designed for recruitment and recruitment practices, and who results are reported in Table 3 had Cronbach coefficient of 0.657, whereas the instrument for factors affecting skills shortages (see Table 4.0) and a higher Cronbach alpha value of 0.844. Measures to counteract recruitment problems instrument (Table 5.0) had Cronbach alpha value of 0.751.

3.5 Statistical Methods

The primary focus of the study presented in this paper was to investigate the antecedents to training and training practices and determine whether differences existed in the perceptions of the antecedents between contractors and consultants and whether organisation size influenced the perception of such. The *Statistical Packages for the Social Sciences (SPSS)* was used for the analysis. Two levels of data analysis are conducted: a macro-level analysis of aggregate, surface characteristics of the respondents and a micro-level analysis of deeper, fined data methods. In order to compare the antecedents to training practices of different groups of organisations by size, statistical tests were conducted to compare the mean scores of the training and recruitment practices (variables) between groups of employees classified by organization size. Analysis of Variance (ANOVA) and independent *t*-tests were used to test for significant differences (Chileshe et al [14])

3.6 Definition of terminology

Contractors and Consultants were asked what factors they considered important when recruiting and employing new workers. A short explanation (see Table 3.0) of the factors follows to provide clarity:

Table 3.0: Definition and explanation of terminology

Terminology	**Definition or explanation**
Adaptability to changing working environments	Whether the employer felt it important that prospective employees were able to be flexible and adapt to changing environment
Ability to work in teams (crews)	Whether it was important that employees were "team players" and able to work successfully with others.
Multi-skilled	Whether it was important that employers had more than one skill such as, for example being able to lay bricks, plaster and tile.
Project duration	Whether the duration of the project had any bearing on the recruitment / employment practices of the company
Labour-only contractors	Whether the existence of these contractors had any effects on the recruitment practices of employers
Equity	Whether companies considered employing female, disabled and other previously disadvantaged persons as a deliberate strategy

4. Results and Discussion

Contractors were asked what factors they considered important when recruiting and employing new workers. Table 4 presents the findings by the means of responses relative to those factors. One of the objectives of the study was to investigate the impact of organisation size on the recruitment and recruitment practices. Analysis of Variance was conducted for the Contractor sample and the findings indicate that there were some significant differences in a minority (12%) of the recruitment practices among the Contractors differentiated by the size of the Labour force. The practices were as follows: "Possession of craft (trades specific skills" (*F* (4,

35) = 3.426, p = 0.018 < 0.05); "Profit margins (F (4, 35) = 4.406, p = 0.005 < 0.05)"; "continuity of work" (F (4, 35) = 4.649, p = 0.004 < 0.05); and "citizenship, non South African or South African" (F (4, 35) = 2.900, p = 0.036 < 0.05). The inference to be drawn is that although some significant differences exist due to organisational size differential, overall, the majority of recruitment and recruitment practices are not affected by size. This is of particular importance given that the Construction Industry's structure is comprised of Small and Medium sized organisation. As argued by Robertson [11], SMEs often lack the knowledge and resources to engage in training programs; however their success in upgrading themselves technologically may depend crucially on subsidised educational and training infrastructure provided by their governments

4.1 Recruitment and recruitment practices

Table 4: Mean Score Comparison of Importance of Factors to Recruitment and Recruitment Practices: Consultants and Contractors

	Contractors (N=60)		Consultants (N=24)	
Aspects of Recruitment and Recruitment Practices	**Rank**	**Mean[1]**	**Rank**	**Mean[1]**
Adaptability to Changing Work Environments	1	4.325	4	4.583
Ability to Work in Teams (Crews)	2	4.325	1	4.299
Multi-Skilled	3	4.225	7	4.000
Project Duration	4	4.025	14	3.565
Profit Margins	5	4.000	9	3.958
Possession of Craft (Trade) Specific Skills	6	4.000	8	3.958
Continuity of Work	7	3.921	2	4.417
Rates of Pay	8	3.948	5	4.217
Possession of Generic Skills	9	3.900	11	3.696
Consideration of Retraining Existing Workers	10	3.900	10	3.875
Previous Work Experience (Occupational History)	11	3.875	3	4.333
Citizenship (non-SA or SA)	12	3.825	16	3.417
Training of Inferior Labor (Poorly Skilled at Employment)	13	3.736	12	3.625
Learner ships	14	3.700	5	4.083
Gender Equity	15	3.675	18	3.208
Medical History	16	3.650	17	3.375
Secondary/High Schools	17	3.615	13	3.609
Equity (e.g. Disabled Persons)	18	3.625	15	3.542
Labour-Only Contractors	19	3.526	20	2.957
Language Issues	20	3.307	-	-
Age	21	3.282	19	3.000

Note[1]: Where 1= extremely unimportant; 2 = slightly unimportant; 3 = neutral; 4 = slightly important and 5 = extremely important.

The results in table 4 indicate that contractors ranked the following as the most important aspects that influence recruitment decisions and employment practices (ranked by the means of their responses): Adaptability to changing work environments (mean = 4.325, rank =1st); Ability to work in teams or crews (mean = 4.325, rank = 2nd); Multi-skilled (mean 4.225, rank = 3rd); Project duration (mean = 4.025, rank = 4th); and Profit margins (mean = 4.000, rank = 5th). On the other hand, the following factors were considered to be least important: Age (mean = 3.282, rank =21st); Language issues (mean = 3.307, rank =20th); Labour-only contracts (mean = 3.526, rank =19th); Equity e.g. disabled persons (mean = 3.625; rank = 18th) ; and Secondary / high schools (mean = 3.615; rank = 17th)

Respondents were asked to give reasons for the recruitment practices that they follow. Several citied training as being important in the recruitment of staff. Comments relating to training include:

- We recruit people that are willing to work and learn the trade with a view of growing with the company.
- Workers can also be employed in construction if they are trained. Then you need the construction, but they must also be trained.
- Training schemes have collapsed. Sub-contractor approaches not contracted. All of this resulted in unskilled labour (that will never receive training) being placed in skilled labour positions.
- Lack of quality training as well as knowledge and not forgetting education and that training happens mainly at the work face
- As the demand increase for all employees within the construction industry so does the bargaining power of the employees and the opportunities out there in the market. The increase in the number of projects means that "young" employees are thrown out in the "deep end" and have to learn the hard way other than formal training over the years.
- People must be taken to school to learn the building trades as they used to do in the past, not only come back with the certificate. We all need money to work so women must also get opportunities same as men.

4.2 Training and training practices

Factors affecting skills shortage Constraints and barriers to training were assessed in this study via twenty three items scored on a 5-point Likert style scale. Contractors and Consultants were asked to rate several factors that may have had an impact on skills shortages in the South African construction industry, where 1 = extremely negative impact; 2 = moderate negative impact; 3 = no impact; 4 = moderate positive impact; and 5 = extremely positive impact. These responses provided a basis to establish to what extent the factors had a negative influence on skills shortages in organisations. Table 5.0 presents the comparisons of the rankings by the means of responses relative to those factors. A one-way ANOVA was conducted to compare scores on the factors affecting skills shortage by organisation size (number of labour turnover). The findings indicate that there were some significant differences in only a minority (2) of the factors affecting skills shortages among the Contractors differentiated by the size of the Labour force. The factors were as follows: "Skills gained experientially without formal training" (*F* (4, 31) = 3.164, *p* = 0.027 < 0.05) and "Recruitment Policies" (*F* (4, 32) = 3.977, *p* = 0.010 < 0.05). Consultants only reported significant differences on one of the factors namely "Skills gained experientially without formal training" (*F* (3, 18) = 4.133, *p* = 0.022 < 0.05)

Table 5: Mean Score Comparison Impact of Skills Shortages on the Construction Industry: Contractors and Consultants Views

Cont Rank	Cons Rank	Factors affecting skills shortages	Contractors Mean Score (N=40)	Consultants Mean Score (N=24)
1	1	**Lack of Training**	1.816	1.391
2	4	**Lack of Financial (Monetary) incentives (to train)**	2.027	1.783
3	=13	**Quality of Available Training**	2.132	2.304
4	12	**Profit Margins**	2.333	2.174*
5	10	**Qualifications that are broken into narrow task-related units**	2.361	2.174*
6	9	**Lack of Multi- skills**	2.368	2.087
7	3	**Cyclical Nature of Industry**	2.417	1.636
8	2	**Skills Leakage**	2.432	1.435
9	11	**Image of Construction Industry**	2.528	2.174*
10	20	**Technological Changes (New Methods, Techniques, Materials)**	2.688	2.545
11	-	**Labour intensive construction (labour based)**	2.684	2.435
12	6	**Continuity of Work (Supply)**	2.729	1.957
13	19	**Legislative Framework**	2.765	2.435
14	7	**Basis of Remuneration**	2.806	2.046
15	17	**Procurement Approaches (e.g. Preferential Procurement)**	2.821	2.435
16	5	**Casualization (Itinerant/Temporary Workers)**	2.842	1.955
17	16	**Arrangement of Work**	2.848	2.619
18	18	**Labour-only subcontractors**	2.892	2.435
19	22	**Self Employment**	2.917	3.087
20	8	**Labour Saving (Technological/Mechanical Methods)**	3.053	2.136
21	=13	**Skills Gained Experientially Without Formal Training**	3.056	2.305
22	15	**Recruitment Policies**	3.108	2.348
23	21	**Effects of Higher Education**	3.278	2.826

The inference of Table 5 is that, the higher the mean, the more positive the impact of Construction Skills shortages, whereas, the lower the mean, the greater the negative impact of Construction Skills shortages. It is evident from Table 5 that Self Employment (mean = 3.087) had the highest positive impact on Skills Shortages followed by the effects of higher education (mean = 2.826). On the other end of the spectrum, lack of Training (Mean = 1.391) had the highest negative impact on Construction Skills shortages according to the Contractors. These were followed by: Quality of available training (mean =1.816; rank = 1st); Lack of financial (monetary) incentives to train, (mean = 2.027; rank = 2nd); Quality of available training (mean = 2.132, rank = 3rd) and Profit margins (mean = 2.333; rank = 4th). The findings are consistent with the literature review, for example the study [12] conducted in the West Yorkshire Construction Sector regarding the barriers to training drew similar conclusions as common barriers being related to costs associated with training. Webster and Wood [10] also found that the Construction industry in comparison to other sectors such as tourism was highly unlikely to make use of even informal methods of workplace training. Visagie [7] further opines that lack of training / development as a generalist which inhibits the ability to deal with the SMMEs as a composite whole.

4.3 Measures to Alleviate the Recruitment Crisis

Measures to counteract recruitment problems were assessed in this study via six items scored on a 5-point Likert style. Contractors and Consultants were also asked to what extent they agreed with the statements pertaining to measures to counteract recruitment problems. Table 6.0 presents the comparisons of the rankings by the means of responses relative to those measures.

Table 6: Rank Comparison of Measures undertaken to alleviate the recruitment crisis

Contr Rank	Cons Rank	Measures to counteract recruitment problems	Contractors Mean[1] Score	Consultants Mean[1] Score
1	2	**Skills shortage results in inflationary wage rate increases**	1.391	3.792
2	1	**Skills shortage leads to poaching of staff from competitors**	1.783	4.130
3	5	**To avoid skills shortage companies should build relationships with schools**	2.304	3.625
4	4	**In times of shortage, we pay above average industry rates to attract workers**	2.174	3.696
5	3	**We consider employing women as an alternative source of workers.**	2.174	3.739
6	6	**Companies should provide incentives that include financial rewards to attract school leavers to work for them in construction**	2.087	3.478

Note[1]: Where 1= totally disagree; 2 = slightly disagree; 3 = neutral; 4 = slightly agree; and 5 = totally agree. **Contr** = Contractor and **Cons** = Consultant.

4.4 Constraints and Barriers to Training

Contractors and Consultants were asked to rate to what extent by indicating the levels of agreement (where 1 = totally disagree, 2 =   and 5 = totally agreed) the following statements tabulated in Table 7 acted as constraints and barriers. Table 7 highlights the view of the Contractors and Consultants on a number of constraints and barriers to training. Both Contractors and Consultants reported the sensitivity or lack thereof to the needs of the industry of training service providers and unsuitability and / or lack of existing training courses as the greatest constraints and barriers to training. As reported by the CITB study [12], the majority of small organizations did not even have written training plans. Interestingly, unlike the cost of training that ranked second lowest, restrictive funding arrangements were ranked the third highest barrier to training. This finding suggests that contractors may have greater problems accessing funds for training. On the other hand the cost of training itself was perceived as being less problematic.

Table 7: Rank Comparison of Constraints and Barriers to Training

Cont Rank (N=24)	**Cons Rank (N=40)**	**Constraints and barriers to training**	**Cont Mean Score (N=24)**	**Cons Mean Score (N=40)**
1	**1**	$C\&B_1$=Sensitivity or lack therefore to the needs of the industry of service providers	4.000	3.917
2	**2**	$C\&B_2$=Unsuitability and / or lack of existing training courses	3.913	3.892
6	**3**	$C\&B_3$=Restrictive funding arrangements	3.500	3.889
4	**5**	$C\&B_4$=Duration of training courses	3.696	3.834
8	**4**	$C\&B_5$=Unsuitable and / or inappropriate unit standards	3.261	3.874
5	**7**	$C\&B_6$=Structure of training courses	3.571	3.714
10	**8**	$C\&B_7$=Procedure to claim back training expenses	2.727	3.655
9	**9**	$C\&B_8$=Legislative requirements	3.143	3.600
3	**10**	$C\&B_9$=Cost of training	3.783	3.541
7	**6**	$C\&B_{10}$=Multiplicity of new initiatives	3.286	3.806

Analysis of Variance was also conducted to ascertain the organisational size differentiation on constraints and barriers for the Contractors. There were significant differences in 30% (3) of the extent to which following issues acted as constraints and barriers: "Unsuitable and or inappropriate unit standards" (F (4, 32) = 3.344, p = 0.021 < 0.05); "duration of training courses" (F (4, 29) = 3.297, p = 0.024 < 0.05); and "Sensitivity or lack therefore to the needs of the industry or service providers" (F (4, 31) = 3.841, p = 0.012 < 0.05). On the other hand, no significant differences among the scores of the contractors were reported; therefore organisation size does not impede the perceptions of these barriers for the Consultants. However these findings contradict those of CITB [12] who found that small firms with 1- 10 employees making up more than 89% of all construction companies in West Yorkshire, the nature of organisation size in fact had a significant impact on the amount, type and level of training that construction companies provided for their staff.

5. Conclusions

This research paper has presented an overview of the perceived skills base and shortage of the construction industry in the Western Cape province of South Africa. In order to achieve a global perspective of the current position relative to skills shortage and development, recruitment and recruitment practices, training and training practices, retrenchments and retirements, project management and participation in construction, the study was contextualised against international experiences as extracted from a review of international literature and study visits. This section summarises the key findings and the various issues associated with the construction industry in the Western Cape. It draws conclusions from the research discussed in various sections of this paper and gives recommendations on how to address challenges. In terms of ranking, contractors rated the collapse of the apprenticeship scheme, company operations or ambitions to grow and diversify and project costs and over-runs as being the main causes of a shortage of skilled workers. Their reasons for the basis of skills were given as a lack of artisans, operators and skilled labour. Contractors ranked the lack of training, the lack of financial incentives to train, the quality of available training, profit margins and qualifications that are broken down in narrow-task related units as the factors that had the most negative impact on skills shortage. The factors that had the least impact on skills shortage were the effects of higher education, recruitment policies, skills gained experientially without formal training, labour saving methods and self-employment. The views of the contractors and consultants confirm the findings are supported by literature conducted by Dainty et al [15] who argued that tight labour market conditions a shortage of high quality skills have forced construction employers to discard training and workforce development activities in favour of aggressive recruitment practices. Holt et al [3]) citied poor labour retention, the failure to develop and train workers, inability of workforce to keep up with change and the introduction of new technology as the primary causes of skills shortages.

Abstract

Education for the building and construction industry in New Zealand is facing a considerable shift in scale because of the requirement for builder licensing by 2010. The Department of Building and Housing has authorised five educational options for the industry up-skilling programme: self-directed learning, reading materials provided by the Registrar, receiving formal instruction, attending an information session, or any other activity considered by the Registrar to be relevant. This paper questions the efficacy of two of these options based on research that was undertaken in 2005 to identify the preferred learning styles of those in the construction industry. We conclude that the options 'self-directed learning' and 'reading materials provided by the Registrar' will not provide pathways to educational qualifications, but may be barriers to the success of the up-skilling project.

Keywords: Learning styles, Builder licensing requirements, New Zealand

1. Introduction

Education for the building and construction industry in New Zealand is facing a considerable shift in scale. A significant number of professionals must be licensed by 2010. This new licensing system has been introduced to address a number of recent building failures in New Zealand. Problems with building quality appear to have arisen from a number of causes, such as: a move away from prescriptive standards to a performance-based building code, the growth of more complex residential buildings and the rapid development of new technologies, materials and systems [1].

However, from an educational perspective, the most glaring cause of complaint in the industry during the last 15 years has been the removal of formal educational requirements for builders. Therefore, the need to up-skill the construction industry is perceived as a primary solution to an endemic problem. Consequently, the Department of Building and Housing (DBH) has introduced a new licensing system, based upon nationally recognised standards of competence [1].

It is reported that in 2006 less than 50% of employees or owners in the construction industry had formal qualifications. These numbers are more staggering for the builders and carpenters. Only 35% had a formal education, which means that 65% of builders will require some educational support to meet the new industry requirements by 2010.

The DBH [1] has determined a programme for up-skilling the building and construction sector which includes a number of learning options:

1. self-directed learning,
2. reading materials provided by the Registrar,
3. receiving formal instruction,
4. attending an information session, or
5. any other activity considered by the Registrar to be relevant.

The balance of this paper attempts assess the efficacy of the proposed learning options in light of available data concerning the preferred learning styles of the building sector. Section 2 describes research undertaken in 2005 concerning the preferred learning styles of a sample of the building sector in New Zealand. The section provides a brief overview of the learning styles literature that underpins the objectives and methodology of the study. Sections 3 and 4 discuss the findings of the study in relation to two of the proposed learning options; self-directed learning and reading materials. Section 5 speculates on the outcome of the industry up-skilling project.

2. New Zealand building sector learning-styles study

In 2005 a team of researchers from the Centre for Property and Construction Research, Unitec New Zealand explored the learning preferences of the building industry in order to design a teaching model specifically for the building and construction industry [2]. The study included representatives of four stakeholder groups within the sector:

apprentices
experienced trades people
building company principals
building control officers.

If the extent of the literature is an indicator, educationalists believe that student learning styles are important (see Coffield et al, 2005 for an extensive review). Popular examples of learning-styles profiles are based on the process of learning suggested by Kolb [3]. In these models learners are attracted or repelled by individual preferences and expectations. For example, the ‘reflector’ needs time to think through the implications of any new material and is thus repelled by the necessity of having to provide evidence of instant learning. The ‘activist’ is repelled by excess detail when learning new material and prefers to focus on uncluttered tasks.

The social dimension of learning was identified in the 1970s. Witkin, Moore, Goodenough, and Cox [4] suggest that children learn through a variety of social factors: learning alone, learning with peers, or learning with teachers. They developed a dichotomy model based on dependency. Field-dependent children prefer learning in groups and with teachers setting the agenda and structure of the learning outcomes. On the other hand, field-independent learners prefer independent activity, self-defined goals, and structuring their own learning.

Another stream of learning-styles research focuses on learning preferences which are a series of ‘information processing habits’. Bandler & Grinder [5] suggested that information is accessed through specific senses including through the eyes, ears or hands. Therefore attention needs to be given to learning locations and the kind teaching materials available. For example, learners have preferences for how new information is presented; graphically, verbally, as text or by learning through personal experience.

A wide variety of questionnaires are available to identify learner preferences based on the specific models, usually from a single perspective. An exception is the model developed by Dunn and Dunn which is predicated on a view of learning that integrates the influence of social preferences and preferred information processing modalities [6]. These two types of preferences may be measured using the Productivity Environmental Preference Survey (PEPS) [7].

In the New Zealand construction industry study, representatives of all groups self-administered the 100 question PEPS. About 250 questionnaires were completed. However information concerning individual education qualifications was not requested, so we do not know how many people in this sample would be involved in up-skilling. Therefore, in this paper, we will use the data obtained from 153 building and construction students as a proxy for people who would undertake additional education as part of the industry up-skilling programme.

PEPS is designed to capture social as well as information accessing preferences. The PEPS contains 20 factors. Responses are analyzed to produce a score for each factor, rendering a mean of 50 and a standard deviation of 10. For each of the factors, a score of one standard deviation above or below the mean indicates an element that is significant for the respondent. Factors which fall in the ‘low’ 20 to 40 and ‘high’ 60 to 80 ranges are the factors significant for individual learning-style profiles [7]. Scores between 40 and 60 indicate some other mediating element [8]. Due to limited space only five of the 20 PEPS factors will be discussed in this paper because these factors relate specifically to the proposed DBH up-skilling programme.

3. DBH option 1: self-directed learning and PEPS factors

Self-directed learning is the first education option proposed by the DBH [1]. A cluster of four PEPS factors, **responsible, structure alone/peers and authority figures** provides insights into learning preferences related to self-directed learning.

As noted above one stream of the learning-styles literature suggests that there are two commonly identified types of learner: field-dependent and field-independent [4]. The difference between the two types of learner is the level of ‘other’ support required for learning. Thus, the preferred elements in the environment within which learning takes place are significantly different between the two types (Coffield et al 2005).

Table 1- PEPS factors indicating self-directed learning preferences

PEPS factor	>40 Low score indicative of independent learning	<60 High score indicative of dependent learning
Alone/Peers	A low score indicates that a learner prefers to work alone and may find the company of others distracting.	A high score indicates a strong preference for learning with peers because talking aids learning and understanding.
Authority Figures	A low score indicates a learner prefers to ‘get on with it’ and does not want continuous guidance.	A high score indicates that a learner prefers to work with an instructor or expert present.
Responsible	A low score means that a learner is less willing to follow instructions and prefers to carry out tasks they have initiated themselves.	A high score means that a learner requires detailed instructions and will normally attempt to complete the required tasks.
Structure	A low score indicates that a learner prefers to work out the details of a task and prefers to interpret the necessary requirements.	A high score implies that a learner wants the instructor to provide a large amount of detail so that no interpretation is required; timelines, itemised resource lists, and criteria for successful completion of tasks.

Table 1, based on what the PEPS factors, shows that low scores indicate field-independent learners and high scores indicate field-dependent learners. Field-independent learners prefer to initiate and design their own tasks while working alone and only having input from teachers once they have completed a task. Field-dependent learners prefer working with their peers on assigned tasks that have detailed instructions while having constant interaction with an instructor [4].

3.1 PEPS factors: Alone/Peers and Authority Figures

As noted the New Zealand study did not collect data on qualifications of the participants in each of the four stakeholder categories. However, we know that students are in the process of 'up-skilling' and thus, an analysis of their learning preferences may provide some insights into the possible success of the DBH up-skilling project [1]. The 153 building and construction students all had some connection with a tertiary educational institution in one of three New Zealand cities. The range in age was 16 to 45 and students were enrolled in courses ranging from pre-carpentry to Bachelor of Construction. Only one student was female. However, analysis of the data from this pragmatic sample indicates that little difference was noted in any sub-set [10].

The PEPS factor *Alone/Peers* has highest level of preference in this study. 80 individuals or just over half of all students (52.3%), the largest single group in this study, prefer learning with their peers. Only five students in this study indicate a preference for *learning alone*. The next highest number of students indicating a high level of preferences is for the PEPS factor *Authority Figures*. 76 (49.7%) of the 153 students have a strong preference for learning with authority figures close at hand to constantly provide feedback on student progress.

These findings concur with a study of construction students in the USA. Choudhury [11] introduced Reciprocal Peer Tutoring (RPT) to construction students in classes over three semesters at Texas A&M. Small groups followed a set protocol of devising questions and quizzing one another and handing in correct answers to the teacher during class time. The Choudhury experiment models the preferences of the New Zealand construction students to work with peers in close proximity of an instructor.

3.2 PEPS factors: Responsibility and Structure

There appears to be little tendency within the sample towards taking individual responsibility for learning. In relation to the PEPS factor *Responsibility*, only about 12 % of respondents, 24, have a score below 40 indicating a preference for personal decision-making in relation to learning. On the other hand 64 students (41%) have a marked preference for following detailed instructions to completion of learning tasks. The PEPS factor *Structure* has a similarly high level of preference in this study. 74 individuals (48.4%) of all students prefer learning materials to be structured. In addition, the trend line is 60. Taking these two factors together implies that the majority of students in this study want well-defined learning outcomes, task completion timetables and assignments with an absence of ambiguity. As well they want instructors close at hand to check the progress of learning tasks that have a single learning outcome.

These learning preferences for New Zealand building students are not unusual. For example, accommodation of high levels of structure with low levels of personal responsibility is evident in a Toolkit designed for construction instructors in the UK [12]. An eighteen slide presentation provides students with a virtual tour of dry rot in a building. In addition, each slide poses a question to direct student attention to important points and to maximise their observation capabilities. The limited number of slides provides a high degree of structure, while the questions indicate that the responsibility for knowing what is important remains with the instructor.

How do educationalists account for the need for a high degree of structure, plus a desire for sharing the responsibility for learning with peers and instructors? One explanation is that the majority of construction students in this study are surface, not deep learners [13]. Deep learners seek an understanding of what they are learning and need to be able to fit it into their cognitive structure. Surface learners focus on completing a task. The results of this study are indicative of the learning preferences of surface learners. While surface learning may not be the expectation of educators, it seems to be a common preference for construction students in Hong Kong [14] as well as New Zealand.

Whether or not the students in this study are surface learners, the preferences indicated by a majority of students in this study do not meet the criteria of independent learners. Thus, the ideal of an independent learner who works alone and takes responsibility for designing and completing learning tasks as suggested in the DBH [1] option for ‘self-directed learning’ is problematic. Based on the findings of this study, DBH option 1 will not be chosen by a majority of the industry to move forward the up-skilling project.

4. DBH option 2: reading materials provided by the Registrar in relation to PEPS and VARK factors

The second suggested education option to up-skill the construction industry in New Zealand is ‘reading materials provided by the Registrar’ [1]. As this option is very specific in what kind of learning is being offered, it would be prudent to gain a more accurate definition of the meaning of this information accessing modality [6].

The principle assumption of learning styles theory is that learning is a transformative process [13]. Information is presented, then internalised and transformed by individual cognitive processes to become individualised knowledge which can in turn be presented as information [8]. Bandler & Grinder [5] suggest that if information is not presented in a format that the learner prefers, then the information is probably ignored. However, the four information accessing modalities - auditory, visual, tactile and kinaesthetic - are the least used factors in the numerous learning-styles models according to Coffield et al. [9]. The difficulty in defining and then measuring a modality may be the reason.

In the PEPS model the distinctions between each modality are simplistic. However, a more accurate description of information accessing modalities is currently to be found on the VARK internet website [15]. Table 2 illustrates the difficulty of comparing different models, but it does seem important to do because of the additional insights that may become apparent concerning construction student preferred learning styles.

This paper will focus on two factors that appear to be significant to the New Zealand construction industry; visual and tactile modalities. Visual learning seems self-explanatory--

learning by seeing. In the PEPS model *Visual* has the specific meaning of learning through the process of reading. The Fleming model shifts the focus from the process of reading to the packaging of the reading material suggesting that it should include drawings and images [15].

Table 2 - Comparison between PEPS and VARK factors for information accessing modalities

PEPS	**Visual**	**Auditory**	**Tactile**	**Kinesthetic**
	The learner transforms information into knowledge by reading.	The learner transforms information into knowledge by listening.	The learner transforms information into knowledge by handling and manipulating instructional resources.	The learner transforms information into knowledge by active involvement and experience.
VARK	**Visual**	**Aural**	**Read/Write**	**Kinesthetic**
	The learner prefers the emphasis to be on the packaging of information: attractive shapes, colours and contrasting spacing composition. The learner transforms information into knowledge by making drawings or images.	The learner prefers information to be heard. The learner transforms the information into knowledge by telling somebody else.	The learner prefers information to be in the form of dense text. The learner will probably verify the information heard or seen by finding it in written form. The learner transforms information into knowledge by creating a written text.	The learner does not accept ideas presented as abstractions which the learner can not experience. The learner transforms information into knowledge by observing then doing.

In the PEPS model *Tactile* learners are advised to write as a way of satisfying the need to learn by handling instructional resources, one example might be to write what has been read [7]. Fleming creates a new category by combining the *Visual* and *Tactile* factors of PEPS to a Read/Write modality to describe the process [15]. Thus, even though both models use common words to indicate information accessing modalities, the models appear to provide significantly different process explanations. The PEPS model implies a single sense transformation process whereas the VARK model describes linkages between a number of modalities in the transformation process. For example, people who prefer to learn by reading will also need to

write what they have heard thus transforming information accessed through the ears into knowledge using both eyes and hands [15].
These definitional shifts between the two models may relate to the currency of the model. The Dunn and Dunn model was initially developed over 30 years ago [6]. Much research into learning-styles has been undertaken since then [9] and if the constructs are valid, then it would be expected that newer and clearer definitions of the learning process would be expected as suggested in the VARK model [13, 15].

4.1 PEPS and VARK information accessing modalities

As noted in Figure 1 a significant number of students in this study appear to have rejected *Visual* as a preferred mode of accessing information. Fewer than 5% of students preferred the *Visual* mode, but almost 15% rejected it outright and the majority of student scores were below the mean [10].

It may be that the obvious lack of preference for the PEPS *Visual* modality is an indication that construction students prefer the VARK definition of how information should be presented. Abdelhamid [16] found that construction students showed a marked preference for visual information defined as 'pictures, diagrams, graphs, demonstrations' in his study of Michigan State University construction management students. The US students appear to have the same preferences as the NZ students, if reading must be done, then the material should be visually ideographic.

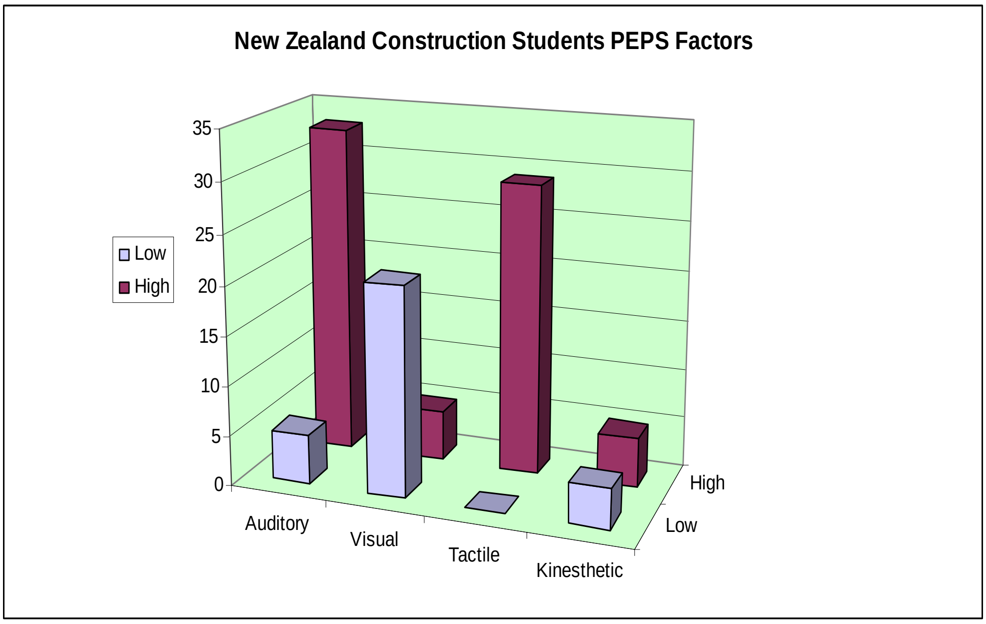

Figure 1 - Information accessing modality preferences of New Zealand building students

Figure 1 shows that the students in this study did not indicate an obviously negative response to *Auditory, Tactile or Kinaesthetic* modalities. Although the number of students with decided preference for *Auditory* and *Tactile* are not great, only about 20% each, the mean for both was toward 60 rather than towards 40. And indeed not one student rejected *Tactile* as way of accessing information.

In a 'hands-on' industry such as construction, it comes as no surprise that students prefer to learn in ways that allow them to observe and try. Murray et al. [12] describe the SLICE Lecturers' Toolkit. This initiative appears to be based on the perception that students learn in a variety of ways and construction students prefer visual as defined in VARK and tactile information accessing as defined in PEPS. Their course content is in the form of workbooks, so students can use their tactile preference. The workbook is highly visual 'containing 22 colour photographs and 12 professional-level drawings. And learners are able to write in their workbook, either to satisfy a need for *Tactile* experience (PEPS) or a *Read/Write* information transformation process (VARK).

On the other hand, Dunn claims that 'many adult males are neither auditory nor visual learners and some remain essentially tactile or kinesthetic all their lives' [6]. If this is the case, it may account for the rejection of *Visual* as a modality of learning with this group. However, it is difficult to interpret the meaning of the low levels of preference for *Kinesthetic* information accessing found in this study of 152 male building students if the Dunn contention is true. At the same time the results may only be a reflection of the criticisms by some scholars that the PEPS lacks clarity as a survey instrument [9].

Another explanation for these difficult to interpret results may be the lack of compatibility between student preferred learning styles and the data collection process. Completing an unfamiliar questionnaire is a learning task. For example, the questionnaire required students to read text but not to write, and peer consultation was not encouraged. Maybe the learning environment that the building students prefer was absent while they completed the questionnaire, thus making learning difficult for some students. We can only speculate, but it does seem possible that if students had been able to talk with their peers and ask questions of instructors; if students could have written, drawn and found ways to tell others about the meaning of "I can sit in one place for a long time.", then their scores for preferred information accessing factors may have been different.

Which returns us to the question of the appropriateness of the DBH [1] providing 'reading materials' as an educational option to ensure a competent building and construction industry. Even with the flawed PEPS instrument and difficulty of interpretation, construction students in this study clearly do not prefer to access information through text. Many of the students in this study appear to outright reject reading as a way of learning. But the extent of the problem appears to be more wide-spread because all groups in the exploration of construction industry learning styles indicated an aversion to visual information accessing [2]. Thus, educational options available for up-skilling the New Zealand industry must use other information accessing modalities.

5. Conclusion

We began this paper by asking the questioning the efficacy of the educational options proposed by the DBH in their attempt to expedite up-skilling of the New Zealand building industry. By focusing on two options in relation to the preferred learning styles of a sample of building students, we have concluded that these two options may prove to be a barrier rather than a pathway to a competent and formally educated workforce.

The first DBH educational option is ‘self-directed study’. All stakeholders in this research preferred learning with peers in the presence of an instructor. The students in the study did not overwhelming prefer to design and carry out independent study. They wanted highly structured learning materials that detailed both inputs and outcomes.

The second DBH educational option is ‘reading materials provided by the Registrar’. Participants in this research rejected text or reading as a preferred option of paying attention to information or transforming the information into personal knowledge.

It appears that DBH option one and option two are exactly the opposite of the educational alternatives that would provide successful pathways to up-skilling the building sector. Although this discussion focused on building students, data were also collected from a variety of other occupations such as fitters and plumbers, electricians, engineers, architects and building inspectors. We found a similarity between the builders and the other occupations but the number of responses was too small to make definite comparisons. However, if even a small number of other occupations have similar preferences, it could be argued that success of the construction industry up-skilling programme is more likely if an education opportunity takes into account the preferred learning-styles of the sector [9].

In addition the findings of this study have implications for a wider audience. Students in all subject areas that are encompassed in the field of the Built Environment may have learning preferences similar to the students in this study. If this is the case, then traditional classroom practice [12], as well as the push for use of distance learning, needs to be re-examined for effectiveness.

This research was funded by Building Research Association of New Zealand Inc.

Abstract

Emerging countries have to develop their own specialised institutional frameworks in order to diffuse and foster innovation in their construction industries. In establishing new institutions, developing countries can take the industrialized countries as a model. However, the differences should be analysed in detail, and the model developed should be adapted to the environment in which the new institution will work. Examining the UK construction industry within this perspective, in this study, universities are taken into consideration as one of the major elements of innovation diffusion and two of the enterprise centres of University of Salford, CCI and SCRI are analysed with the case study method in order to reveal its success factors with an institution building conceptual model. As a result, the important role of these centres in fostering innovation in the construction industry is explored and lessons are driven for emerging countries on how to develop appropriate institutional frameworks.

Keywords: construction, innovation, institution building

1. Introduction

Higher education institutions play a significant role in the production of knowledge and stimulation of innovation within the industry. From the perspective of the construction industry, however, the literature indicates the poor relationship between the universities and the industry. The Fairclough Report [1] describes the construction industry as wary of academia. In order to overcome this barrier for innovation, engagement mechanisms play a crucial role in bringing together the knowledge of the higher education and the construction industry. Four types of engagement mechanisms are identified by Lambert [2] in the UK context: Personal contacts and staff exchanges (such as visiting professors, guest lecturers, or industry secondments); business support and consultancy; collaborative and contract research; establishment of joint ventures and spinout companies. Building specialised institutions is a more holistic approach which comprises a variety of mechanisms designed for bringing together the universities and the industry. Therefore, good practices of the developed countries can be successful models for developing ones.

In this context, the success factors for an institution in diffusing and implementing innovation will be explored according to an institution building model and the applicability of this model for developing countries will be set up for further discussion.

2. Innovation and the Construction Industry

Competitive environment of the world economies is getting more severe as globalization changes the world. Developing countries are challenging developed countries for the value added products and high-tech industries. In this severe environment of competitiveness, even successful companies of the past are trembling against the rapid change we face.

Porter [3] states that, during the past 20 years, western companies have responded the competition with continuous improvement. Companies are remaining competitive by information technology (IT) investments, re-engineering, Total Quality Management (TQM), lean production and other similar techniques for optimizing their productivity. He also suggests that companies have to offer value creating and differentiated new products for creating unique competitive positions by integrating all their competencies.

In addition to these competitive needs, spectacular achievements of the high-technology sectors of the economy have driven interest in the generation of new ideas and its implementation, i.e. what is now being considered innovation [4]. Differentiation of products, processes and services in an innovative way is a major key to sustainability and competitiveness for the market share. This differentiation may be achieved through a completely new product/process or an adaptation, whereas it can be achieved by developing an existing product/process or service.

In this context, there are several different definitions of innovation reflecting its principal characteristics. Rogers [5] defines innovation as "… an idea, a practice or object that is perceived as new by an individual or other unit of adoption". He argues that the idea should be to new to the observer rather than being newly discovered in that period of time. Freeman [6] defines innovation as "... the actual use of non-trivial change and improvement process, product or system that is novel to the institution developing change" in his popular definition which is also used by Koskela and Vrijhoef [7] and Slaughter [8]. EU and OECD legislations define innovation as "...the implementation of a new service or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organisation or external relations.".

The definition of innovation in the construction industry is not far away from these above. Tatum [9] highlights the subjectivity of being new, and defines innovation as the first use of technology for construction firms. Toole [10] used the definition of "Application of technology that is new to an organization and that significantly improves the design and construction of a living space by decreasing installed cost, increasing installed performance, and/or improving the business process". Construction Research and Innovation Strategy Panel (CRISP) defined innovation as "The successful exploitation of new ideas, where ideas are new to a particular enterprise, and are more than just technology related – new ideas can relate to process, market or management". "The successful exploitation of new ideas", which is also used by the Department of Trade and Industry (DTI), is widely used and accepted in the construction industry and academia in the UK.

Academicians seem to share an increased understanding of the differences between construction and traditional manufacturing sectors. Traditionally, product suppliers perform similar to other industries to improve the performance of their products or the process creating them [11]. However, construction activities are project based which have a discrete nature and many different types like roads, bridges, houses, airports. One of the major differences between the overall construction process and most of the other industries is that in the construction sector, design and production are often separated. In most of the industries, design and application are integrated or performed in the same company. In construction industry, design and construction are sub-divided and fragmented. Contractors usually build projects designed by design professionals. Diverse and discrete nature of these projects makes long term development and improvement very difficult. Contractors are reluctant to spend money on anything rather than the immediate needs of individual projects. Even most of the employees are hired for specific projects and firms are being reluctant even for training their work force, because of the possibility of loosing their staff to another company for the next project. In these circumstances research and development are usually being neglected. This market structure seems to be the main barrier for the long term improvement and innovation in construction.

In literature, Construction industry has been examined with some concerns about its innovativeness but these concerns have motivated some researchers to pay attention on the issues and solutions for the construction industry [11]. Although the level of innovation is considered as low compared to other industries and poorly innovative, potential of the industry to innovate is also acknowledged [8,12]. Winch [13] argues that the evidence for this perception is usually based on comparative industrial performance data which is not suitable for construction, as argued above. Hence, like any industry, construction needs to increase the rate of innovation [8].

Most of the literature on technical change and innovation focuses on creation and development, but the real gain will be achieved when they are widely spread and widely diffused [14]. Moreover, innovation theories and diffusion is extensively discussed in the literature but most of these discussions treat diffusion as a non-integral part of the innovation process. Innovation theory and particularly diffusion theory has a gap for project-based sectors such as construction [15].

3. Institutional Development for Innovation in Construction

Without diffusion, innovation would have little social or economic impact [14]. Hall [14] and Widen [15] also state that diffusion is not the means by which innovations become useful by being spread throughout the population but it is also an intrinsic part of the innovation process : Understanding the diffusion process is the key to understanding how conscious innovative activities conducted by firms and governmental institutions (activities such as funding research and development, transferring technology, launching new products or creating a new process) produce the improvements in economic and social welfare that are usually the goal of the activities. For entities which are "catching up", such as developing economies, backward regions, or technologically laggard firms, diffusion can be the most important part of the innovative process [14].

Existing institutional structures in developed countries have strong influences on the process of construction like "invisible hands", but this influence can be benignly as well as malignly [16]. Industrialised countries have an evolved construction industry with specialised institutional frameworks where it relies on the interaction of a variety of institutions, each with its own specialist priorities like training and development of professional skills, organisational management, regulating the industry through contractual procedures, standard setting and implementation. Developing countries have to create their own frameworks by establishing dedicated institutions [17]. On the other hand, besides the strong need for institution building in developing countries, there is a possible danger of creating unwieldy bureaucracies.

In order to find the success parameters in construction industry development and answer questions like how successful institutions fulfil their client's needs, the institutional factors that carry them to success and their dynamic linkages in their operational environment should be analysed well. Operational environment of organisations are much more complicated than what it seems because they contain both man-made and physical elements. In contrast with the physical environment, man-made-elements tend to be more"...irregular, nonrecurring, irrational and unpredictable" [18].

Institutions are the rules of the game in a society or, more formally, are the humanly devised constraints and the framework that shape human interaction. World Bank's Building Institutions for Markets Report [19] defines institutions as the rules, enforcement mechanisms and organizations supporting market transactions. Policies affect which institutions evolve – but institutions too affect which policies are adopted. The major role of institutions in a society is to reduce uncertainty by establishing a stable structure to human interaction.

In institution building one size does not fit all and guidance is always needed on how to develop appropriate institutions by building on the successes of the countries and the good practices, and learning from the failures. But not withstanding the uniqueness of countries, analysis of country experience does hold important lessons for institutional development. There are roles for private and public, and national, local, and international actors. The World Bank's Report [19] distils lessons on building effective institutions. Importance of the supporting institutions, human capabilities and available technology that exist are underlined. Countries are invited to innovate to identify institutions that work and that do not as they would gain from expanding successful public innovations. Connecting communities through open information flows will help create the demand for the institutions and the forces for change within the countries and promoting competition will modify the effectiveness of existing institutions and create demand for new ones.

In establishing new institutions, developing countries can take the industrialized countries as a model. However, the differences should be analysed in detail, and the model developed should be adapted to the environment in which the new institution will work. Complementary institutions, such as those promoting transparency and the enforcement of laws, existing levels and perceptions of corruption, costs relative to per capita income, of establishing and maintaining institutions, administrative capacity including human capabilities and the technology available should be considered as the main differences that would produce dissimilar results.

Both existing and newly transplanted institutions can be more effective in developing countries if they are systematically modified to take these differences into account. Institution building is generally a cumulative process, with several changes in different areas building up to complement and support each other. Even small changes can build momentum for future changes, the whole is greater than the parts and even moderate progress in parts can contribute to a better system. Institution builders can be diverse such as policy makers, business people, or community members. Institutional reform is not just the preserve of national governments. Individuals and communities, entrepreneurs, companies, organizations can build institutions, often in partnership with each other. National governments may initiate reform or may simply respond to pressures from the private sector or from external actors.

Developing countries have to find ways to accelerate this evolutionary process, and this usually implies the establishment or development of dedicated institutions. Evidence has been accumulating that such institutions can yield significant benefits in terms of improved national construction capacity and performance, provided they focus realistically on the ambitions and needs of their clients rather than engage in fruitless empire-building (or academic status-building) for its own sake. The qualification is important, since there are other examples of institutions which have failed to understand and meet the needs of their clients, and later foundered through a combination of inertia and the weight of self-imposed bureaucratic procedures. The question to be asked here is if these institutions are accepted as successful in terms of their clients' needs and priorities, how they managed it and whether the seeds of the success be identified and planted elsewhere. In order to answer this question, it is necessary to analyse the institutional factors which lead to success in this specialist area of institutional development and in particular examine the dynamic linkages that must exist between such an institution and its operational environment [17].

4. Research Methodology

This study is structured as a multiple case design with embedded units of analysis.

Case study approach is considered to be week and dubious [20] by some researchers. However other researchers have regarded this method as effective for appropriate conditions. Cook et al [21] defines this strategy as a fundamentally different research strategy with its own design. This approach allows investigators to gather the holistic and meaningful characteristics of real life events Yin [22].

Evidence for case studies may come from six sources: documents, archival records, interviews, direct observation, participant-observation and physical artefacts [22]. As the various sources are highly complementary, a good case study should use as many sources as possible. Yin [22] explains extremely important characteristics of high-quality case studies as: using multiple, not single source of evidence, creating a case study database and maintaining a chain of evidence where possible.

Institutions can be placed in three broad categories: learned societies, trade associations and training, research and development institutions. This third type, training, research and development institutions are more at the centre of interest of this paper as an institutional category, and the case studies are chosen accordingly.

These case studies rely on multiple sources of evidence. These sources are: documentation, archival records, interviews and direct observations. Agendas, announcements and reports online from the web page of Centre for Construction Innovation CCI (www.ccinw.com) and Salford Centre for Research and Innovation SCRI (www.scri.salford.ac.uk) are used as present documentations. Director of CCI, Mr Andrew Thomas is interviewed. He explained the Centre's past, targets set, activities and services given, their relationship with public and private bodies and the future predictions for CCI in a two hours open-ended interview. Most of the documents which are not accessible on the internet are provided by him. Director of SCRI, Mr. Carl Abbott answered open ended questions in a meeting and provided SCRI's last annual report of 2006 for further information. Academicians from the University of Salford like Dr Peter McDermott and Prof Mike Kagioglu filled some gaps by their valuable contribution. Participation to a Twilight Seminar-Innovating in the built environment, held on the 25th of April by CCI, added direct observations to this framework. Finally, a previous case study on CCI "Facilitating Innovation-The Role of CCI" by Carl Abbott and Stephen Allen [23], was both informative and testimonial partially for this study.

Case studies are explored by Esman's [24] institution building conceptual framework. The same model is used by Miles and Neale [17] for structuring case studies on a construction programme of ILO, and McDermott [16] for criticising Latham Report on its proposed institutional framework for implementation.

4.1 Esman's Model

Milton J Esman [24] captures the essential elements of the institutional process in his conceptual framework "The institution building universe". These essential elements are characteristics of the institution itself, institutions linkages with its environment and purposeful exchanges in between: "transactions" (Figure 1).

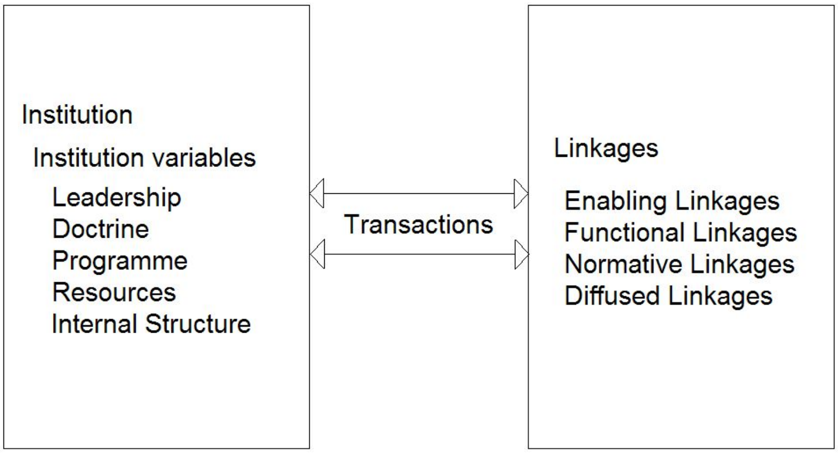

Figure 1 - The institution building universe

Five major variables of the institution are listed as follows:

- Leadership: An innovative organisation needs strong leaderships to reach their aims; especially when they are new. Every single organisational procedure should be set from the beginning, from a draft of ideas. This appears to be the most important factor an organisation should have.
- Doctrine: Defines the institution's aim to achieve, what the institution stands for and in relation with the leadership, its values and style.
- Programme: What the institution does to achieve its goals, services and functions defining the resource needs.
- Resources: The main expenditure of the institution-building is usually the staff they recruit.
- Internal Structure: Institution's management framework. As it has strong cultural dimensions, it should be devised to suit the needs of its local environment.

As the existence of an institution strongly depends on its relations with its environment, these links are considered in four categories:

- Enabling linkages: Vital relationships which give the institution its legality, purpose, resources and form.
- Functional linkages: linkages with complementary or competing organisations that support or help in general to achieve objectives.
- Normative linkages: These are relationships with institutions which have similar interests and purposes. Such relations can be either friendly or on the icy side.
- Diffused linkages: Individuals or groups who are not directly related with the Institution but may have big impact for reaching the desired objectives with their influence and create acceptability. Project champions can be an example for this kind of relationship.

5. Case Study 1 : Centre for Construction Innovation (CCI)

CCI was formed in 2000 for the promotion of the Rethinking Construction agenda in the North West region of UK. North West Development Agency NWDA and CCI was partnering in the first years of the establishment. CCI is a 'not for profit' enterprise and one of the three enterprise centres of University of Salford's School of Built Environment.

- **Leadership:** Centre is being managed by an operations director, an associate director and a general manager. CCI has a strong leadership, directed by a professional from the industry who has a successful past and an extensive knowledge background. He is the one who provides leadership and directs the team strategically. He is the second director of the centre after Dennis Lenard but he has been within the centre from the first day of its foundation. Co-director of the Centre is an academic who has publications on supply chain management, decision support systems, trust, and implementing innovation in construction. Dealing with the centre's projects and supporting the project managers is the duty of the general manager and he is also responsible for the future work.
- **Doctrine:** CCI is formed to promote the Rethinking Construction agenda derived from the Egan Report, in the NW region. Whilst this started with the 'Rethinking Construction' agenda it has now been expanded to wider issues of the built environment such as sustainability, design, procurement, skills and process. The main aim is to provide industry and its clients act collectively to improve performance in the means of productivity, profits, defects and reduced accidents, through the application of best practices and create a 'movement for change'. The Centre was also positioned as an organisation for the diffusion of innovation created by the research in its academic sister SCRI.
- **Programme:** CCI has a wide range of activities like training, coaching, consultancy, mentoring, procurement and event management services. Training programmes include Respect for People, Better Public Buildings, Sustainability and Environment, Lean Construction, KPI & Benchmarking, Supply Chain Management, Procurement Value Based, Contractual Agreements, Whole Life Costing, Integrating Teams and Post Project Review. Other main service modules are: Procurement Coaching, Partnering and Team Integration, Bid Coaching and Debriefing, SME Capacity Building and KPI. The Centre also has some 'products' like 3D visualisation / VR suite aiming to present practical uses of visualisation in various industries from construction to retailing, showing ideas on how 3D visualisation can implemented for different economical and consultation issues; on-line KPI management tool to allow companies to store and analyse their own data supported through consultancy and advice. The Centre hosts 6 of the region's Best Practice Clubs, manages the CUBE – regional ABEC Gallery and Seminar space and participates in many AE / Industry Link for University Research.
- **Resources:** CCI is not a large organisation. Total number of employees is currently about 20, including management team, project managers and administrative staff. 9 of them are Project Managers, 3 of them are administrative staff. They also have gallery assistants for the ABEC gallery and seminar space. The ratio of the professionals to the academics is %70 to %30. Academics and postgraduate students also participate in process and services. There is a 'ring-fenced' structure between the centre and the University of Salford. This structure enables them to invest surpluses for future research and development. Annual turnover is between 1.5 to 2 million Pounds. Main amount of this turnover comes from ERDF, NWRDA, Construction Industry Training Board (CITB), Manchester City Council (MCC) and Constructing Excellence. Apart from these, sales of the products and services developed by CCI have an important share in the total turnover. 3D visualisation / VR suite and on-line KPI engine are two of the most money-earning 'products' of the Centre. Apart from the listed above, at least half of the income is from the other small projects and consultancy services. The centre is trying to secure itself by bidding for new opportunities continuously. The main expenditure of the Centre is its staff, which is common for similar institutions all over the world [17]. Termination of the ERDF funding in 2008 will be challenging for

the near future. A replacement should be found in the near future, to secure the Centre's human resources and activities.

- **Internal Structure:** Being a small organisation, CCI does not have a complex organisational structure. The Centre is guided and advised by a non executive Board. The Board consists of representatives of University of Salford and other academics, representatives of other organisation's (like Northwest Development Agency, Constructing Excellence, CITB and so on), contractors and even clients who all have an influence on the Centre's activities. They come together bi-annually and focus on the sectoral activity and interaction of the CCI. Under the management level, there are two functional divisions: Project Management and Project Support. The centre has nine Project Managers (PM), each of them experts of their field. Every PM runs projects and service modules of his/her own interest. However, the team work approach adopted by CCI is also leading them towards supporting other projects of expertise, running under the initiative of other colleagues and work together as equal parties in the workshops. Administrative staff including an events manager and exhibition assistants are in the Project Support section.
- **Linkages:** In many ways, CCI case study is a study of linkages. The Centre has strong relationships with every stakeholder in the NW construction industry with a contact database of 14.000 individuals and 2300 companies of varying sizes. The number of people the centre engages through its many activities in a year is over 2000. The fact that it was founded, and is governed in partnership by academia, members of industry and public bodies gives CCI strong enabling and functional linkages. Its educational programmes involve significant number of members of academic institutions and professionals from the main sectors of the industry, thus enhancing the functional linkages and promoting normative ones. Through the development of the 'Rethinking Construction' agenda CCI has become a key provider of advisory and grant aided services to the construction sector. The Centre is now promoting influence of a powerful agenda-rethinking construction and is promoting these agendas for the UK construction industry. CCI keeps its good relations with all the participants of the Industry and is part of a wide industry network including research centres, governmental and regional policy bodies, training organisations, professional organisations like CIC, RICS and RIBA as well as private sector companies and clients. The Centre is now at a stage of establishing both national and international franchises.

6. Case Study 2 : Salford Centre for Research and Innovation (SCRI)

The Centre has been established since January 2002, and it brings together a diverse group of leading international academics from the schools of Construction and Property Management, Information Systems Institute and Art and Design. SCRI is positioned within the most highly rated Built and Human Environment (BuHu) research institute in Britain. SCRI is collaborating closely with more than 60 national and international companies and institutions, representing all elements of the supply chain. The Centre develops industry relevant and appropriate research-based processes, management and operational frameworks, and Information Technology solutions in a holistic, multi-disciplinary, integrating and inclusive manner.

- **Leadership:** SCRI is managed by the integration of four committees. The Executive Committee is responsible for the overall management of the Centre and it comprises the Chairman, Director and the Centre Manager. The Centre Manager has changed recently as the previous manager is appointed as professor in University and now co-directing SCRI, with responsibility for Health and Care Infrastructure Research and Innovation Centre (HaCIRIC). The Executive Committee meets as and when need arises.

- **Doctrine:** SCRI is a major influencer of the international research agenda. According to the Centre's vision and strategy statement, they are targeting an institution that will reveal the long term needs of the industry and society to challenge current thinking and develop integrated solutions as well as exploiting research outputs. They are helping create a built environment for society that will facilitate future aspirations and compares well with world-class standards in the provision of built environments. Centre's industrial perspective is a construction industry that is socially responsible, sustainable, innovative, diverse and flexible. They are actively engaging with the agendas of national and international academic and industrial communities. These engagements create sustainable strategic alignments. In this context, they are addressing selected research areas in which SCRI has international intellectual leadership. In order to achieve these goals, they are operational to be recognised as one of the leading multidisciplinary centres in the built and human environment globally, trying to increase the value set on the construction by society. They are regularly revising the vision and strategy of the Centre are being revised regularly with workshops, scenario planning and vision development activities.

- **Programme:** Consistent with the doctrine of the Centre, research is conducted with four themes : process, people, IT and integration and five programmes that are : revealing long term needs, challenging current thinking, developing integrated solutions, building research capability, exploiting research outputs. Under the IT theme SCRI develops its integrated IT platform. They work on tools for measurement of work in progress on site and technology foresight. In the process theme, they are focused on research into a better understanding of design process, health outcomes of the built environment, agile project management, production control in construction and the incentive flow down in complex product service projects. People theme involves research such as conflicting policy objectives, and future policies. In the integration theme, the Centre has successfully applied the development of a new centre dealing with health and care infrastructures. Health and Care Infrastructures Research and Innovation Centre (HaCIRIC) has a high potential as it is addressing an important field of research in which recent work is far from convincing the rising requirements. In this context, SCRI has a number of collaborative research with other leading research centres and industry partners. Researchers of the Centre are also involved in the teaching within the University. This is a policy of the Centre both for their careers and dissemination of the work undertaken in SCRI. The Centre organizes many seminars and conferences like SCRI forum and the Annual International Research Week. SCRI forum brings together a wide range of industrialists and key academics enabling them to discuss range of issues. Annual International Research Week brings together researchers from all over the world and they find the opportunity to represent their work to other researchers and also people from academia. This event makes valuable contribution to the researchers work as well as providing a fertile ground for new projects.

- **Resources:** Under the steering Committee, SCRI has 2 different "teams" which are management team and research team. Management team comprises centre chairman, centre director, centre co-director, centre manager, lead investigator, EPSRC star recruit coordinator, centre administrator, assistant administrator, academic enterprise-industry engagement coordinator. Research team involves 15 Investigators, 18 researchers, 10 associates and 15 academic associates. The Centre also has 3 support personnel. SCRI is funded by the Engineering and Physical Sciences Research Council (EPSRC). They have been funded 2.950.000 GBP for the 2002-2006 period as Salford Innovative Manufacturing Research Centre (IMRC). Renewal of this funding was a total of 4.950.000 GBP for another 5 year period (2007-2011). This amount is expected to be the last full funding. There are also various contributions to the Centre from project partners and collaborating companies. Contributions both in kind and cash have a total amount of around 2.150.000 GBP since the date of its establishment.

- **Internal Structure:** SCRI is managed by a group of integrated committees. Steering, Executive, Management and Research committees are acting to enable a constant dialogue between the members of research and administration and to certify a transparent management and effective decision making system. Steering Committee embraces key individuals of academia and industrial sectors, both from the UK and abroad. It is responsible to improve the Centre's activities and portfolio as well as developing its strategy and vision. This committee includes the Centre manager, Director, Co-director and consultants with a total number of about 20 people. SCRI Executive Committee involves the Chairman, Director and Centre Manager. It is the board that is responsible from the overall management of the Centre and reports to ESPRC on progress, finance and human resources. Structure of this committee is recently changed, altering the previously existing Management and Extended Management Committees that existed before in order to accelerate the routine decisions. The Extended Management Committee is changed and titled as the Management Committee which is responsible for the academic leadership and strategy of the Centre. It is established to ensure transparency and for greater engagement with academicians. Co-director of CCI is also a member of SCRI Management Committee. And finally the Research Committee provides a forum for all members of SCRI to discuss research issues as well as workshops where issues like research methodology, theory development etc. are debated.

- **Linkages:** The SCRI chairman is a member of European and National Technology Platforms (ECTP and NTP). That ensures the Centres international influence but also SCRI's research agenda to be strongly influenced by international issues. Their research under the Revaluing Construction theme has influence on construction strategies of both UK and EU and they lead in many CIB workgroups internationally. SCRI is the highest rated Built and Human Environment Research Centre in the UK. Multi-disciplinary research landscape of the Centre includes many activities within the University of Salford. Research Institutes like IRIS and Adelphi and other IMRC centres and institutions as well as some project groups they are involved are closely linked to each other in the SCRI's research area. They have strong relations with industry intermediaries that diffuse knowledge from academia. Centre for Facilities Management (CFM), Construct IT (CIT) with many others are examples of such intermediaries. The other case study of this paper, Centre for Construction Innovation (CCI), is one of these centres as positioned to diffuse and implement the research of SCRI. Teaching activities within the University forms the Centre's linkages for teaching. They are in masters training, courses and they work with Education in the Built Environment (CEBE) as well as their research into teaching. Relations with government and policies, such as Regional Development Agency (RDA), ERDF regionally, DTI nationally, EU and CIB internationally complete the picture of linkages.

7. Conclusion

Centre for Construction Innovation is an institution established and formed with the influence of the reports commissioned by both the Government and industry, towards enabling the construction change agenda in the Northwest region of UK. Affiliated to the University of Salford, the Centre transfers knowledge and acts as a hub for the industry. They bring together research and industry and help working in close partnership with other agencies to deliver knowledge, skills and services to all members of the construction supply chain; from clients through to construction delivery teams and product suppliers. CCI is a sound example for diffusing and fostering innovation in the construction industry. The Centre has a flexible structure that can easily adopt the market conditions of the construction industry.

SCRI, on the other hand, have a strong vision to reveal and build research competencies and capabilities. They are trying to challenge the current way of thinking, exploit research outputs and develop integrated solutions for the long term needs of the industry. They are funded by ESPRC as one of the 16 Innovative Manufacturing Research Centres in the UK. Their research based environment is managed by committees consisting key people in their scientific field of interest. Researchers of SCRI produce a vast number of scientific journal and conference papers, reports, articles, book chapters and books. In accordance with its research based structure, SCRI is managed by a hierarchy of committees.

These two case studies show the importance of the efficient governmental policies and support of public and private bodies for their common interest. University/research link provides prestige and gravity to the institution. Strong leadership, close relations with public and private bodies as well as the industry, wide range of activities, not for profit structure of the centres are all important issues for being leading institution examples. However the governmental policies and the movement for change agenda shapes the UK construction industry and requires a good understanding to form similar institutions in developing countries for the diffusion and implementation of innovation in construction. Further examples should be studied and number of case studies should be increased for further decisions.

Abstract

The quality of workforce is one of the major determinants of the organisational success which ultimately lead to competitive advantage. Being predominantly a labour intensive industry, construction gets high benefits from the skilled workers. In this regard, effective training programs to enhance the skill levels of the workers are of paramount importance in the construction industry. This research was undertaken to unearth the answer to the research question of "how the skilled labour production is catered for the acceptance in Sri Lankan construction industry". A desk study was carried out to find training courses which are available for construction trades. Accordingly various training programs for different trades were identified which are conducted by five key training institutes, viz. ICTAD, NAITA, DTET, VTA and CCI. A questionnaire survey was conducted among 77 recruitment officers in medium to large size contracting firms and 34 subcontractors in six distinct trades. The findings suggested that when recruiting workers who belong to trades such as plumbing and electrical, the contractors gave extra concern to their training qualifications. However, when it comes to trades such as masonry, carpentry, bar bending and painting the contractors' consideration on training qualification was at a lower level. The study further revealed that HR managers were more knowledgeable about training institutes than the Site Engineers or the PMs.

Keywords: Contractors, Recruitment, Skilled workforce, Sri Lanka, Training

1. Background

1.1 Skilled Workforce

In contracting organisations it is evident that there are number of groups of people who have special skills that are essentially needed for the construction processes. One of the groups that were less discussed than others is skilled workforce or tradesmen. They are crucial, because without them Architect's concepts and Engineer's designs would not be a reality. According to

Tradesmen [1] "A tradesman is a skill manual worker in a particular trade or craft. Economically and socially, a tradesman's status is considered between labourer and a professional with a high degree of both practical and theoretical knowledge of their trade". Skilled trades' workers have always been a benefit to a local economy. They are instrumental in turning materials into useful items. Their training, expertise and experience have helped craft products and build industries [2]. When it comes to construction phase, the performance of skilled workforce is one of critical factors to the success of any construction project. For the year 2003, it is estimated that the direct labour engaged in the construction industry is around 330,000 while the total labour force of all industries is 6.9 million and, the contribution to the Gross Domestic Product by the construction industry sector was 6.97% in Sri Lanka [2].

According to Gunawardane and Jayawardena [4] Sri Lankan construction industry is dominated by unskilled workers and has only six traditional skills as shown in the figure-1. In addition they further stated that Sri Lankan workers are "all rounder" within their broad field. For example masons very often do all work related their trade such as brick laying, concreting, plumbing, plastering, tiling, scaffolding and even bar bending. When it comes to carpenters often erect formwork and false work, fabricate door and window frames, fit glazing and so forth. These practices are common in building projects.

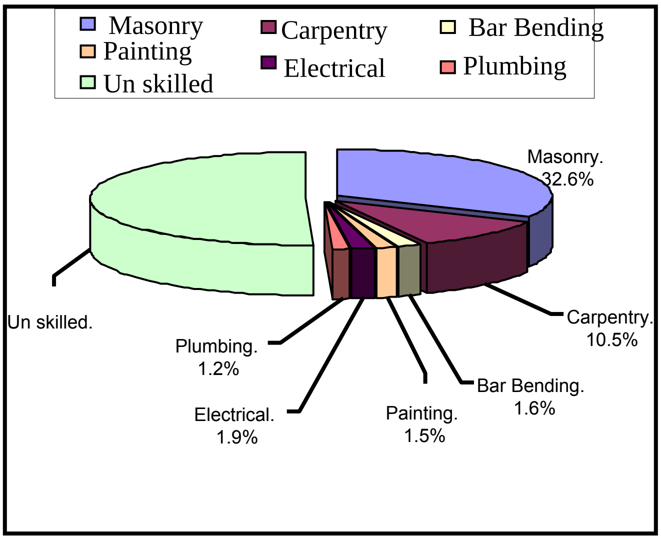

Figure 1- Occupational Structure of Sri Lankan construction trades

Construction is a labour intensive industry that places heavy reliance upon the skills of its workforce [3]. Paucity of skilled workforce results poor quality, high wastage and long-term productivity decline in the industry [4]. According to Dainty et al. [5] insufficiency of skilled workforce in the industry can generate poor work quality and delays in completion times of the projects and it leads general contracting firms to restrict their ambitions for growth, despite the buoyant nature of the construction industry. Therefore it is evident that the recruitment of skilled construction workers emerged as one of the key concern of the contractors. Although skilled workforce offers several benefits there is no standard method for determining the skill level in construction at the recruitment. Agapiou et al. [3] highlighted the contractor's recruitment criteria vary from one to another and it depends on local labour supply factor in construction.

1.2 Training of Workers

Since, training provides an indication of the skill level of the workforce [6] some employers tend to consider qualification acquired from undergoing formal training course as the basis of recruitment of workers. Therefore training is vital important for any sort of employment. In literature, it is defined “employee training” in a variety of ways. Amongst these, following Wickramasinghe [7] is one of the most commonly cited definitions related to human resource management. According to them, “Training is a process of updating the knowledge, developing skills, bringing about attitudinal and behavioural changes and improving the ability of the trainee to perform his or her tasks efficiently and effectively.” It demonstrates that training can enhance the worker’s skills and ability for the better performance of the career. In addition training can change attitudes and behaviour of the trainee. Therefore it is evident that, “Employee Training” has been and is being widely used to denote updating of skills, knowledge, attitudes or behavioural patterns of the employee. It means changing what employees know, how they work, their attitudes towards their work or their interaction with the co-workers or supervisor. To the extent that the construction industry is concerned the above scenario can be similarly applied for workforce in contracting organisations. In recent years there are number of training institutes have been established for skilled workers in Sri Lanka which provide training of varying quality at different levels and awarding standard qualifications certificates such as National Trade Test (NTT) equivalent to National Vocational Qualification system (NVQ) in United Kingdom.

1.3 Recruitment of workforce

Vacancies in organisations generally come up because of the departure of existing workforce which is called as labour turnover. Additionally it may arise because of a new position has been created. In such occasions organisation has to make a strategic decision regarding how it will build its workforce. Accordingly effective recruitment is essential for the successful functioning of an organisation. Recruitment is a process to discover the sources of man power to meet the requirements of the staffing schedule and to employ effective measures for attracting that manpower in adequate numbers to facilitate effective selection of an efficient workforce” [8]. Successful recruitment depends upon finding people with the necessary skills, expertise and qualifications to deliver organisational objectives and the ability to make a positive contribution to the values and aims of the organisation. This scenario can be similarly applicable for recruitment of skilled workforce for contracting firms too. According to literature there are criterions such as experience, work history, formal qualifications, attitude, task flexibility which are normally adopted by the employers at the recruitment of skilled workforce in construction industry.

Dainty et al. [5] stated that in United Kingdom most of construction organisations recruit workers who had not completed their qualifications. Few firms recruit workers who had progressed on to advanced apprenticeships and higher-level National Vocational Qualifications. They further revealed that, contractors think modern apprenticeships and the qualifications systems underpinned them did not produce the quality of skilled worker's experienced. According to Gunawardena and Jayawardena [4] most of the contractors and clients in Sri Lanka do not demand workers have trade test qualifications or National Vocational Qualifications for employment. As well as, most of skilled workers do not possess formal qualifications and having gained their skills experientially. CCI Bulletin stated that the majority of Sri Lankan contractors adopt their own criteria for the recruitment of the skilled workforce such as year of experience. It was further stated that the contractors who follows careful conceived recruitment practice are in difficult stage to consider which certificate to accept and which one is complying with industry requirements. Therefore by looking at above, it is evident that the skills gained through undergoing training programs is not the major concern when determining the skill level of the workers in both foreign and Sri Lankan context. If the skills gained from the training programs are not treated on its merits by the contractors then the huge amount of money and time which spends on these will be wasted. This put the workers to an ambiguous state as they do not have a proper idea on what is more important to carter the demand in construction labour market [9].

Even though various researches have been carried out on training, only a limited number of these have focused on construction. Out of those limited number of researches, only a few have been conducted in the Sri Lankan context. But none of these have addressed the issue of "How the skilled labour production is catered for the acceptance." Thus, this research intended to fill the research gap by studying skilled workforce production and acceptance in the Sri Lankan construction industry.

2. Method of Study

Desk study was carried out to collect secondary data regarding training programs existing for construction workers in Sri Lanka. Survey approach was adopted for the primary data collection. Sample of contractors was selected based on probability stratified sampling technique. Questionnaires were presented among 77 recruitment officers (Project Managers or Site Engineers and Human Resource managers) and 34 Sub contractors in six distinct trades (Masonry, Carpentry, Bar Bending, Painting, Electrical and Plumbing). Descriptive statistical methods were used for the analysis of data collected from questionnaires. To find out the most typical values for the group of data obtained by questionnaire survey, statistics called minimum, first quartile, median or second quartile, and third quartile or maximum were used.

3. Research Findings

3.1 Skilled workforce Production

In Sri Lanka the training of construction industry craftsmen is mainly carried out by a series of training institutions, which belongs to public and private sector [10]. The public sector training institutions are the Vocational Training Authority (VTA), National Apprentice and Industrial

Training Authority (NAITA), Department of Technical Education and Training (DTET), Institute of Construction Training and Development (ICTAD). In addition, there are few private sectors training institutions as Chamber of Construction Industry Sri Lanka (CCI), Jayalath construction and so on. They have larger number of trainers who involved in specific training. Those institutions have their own curricula which were prepared for six to eighteen months training courses. Following table illustrates the training programs which are conducted by key training institutes in Sri Lanka at present for different trade workers.

Table 1- Training programs for construction workers in different trades

Key Training institutes	Courses Conducted					
	Masonry	Carpentry	Bar Bending	Painting	Electrical	Plumbing
ICTAD	√		√	√	√	√
NAITA	√	√		√	√	√
DTET	√	√		√	√	√
VTA	√	√	√	√	√	√
CCI	√	√				

In addition it was revealed that there are two schemes of establishing skill levels of construction workers by training institutes in Sri Lanka.

National Trade Test (NTT)

This is a program to trade test and issue “certificate of proficiency” to those who possess relevant skills. Informally trained practicing craftsmen mostly use this scheme to obtain a recognised certificate for upliftment of their local and foreign employment opportunities. At present there are three levels of certificates namely grade III, grade II and grade I which means semi - skilled, skilled and highly skilled levels respectively. In Sri Lanka, NTT is carrying out by National Apprentice and Industrial Training Authority (NAITA).

National Vocational Qualifications System (NVQ)

National Vocational Qualifications are designed to measure the competency of different vocational skills. The intention of having NVQ is to produce Sri Lankan workforce globally competitive, through a standardised technical and vocational education system. The main objectives of setting up of NVQ are to recognise vocational skills locally and internationally, match and cater vocational training or skills with market demand, recognise the certificates those possessed through the NVQ system and to create an internationally competitive workforce in Sri Lanka.

The National Vocational Qualification Framework of Sri Lanka (NVQSL) has been established to support the efforts of fulfilling above objectives of NVQ.

National Vocational Qualifications Frame Work of Sri Lanka (NVQSL)

National Vocational Qualification (NVQ) framework makes provision for a nationally consistent skills development relevant to economic and social development and is of an international standard. The National Vocational Qualifications (NVQ) of Sri Lanka is based on national skills standard identified by the industry stakeholders. The skill standards include relevant core and generic skills. Recognition of skills of Sri Lankan is important to fulfil the requirements of National policy for Human Resources Development. The Skill Development Project (SDP) has initiated with the Government (TVEC) to resolve problems of mismatching training programs with current market demand, duplication of training provided by institutions and non-availability of a unified standards.

The NVQSL is therefore supporting the sustainable and strategic solutions to national training needs. As such NVQSL is now able to achieve international recognition for qualifications of skills those set up by the system and certificates offered by the institutes. Competency Based Training (CBT) curricula and appropriate training, learning and assessment materials are included in the framework. The system awards qualifications at seven levels as given below. The each level describes the process, learning demand and the responsibility applicable to each level of performance.

Table 2 - National Vocational Qualifications Levels

Level No.	Qualification	Description
Level 1	National certificate	This level 1 recognises the acquisitions of a core or entry level skills.
Level 2 **Level 3** **Level 4**	National certificate	These level 2, 3, 4 recognise increasing levels of competencies. Level 4 qualification provides for full national craftsmanship.
Level 5 **Level 6**	Diploma	These level 5 and 6 recognise the increasing levels of competencies ranging from technician level to management level.
Level 7	Bachelors degree or equivalent	This level includes planning, making resources, management processes.

3.2 Skilled workforce Acceptance

Contractors' Awareness on Training Institutes in Sri Lanka

Results of the questionnaire survey revealed that the majority of medium size (M4 and M5) contractors' Site Engineers/ PMs have substantial awareness regarding training institutes rather than large size (M1, M2 and M3) contractors'. Thus it is obvious medium contractors recruit more workers with formal training qualifications on project basis rather than large contractors. It was revealed that most of large size contractors tend to sub contract the almost all of their work rather by adopting their own labours. As a result, Site Engineers or PMs who are recruiting workers on project basis may not be bothered about recruitment of skilled workers and they may not have much of awareness regarding training institutes. Since medium size contractors have a higher tendency to perform in the industry by means of their own labours especially on project basis, they were vigilant about recruitment of workers. As a result the largest part of Site Engineers/ PMs of medium size contractors have considerable awareness on training institutes for construction skill trades in Sri Lanka. When evaluating HR managers' awareness large size contractors were advanced to medium size contractors. Hence, it is clear that large contractors much consider about permanent workforce than medium contractors do. However, comparatively HR managers have superior awareness rather than Site Engineers/ PMs in both medium and contracting firms. It explicates HR managers who recruit permanent workforce give much concern about awareness about training institutes with the intention of recruiting high quality workforce with formal qualifications than Site Engineers/ PMs who are recruiting project basis temporary workers. In the case of subcontractors, it was revealed that electrical and plumbing trade subcontractors held supreme awareness on training places while bar bending and painting subcontractors were having a lesser amount of awareness about training institutes. Carpentry and masonry sub contractors have had considerable awareness regarding all five key training institutes in Sri Lanka.

Contractors' Correct Awareness on Key Training Institutes

Eventhough contractors have awareness on training institutes, it is imperative to test out whether their awareness is correct or not. It was determined through testing the marked courses for particular trades by contractors are really conducted in those training institutes. Large size contractors' correct and incorrect awareness was compared with the medium size contractors'. Sub contractors awareness was compared trade wise. Accordingly even though the majority of medium size contractors' Site Engineers/ PMs have substantial awareness regarding training institutes rather than large size contractors, large size contractors have correct awareness than medium size contractors. Results of the survey demonstrated that HR managers who are working in both large and medium size contracting firms have equal correct awareness regarding training institutes. Taking into consideration sub contractors situation it is evident that exclusive of bar bending and painting sub contractors all of remaining sub contractors were well known about training organisations.

Popularity of Training Institutes for Different Trades

According to responses, it was identified NAITA as the most popular institutes among recruitment officers for trades like carpentry, electrical and plumbing while ICTAD and DTET were popular institutes for masonry, bar bending and painting respectively. Although some contractors recognised VTA and CCI as training institutes for skilled trades in construction industry, they were not well popular among all.

Results of questionnaires presented for sub contractors revealed that NAITA was the most popular training institute for masonry trade among masonry sub contractors while ICTAD, NAITA, DTET, VTA and CCI were popular equally among carpentry sub contractors. VTA was identified by most of bar bending subcontractors as a training institute for their trade. Although there was no most popular training institute identified for painting trade ICTAD, DTET and VTA were evenly identified by painting sub contractors. In electrical trade, some other training institute/s was well liked among particular sub contractors. However ICTAD, NAITA and DTET were similarly popular among electrical sub contractors. In the case of plumbing trade, most of plumbers were familiar with some other institute/s and they have had similar awareness about ICTAD, NAITA, DTET and VTA.

Level of Consideration of Skilled Worker's Formal Training Qualifications at the Recruitment Stage

By doing the research it was able to assess to what extent contractors consider training qualification as a citric at the recruitment stage of a construction worker. The results were categorised trade wise such as masonry, carpentry, bar bending, painting, electrical and plumbing for the easy of comparison.

Most of the recruitment officers of medium and large size contractors and sub contractors suggested that they sometimes consider training qualifications at the recruitment of masons. It implies they do not give much weightage for training at the recruitment. As the reasons for that, the majority of recruitment officers revealed that for masonry trade formal training is not much essential and there is a deficiency of trained fresh workers for masonry trade due to it is a hard working and less reputable trade within the society.

Considering the circumstances of three types of recruitment officers, it is evident that exclusive of carpentry sub contractors, the majority of Site Engineers/ PMs and HR managers of both medium and large size contractors sometime consider training qualifications at the recruitment of carpenter.

It was apparent that according to recruitment officers' judgment, during bar benders' recruitment they give less weightage toward formal training qualifications and rarely consider for not only permanent workers but also project basis workers as well. As the reason for that, they said although appropriate training is important for bar benders' employment due to the nature of works, there is a lack of qualified bar benders. They further revealed that bar benders should have ability to interpret drawings and undergoing a formal training course is necessary for that.

In the case of painting trade, the largest part of recruitment officers of large and medium contractors and sub contractors give slight weightage for formal training requirements during both permanent and project basis painting workers selection. Majority of recruitment officers declared that painting is a trade, which is not needed as much of awareness and formal training for the workers and it is sufficient to have experience to carry out the task successfully.

Electrical trade results demonstrated that most of HR managers of large size contractors consider always formal training for permanent electricians than Site Engineers/ PMs while contrary situation exists in medium size contracting firms. Taking into consideration the overall circumstances it can be concluded that most of recruitment officers state training is crucial for trade like an electrical. Because workers have to deal with technical works and necessary technical awareness should acquire through undergoing a formal training courses rather trial and error.

According to the recruitment officers' of large and medium size contractors' viewpoint, they often consider training requirements for plumbing trade while subcontractors consider sometimes. Their opinion was formal training is needed for plumbing trade because skills required to perform tasks in the trade cannot obtain through trial and error.

4. Conclusions

The prime aim of this research was to find "how the skilled labour production is catered for the acceptance in Sri Lankan construction industry."

The desk study revealed that, there are number of training programs available for the construction workers in Sri Lanka, which were structured in various trades. Some organisations have widened their spectrum up to island wide training programs which focused both rural and urban youth; while others are limited only for urban trainees. Furthermore it was discovered that all selected five key organisations of ICTAD, NAITA, DTET, VTA and CCI are not providing training programs for every trades. The study unearthed two schemes of establishing skill levels of construction skilled workforce namely, NTT and NVQ. NTT can be identified as a program set to trade test and issue "certificate of proficiency" at three levels to those who possess relevant skills. Informally trained practising craftsmen mostly use this scheme to obtain a recognised certificate. National Vocational Qualifications systems are designed to measure the competency of different vocational skills with the intention of producing globally competitive workforce in order to suit industry specific, through a standardised technical and vocational education system.

The data analysis revealed that Site Engineers from medium size contractor organisations were more knowledgeable regarding training institutes than the large size contractors. However, it was found that HR managers in large contracting firms possessed higher awareness regarding training institutes than those who were in medium size contracting firms. The empirical findings further disclosed that HR managers have ascendancy over Site Engineers/ PMs in terms of awareness regarding training institutions both in medium and large contracting firms. In the case of sub contractors, electrical and plumbing trade contractors held the upper hand in terms of awareness on training institutes whereas, bar bending and painting sub contractors were having a lesser amount of awareness about training institutes. With respect to the correct awareness, it was disclosed that Site Engineers of large contracting firms have correct awareness regarding training organisations while HR managers' correct awareness was alike in both large and medium contracting firms. Nevertheless, Site Engineers possessed highest correct awareness than HR managers of above two types of contracting firms. Considering sub contractors' correct awareness, the study found that masonry, carpentry, plumbing and electrical sub contractors have 100 percent correct awareness regarding training institutes for construction skilled workers in Sri Lanka while bar bending and painting counterparts have not so. NAITA was found out as the most popular training organisation among carpentry, electrical and plumbing trades. Results Masonry and bar bending sub contractors' revealed that ICTAD is the most popular training institute among them and DTET was most popular amongst painting sub contractors. The study further discovered that the recruitment officers often consider formal training qualifications for electrical and plumbing trades while some times they think about it for masonry and carpentry trades. The empirical findings further disclosed that the recruitment officers rarely gave consideration for formal training qualifications when recruiting workers the trades such as painting and bar bending.

Therefore, it can be concluded that most of Sri Lankan contractors and sub contractors are aware of available training institutes and courses for construction skilled trades. Another important finding of this study is, although contractors were asked to list down formal qualification of skilled workers which they recognised at the recruitment, even no body have come up at least with one training qualification. Therefore, it is obvious that contractors are familiar with training courses rather than training qualifications. According to literature, the general presumption was contractors' acceptance of formal training courses is not in a significant level. However, this study revealed that contractors consider training qualifications at the recruitment stage as significant basis for trades like electrical and plumbing. The higher intensity for technical knowledge for the trades such as plumbing and electrical were identified the as the reason behind this regard. However, the results proved that, contractors did not give much attention for trades like masonry and carpentry; since, these trades are still enclosed within its traditional boundaries and has undergone a lesser improvements in terms of technology. Therefore, the workers were still capable of earning skills through trial and error.

Abstract

Innovation is one of the major issues identified as being important to improve the performance of the construction industry. Construction firms are increasingly being challenged for successful innovation. The knowledge resources such as human, structure and relationship of the firms are taken a significant part in the process of innovation. Managing these capitals to achieve innovation is a challenging task to firm's management. Thus, the aim of this study is to explore how consultancy firms in Sri Lanka, manage this knowledge capital towards innovation. Multiple case studies were conducted by direct observation and interviews with top and middle level managers of the firms. During interviews documents and archival records were examined. Nvivo software was used to codify and content analyse the transcripts. The findings explore the nature of innovation in Sri Lankan consultancy firms. The results indicate that in the process of innovation, client's requirements are a key factor. The firms mostly focus to satisfy their clients and survive in the market. The innovation is pushed by client's requirements and internal professional's skills. At the same time inadequate resources and clients' inadequate attention obstruct the process. Firms have enough knowledge capitals such as communication networks, efficient management, professional's skills, energetic young peoples and standard documentation to produce innovation. However, due to the less intention of clients and the management on innovation, the innovation process is slow in Sri Lanka. Through established guidelines, training and development programs employees can be given opportunity to manage knowledge capitals effectively.

Key words: Construction Innovation, Knowledge Capitals, Consultancy firms, Sri Lanka

1. Introduction

This research focuses on managing knowledge to produce innovation in Sri Lankan consultancy firms. The paper contains several sections: introduction, research methodology, development of conceptual model, case study findings, and conclusion. Innovation is one of the major issues in many industries around the world. It is essential for the success in industry performance and for development. Innovation is one of key activities identified as being important to improve the performance of the construction industry [1]. Construction industry faces major challenges, including that of improving its environmental performance and every new construction project has its specific new requirements depending on the demands, existing knowledge, technical and other developments which are combined to form something new.

There are several definitions for innovation introduced by authors from time to time with different viewpoints. For example, Urabe (1998 cited [2]) revealed that innovation includes the generation of a new idea and its implementation into a new product, process, or services that lead to the dynamic growth of the national economy and the increase of employment, as well as the creation of pure profit for the innovative business enterprise. The similarity between those definitions is that something new is created, a product or a process, and put to use. Innovation really means change [2] and the change can be one of the two types; firstly, change in the product or service being provided, or secondly, change in the process by which the product or service is created.

In the current thinking, innovation is not treated as a purely technological change; it can be classified according to its process; as *radical* and *incremental* innovations [3]. Radical is a very new product or service for the community whereas, Incremental innovation is a significant improvement of the existing product or service that happens gradually. Each case of innovation is affected by factors such cultural, human and management factors [4]. Cultural factors are the factors, which related with the organisational environment. Individual's personal characteristics are included in human factors and the management factors are especially connected to the support from top management.

The generic innovation model (see Figure 1) show, that successful innovation *outcomes* are achieved through an appropriate innovation *focus* that is responsive to *contextual factors*, realised by appropriate *organisational capabilities* and channelled through effective and efficient innovation *processes* [2]. There are two principal clusters of thought in the general innovation literature concerning the process of innovation in firms: multi-stage process, which comprise of recognition, invention, development, implementation and diffusion stages [2] and non-linear cycle process of different and convergent activities [5]. The contextual factors and organisation capabilities in the generic model shows that innovation process in the firms depend on the internal and external driving factors as well as barriers.

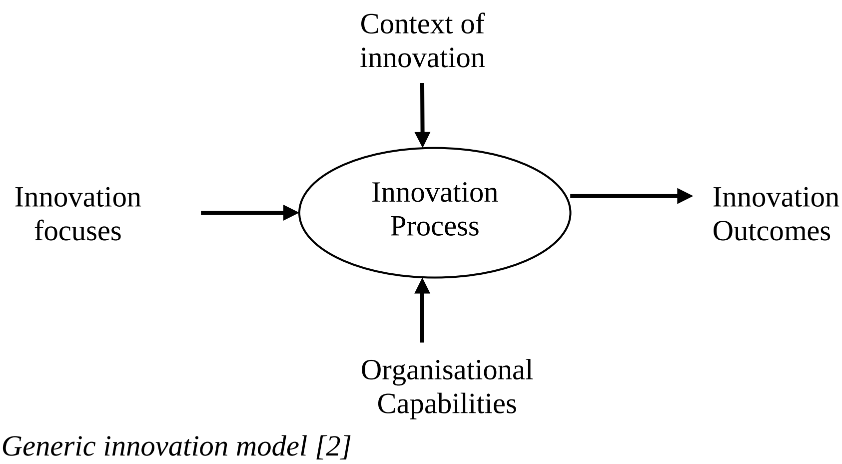

Figure 1 - Generic innovation model [2]

Egbu [6] revealed that knowledge is a vital organisational and project resource that contributes organisational innovations and project success. Knowledge management takes an essential part in the process of innovation. One starting point for the study of the role of knowledge in innovation at firm level is to focus on the various forms where knowledge can be taken and the modalities in which it plays a role in innovation.

Managing knowledge is a critical challenge for knowledge-intensive firms in bringing innovation. As Lu and Sexton [7] suggests, appropriate human capability within construction firms is vital for successful innovation and performance improvement in the construction firms. Furthermore, they argue that innovation in service firms are significantly different to manufacturing firms, and; also, project-based firm to non-project-based firms. This has implications to construction industry, which is project-based and more service-oriented. Consultancy firms are more service-oriented and identifying their innovation behaviours is noteworthy in nature.

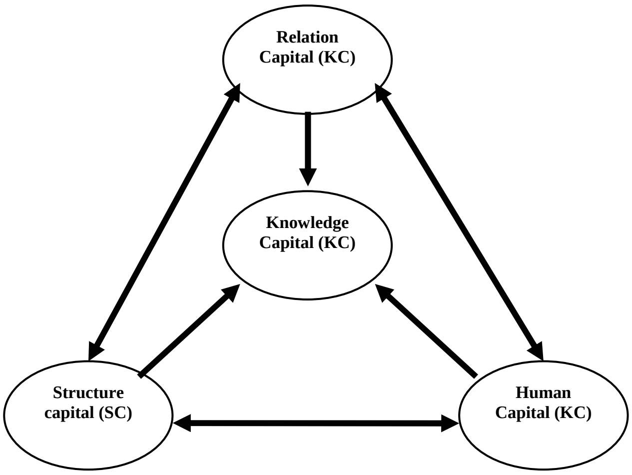

Figure 2 - Knowledge-Based innovation model [7]

Egbu [6] mentioned knowledge is the vital organisational resource, at the heart of innovation. Coombs and Hull (1997 cited [8]) have stated path–dependency is a very important concept to the understanding of mechanisms which link knowledge to innovation. Path-dependency means that firms acquire specific capabilities over time and these capabilities create a strong shaping force over what the firm will do in the future.

Lu and Sexton [7] recognised knowledge capital (KC) (see Figure2), which is a combination of human capital (HC), relationship capital (RC) and structure capital (SC), is the driver for innovation in knowledge-intensive firms. By effectively managing these HC, RC and SC, firms can achieve successful innovations. Innovation in consultancy firms can be a new idea or new process put to use. Managing the human knowledge (HK), structural knowledge (SK) and relationship knowledge (RK) is a major challenge for the firms to produce innovation. Next section describes the research methodology adopted for the study.

2. Research Methodology

Based on the background study, the aim of this research is to explore the overall approach of managing knowledge to produce innovation by consultancy firms in Sri Lanka. The aim was achieved through several objectives; identify key drivers and barriers, understand the innovation with its focuses and outcomes, explore how to manage knowledge capitals to produce innovation and develop an appropriate framework for successful innovation.

The literature search was made more specific and more focused by restricting the analysis to the fundamentals of innovation. Whilst carrying out the literature review much care was given to inculcate appropriate breadth and depth; consistency; clarity and brevity and effective analysis and synthesis. The collected literature was used to develop a conceptual framework denoting the research problem.

The research focused on consultancy firms in Sri Lanka and studied three cases (see Table 1), as it provides multiple sources of evidence and probable replication of findings. The case study method was chosen as it allows an in-depth investigation into a phenomenon in its real-life context [9]. The data were collected from the key participants of organisations such as Architects, Engineers and Quantity Surveyors (QSs) through semi-structured interviews. The interview questions were open-ended to allow the discovery of new issues. While conducting the interviews, follow-up questions were used to receive more details. At each interview, a brief introduction about research was given to help the respondent understand the context. Interviews were tape- recorded with the permission of the interviewees. Interviews were followed based on the guidelines prepared prior to interviews. At the same time documents were accessed to strengthen data collection. The organisational culture, communication system and flexibility of the organisational structure were observed. The interview data was analysed using content analysis with Nvivo software. The following section illustrates the development of conceptual model.

Table 1 - Case study details

Organisation	Name of the interviewee	Designation	Duration	Description of the organisation
Case A	Engineer Architect QS	Senior Engineer & Director Senior Architect Senior QS	One hour 40 minutes 30 minutes	Case A is the leading consulting organisation and is in the good books in the local construction industry. The company was founded in 1977 to include a consortium of main professional skills required for construction projects of any type of works.
Case B	Engineer Architect QS	Engineer and Post contract manager Senior Architect Senior QS	50 minutes 30 minutes 40 minutes	Case B is a multi-disciplinary independent consulting organisation established in 1968 as a partnership firm. After 30 years it was incorporated in 1997 as a private limited liability company. The organisation structure includes the major functions of engineering consultancy and architecture.
Case C	Architect Engineer QS	Chief Architect & Director Senior structural engineer Chief QS	35 minutes 30 minutes 40 minutes	Case C is one of the leading consultancy organisations in Sri Lanka. It was established in 1976 and, it is a limited liability company consisting of charted Architects, Engineers, Quantity Surveyors and Urban planners. The firm offers comprehensive architectural and engineering services for all types of projects.

3. Development of Conceptual Model

The literature findings were synthesised, in particular, Sexton & Barrett and Lu & Sexton work, in developing the framework. In this, organisational capabilities and context components were represented by drivers and barriers. Knowledge capital was added to explore knowledge-based innovation.

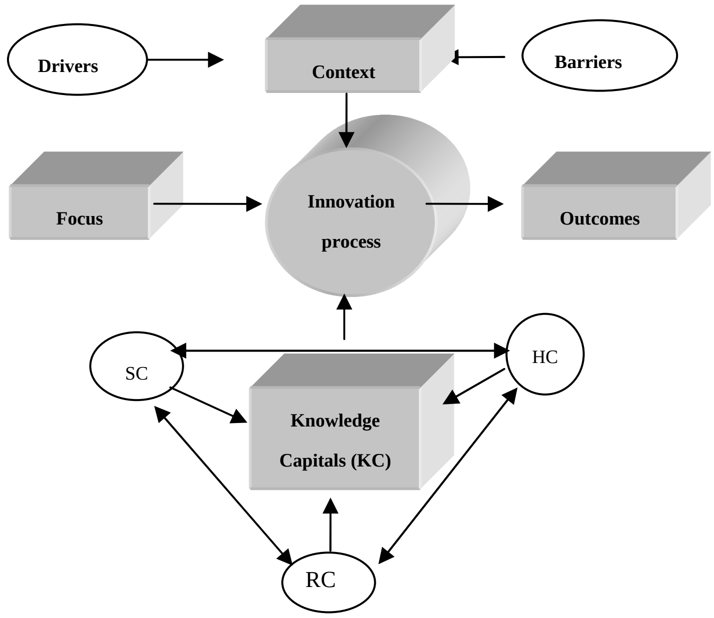

Figure 3 - The Conceptual framework for SL construction consultancy firms.

In this model, innovation is initiated by Focus and influenced by contextual factors in terms of drivers and barriers (see Figure 3). These factors are acting internal as well as external. Knowledge is highly associated with innovation and as an essential element for innovation. Thus, Knowledge capitals are incorporated in to the model to balance these drivers and barriers and achieve successful innovation outcomes.

The overall approach and nature of innovation in consultancy firms was explored, in the case study firms through focus, outcomes, contextual factors in terms of drivers and barriers and knowledge capital includes human capital, structural capital and relationship capital. These findings are discussed in the next section. Case study findings are analysed in the following section, which includes innovation focuses, innovation outcomes, innovation drivers, innovation barriers, knowledge capitals, and managing knowledge capital.

4. Case Study Findings

Through the field study, the conceptual framework was reviewed with the identified factors under each elements of innovation. In this model (see Figure 4), key innovation focuses, outcomes, drivers, barriers, and knowledge capitals were identified and managing knowledge capital to successful innovation was explored in selected consultancy firms in Sri Lanka. This section discusses factors under each element in detail to understand the overall approach of innovation.

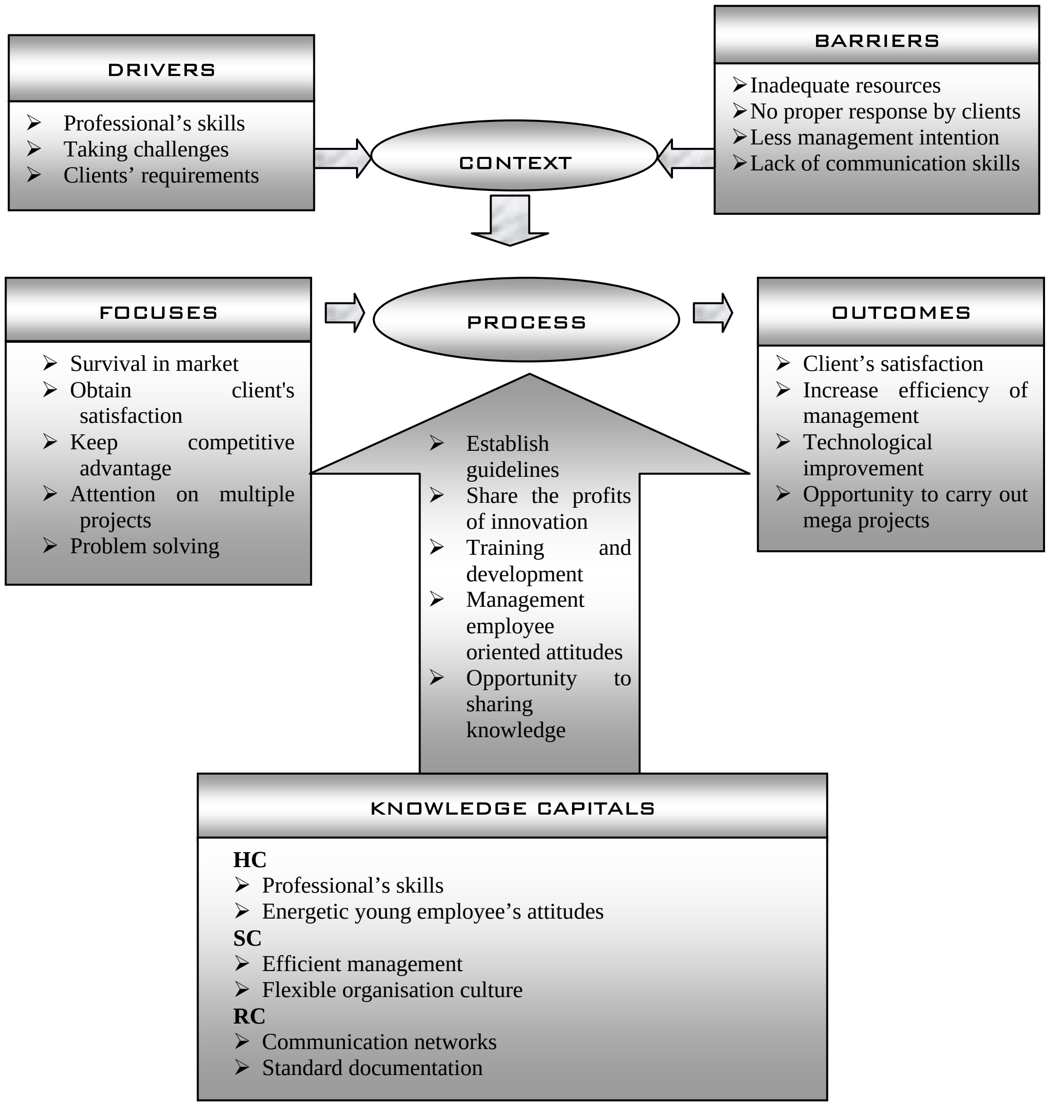

Figure 4 - Framework for Successful Innovation in SL Consultancy Firms

4.1 Innovation Focuses

Survival in the market and **intention on multiple projects** were the most dominating focuses in each case. In all three professionals view, **survival in the market** was the most significant focus. Engineer, in Case B mentioned, "*as a private company, nobody thinks about innovation. To make profit, organisation is carrying some new idea. As was as by doing this we could survive in the market with the good name*". **Problem solving** was identified as a focus by the engineer as well as a director in Case A. He said, "*basically, every day we are doing innovation.*

Every site has problems. Even a house project we have to do some work for the first time. There is an innovation".

Architect, Engineer and Quantity Surveyor's of the three cases indicated that **intention on multiple projects** as a focus of the firms. Through this, they supposed to increase the efficiency of firms as well as give value for organisation rather than give value to a particular project. The QS in Case A said, "w*e are considered to give a value to organisation rather than make success in a particular project*". Respondents from Case A and C and one from Case B indicated that **get competitive advantage** is also one of the key focuses for innovation. Offer a sustainable product with client and end-user satisfaction and linearly increase the profit was a point highlighted by them. Pay attention on getting **Client's satisfaction** was explained as a focus by the engineer and QS in Case B. Engineer of Case A also supported to this factor. The QS of Case C stated, "*we have to satisfy the client. Otherwise they won't come to this organisation for their future projects*".

As per the innovation focuses, factors identified through the research, the key factors that the consultancy firm's focuses could be summarised as **survival in market, keep competitive advantage, intention on multiple projects, client's satisfaction** and **problem solving.**

4.2 Innovation Outcomes

The **client's satisfaction or client relationship development** was identified as a most dominant outcome. Respondents from all three cases supported this. Focus on survival in the market; get competitive advantage and client's satisfaction encourage the firms to produce the outcome of **client's relationship development**. Architect of Case A said, "*most of our client have trust on us, and keep them with us, our inputs are more flexible. Not like other consultants, some times we are trying more options for them to feel comfortable and, they require us to do the feasibility study as well*".

Both architect and QS from Case A and B, declared that **increased management efficiency** is an outcome of innovation. In Case A, all three respondents stated that **opportunity to carry out mega projects** of the country is their successful outcome due to their reputation. The architect of Case A expressed, "*if you take tallest project in the country, nobody knows what to do at the beginning. Even the client is also confused with local consultants, so we took the challenge and were able to produce drawings*". As well, in Case C, carrying out unique **hotel project** was identified as an outcome. For example, two respondents from Case C proudly expressed, "*we are specialist for hotel projects in the country*". **Technological improvement,** which could be computer-aided drawings and communication were stated by respondent in each Case A and C.

4.3 Innovation Drivers

Client's requirement was identified as a key driver from outside of the organisation. In Case B, all three respondents and two respondents from other cases mentioned that the **client's requirement** of the project is the most important driver towards innovation. For example, Architects of Case A's statement was as follows; "*nowadays clients are very sophisticated. They need product within a short period. We are capable to do that, and our philosophy is to satisfy the client is the main thing*". Architect of Case B confirmed the views of the former stating, "*client's tight time schedule, meet client's cost targets are externally and our professional skills, knowledge are internally forced for the innovation. External factors take important place in the innovation approach. We mainly concern about the external factors*".

Among internal drivers, the capabilities of the professionals who are working in the organisation drive the innovation process. The capabilities are articulated in different forms as **professional's skills,** and **knowledge from education**. Professional's skills on individual fields as well as individual skill force towards innovations. This fact was supported by architect and QS from Case B and C.

Other important pushing factor was identified that the attitudes of the individuals which is **taking challenges and professional's intention** were drivers for innovation in Case A and C. Professional's intention towards innovation was recognised as power to innovation in Case A and C. Director as well as architect of Case C mentioned that "*the intention of a professional or a person will affect the innovation of the project. It will vary according the project. The person is earning for living. If the person will get more salary, he will spend enough time on project success*". The respondents indicated that employees may motivate to take challenges due to their knowledge and their experience. In particular, young professionals generally like to take challenges. One of the directors of Case A confirmed; "*we have given maximum freedom to young professionals. That's why we are better. There is a reason, that is young people can take challenges. Some people don't like to take challenge. If you motivate to take challenge, it will be an innovation*". The discussion identified that from the architects, engineers and QSs view; **client's requirement, professional's skills and attitude of take challenges** are the key internal and external drivers to innovation.

4.4 Innovation Barriers

Inadequate resources for projects were indicated as a leading barrier by QSs of Cases A and B. In addition to this point, Engineer of Case C said; "*not allocating enough human resources; resources with less experience; not supplying the drawings on time and inadequate technology are responsible for unsuccessful innovations*". In Case B, architect and QS declared that not receiving the **proper response from the clients** contribute for unsuccessful innovation**.** In addition, most of the clients are concerned only on their time and cost limits but not on innovation. That makes professionals to think and work on cost and time dealing not even on quality of final product or service.

Some other barriers were identified in Case A and C, such as less management intention towards innovation**;** high employee turnover; not updated knowledge; and lack of communication. Even though, these factors were mentioned mainly by one respondent; the effect of these factors on innovation process is significant. Team members not having the attitude to share knowledge on problem-solving and other important matters, was referred as lack of communication. Director from Case C indicated that **non updated knowledge** as a significant barrier to innovation. In addition, he explained as follows, "*here our professionals are not updated most of their knowledge. We have to be always updated, when the new technology comes. That is the main problem we have. Other one is communication problem (not a language problem) there is a lack of discussion between individuals. Due to that the knowledge is not transferred among the individuals*". Engineer from Case A mentioned, "*top management has less intention towards the new ideas rather they are interested in making a good profit"*. Barriers to innovation in consultancy firms can be summarised as follows; **inadequate resources, no proper response by clients, less management intention** and **lack of communication.**

4.5 Knowledge Capitals

The case studied organisations have **professionals' skills, knowledge from education and young energetic people attitudes,** which are recognised as human capital. In both Cases A and B, **professional's skills** were the most dominant factor. The professionals posses a good technological knowledge with experience and they were graduated from leading universities. Their skills lead them to come out with new ideas based on their knowledge. In Case A, one respondent stated that **attitudes of employees and energetic young people** are their secret for success. In addition, they declared, "*as a Sri Lankan we have a remarkable history, we can make good buildings if we are willing to take challenge*". This thinking was motivated towards innovation as well the young people adapted to this thinking and they think in new ways rather than going with what is existing. They feel that enough responsibility and authority to be given to young professionals to carry out the tasks entrusted. Engineer of Case A said, "*we are thinking about foreign knowledge and people. But we could do innovations with local knowledge, local people when taking challenges*".

Structural capitals such as **standard documentation**, **established system** and **the efficient organisation structure** were identified through the interviews as well as observation. **Standard documentation** by using new computer technology was identified in Case B. The computer technology gives good opportunity to share information quickly and firm maintains a small library within the organisation too. In Case C, there is a recently established system, which gives opportunity for its employees to carry on tasks of each division without delays and errors. Director of Case C declared; "*being professionals we should perform well in the project whether the project is small or big. Starting from the design, our capable architects are producing good design. We have good documentation system for each and every project and well established process towards innovation"*. Respondents indicated that the flexible hierarchy of **organisation structure** with adequate communication channels also support to carry out the work efficiently. **Efficient management system** was identified as a good structural capital and relationship capital. For example, give opportunity to employees to come up with new **ideas (decentralization); informal parties; and, site meetings** can be seen as efficient management activities.

The **communication network** is helpful to increase the relationship internally as well as externally, which was mentioned in Cases A and C. In Case A, **deal with foreign consultants** was identified as power to relationship capital. Other than these, **flexible friendship culture** and **informal get-togethers** were recognised as good relationship capital. The relationship capital is used to integrate the human and structural capitals.

4.6 Managing Knowledge Capital

Most of the respondents indicated that managing human knowledge towards innovation was a critical task for management. The research findings on managing knowledge capitals (KC) identified that the most of the activities are related to human capitals. Arrangement of **training and development program** is a key way to increase innovation. This was declared by engineers, architect and QSs in three cases. The organisations send out or abroad their employees for trainings and arranging workshops within the firms as well. Case C allocates funds to pursue higher studies to their professionals. The senior people shared their knowledge and experiences with juniors, which helped juniors to think creatively. This indicated knowledge sharing takes important place in managing KC. Make opportunities to share the knowledge is one of the efficient ways to produce innovation.

The management is sharing their success of innovation ideas in monetary terms with employees by giving them monitory incentives. This makes employees to feel happy and remain in the firm. In all three cases, respondents declared that giving additional compensation encourages the humans. The next important management activity is **established standard guidelines** to carry out the tasks as a way of managing relationship capital. In all three cases respondents identified that the working procedures, practicing formal relationships, and coding knowledge were built good base towards innovation. Not only formal relationship but also improving informal relationship by arranging get-togethers, trips and celebrations make sprit between employees. In Case B, top management has been arranging celebration every month called 'Happy hour'. Statement of director in Case C was as follows; "*really we have not a very systematic programme .but, when any problem occurs; informally we are solving that with the involvement of top level management by using the relationships with other individuals or other parties*".

Other than these, some of the other management activities were identified from the cases; g**ive adequate responsibility; develop database; and, cost planning**. In the middle of these, allocate and give adequate responsibility to suit their skills, increase the productivity of employees are on the way to innovation. In Case A, respondent said that allocating proper tasks to young professionals facilitated innovative ideas on the way of innovation. Next section concludes all the findings of this section.

5. Conclusions

The results indicated that in every project, there is an innovation to satisfy client. To get **competitive advantages**, firm introduced new ideas and process from time to time. Mostly, firms are concerned with **multiple project success** and they are not in favour of getting success from a single project. Outcomes of innovation depend on focus. Findings indicated that there is a relationship between focuses and outcomes. Case study firms achieved satisfaction from the client and they are contented with that. In addition, innovation approach helped to increase the efficiency of management in organisational level as well as project level.

The findings indicated that external drivers were considered as the most affecting factors. Client's requirements represent tight time schedule, budget and special requirements, which are related to the project. Though they had resources, not delivering or allocating resource to project on time was observed as an obstacle to innovation process. Most of the clients require projects adhere to time and cost but less concerns on new ideas or processes. The results indicated that the **management intention** was mainly on profit making. They do not realise the advantages, which can be achieved from innovation**. Lack of communication** between team members also obstructs the process of innovation. The members do not have the attitude to share the ideas and other important matters with other team members. These circumstances discouraged innovation. Knowledge capital plays an important role in the process of innovation. Improvement in knowledge capitals increases the efficiency of top management. In addition to this, results show that three capitals cannot be treated separately. However, case study firms mainly concern on managing human and relationship capitals.

In Sri Lankan consultancy firms, innovations have been taking place through their operations. However, they could not be recognised as innovations. Since they could not identify the performance lying on that, the process was not successful all the time. In this context barriers have more power than drivers. To balance this, top management needs to manage knowledge capital. This research explored a framework for successful innovation in the Sri Lankan context (see Figure 4). This framework may be used as a decision making tool by the top management in the direction of innovation.

Abstract

Clients or users of products, processes or services are being identified as the potential sources of innovation in research conducted in various sectors (e.g. IT, aviation, and laboratory equipment). At present there is concern about the construction client’s potential to be an innovation promoter within the construction industry. Several researchers have recommended proactive client involvement in construction. Within this background, the authors have designed a research with the aim of ‘improving the role of the client in promoting innovation’. In this context, this paper is an attempt to elaborate on the initial findings that emerged from the initial pilot case study

Keywords: Construction industry, Construction client, Innovation, Case study design.

1. Introduction to background of the research

Literature shows that there have been concerns regarding the level of innovation in the construction industry for some time despite having a considerable potential to be innovative [1, 2]. These concerns have motivated a number of researchers to conduct research on the innovation related issues in construction to identify solutions [3]. It was also identified that the lack of innovation is not caused by lack of capability but due to the lack of coordinated effort. Therefore there is a need for key personnel in the innovation process who can coordinate the team towards innovation using resources already available [4].

In the recent era, the construction client is looked upon as a person who can coordinate and direct the construction process towards innovation [5],[6]. Egemen & Mohamed [7] state that the “traditional assumption that clients only need projects which are completed within budget, on schedule and with a reasonable quality should start to change” implying a more proactive contribution is needed from the client for the development of the construction industry and its innovative outcomes.

Within this background authors have formulated a research with the aim of "improving the role of the client in promoting innovation" (see [8]). It is expected to derive answers to three main research questions that are 'what are the roles and characteristics of client that favour innovation?', 'how do the identified characteristics effect innovation?' and 'what are the best practices that can be derived to promote innovations in projects?'. To cater for these research questions in line with epistemological, ontological and axiological assumptions, the authors have argued that the case study method is the best fit research strategy for this research. (see [9]).

After the philosophical stance and the research strategy the authors have moved on with the case study design, case study selection and execution of a pilot case study. The objective of this research paper is to highlight the criteria behind the case study process (section 2) and discussion of the main themes that emerged from the pilot case study (section 3). Finally the paper will be concluded with a summary and an introduction to the future direction of the research (section 4).

2. Case study design

"A research design is the logic that links the data to be collected to the initial question" [10]. Saunders et al [11] agree and further adds that the research design is required to satisfy the identified aim and objectives within the practical constraints where the constraints can be time and money etc. In the above section the authors have briefly introduced the background to the research design and how the 'link' between initial question and the data to be collected is established up to the research strategy selection. In this section the discussion on 'link' development is extended up to case study design. In the sub sections below the process is discussed briefly in logical sequence.

2.1 Definitions

As a first stage of the case study design the authors have developed working definitions for key elements of the case study design, which are discussed in following sub sections.

2.1.1 Case, unit of analysis and boundary

Construction is a loosely-coupled system with subsystems which are independent to a certain degree [12]. Further, the discontinuous and temporary project-based nature of construction presents a problem for the accumulation of knowledge [13]. Under this scenario, there is a risk that the knowledge and experience gained in one subsystem will not efficiently diffuse to other subsystems or to the whole system. Further, the temporary project-based nature hinders knowledge transfer beyond the project concerned. Under these circumstances the authors believe it is more effective to analyse the core of the knowledge. Therefore, the core; 'the client's role in innovation' is being selected as the unit of analysis within the case of innovation of the project.

2.1.2 Innovation defined

Innovation; it can be a result of formal research and development or day to day problem solving [14]. A number of researchers have developed definitions for innovation. However in essence all the definitions refer to implementation of new products or processes that are new to the given context which yield an enhanced economic value [15-20]. In line with these established definitions the authors have adopted the 'application of knowledge to a given context in order to implement significantly new processes, products or management approaches that will lead to increase efficiency and enhance rate of return' as the definition of innovation for this particular research on innovation.

2.1.3 The 'Client' defined

Kometa et al [21] simply define the client as the one who pays the bills. The client can be an individual or an organisation responsible for financing the project. The authors agree with Kometa et al [21] and take the view of the client as the one who funds the project. However authors narrow the definition of client to member(s) of the funding body who directly interact with the project whereas the funding body can be an organisation or an individual.

In this research it is envisaged to study how the client interacted with the project in order to identify the client's role in the innovation. If the whole organisation is to be taken as the client (in a case of client organisation) the focus on this core issue would have been diluted. Further it would not facilitate the study of personal value of individuals as the focus would have been on organisational culture. On the other hand by narrowing down the definition of client to the individual level could enable the discussion on personnel traits and values. In addition, as a member of a larger organisation the "individual" will represent the overall organisational culture. Therefore, the authors argue that the focus on individuals rather than on the organisation is more suited and takes up the definition stated above for this research.

In this section the authors have highlighted the relevant definitions developed for the study. In the section below the discussion will be focused on the case selection aspect of the research design.

2.2 Case selection

The authors have selected the holistic multiple case study method as the suitable approach to case study design. Yin [10] identifies 4 types of case study - they are single embedded, single holistic, multiple embedded or multiple holistic in a 2 x 2 matrix. For a single case study to be justified the case should be critical, unique (or extreme), typical, revelatory or longitudinal case (see [10]). The authors do not intend to prove a well formulated theory thus this research does not fall in to the critical case criteria. Further, innovation is a common phenomenon thus cannot be argued to be unique or revelatory. Even though innovation is not unique, the context specific nature of construction leaves little ground to consider the typical case option. Furthermore, study the same case at different points of time is also not required as it will not add any value to the achievement of aims and objectives. Thus this particular research cannot be justified as a longitudinal study.

The possibility of having multiple units of analysis within a case ceased with the selection of 'innovation' as the case, and 'client's role in innovation' as the unit of analysis; because of the none existence of two clients within a one case. Therefore, the authors argue the holistic multiple case study approach as the best fit method for this research.

In multiple case design, case selection had to be selected deliberately as one which predicts similar results or contrasting results for predictable reasons [10]. This approach in case selection enables the researchers to select cases that demonstrate characteristics which they are interested in [22].

To fulfil the aim of this particular research on 'client's role in innovation' it is required to select a case from a context where innovation is present or from a context where innovation is not present due to predictable reasons. However, authors have selected the option of 'context with innovation' because it provides comparable scenarios without the need of isolating other variables to achieve the objectives of the research. Further, it is also required to select a case with a high possibility of finding a well committed well interacted client.

In pursuit of the above requirements, authors have selected cases from the partnering or collaborative construction contracts. The partnering contracts provide opportunity for better communication, learning and innovation across supply chain [23]. The fact that 'innovation gets benefited from partnering environment' is well established in the literature [24]. Therefore, it can be argued that such an environment provides the client with better opportunity to participate in the innovation process more actively; thus there is a greater scope to study and reveal hidden knowledge regarding clients' roles in innovation within such environment. Further, the knowledge revealed from this study could also benefit the clients of projects where partnering is not the most suitable procurement method of delivery. In line with this argument authors have selected a project code named Project Y as the pilot case study. The background of the Project Y is discussed in the section 3.

In this subsection authors have described the process and arguments behind case selection. In the following subsection discussion is extended to data collection and analysis

2.3 Data collection and analysis

The researchers have devised the semi structured interviews as the main data collection method for this study due to its ability to facilitate in depth inquiry into the issues [10]. The interviews were conducted in two stages. In stage one, identified participants to the innovation (except clients' side participants) were interviewed to gather information related to the client's role in innovation and to identify 'what are the issues?'. The interviews were kept open ended to the maximum possible extent to make the interviewees feel free to express their views. The data gathered was transcribed and analysed to identify main themes or issues highlighted by the interviewees. At stage two the clients were interviewed. Those stage two interviews were also semi structured open ended but took more focus on the themes identified with emphasis on 'why those happened'. This process enabled the researcher to gather an understanding of the issues in at least two distinctive perspectives as well as to triangulate findings to derive firm conclusions.

In this pilot study the data analysis was conducted using computer aided qualitative analysis software packages. The speed and rigour provided by these software as emphasised by Seale [25] is considered to be an advantage. Two types of software have been used in this study – namely *nVivo 2.0* and *Decision explorer 3.1.2*. The combination of software enabled the researcher to exploit the advantages of both for the successful data analysis. *nVivo 2.0* shows strengths in document or transcript management, coding and retrieval functions required for data management and analysis. It is, however, weak as a modeller which was then complemented by using *Decision explorer 3.1.2.*

The data collected from the pilot case was categorised or coded as initial step of data analysis (see [11]). General themes were identified from the set of data collected as well as from literature. These themes identified are discussed in the following section which includes a description of the background of the pilot case study; Project Y

3. Initial findings of the pilot study; Project Y

3.1 Project background

Case study Y is about the client's role in development and execution of an innovative repair solution to a condemned central pier of a bridge in North West of the UK. At the time the project team concerned in the case study took over the project, the bridge pier was expected to be completely demolished and a new pier to be reconstructed in its place as per the recommendations made by a third party. The recommendation was accepted and budget allocated for the reconstruction was also made available by the client organisation at that time. However, due to the possible disruption to traffic that would be caused by the reconstruction, the project team sought other ways of finding a solution to the problem. Through extensive value management and value engineering processes, a repair solution to the existing bridge pier using advanced concrete repair and cathodic protection systems was developed. Even though concrete repair and cathodic protection techniques have been in used for some time within the construction industry, using these techniques in a context where traditional reconstruction is expected had been considered to be an innovation. By challenging the established expectation of the bridge pier reconstruction the project delivery team managed to complete the project at a cost of £2.3 million saving approximately £2 million compared to original budget allocation.

Within this pilot case study three interviews were conducted. The Project Manager, the Designer and the Client were interviewed to gather data from diverse perspectives.

In the following sections findings and major themes revealed are discussed in a logical sequence.

3.2 Client as a manager of the innovation

This particular research on the client's role in innovation confirmed that the client is performing the basic functions of management which are planning, organisation, direction, and control [26, 27]. The client mobilised not only the innovation but the whole process of construction by planning and setting the scene for the project team to perform. The current literature identifies the client of a construction project as the initiator of most of the construction projects by identifying novel requirements to be delivered by the construction sector [28]. One of the interviewees in the study from the clients side stated "*What I used to do was to design the project in year 1 (one year before the construction). I also got innovation there because I got time to go up to other people in client organisation to get approval*" The planning and organisation for the innovation culture was done well ahead of the project to derive successful innovative outcomes. The importance of planning was further stressed "*What I need to do, research wise, is to bring that (innovation) forward and include it in my project. (if not) Lot of that is lost on ... sorted too late in the process*". The findings coincide with coordination role of the client that was stressed by Nam & Tatum [4], "they (clients) establish the mechanism by which the involved parties communicate and collaborate, make decisions on important technical matters throughout the project execution and sometimes share a high proportion of the risk".

The client takes an active part in the direction and control of the innovation process. "*I like to hear some good ideas and then say yes you can do that or no you can't do that depending on other criterion of the client*". The client's involvement in direct and control went beyond the initial planning of the innovation to the completion of construction. One of the other participants attests to the client's innovation director role "*Without doubt the client was behind encouraging the innovation*".

These initial findings enable the authors to confirm the managerial role played by the client in the process of innovation, by proving that the client inevitably performs the basic managerial functions of planning, coordination, direction and control in promoting innovation.

With this understanding of client as a manger the findings are further discussed below.

3.3 Roles of the client

The authors have thus argued that the client functions as a manager within the context of innovation. Within this section the emphasis is on the identification of specific roles played by the client within the context of innovation. As a structure for the analysis and the discussion, the authors have taken up the roles of manger identified by Mintzberg [26, 29, 30]. Mintzberg [26] identifies ten major roles of a manager within three broad categories which are interpersonal, informational and decision roles. In the following sub sections the role of the client will be discussed within these main categories.

3.3.1 Interpersonal role of the client

The activities or roles of the client that arise from formal authority and status are discussed within this subsection. The client's ability and willingness to be a team player was identified as one of the most important contributory factors to the innovation by the interviewees in the case study. Relationships built between client and the rest of the project team, strengthened by mutual trust and understanding and respect for people and clients' proactive approach resulted in highly satisfactory achievements. Participants to the project appreciated the team sprit of the client by stating "*it was precisely because of this interaction, trust and team work and I might say friendship that it worked so well*". The client admitted the team sprit that went beyond the professional members of the delivery team. "*I was invariably rubbing shoulders with the guy that did the painting. It was not a question.*" The mutual trust developed gave courage to other team members to make bold and inevitably risky decisions that formed the backbone of the innovation. "*Without doubt I can say that the client would have stood beside the team even if the project had failed*", stated the project manager.

Coordination is another important interpersonal role performed by the client. The client interviewed, overviewed the work involved "*it's not just me and the project team delivering Project Y. It is me working with various offline divisions delivering services to me so that I can deliver that product.*" The bringing in other offline divisions (divisions of the client organisation that are not directly linked to the project but essential, such as technical approval divisions) expedited the innovative solution. In the client's eye the innovation is essentially a "*departure to standard method of working*" which required an approval from the relevant division within the client organisation. The effective coordination mechanism set up by the client enabled the designers to directly liaise with relevant personnel in the technical division without going through the lengthy bureaucratic route. One designer recalled his experience regarding the dealings with offline divisions. "*It was just like talking to your colleague on next desk. OK, this is the idea, what do you think about this; and that's the way more or less we battered it from one side to another and knocked it into shape*".

The effective coordination mechanism established by the client helped to raise the innovation culture among the team members. Early contractor involvement was a key instrument behind the innovation outcome. One designer appreciated the client's effort by stating "*we are very lucky as the client actually funded these early consultations with specialist contractors who were able to convince the designers that new methods of working could actually solve this problem*".

During the interviews it was asked whether client can be seen as the driver of the innovation as it is a well debated topic among scholars. However, most of the participants were doubtful of considering the client or any one person as the driver but instead a collective team effort was emphasised. Even though the client half-heartedly admitted after some thought "y*es I like to think so (as a driver)...yes*" he went on to acknowledge the designers and specialist contractors as the main source of innovation.

3.3.2 Informational role of the client

It became evident that the client is engaged with a large amount of information processing and monitoring activities that have a bearing on the innovative outcomes.

The client's willingness to be kept updated with the scheme's development rendered positive outcomes. "*The client was so well up to speed about what we were doing. So they are able to sign things off very quickly for us*". However, it should be noted that the other members also played an important role in keeping the client updated. The project manager stated "*we kept the client informed from the day one*". The client also expressed gratitude for being allowed to be part of the scheme's development. "*I am also with them on site monitoring costs and everything else as it goes through the actual execution of the project*".

"*The client brought in … the knowledge about procedures and process (of client organisation) that we need to get through to get the project approved*" said the project manger. The client emphasised the importance of disseminating the knowledge of those procedures. "*I am well versed with the loops that we need to jump through to get the job from conception to completion. And I know which famous projects may be gone through which haven't quite worked*". The correct information leads the design team towards the correct goals that determined the project success.

3.3.3 Decisional role of the client

Within the context of the project the client was required to make decisions based on authority vested and the information received.

Any decision made regarding an innovation involves a proportion of the risk. Other participants were impressed with the client's ability to face that risk. The project manager complemented the client "*what we did at Project Y, was a quite bold piece of work to do*". The client also admitted that there was considerable risk involved but attributed the strength to face that risk on his experience and competence. "*As a professional engineer I keep up with the profession and I see what's going on out there in the wide world.*"

The client's ability to look forward at different angles was identified by the project participants as a major advantage. "*This particular project sponsor was a quite forward thinking man who was open to ideas and innovations*", stated the project manager. The client attested the statement of the project manager and further added "*the obligation is not just to take the obvious but to challenge (the present way of working) with a … risk and safety on board*". The vision of the client led the designers towards the innovative solution and the saving of considerable time and money.

Another one of the most valued aspects by the project participants was the timely decisions made by the client. However, project participants attribute it to the successful informational role of the client. The project manger stated "w*hat he didn't need to do is go away and then try and* *understand what we were asking*“ (because the client was well versed with the present development of the scheme). The designer stated “*they were quicker than what their procedure said*” appreciating the decision making efficiency of the client.

In this section the authors discussed the positive characteristics of the client and how they effected the innovation and the morale of other team members. In the next section effort is taken to identify areas where further improvement can still be made.

3.4 How can client improve in the role of innovation promoter

One of the designers of the project admitted that he is absolutely satisfied with the performance of the client, stating “*it would be very pragmatic or very picky (if you started to find fault with the client)*”. Another participant identified inter-department relationships of the client organisation as a possible area of improvement. The client identified that they could have taken some action to prevent knowledge loss with the disbandment of the project team. “*I am not sure … lessons learnedt from that project, whether they are disseminated where they need to be within the client organisation*”.

In the above sections the authors have discussed initial findings from the case study Y. In the following section the initial findings are summarised with an indication of the planned way forward.

4. Summary of findings and way forward

The study revealed that the client is performing a role of manager within the innovation setting. The ability of the client to be part of the project delivery team was highly treasured by other professionals. The development of mutual trust, coordination among various stakeholders, including in-house offline divisions of the client organisation, are valued contributions from the client. Even though the participants failed to identify the client as a source of innovation everybody acknowledged the client’s contribution to setting the scene for the innovation. The knowledge brought in by the client regarding his organisation’s internal processes and procedures together with his ability to ‘ask the right questions’ helped the design team to steer their design towards the correct direction. The study confirmed a correlation of the client’s commitment and technical competency with the level of innovation which was identified by Nam and Tatum [4]. The commitment coupled with the technical background enabled the client in prompt decision making which was looked upon as a major advantage by the rest of the project team in developing the innovative solution. Even though the client managed the coordination between the project team and the in house divisions of the organisation, other participants identified it as a possible area of further improvement. The client identified that action should have been taken to preserve lessons learned for future use which is another burning issue within the construction industry.

The authors identified the collection of data from a further case study as an essential next step in the research. The data collected from a further case study will enable the researcher to carry out in depth case data analysis as well as cross case data analysis which will improve the reliability and the generalisability of the findings.

Abstract

The importance of 'Capacity Building' across industries was realised in the last decade and it brought number of repercussions in most of the industries including the construction. The construction industry has been criticised for its underperformance, which results of several problems and the insufficient capacity of contracting organisations. The capacity building concept and its applications are rarely concerned in contracting organisations due to the nature and features of the industry. The paper focused to develop a framework that highlights the capacity building in contracting organisations towards the sustainable enterprise development. The framework is developed by obtaining the information through the comprehensive literature review and the questionnaire survey and it was tested its adoptability and the acceptability in contracting organisations through the interviews. The research found that most of the leading contracting organisations are willing to adopt the developed model because it focused the organisation's vision and mission which ultimately drives towards the enterprise sustainability.

Keywords: Capacity Building, Sustainable Development, Contracting Organization, Sri Lanka.

1. Background

1.1 Capacity building

The term 'Capacity Building' often implies, the activities, which are carefully planned and executed, in order to build the capacity. It is the heart of many development agencies' current strategies [1]. It encompasses the country's human, scientific, technological and resource capabilities [2] and the fundamental aim is to enhance the ability to evaluate and address the critical questions related to policy choices and modes of implementation among development options. With reference to the International Development Research Centre [2] capacity building provides organisations to access the current knowledge sources and skills, innovative and proven methodologies; networking and funding opportunities, replicable models for addressing community needs and managing resources, options for organizational management and governance and strategies for advocacy, government relations and public outreach. Therefore it was recognised the capacity building is one of the most decisive issues that need to be addressed in world wide scale in construction organisations.

It's hard to find a concrete framework for organisation capacity development. Because the capacities are differ from one organisation to another and it will vary with organisation's vision and the mission. But it is significant to introduce the capacity building activities for construction organisations in developing countries, since most of them are compelling on lack of resources and inefficient use of the available resources.

1.2 Contracting Organisations' capacities

In simple terms, an organization's capacity is its potential to perform its ability to successfully apply its skills and resources to accomplish its goals and satisfy its stakeholders' expectations [3]. It can be expressed in terms of effectiveness, efficiency, relevance, and sustainability [4]. It further refers to the staff and resources, as well as its structure, management systems, and linkages with other organizations. The capacity building in organisations was emphasized as transferring the physical and financial resources and modern technologies to weak organizations, coupled with specialized technical education and training during the last decade. But this effort failed, because of the local capacities were not developed to manage the activities and maintain the facilities that they were depend upon the outside aid. At present, the technological enhancement, institutional change and declining budgets for improve the capabilities of individuals and organizations were supported for sustainable enterprise development. Organizational capacity development is an ongoing process by which an organization increases its ability to formulate and achieve relevant objectives [2]. It involves strengthening both its operational and adaptive capacities.

When it comes to the construction, the contracting organisations are needed to be sharpening with their existing capacities as well as drive for the new capacities. They are the key party who is going to physically build the structure for their client and waiting the profit. The organizational capacity development is undertaken by the contracting organization through its own decisions with relates to the several elements of it. Because they are highly dealing with large number of transactions, that is need to create an efficient and effective system in the organisation. Therefore the concept of capacity building becomes critical in contracting organizations. Institute for Construction Training and Development (ICTAD) grade is a yardstick to measure the capacities of construction organizations in Sri Lanka. To determine the capacity of a firm, ICTAD has a point system for grading the each resource. Basically, organization capacity falls under the factors such as finance resources, human resources, plant & equipment, work experience and the organization management.

1.3 Sustainable enterprise development

The concept of sustainability in building and construction has evolved over many years. The initial focus was on how to deal with the issue of limited resources, especially energy, and on how to reduce impacts on the natural environment. Emphasis was placed on technical issues such as materials, building components, construction technologies and energy related design concepts. More recently, an appreciation of the significance of non-technical issues has grown. It is now recognised the well balance between economic, social and environment sustainability. Sustainability is a systematic concept, relating to the continuity of economic, social, institutional and environmental aspects of human society [5]. It can be further defined as the 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs' [6]. Sustainability seek to create conditions where social and environmental benefits which can simultaneously help to drive the business forwards. Sustainability is innovating and thinks beyond the current paradigm. However the lack of respect for sustainability within the construction industry would also appear to be a problem across developing countries. With reference to Danny [7], there are ten key factors that influence any organization towards the sustainability. Those are valid to apply the contracting organizations too.

- Participation and ownership
- **Capacity building** and training
- Government policies
- Financial
- Management and organization
- Social, gender and culture
- Technology
- Environment
- External political and economic factors
- Realistic duration

Therefore it is recognized that the sustainable enterprise can be created through the capacity building.

1.4 Capacity building for sustainable enterprise development

According to Hortan, [8], Capacity-development efforts generally include one or more of the five approaches in any organisation. Such are Information distribution, Training, Facilitation and monitoring, Networking, and Feedback, to promote learning from experience. Practically all capacity-development efforts distribute information in one form or another. Capacity development for an organization is one of the most fundamental management activities that realise the vision where the organization wants to be in the short and long term future. Therefore any performance management system will need to have strategy as the main input to build the organizational capacity, so that any result coming out of the system could be used to evaluate the extent to which the organization has met its capacity in terms of management, people, resources, partnership, financial, marketing, risk, knowledge, facilities etc. Since the sustainability is the most significant concept which greatly influence on the quality of human life, the organization should always decide on behalf of the sustainable values and establish their vision and mission. However by developing the organizational capacity it will automatically drive the organization towards the sustainability.

2. Research Methodology

This research was focused to introduce a framework for capacity building in contracting organizations towards its sustainable goals. It basically explores the current organizational capacity, key areas to be improved, existing development programmes, and future avenues of new capacities. The survey was limited to M1 and M2 grade contracting organizations that are operating in Colombo metropolitan region. Data was gathered from twenty five contracting organizations (25) to develop the framework.

Through the literature review, a questionnaire guideline and capacities relates to the contracting organisations were identified. The questionnaire was consisted of two parts. General information of the organisation was obtained at the very first stage and the factors which significant to the organizational capacity building towards sustainable goals in the last. In order to identify the importance of those factors the Likert scale and the Important Index (II) was used. By analysing the data derived through the literature review and the questionnaire survey a framework for the organizational capacity building was developed. The semi-structured interviews were conducted among six senior management personals of the selected organisations to check the adoptability and the acceptability of the developed model.

The framework analyses how the organization can performs successfully to achieve the sustainable goals through capacity building. It comprises of two main processes. The identical driving factors and the way they are able to achieve the organisation’s sustainability will be discussed. IDEF (Integrated DEFinition) methods were used to create graphical representations of various systems, analyze the model, create a model of a desired version of the system, and to aid in the transition from one to the other. It’s a group of modelling methods that can be used to describe operations in an organization. Among them IDEF0 method was used to model the functions of the contracting organizations, which creates a graphical model of what controls the function, which performs it, what resources are used in carrying it out, what it produces, and what relationships it has with other functions and at the last to visualize and present the framework, which express the relationships as a sequential in a process manner.

3. Data Analysis

It was identified the under mentioned capacities derived from the respondents of the contracting organisations that they believe the organisation can drive towards the sustainable goals through incorporating those to the system. The ranks were assigned on a five point numerical rating scale, where 1 represented 'low important' and 5 stood for 'significant'. Same value of the each number has been assigned as the weights of particular number. The mean rating of the variable was obtained using the sum total of point obtained and the number of responses for that particular variable. The equation is as follows.

$$m = \sum_{a=1}^{5} \frac{Y_a Z}{R}$$

Where,

Y - Number of respondents

Z - Weights

R - Number of responses to that particular variable [9]

By calculating the mean rate, the capacities were ranked and the framework was developed.

Table 1: Contracting organisation capacities and their importance level

Capacity	Percentage of all companies
Management	
Leadership	92.20 %
Strategic planning and management	92.20 %
Decision making	87.80 %
Project management skills	85.37 %
Financial	
Payment procedures	81.46 %
External financial support	74.63 %
Resources	
Material and Plant and machinery management	89.76 %
Human Resource	
Skill development of personals	88.29 %
Workforce retaining strategy (Restricting the migration)	85.37 %
Technical and in-house expertise	85.37 %
Personal attitudes (Positive attitudes to create better relationship)	79.51 %
Marketing	
Customer satisfaction	84.88 %
People and other stakeholder focus	78.54 %
Information systems	
Knowledge development	85.37 %
Research and development	
Innovation, learning and knowledge management	89.76 %
Documentation	
Knowledge of contract documentation and procedures	83.90 %
Contract conditions	82.93 %
Other management systems	
Quality assurance system	86.34 %
Process management	82.44 %
Risk management	72.20 %

External Factors Industrial regulations, laws, policies	70.24 %
Others Environmental sustainability Project joint venture	84.39 % 80.00 %

Through the respondents it was identified the following capacity development activities to direct the contracting organisation towards sustainability.

- Take action to deal with financing problems
- Improve practical education
- Institute arrangement for leadership succession in firms
- Improve the corporate knowledge by train participants to work as team and stick them on the organizational success
- Improve the knowledge on law, regulations, policies and administrative systems
- Improve and modify the existing networks of strategic allies, suppliers and sub contractors
- Access to inexpensive, highly skilled labour and capital
- Access to most efficient means of production, affordable and eco friendly building materials and engineering knowledge.
- Proper maintenance of firm's track records
- Establish proper communication structure and enhance the communication skills of the participants
- Increase the resource capacity in terms of assets, equity, materials and plant and machinery
- Improve the risk management capability of the organization
- Apply innovative and cost effective technologies those facilitate efficiency and productivity in all aspects of the organization
- Managerial expertise is important because of the peculiarities and problems of the organization
- Recruit technical expertise and experienced professionals and achieve reputation
- Improve corporate infrastructure
- Introduce Research and Development unit for the organization

In order to realise sustainable development, through building the organizational capacity, all the above activities should be highly conform to the sustainable values. Merely consideration on the profit making may leads to achieve development in one aspect over the other aspects.

The survey result found the potential areas of capacity building in contracting organisations.

Table 2: Potential areas of capacity building in contracting organisations

Element	**Potential Areas**
Materials	Procurement , Delivery, Storage, Prefabrication, Standardization, Product availability, New products, Waste
Management	Estimating, Cost control, Negotiations, Scheduling, Field inspection, Marketing, Communication
Engineering	Design standards, Design practices, System engineering, Drafting, Specification, Value engineering
Construction techniques	Pre-cast elements, Pre-assembled modular, Foreign development
Labour (Human resources)	Turnover, Availability, Labour relations, Contract agreement, Training, Quality control
Regulations	Contract conditions, Government economic policies, Taxes and levies, Financial policies, Sales policies
Equipment	Capacity , Simplicity , Maintainability , Utilization
Information system	Forecasting (labour, plant, cash requirement, estimation, etc), Communication, Network with suppliers and sub contractors, Information technology

4. The framework for capacity building in contracting organisations

The construction industry has been shifted from its traditional processes towards a more client oriented business approach, which recognizes the importance of innovation, training and research. It is encouraged to modernize and adopt collaborative and sustainable approach. By means of developing the contracting organizational capacity, through the financial, managerial, human resource, marketing and information system, it can be achieved the organisational sustainability.

The developed framework for the capacity building in contracting organisations was based on the proper identification of inputs, outputs, processes and the controlling factors of the organisation. The identical activities under each process are as follows;

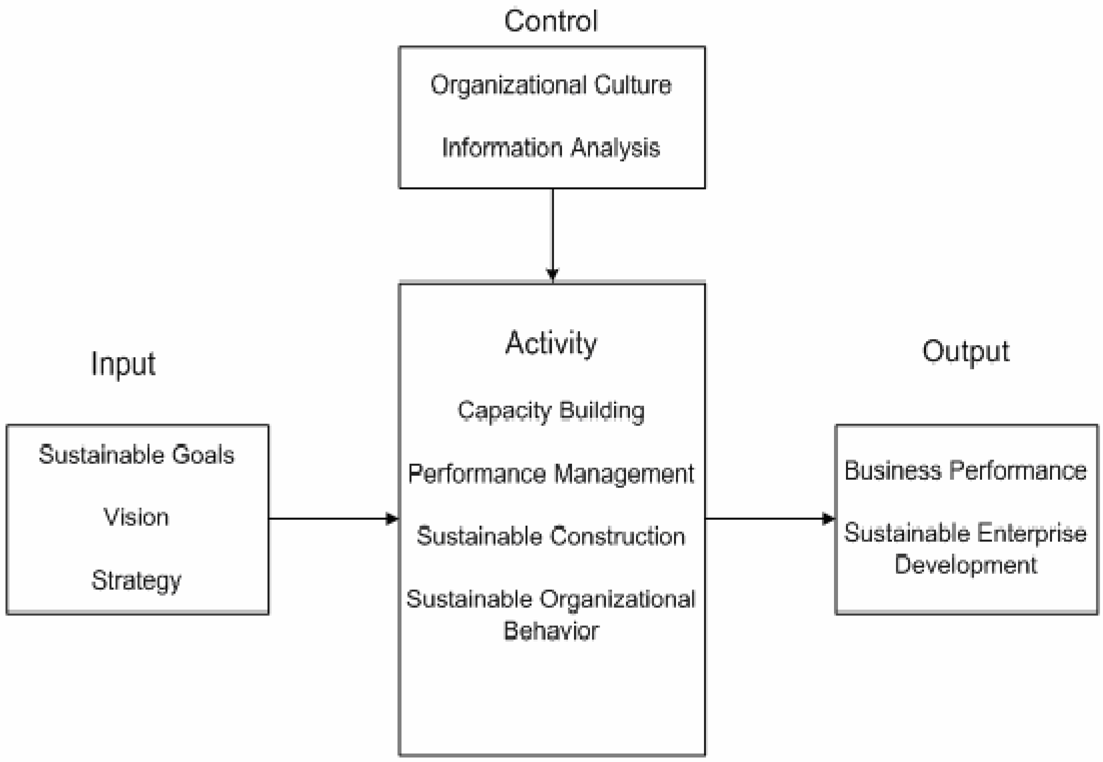

Figure 1 - Structure of the Framework

The framework is focused on the organisations' vision and missions. To make sustainable enterprise it was outlined the critical capacities that should be incorporated to the framework.

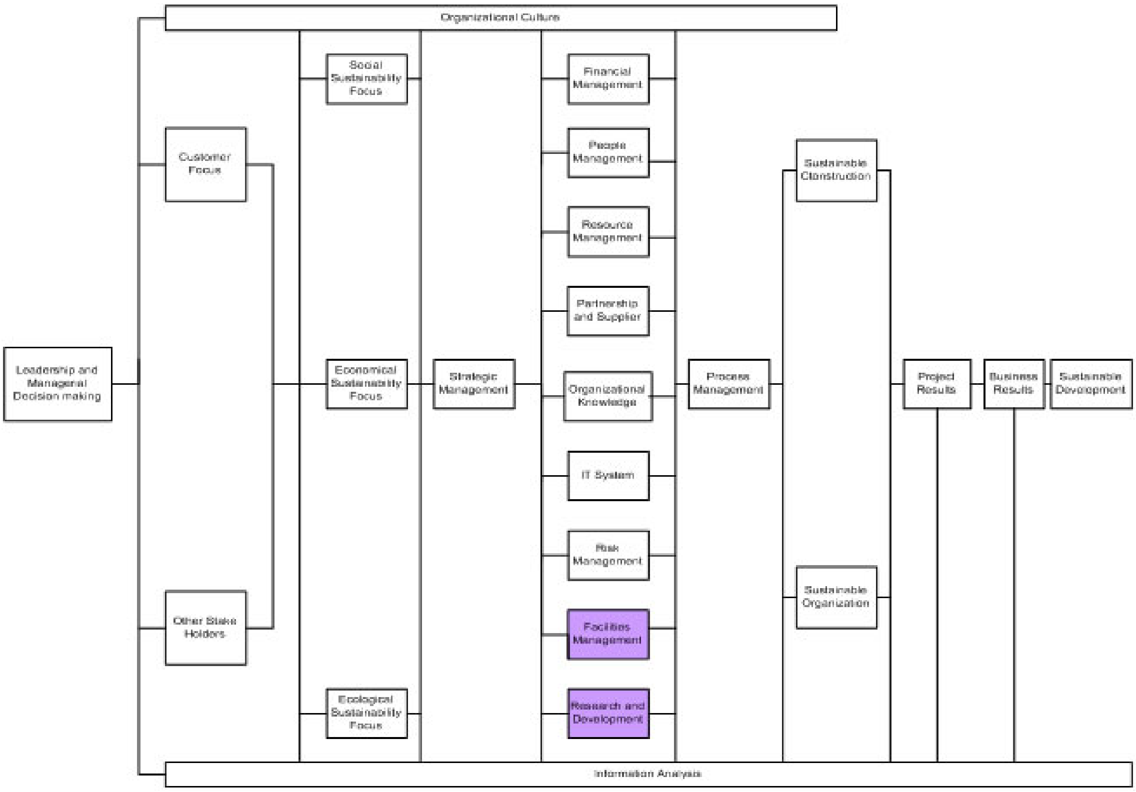

Figure 2 - Framework for capacity building in sustainable enterprise

The framework starts with leadership as the main driving factor for change and the improvement of the organisation. Leadership should focus on customer, people and other stakeholders while focusing on sustainability in terms of social, economical and environmental, which in turn should guide the development of strategic plans. The strategic plans are further detailed into functional and programmatic capacity building plans such as financial management, human resource management, resource management, facilities management, partnership and supplier management, organizational knowledge management, information system management, risk management and research and development. Those are incorporated to the process for establish the sustainable construction and the sustainable organisation. Once when it is implemented the project plans and the organizational processes, improved project results. Improved project results will affect customer, people and other stakeholders' satisfaction on the organizational level, which would finally reap organizational business results and carry the organization towards sustainable development. Organizational culture and information analysis were identified as the controlling factors of contracting organisation towards its journey to sustainability. The coloured cells of the framework have identified as the new capacities that proposed to incorporate to the existing capacity building plans of the contracting organisations. The framework facilitates the capacity development through joint venturing, handle a proper network of contracts, producing a qualitative products as well as the customer satisfaction in contracting organisations.

Contracting organisation can share resources, expertise, risks and rewards with other firms and parties. This concept facilitates some advantages such as reduce risks, improve knowledge and access to advance technology, which help to expand the organizational capacity. The initiating of this theme is needed for construction industry to change its traditional fragmented process towards more sustainable approach, which recognize the importance of innovation, training and research to achieve sustainability within the construction process and organization as well as it enable to acquire almost all the expertise knowledge, resources,

Further the build up a network of contacts is very much important when the organisation towards its sustainable goals. The network with correct people is essential, since inappropriate choices parties' leads to loss the business. This provides access to people for information of potential value and enhance reputation power and influence for effective business relationships. This collaboration and inter relationship is encouraged the sustainable approach, since it making more market responsive, create better integration of supply chain, engage with all stakeholders and create far more ethical and enhanced sustainability profile.

The production of high quality product to an affordable price through process of disruptive innovations brings the competitive advantage. Superior quality may attract higher cost, but it can be control by merge other innovative strategies to the production process. In effect the importance of the construction industry in contributing to everyone's quality of life has taken on a greater significance. It depends on the quality, specialty and cost competitiveness of the products and services. Sustainable capacity building is determines the nature, function and appearance of our communities at last.

Further the link between Contractor and the client brings the continuous job opportunities. Through the capacity building it is important to train the contractor's staff to have a good attitude to build a strong relationship with clients through the exposure, mutual respect and sincere. The construction team and operations team in the contracting organization are both important for achieving the design objectives, and ideally these teams should be represented in the design process to assure that there is continuity of thought and understanding of the sustainable concept that affects the implementation. The correct balance between time, cost and quality can be achieved through the client-project management agreement by making decisions in a sustainable manner and then customer satisfaction can be obtained.

5. Conclusions

The developed framework is tested in its adoptability and the acceptability among the selected contracting organisations. Out of six, five organisations (83%) are accepted the framework and they were commented it is par with their organisational vision and the mission. Therefore it can be concluded the developed framework on capacity building direct the contracting organisation towards its sustainable goals.

Lifelong learning as a tool for updating technical knowledge

Daniela Dvornik Perhavec,
Head of Centre for Education and Professional Studies, University of Maribor
(Email: daniela.d-perhavec@uni-mb.si)

Abstract

Skills and competencies acquired in university are rarely sufficient for a lifetime's work. While careers can last more than thirty years, skills often become obsolete within five. This is particularly true for technical professionals. Others, particularly those lacking higher education, have many barriers set in the way of obtaining further schooling; age limits are often set on support for these potential students.

At the same time, adults living in modern Europe do not have much time to devote to learning. Family and other personal obligations start to take priority, and balancing these with professional obligations can be overwhelming already, even before we consider possible academic pursuits.

Employers are looking for proficient and skilful workers. They cannot ignore the health and happiness of their workers, for without these attributes, workers cannot be fully proficient. The personal demands of the workers have to be balanced with the economic demands for training and education. Many employers have chosen to adopt a policy of emphasizing education and training that lasts throughout workers lives. We agree that lifelong learning is important given the context of today's rapidly developing technology and business practices in a global economy.

Our goal is to determine how we can organize workforce education, and make knowledge more approachable to women and people who live far from universities. We will also consider ways to help those who need to improve their technical knowledge late in their careers, and also to help those who have entered the workforce without higher education.

Keywords: Education, research, lifelong learning, training, adults, women, family

1. Background

1.1 Adult learner and life – long learning

"Adult learner" defined by the European Parliament, means a learner participating in adult education [1]. Life-long learning refers to persons aged 25 to 64 who stated that they received education or training. [2].

EU Commission to the Council – Adult learning published on October 2006 paper with the title,” It is never late to learn". They wrote about lifelong learning and how important lifelong study is for economic competitiveness, demographic change, poverty and social exclusion. Also they showed types of actions needed. By the end of 2007, the Commission intends to draw up an action plan based on the experience gained from the Socrates and Grundtvig programs [3].

1.2 New countries in EU – position and work condition

The EU numbers 27 countries [4]. In 2004 the European Union accepted ten countries (Cyprus, Malta, Slovakia, Slovenia, Poland, Hungary, the Czech Republic, Latvia, Lithuania, and Estonia), Romania and Bulgaria joined in 2007. All new EU countries had been in a new position. Ten countries, excluding Cyprus and Malta, come from a socialist system. From 1998 to 2004 the EU economy was in a new transition and they accommodated to new market in EU. This period registered big progress and good impulsion to start in the EU.

Now is 2007. Many companies have had extensive experience in marketing, lots of new knowledge and have good experts. They have worked and made contact with many experts everywhere in the EU. For further progress they need a good education and the possibility to acquire new knowledge. Technical knowledge and high technical profession experts are wanted because this kind of people are lacking. Why? In fact, technical knowledge is not as popular as other knowledge like law or economy. All around the world the situation is similar and in the last few years many governments strive to make these fields of knowledge more popular. Other reasons are work conditions. It is not just indoor work, mostly outdoor work under bad or good weather conditions (civil and mechanical engineers) and under extreme workplace conditions (mining engineers). People in technical fields mostly work ten and more hours per day and if they don't have degree education, they very hard to take it, especially if live on part of Europe from 12 new countries after 2004.

1.3 Courses in University

Most universities in the EU offer fixed programs, which proofed by government before they are implemented. Universities do not have options to prepare something interesting every year, because it takes too much time and too many people to develop new programs.

Undergraduate program last 180 ECTS (1 ECTS is to Bologna Declaration about 25-30 hours which included lectures, personal work [5]). Most of programs are designated for a population that does not have work obligations, family obligations and so on. Undergraduate programs consisting of 180 ECTS is about 5400 hours. If one spends 3 hours per day for study, one can study 90 hours per month. In this situation study is last 6 years.

1.4 Why are high degrees not good for adult learner

Across the EU the work week averages 35 to 42 hours. We work Monday to Friday. Saturday and Sunday we have free. In this days family take priority.

In Slovenia, we work from 8 a.m. to 5 p.m. A lot of people spend more then one hour per day commuting. If we add that together it amounts to 11 hours per day. Average required time to sleep is six to nine hours per day [6]. For family, hobbies and personal activities this theoretically leaves six hours per day free (Figure 1).

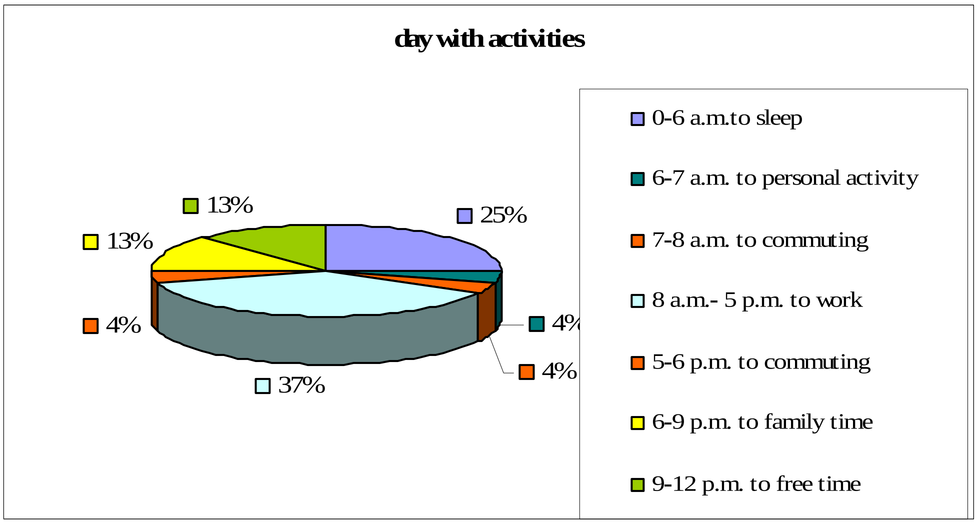

Figure 1: activities in on day

Technological development and technical knowledge requires continual education for people who work. The progress of computer tools advanced much in the last 15 years. The knowledge of new standards and legislations are required to be competitive. This is very difficult also for people with higher education, who in average are 40 years old.

What are the differences between men and women in the workplace? They do not exist as far as employers are concerned. But as a matter of fact differences exist and are large. Women bare children, they become pregnant (including all complications) and children need maternal care, especially in the first 3 years. Women get paid less for the same education and have a worse workplace environment than men. Women often have difficulty juggling their professional and family lives.

2. New solutions

If we look around universities in EU we can see universities in England and some universities in other parts of Europe offering short and summer courses in technical fields. They are designed for people, who want education and new knowledge during their life time careers. They also offer distance learning or e-learning programs.

For all of these activities special programs at universities are designated with titles "Centre for education and professional skills" or "Life-long learning education" or "Learning through work" amongst other titles. There are employees who maintain all of it education and professional development specialists.

2.1 Distance and e-learning is a good solution for adult learners

Some universities offer distance learning with e-learning tutorial hours and in the past more popular e-learning. Both of them are suitable for use in work place, because they don't need to go to a university. Through distance learning one can study at any time, but in a fixed time with e-learning. In addition, Klinc (2007) warned of problems during the e-learning course ITC Euromaster (9 universities over the World). On a survey question "Did you experience any problems during the course?" 86 % students answered Yes [7]. In fact e-learning is not completely developed, but the distance approach to education offers numerous benefits:

1. Accommodates different learning styles and schedules
2. Uses various educational resources or media (paper, video, audio, online) as instructional tools
3. Allows use of multiple communication methods (e-mail, teleconference, video conference, instant messaging)
4. Supports self-directed and self-paced learning style and methods

Many students choose this type of education because full-time jobs, physical limitations, or other commitments prevent their participation in the more traditional approaches to instruction.

The other form of distance education, often called hybrid, supplements traditional classroom instruction with online resources. The instructors deliver classroom lectures, but homework, assignments, and supplemental material may be retrieved online.

New computer technology made virtual worlds that are beginning to change higher education. Companies are developing tools to help universities better manage students and courses delivered in cyberspace, the trendy three-dimensional online world called »Second Life« [8]. Second Life has recently become one of the cutting-edge virtual classrooms for major colleges and universities, including 22 partners from USA, UK, Australia and Israel. Second Life fosters a welcoming atmosphere for administrators to host lectures and projects online, selling more than 100 islands for educational purposes, according to a New York Times article. Rebecca Nesson, an instructor at Harvard who brought her Legal Studies class to Second Life in the second half of 2006 said: "Normally, no matter how good a distance-learning class is, an inherent distance does still exist between you and your students. Second Life has really bridged that gap. There is just more unofficial time that we spend together outside of the typical class session." [9].

The more important information is how students overcome the technical and interface difficulties with Second Life? How is this way of education suitable for adult learners? We know that the group “Adult learner” is not a “Net Generation” (a group that has never known a world without computers and the Internet). Is the Second Life a suitable educational way in all professionals?

Learning through the media is important, especially for workforce people, but nothing can substitute for the experience of hearing, talking to and building a relationship with a real person from another culture. The purpose of using the latest communications technology is to expand student's communications skills, enhance fundamental goals of education, including critical thinking and problem solving.

With all the technical progress, faculties and instructors will find the learning styles oriented towards teamwork, experiential activities, and the use of technology such a online discussions or simulations.

But in spite of this, in the next 5-10 years, distance learning and e-learning will be a good option for adult learners.

2.2 Fees and financial situation in Europe

Some universities will be providing online professional development courses at varying prices, depending on the provider and the nature of the course. As with credit, this is an important question to ask prior to enrolling in an online professional development course. Credits for online courses are often charged at the same rate as credits for traditional courses.

For a good education you often need a lot of money. The fees are not low. On university web sites, we can find this data:

- 1100 £per 60 credits at Level M at the University of Cambridge (UK),
- 180 £ per one online course at the University of Oxford (UK)
- 674 £ per Day and Weekend Day or Evening Classes for Professional Development in University of Oxford (UK)
- 895 £ for 3-4 days short course, 18.500 £ per undergraduate degree and 4.240 per postgraduate degree at the Imperial College in London (UK)
- 8.380 £-10.920 £ per undergraduate degree and 7.500 £+ per postgraduate degree at Herriot Watt University (UK)

And some universities across Europe:

- 2660 CHF for two years of part time or one year full time study in MAS ETH in Zurich (CH),
- 2800 CHF for a block course (200 hour split 2 year) in MAS ETH in Zurich (CH),
- 895 Euro for 3 days short course in Tehnishe University in Graz (A),
- 1000 Euro per year for a undergraduate degree at TU in Munich (D),
- 1500 Euro per year per undergraduate study and 1800 per year per postgraduate study at the University of Maribor – Faculty of Civil Engineering (SLO).

In the 27 European countries there are 268 regions [10]. We have big differences between the highest and lowest regions ranged. If the average GDP expressed in terms of purchasing power standards (PPS) European data is 100 %. In table 1 show how high is PPS in 10 regions in Europe Union.

Table 1: GDP data expressed in terms of PPS in % - the five higher and five lowest regions over Europe

Region (Country)	PPS in %	Region (Country)	PPS in %
Inner London (UK)	**303**	**Sud - Muntenia (RO)**	28
Luxembourg (LU)	251	**Severen tsentralen (BG)**	26
Bruxelles-Cap. (BE)	248	**Yuzhen tsentralen (BG)**	26
Hamburg (DE)	195	**Severozapaden (BG)**	26
Wien (AT)	180	**Nord - Est (RO)**	**24**

In fact, for many people from countries with low PPS (purchasing power standards) areas in Europe, studies in other countries, with good faculty and good programs are too expensive and unattainable.

2.3 Degree education inaccessible to adult learner

More and more adult learners are finding the convenience and flexibility of online learning to be a good match for their learning goals and busy lifestyles.

Right now there is a strong demand for online studies. Most degree programs in technical fields at the universities or faculties are not suitable for adult learning working people between 25 and 64 years of age. In a degree program, it is not possible to choose individual subprograms and work on them at ones own pace and time.

2.4 What are the reasons for insufficient offering of programs

Why don't the universities or the faculties in technical fields offer more degree programs for adult learners? What are the reasons? Is basic knowledge like math and physics a great difficulty for adult learners? What about the popularity of technical knowledge? Do industries not require formal education? Are they satisfied with workers who learn in the workplace from other degree educated colleagues? What is the relation between universities and employers? Are they integrated?

We live in a time of revolutionary change. Not only is the world relying increasingly on technology for economic growth and job development, but the countries are making the difficult transition of refocusing a significant amount of its technology investment from national security to international economic competitiveness. Engineers play an ever more significant role. They develop new manufacturing processes and products; create and manage energy, transportation and communications systems; prevent new and readdress old environmental problems; in general, make technology work. For all of this, they need specific technical skills, economy, law, management, medicine, etc. These professions require analytical and problem solving abilities, all of which are part of an engineering education.

Engineering colleges who working in companies must not only provide their graduates with intellectual development and superb technical capabilities, but following industry's lead, those colleges must educate their »no formal education colleagues« or students to work as part of teams, communicate well, and understand the economic, social, environmental and international context of their professional activities. Engineering education programs must attract an ethnic and social diversity of students. Not only does the engineering profession require a spectrum of skills and backgrounds, but it should preserve its historical role as a profession of upward mobility.

Engineering education will be most effective if implemented with the aid of all sectors of the community; and programs must not only teach the fundamentals of engineering theory, experimentation and practice, but be relevant, attractive and connected:

- relevant to the lives and careers of students, preparing them for a broad range of careers, as well as for lifelong learning involving both formal programs and hands-on experience;
- attractive so that the excitement and intellectual content of engineering will attract highly talented students with a wider variety of backgrounds and career interests, particularly women, underrepresented minorities and the disabled, and will empower them to succeed; and
- connected to the needs and issues of the broader community through integrated activities with other parts of the educational system, industry and government [11].

Engineering deans are principally responsible for leading engineering education, they work in partnership with their faculties, secondary schools, the broader university, government and chambers, other engineering colleges, and build even closer ties to industry. These sectors make up the broad constituency of engineering education.

Many universities and their engineering colleges aspired to the model of the "research-intensive" university. This model focused on developing research excellence in scientific and engineering fields, and on creating research-oriented doctoral degrees. Are we in need of this model in all levels and all professinal programs, as well as programs for adult learners?

The world now demands new models. Progress communications technologies are enabling engineering schools to expand their reach and accessibility, and to experiment with alternate modes of teaching and learning.

A variety of models in engineering education will result from the process of schools reexamining their individual missions.For example, some colleges may opt to combine elements of traditional technology-based engineering education with a strong emphasis on broader skills such as written and oral communication, management, economics and international relations. This type of program would aim to prepare individuals for technological decision-making and policy-setting as well as for non-engineering professions. Other engineering colleges may choose to become more like "professional" schools, preparing students for professional engineering practice through the master's level. Engineering education needs own models. No one model suits every engineer or every organization that engineers serve.

Universities must put together an effective study system. A new training and certification program will base on the company's application delivery curriculum. [12]. In that way, the students will have a first hand view of how related concepts are being used in workplace. Thus, engineering education must take into account the social, economic, and political contexts of engineering practice; help students develop teamwork and communication skills; and motivate them to acquire new knowledge and capabilities on their own. Because many modern engineering projects require a combination of several disciplines, students also need exposure to the integrative field of systems engineering. The aims of engineering education will prepare an engineer to be successful in the changing workplace. It aims to equip students with technical knowledge and capabilities, flexibility and an understanding of the societal context of engineering.

Included among the often-mentioned barriers to successful use of online professional development are:

- creating quality courses that meet instructional needs;
- training instructors to successfully provide effective courses;
- ensuring there is proper support to meet student academic and online learning needs;
- and attending to the technical requirements needed to successfully develop, provide and access online courses.

That online teaching will take as much or more time than teaching traditional face-to-face classes (courses). This is because the level of interactivity with each individual student is increased [12].

3. Creating the condition for successful education for an adult learner

In October 27, 2006 in statistical indicator Eurostat shows the relation between female [2] and male [13] live-long learning students in the EU (Figure 2):

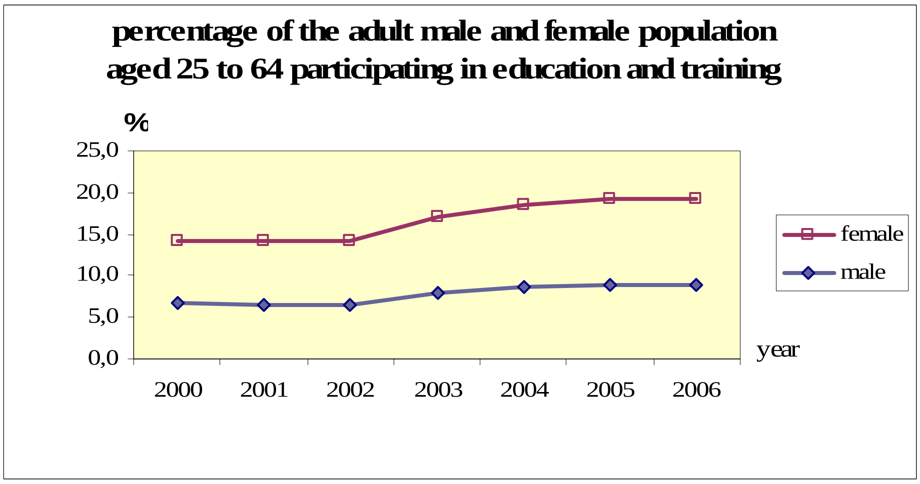

Figure 2 - Live-long learning students in EU

The percentage of adult students, who want to study, is increasing.

One education model, suitable for adult learners in EU, Learning Through Work, is found on University of Derby web site [14]. Learning Through Work is a way of getting a university qualification without having to leave the workplace. It's a form of work based learning. It's based on the simple premise that people don't always need to attend college or university to learn, because learning is part and parcel of everyday working life, and promotes continuing professional development.

In Learning Through Work, they offer opportunities for people to engage in individual and group programmes of study leading to credit and awards ranging from Certificates of Achievements to full Master's awards. They offer support through a learning contract and a simple but sophisticated online managed learning environment. Learning Through Work comparing distance learning, with recorded lectures for self-study and e-learning tutorial hours, such programs are more suitable to women; for them it is very difficult to leave their families and go elsewhere to further their education.

Responsibility for life-long learning and good technical knowledge is not just that of an individual. It is also the responsibility of the EU Commission, government, universities and employers.

In further, we can see some solutions which are connecting learning, work and family, especially in fields of technical education. This way is much more suitable for women with children and families in the EU.

The EU Commission could prepare financial support for adult learners if they want to study in other countries. They should consider PPS for regions, because it is not the same if you come from Romania or Belgium and go to England or Portugal.

Government should reduce taxes for employers who have study workers and have tax exemptions for workers who are studying.

University can prepare quality and actuality short courses to wide specters and flexible learning opportunities, like distance learning and e-learning. Each of the courses should be part of a wider certificate, diploma, undergraduate or post graduate study. All universities in the EU should prepare recorded lectures in their own as well as English language.

Employers should support their own adult learners. For example: a shorter work week (40 and more hours reduced to 30 hours) or part time work. They should offer technical support and places for studying. Many people can study after they finish their workday. They can study at their workplace because they have peace and quiet, as well as all technological support necessary in the learning process.

Finally, this way you can find individuals, who have higher personal motivation for learning in the technical field and get opportunity for their own development.

4. Conclusions

Everyone wants a good job, a lot of free time and money. But for most of us this is impossible. Modern life is like patchwork. Five days a week are for work, family, free time and personal activities. We must balance between many tasks. Study and education in technical fields (especially engineering) are not easy. One must work very hard in the new transition EU countries, because we have to accommodate to a new situation and a new position in the world. Employers want individuals who work hard, are responsible and are constantly learning new skills and widening their knowledge. How can this be done?

Life-long learning is an opportunity for workers who were not able to finish a university degree program. They want to continue their education so they can better themselves and get better jobs, as well as for personal growth. Such students are the best, because they have the personal motivation and energy to get ahead. Nevertheless, adults with good education and the opportunity to get ahead are more inquisitive and innovative.

Learning through work, like open learning and long distance education featuring pre-recorded lectures, e-learning (tutorial hours and practical modules that can be performed over a block week, with flexible schedules, or an individual program) are much better for the adult student then standard and fixed programs that the government proofed ten years ago.

The Importance of the Construction Sector: Measuring its Value

Les Ruddock
Research Institute for the Built and Human Environment, University of Salford, UK. M5 4WT
(L.Ruddock@salford.ac.uk)

Abstract

An essential issue in consideration of the state of the construction sector and its relationship with the macroeconomy is measurement of the activity of the sector. To fully appreciate the economic value of the construction sector, a distinction needs to be made between the value of the sector *in* the economy and the value *to* the economy. A narrowly-defined construction industry contributes around 5-6% of Gross Domestic Product (GDP) in many developed countries, whereas, on a wider definition, the contribution may be roughly twice this size [1],[2]. On the basis that the entire built environment falls into the field of activity of construction, however, the value to the economy may even be considered to be as high as 20% of GDP. The latter figure is based on the 'framework system approach' to analysing the built environment sector. The rationale behind this approach and its use in understanding the construction sector's role are developed and explained. Data on Sri Lanka are presented to consider the validity of the approach in the context of a developing economy.

Keywords: Construction sector, Macroeconomy, Evaluation.

1. Introduction

Construction is an industry of major strategic importance and it is essential that the statistics produced for the industry are valid, reliable and comprehensive in their coverage. In 2003, nCRISP (the UK Construction Industry Research and Innovation Strategy Panel) established a Socio-Economic Task Group with the aim of producing a report, which would paint a picture of the UK construction industry and the role it plays in contributing to the over-arching goal of sustainable development. In the Preface to the resultant 'Pearce Report' (*The Social and Economic Value of Construction: The Construction Industry's Contribution to Sustainable Development),* the Chairman of nCRISP stated that: 'The industry and its contribution to the UK economy and the health and well-being of UK society was neither fully understood nor adequately valued' [1], p.ii).

The United Nations defines construction as comprising 'economic activity directed to the creation, renovation, repair or extension of fixed assets in the form of buildings, land improvements of an engineering nature, and other such engineering constructions as roads, bridges, dams and so forth' [3]. Construction activity represents a significant share of the economies of most countries in terms of its contribution to GDP and total employment and it is also an important market for materials and products produced by other sectors of the economy. Pearce considered construction both in its narrow sense (on-site construction activity) with its contribution to GDP at around 5% and in a broader definition (including quarrying of construction raw materials, manufacture of building materials, sales of construction products and various associated professional services) making a contribution of about 10% of GDP. The nCRISP Task Group considered that it could be taken even wider than that – to include land, property and facilities management but stopped due to data availability and the fact that they 'had to stop somewhere' [1], (p iii).

1.1 The aim of construction activity

To consider construction activity to be merely the act of building is to take too narrow an interest. The productive issue to be solved by construction is more wide-ranging and represents a considerable economic and social challenge. It is a question of producing and managing the living and working environment of the whole population. The entire built environment, as distinct from the natural environment, falls into the field of activity of construction.

On this basis, the principal aim is not merely to produce and manage structures for people's living and working environment, but rather *to produce and manage the services rendered to end users by these structures throughout their physical life-cycle (production, use, improvement through to demolition)* [4]. Valuing the construction industry, and assessing the importance of the industry to the economy as a whole is a difficult yet important task. Highlighting the importance of construction to the economy is a key point to ensuring it is a high priority for government agendas.

There is a distinction between the value *to* the economy and the value *in* the economy, both of which will vary vastly dependent upon the definition of the sector used. The value to the economy considers the construction industries use as a driver for growth, and as a catalyst for other industries to do well. A good construction sector will usually ensure a healthy level of business across the board, as the necessary infrastructure for such actions to occur will be in place. The implicit value in the economy is more easily defined and assessed, and is measured as the contribution to GDP. However, both assessments still rely on a consistent definition of the sector so that reliable and comparable estimates can be made.

The construction industry has an important role to play within the overall economy of any given country but how that role manifests itself will vary greatly from one nation to another. In developing countries it is likely that the extraction of raw materials and on-site construction activity is most important, as the country seeks to set up a significant infrastructure, in the form of roads, railways and buildings. In developed countries, the onus is on professional services and the sale of the end products. It is also possible that a large repair and maintenance sector will emerge, the longer the main infrastructure has been in place, as potential customers seek to maintain and update current dwellings or work places rather than looking to new building altogether.

Broadly speaking, the construction industry is part of the process of creating and sustaining the built environment. In a narrow view, the construction industry is placed solely in the secondary sector, as this accounts for the transformation from manufactured materials into a final product. However the reality is that the construction industry spans across the primary, secondary and tertiary sectors, as the process sees raw materials transformed into manufactured materials and then on into a final product, with professional services and sale of products at the end of the line. The weightings of each part of the chain will vary from one country to another, skewed according to their level of development, with a higher concentration of primary and secondary sector firms in developing countries and more tertiary sector firms in developed countries, such as the UK or USA.

The traditional perception of the contribution of the construction industry to the economy is based on the methodologies employed for the definition and measurement of construction activity according to international standards. Within this context, the limitations of the concepts used in this definition are considered, and an analysis is undertaken of the usefulness of the measures. Construction activity has changed in response to new demands over recent decades and an evaluation is made of a new approach, to focus on construction activity to meet the changing needs of the economy and society. The role of built assets in the development of a nation needs to be considered and it may be that broader measures of the economic value of the built environment are needed in order to allow an assessment of the contribution of the built environment to quality of life and to enable the value of the construction industry to be properly understood. This basic definition of the construction industry does not include other value-adding construction activities such as:

Upstream - manufacturing, mining and quarrying, architectural and technical consultancy, business services.

Parallel **-** architectural and technical consultancy.

Downstream **-** real estate activities.

2. A new approach

In addition to the Pearce Report, the case for a new approach to the valuation of construction activity has come from two other areas. Firstly, the 'International Council for Research and Innovation in Building and Construction' (CIB) *Revaluing Construction* agenda focuses on improving the value of the final construction output and requires that the totality of activities involved in the production of the built environment is reviewed. (See [5] for a holistic assessment of construction). Secondly, Carassus [4] proposes a framework system approach for understanding the construction sector. The rationale for this approach is based on the view that the role of the construction sector should be viewed in a wider context than that of the narrowly-defined 'International Standard Industrial Classification' (ISIC) definition of the industry. Figure 1 illustrates this approach and indicates the extent of the construction sector system.

2.1 The construction sector framework

In recent years the construction industry has come to play a new role within the economy of many developed countries and it has been moving away from a production-based focus, to one where it acts as a provider of services for the built environment. Carassus argues that large-scale production by the construction sector on housing and civil engineering projects formed a necessary part of economic growth policies in post-World War Two industrially developed countries. Since the 1990s, however, there has been a notable change in terms of the demands placed upon the construction sector. Emphasis has moved away from building stock creation and is now placed on the repair and maintenance of the building stock created during the growth years. In order to appraise Carassus' proposed framework, a research project was set up under the auspices of the CIB, to test its application in nine developed countries[1]. One result of the study was to show that repair and maintenance accounted for (on average) about 50% of construction output. Beyond repair and maintenance, managing the existing stock has become a strategic issue for companies and government. The impacts of facilities management and public-private partnerships are strong signs of this trend.

Quality and maintenance cost aspects of the service rendered by the built capital have become important, as too has flexibility of use. This means that the operations and function of the construction sector need to be considered in a different manner. The industry has become much more involved in dealing with whole life cycle issues, which have become the dominant feature of sustainable development.

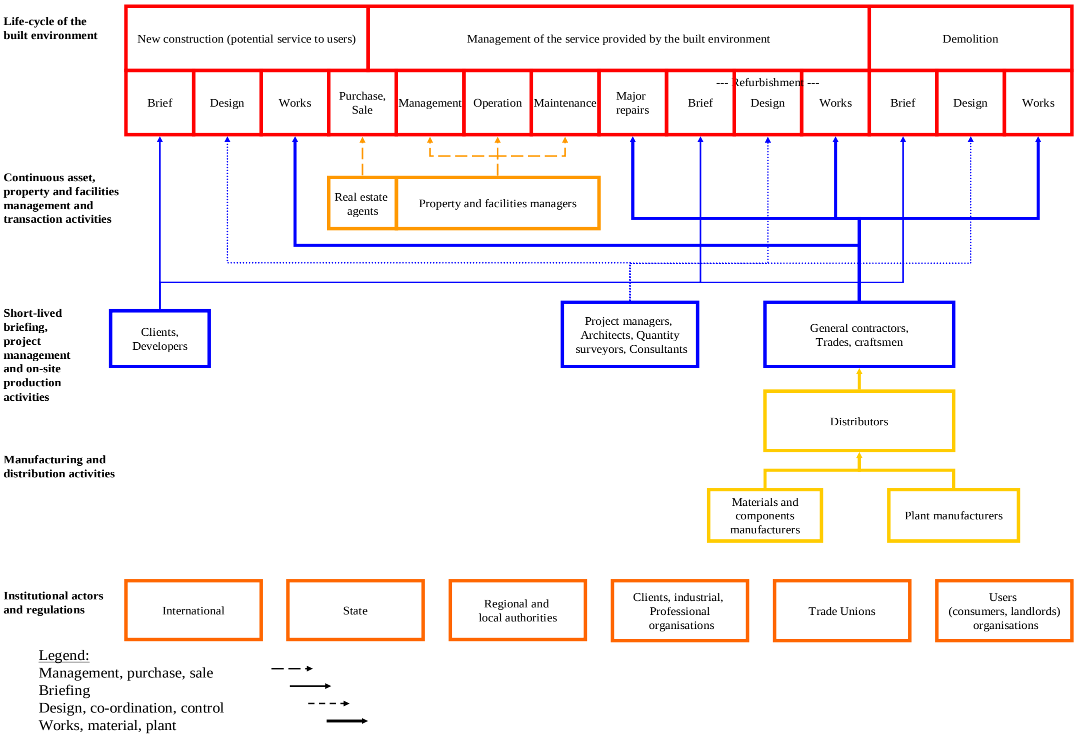

Figure 1 - The construction sector framework (Source: Carassus [4])

[1] The nine countries in the CIB 'Construction Industry: Comparative Analysis' study were: Australia, Canada, Denmark, France, Germany, Lithuania, Portugal, Sweden and the UK.

2.2 Defining the sector

The narrow sector consists solely of on-site assembly including repair work, which encompasses site preparation, construction of buildings and infrastructure, building installation and building completion. The broader definition consists of much more, including the supply chain for construction related products, including the mining of construction materials and the manufacture of construction products. The broad definition also includes professional services such as management, architecture, design and facilities management. These two definitions are illustrated by Figure 2, which depicts the structure of the construction industry, and how the different components feed into the built environment.

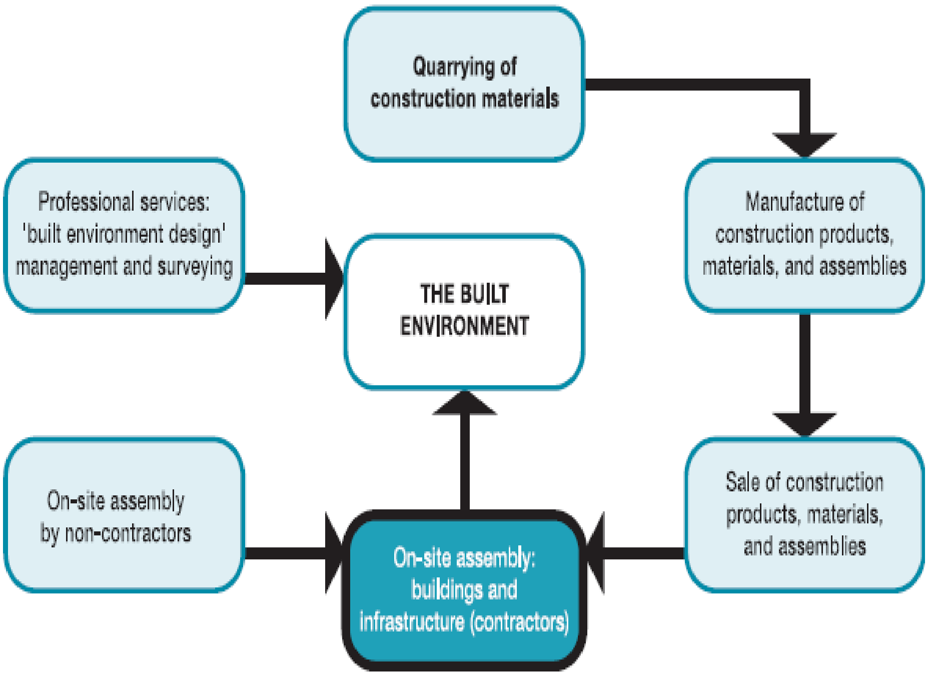

Figure 2 - Broad and narrow industry definitions

(Source: The Pearce Report [1])

There is obviously a significant difference between the narrow and broad definitions and the resulting impact the construction industry has on the economy. However both of these definitions are quite high level, including ‘sectors’ of the construction chain rather than individual tasks. In order to truly ascertain the full value of the construction industry and create a better defined description, a more detailed look at economic relationships between the construction industry and the rest of the economy must be made.

2.3 The economic contribution of the construction sector

Research undertaken at the University of Salford, as part of the CIB Revaluing Construction agenda has produced an assessment of the contribution of the construction sector to GDP, based on the wider linkages of the sector using analysis of UK Input-Output tables. (See Foulkes and Ruddock [2], for a detailed explanation of the procedures).

Table 1 - UK Construction Sector GVA contribution by SIC code

SIC Classification	**GVA as a % of total GVA**
14 Other Mining and Quarrying	0.08
25.2 Plastic Products	0.12
26.1 Glass and glass products	0.02
26.2/26.3 Ceramic goods	0.03
26.4 Bricks, tiles and construction products in baked clay	0.04
26.5 Cement, lime and plaster	0.01
26.6-8 Articles of concrete, plaster and cement etc	0.21
45 Construction Work	6.2
70.1/part 70.2 Real estate activity with own property	1.89
70.2 (part) Letting of dwellings, including impudent rent	7.9
70.3 Real estate activities on a fee or contract basis	0.5
71.32 Renting of construction and civil engineering machinery and equipment	0.42
74.2 Architectural and engineering activities	1.95
Total % of GVA contributed by 'Construction Sector'	**19.37**

Table 1 includes values calculated from Input-Output tables, and only includes the proportion of each category that is actually directly attributable to the construction industry.

The table above makes it clear that, although the broad definition in the Pearce Report is a useful one, it still does not give the full picture. By only using high level descriptions of 'sectors' within the construction industry, it is difficult to measure the total impact caused, as in some cases too much value will be attributed to the construction sector, but more critically many aspects are missed altogether. This more detailed break down of how the construction industry contributes to the economy also has the advantage of showing which areas have most importance (value added importance rather than actual importance within the chain) to the economy.

A similar analysis can be applied to other economies. Based on ISIC rev.3, Figure 3 shows an estimated measurement of value-added by the construction sector, in twenty European countries.

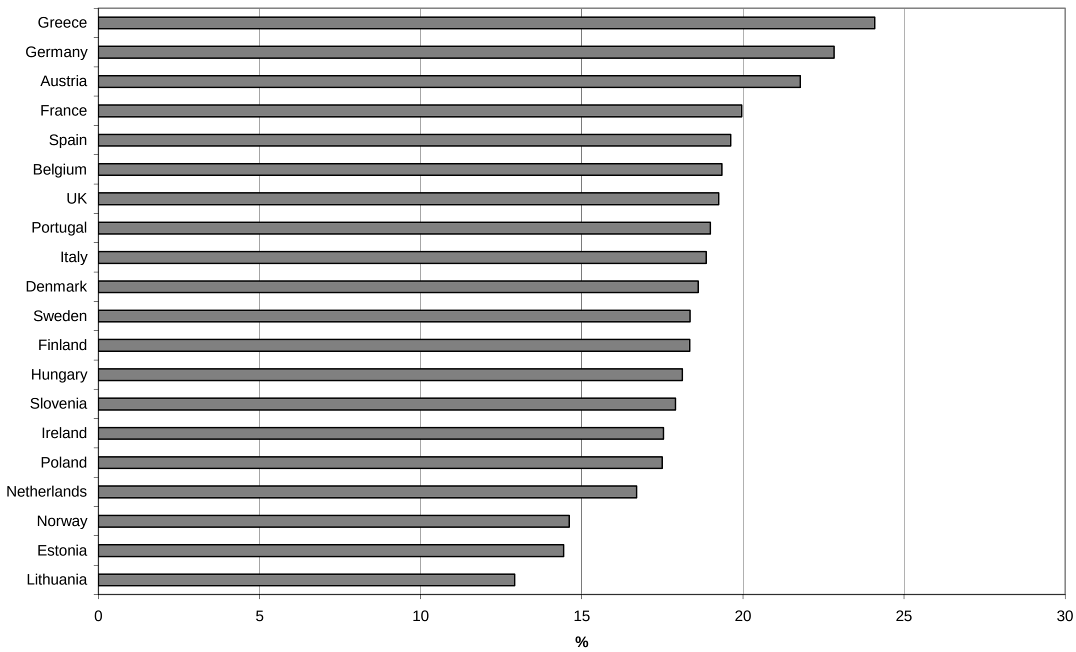

Figure 3 - Size of the construction sector in twenty European countries (as % of Gross Value Added) based on homogenised ISIC classifications. (All years 2000 except Slovenia 2001; Norway 2002)

(Data sources: National Statistics databases)

2.4 A contextual application to Sri Lanka

Consideration can be made, of the application of the construction sector approach in the context of a developing country. In Sri Lanka, in terms of the importance of the construction sector, it is not surprising that, post-tsunami, the 'official' construction sector growth rate has outstripped the growth in GDP (see Figure 4). In the supporting sectors growth has been particularly strong.

For instance, the value of imports of total building materials increased by 21.8% in the third quarter of 2005 from a value of 49.7% for the corresponding period of 2004.

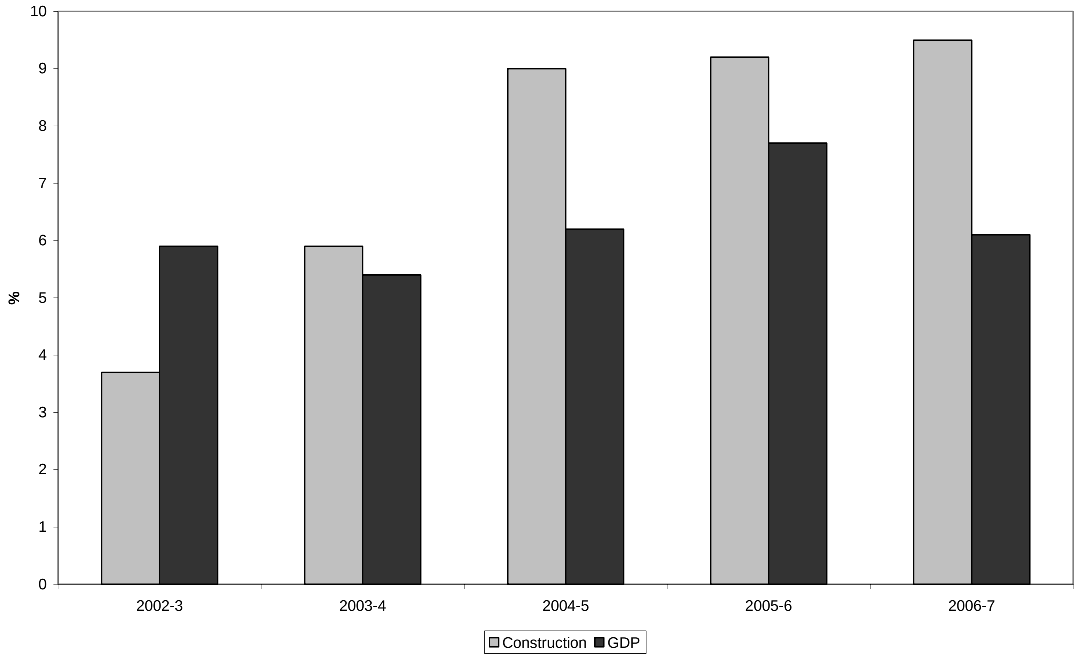

Figure 4 - Growth rates: Construction sector compared to the macroeconomy

Source: Derived from: National Income and Industry Statistics, Department of Census and Statistics, Sri Lanka. (Various years)

The notion of attempting to measure the value of the 'ancillary' parts of the construction sector in a developing country can be much more difficult due to a lack of comprehensive information, particularly inter-industry (input-output) data. Using a methodology, in which the inter-sectoral relationships derived from the aforementioned study of developed countries are used to determine coefficients, Table 2 represents an attempt to evaluate the overall value of the construction sector, calculated by mapping these coefficients on the Sri Lankan data.

Table 2 - Percentage share of GDP by origin at constant (2002) prices of major economic activities. (First quarter, 2007)

Divisions	**%**
Construction [Division 6]	6.4
Parts of: Mining [Division 3.2] Manufacturing: (Rubber and plastics) [Division 4.2.3] (Fabricated metal products, machinery and equipment) [Division 4.2.5] Banking, insurance and real estate [Division 10] Ownership of dwellings [Division 11]	10.4
Total	**16.8**

Note: The Divisions refer to the designation of economic activities by the Sri Lankan DCS

Source: Derived from: National Income and Industry Statistics, Department of Census and Statistics, Sri Lanka.

This measurement is based upon a snapshot, single-year assessment and a consistent set of time-series data would, of course, be needed to give the representation more validity. However, it is interesting to note that this value of 16.8% fits within the range of values observed in the developed countries shown in Figure 3.

2.5 The contribution of the construction industry to economic development

One aspect of the important contribution made by the construction sector to a country's economy concerns the relationship between a country's state of development and the level of activity in the construction sector. At the macroeconomic level, studies have tended to concentrate on developing countries (See Turin [6]; World Bank [7]; Wells [8]; Bon [9]). The idea of an inverted 'U' relationship between construction activity and the level of income per capita (i.e. in the early stages of development, the share of construction increases but ultimately declines, in relative terms, in industrially advanced countries) was put forward by Bon [10] and has been empirically tested by Ruddock [11] and Ruddock and Lopes [12]. As noted by Tan [13]: 'In low income countries, construction output is low. As industrialisation proceeds, factories, offices, infrastructure and houses are required, and construction as a percentage of gross domestic product reaches a peak in middle income countries. It then tapers off as the infrastructure becomes more developed and housing shortages are less severe or are eliminated.' According to the study undertaken by the CIB project group, after allowing for cyclical fluctuations, the general trend in construction activity in very developed countries is for construction activity to be in relative decline [4].

3. Conclusion

This paper has attempted to put forward a case for a re-evaluation of the construction sector in order to discern the true value of the construction sector to the economy and thus consider its role in the development of a sustainable built environment. At the core of the discussion is the issue of the nature of a sustainable built environment – balance of new and old; conversion versus demolition. It is beyond the scope of this paper to plan the journey required to transform the built environment from its actual state to sustainable state but the perceived economic value of the built environment must be appreciated in order to properly evaluate the sector's full contribution to the quality of life.

It is worth reiterating the limitations of existing data sources, which prevent a true assessment of the value of construction activity. As suggested in a CIB Task Group survey report on sources of macro-and market data in construction [11], in many countries, improvements to existing national statistical reporting systems are needed, to ensure that all construction activity is measured. A fundamental principle of sources of data on construction activity produced by national statistical offices is that official statistics are essential for obtaining a transparent picture of the true value of construction. In spite of the UN's attempts to impose standardisation on national statistical bodies, there are still many differences in underlying concepts and definitions for different countries and the problem of coverage to incorporate the 'grey' construction sector is, in many countries, a significant issue.

The importance of relevant data for assessing such effects is of paramount importance and the government cannot be relied upon as the only source of useful information. Official government statistics are not, of course, the only source of data and, in the industrially developed world, there is a plethora of private organisations producing data on the national construction sector. These tend to be forecasting institutions, contractors' organisations or information service providers. In those countries, where a comprehensive information system does not exist, the CIB Task Group survey has shown that options such as, government financing through a public/private agency, a subscription applicable to users or a levy system on members of the industry, could be considered. Improved statistical information would lead to improved awareness of the true value of construction activity. The target audience for this output would, of course, include government agencies for policy and planning activities.

Capacity Building:
A Framework for the Built Environment Education

Abstract

Capacity building is a continuous process which delivers better services by developing and strengthening the skills, instincts, abilities, processes and resources that organisations and communities need to survive, adapt, and thrive in the fast-changing world. The improvement of existing capacities and the building of new capacities provide multiple avenues to thrive the organisation in its visions. It was recognised the demand for the built environment education with the rapid growth of population and their pattern of thinking. Therefore the built environment education is one of the important arenas that requires the capacity development at present. To meet the challenges, it is essential to enhance the existing capacities or introducing new capacities to the built environment education. The study focuses to develop a framework to explore the capacity building in built environment education and test the validity of proposed framework in Sri Lankan context. A comprehensive literature survey and a structured questionnaire survey were carried out to identify the capacities in built environment education in local and international contexts. Further the framework was tested in its acceptance through interviews among the professionals who were proven in the built environment education. The acceptance level of the proposed framework is very high but it needs to check its practical validity by adapting the framework to a built environment educational institute.

Key words: Capacity building, Built environment education, Institutional Framework

1. Background

The term “Capacity building” has multiple meanings and an interpretation depends on a person who uses and the environment which implement. The concept is generally addressed in the areas of education, training, and human resource development events. Capacity building is a continuous process which delivers services has a direct bearing on the performance capacity of the organisation [1] by developing and strengthening the skills, instincts, abilities, processes and resources that organisations and communities need to survive, adapt, and thrive in the fast-changing world [2]. Specifically, capacity building encompasses the country's human, scientific, technological, organisational, institutional and resource capabilities. A fundamental goal of capacity building is to enhance the ability to evaluate and address the crucial questions related to policy choices and modes of implementation among development options, based on an understanding of environment potentials and limits and of needs perceived by the people of the country concerned.

A fundamental objective of capacity building is to enable society to optimize the use of its resources to meet its immediate and future needs and which can be characterized by three main activities: skills upgrading, both general and specific; procedural improvement; and organisational strengthening [1].

It is increasingly understood that "Higher education is the modern world's basic education, but many countries are falling further and further behind" and it is understood that "Higher education is no longer a luxury, it is essential for survival" [3]. There is growing concern for the safety and security of the civil infrastructure in relation to natural and manmade disasters. Safeguarding the future requires the expertise of professionals involved in the design, planning and construction of the built environment. This is particularly important to ensure that safeguards have the long-term vision to not only protect this generation, but future generations also [4]. Capacity development in built environment education is a two-way activity, which is in developing countries is a complex area which is an on-going process that must be based on a national priority and a holistic historical analysis of the national system of higher education and its contribution to social, economic and political development [5]. A number of disciplines dominate the term 'built environment' but there is no agreed definition of built environment as to the remit of the term. Centre for Education in the Built Environment [6] includes Architecture, Construction, Housing, Landscape, Planning, Surveying and Real Estate as the built environment professions. Safeguarding the future, requires the expertise of professionals involved in the design, planning and construction of the built environment.

There is growing concern for the safety and security of the civil infrastructure in relation to natural and manmade disasters. Due to the high demand for Built environment it is important to enhance the capacities of the built environment education. But improving the existing capacities, introducing new capacities are significant in both built environment and higher education system.

2. Capacity building

Capacity building is not a new concept and has been used in a number of fields to improve human resources and organizational structures. Researchers, policy makers and other leaders in different industries have used the concept of capacity building to evaluate and assess the potential, ability or capability of a group of people, team, company or even society to attain self-proposed goals [7]. Capacity building approaches vary and change depending on the organization and its vision and missions. The concept has evolved from a standard approach to a systematic and individualized method of analyzing a system's needs [7].

The meaning of capacity building varies depending on the context where it is being used. Harris [7] defines capacity building as, “creating the conditions, opportunities and experiences for collaboration and mutual learning.” The Center for Disease Control and Prevention (CDC) cited in [7] defines capacity building as, “technical assistance, training, information sharing, technology transfer, materials development or funding that develops, enhances, or sustains and organization to better serve customers or operate in a more comprehensive responsive and effective manner. Subramaniam [8] suggests that capacsity building is similar to “development” or “strengthening.” Further it’s a term which create reform or support activities that facilitate sharing of experiences, strategies and knowledge.

By analysing most of the definitions illustrated by various gurus in the field it was identified the most related capacities for the built environment education. It was hoped that the proper integration of those capacities direct the sustainable built environment education at the end.

2.1 Need for Capacity Evaluation

A serious obstacle to progress is the absence of data on educational efforts and outcomes [9]. It is critical to conduct an evaluation of a system before implementing and setting goals that may turn out to be unrealistic with the current capacity of that system. Porter [9] suggest that capacity building activities should happen prior to implementing a new law or a new service so that an organization can be prepared to independently implement the new requirements and achieve the intended goals. The evaluation of a systems capacity to perform certain skills or reach specific goals is also important to determine what is working and what changes are needed [10] The following figure shows the process of capacity building and at the end how it could be achieve the sustainable built environment education.

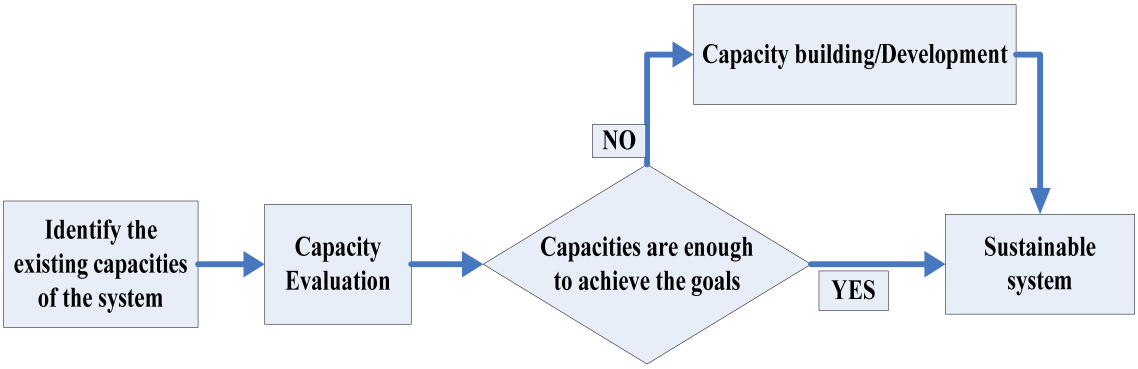

Figure 1- Capacity building process

3. Higher education and its capacities

The definition of higher education differs according to the context in which it is used. There is no overall consensus on the exact objectives of higher education, although some objectives like production of a qualified workforce, training people for careers in research, and enhancing life prospects are more commonly cited [11]. Almost all definitions agree that higher education refers to post-secondary education, where a degree, diploma, or certificate is awarded at the end of the study. Higher education builds on the level of competence, knowledge, and skills normally acquired in secondary education. The exact definition of this level, and consequently of higher education and of a higher education institution or programme, varies from one country to another. Consequently, the concept of 'higher education institution' may also vary. For example, in some countries, teaching is considered to be a field of higher education, while, in others, teaching is considered to be part of post-secondary education without falling into higher education.

Carter [12] mentioned the role of higher education sector related to built environmental as Promote built environment degrees, develop the skills industry needs, develop a long term aspiration for a career in the construction industry, Foster "enthusiasm" in the built environment.

4. Built environment education

There is a great link between built environment education and the construction industry. The built environment is based on the man-made surroundings that provide the setting for human activity, ranging from the large-scale civic surroundings to the personal places.The following diagram illustrates the link between the education system and construction industry in Sri Lanka.

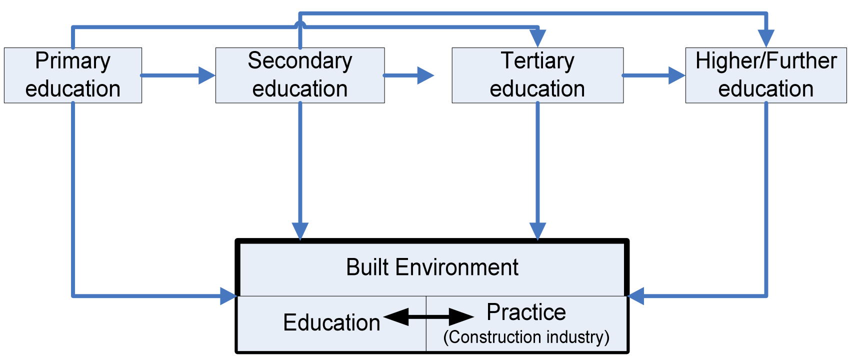

Figure 4 Education system and construction industry

4.1 Built environment education and capacities

Ginny cited in [13] has defined built environment education as, architecture and other facets of the material culture are the focal points of built environment education. For instance, it includes teaching and learning about city planning, architectural and landscape design, preservation of historic sites, and the issues and challenges raised by these activities. In general, the means and ends and the conditions and consequences of human interventions in the natural environment comprise the subject matter of built environment education. This includes teaching students to care for the built environment as it fits into the natural environment. Built environment education pertains to a great variety of places, objects and processes. So are recycling of resources and developing of model communities. And it refers to decision making about public issues, such as saving historically significant sites and balancing the sometimes conflicting goals of environmental protection and economic development. Built environment education prides itself in its design of ladders, nets and bridges to allow students to progress from one qualification to another, to provide some safe guards for students where they do not perform to an adequate level and to allow its qualifications to be recognised by other subject disciplines [14].

Through the literature survey the capacities were identified in two major types. The Institutional level capacities includes teaching, learning, research and innovation, governance, management, and finance. The Programme level capacities are assesment procedures, governance and management, community engagement, programme results and curriculum development.

There is growing concern for the safety and security of the civil infrastructure in relation to natural and manmade disasters. Safeguarding the future requires the expertise of professionals involved in the design, planning and construction of the built environment. Therefore it was recognized the necessity of enhancing the built environment education in local context as well as in the international context.

5. Research Method

A comprehensive literature survey and review was carried out on capacity building in the Built environment education systems. A Questionnaire Survey which was aimed on close ended questions by asking the significant level of capacities from the built environment professionals. The derived level of significance through the Questionnaire Survey was confirmed through structured Interview Surveys among the professionals who are practicing in construction industry and academic institutions.. Then a framework was developed by mapping the Higher education capacities and Built environment capacities together and finally the framework was tested on its acceptance through the expert opinions.

6. A Framework

At present there is multiple capacity development programs undergo in various sectors including the higher education. But the proper integration of capacities in built environment education is lacking. Therefore the research is focused on developing a framework for Capacity Building in built environmental education. The framework encompasses three domains. Those are the Capacities of higher education, the process and the capacities relates to the built environment education. Each domain involves different issues and mechanisms. The domain includes the concepts of built environment as an educational object; capacities in both institutional and programme level; capacity building process in concise way. Capacities of an educational institute can be categorized as Institutional level capacities and course content can be identified as the programme level capacities.According to the literature review; teaching, learning and research are identified as core capacities. So In the proposed framework institutional level capacities can be divided into two categories such as core capacities and supportive capacities. Further a Questionnaire survey which contains close ended question asking the significant level of capacities was carried out among the built environment professionals.This will help a built enviornment institute to identify the significant capacity and to make the capacity development on that capacity.

It is noteworthy that the new framework has been equipped with several user-friendly features than the results obtain through the application of one concept without knowing the other. Introducing this framework will create a path to identify the capacity building in built environment education institutions. Implementation of the capacity building in regular intervals will provide a sustainable output at last. This framework is based on the built environment education and focused only the undergraduate courses. So this framework gives a clear picture of built environment education capacities. Achieving the sustainable built environment through optimum use of resources can be obtained through the capacity building process.The proposed Framework is validated through the expert opinions from expert panel which comprises of four professionally trained experts and whom are presently working in the built environment educational institutions in Sri Lanka. The expert opinions critically analyzed with the literature and some changes have been done to the proposed framework such as addition of benchmarks and stakeholder involvement.

A FRAMEWORK FOR CAPACITY BUILDING IN BUILT ENVIRONMENT EDUCATION

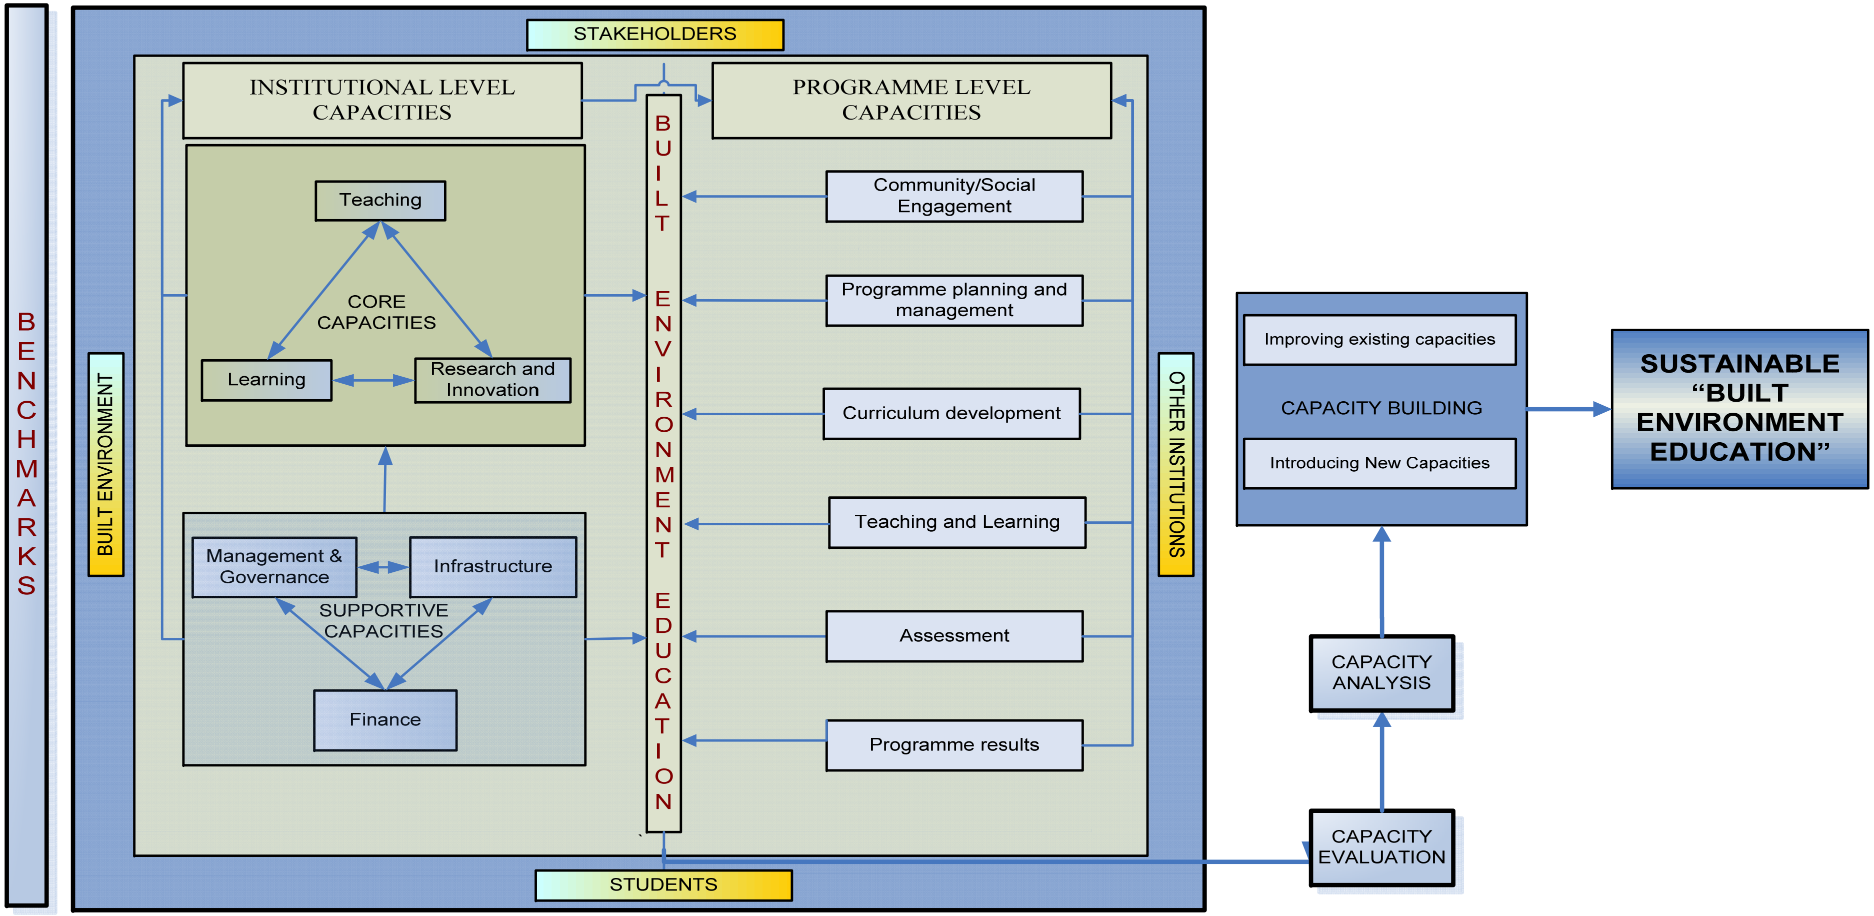

Figure 3 Framework for capacity Building in Built environment education

7. Conclusions

Higher education institutions have been confronted with far-reaching demands and challenges. Safeguarding the future requires the expertise of professionals involved in the design, planning and construction of the built environment. But improving the existing capacities, introducing new capacities are significant in both built environment and higher education system. To deploy the capacity building in built environment education it is significant to develop a framework for the built environment education. So this research aimed to develop a framework for built environment education to explore the capacities. The study aimed, by means of a literature survey, at exploring the perceptions, challenges, capacities of the built environment education, and then this research focused to identify the link between capacities involved in built environment education and finally concludes with a framework development and its validation.

The framework identified the capacities in terms if institutional level and programme level. The framework further sharpens with identification of benchmarks and the environment both internal and external. The developed framework is tested in its validity through expert opinions. Through the opinions it was caused to further modifications in certain intervals. The completed framework needs to check its practical validity by adopting in a built environment education institute. But it already accepted by the experts who were proven in the built environment academia. Therefore it can be concluded that the proposed framework could be sharpen through its practical application.

When an institute is practically implementing the proposed framework it is advisable to identify its capacities. Also mission, objectives, benchmarks may vary to institute to institute. So the institute whom is applying this framework should clearly define there organizational goals, objectives, missions and bench marks for activities. The framework can be recommended for the built environment educational institutes up to the undergraduate levels. But it needs to further develop for the postgraduate levels by incorporating the remaining capacities. . This framework will give a clear path for the capacity developments in built environment education institutes, thus it will lead to the sustainable built environment education.

Small and Medium Size Contractors in Swaziland: Current Challenges

Wellington Didibhuku Thwala and Mpendulo Mvubu
University of Johannesburg
Department of Construction Management and Quantity Surveying
Email: didibhukut@uj.ac.za

Abstract

In Swaziland the construction sector is not only a significant source of direct employment but also a sector which contributes, through its wide range of projects and operations. The Swazi economy is unable to deliver employment for a growing number of would-be workers. Structural unemployment and poverty are persistent and growing problems in contemporary Swaziland. Small businesses have been advocated as an important means of generating employment in which Swaziland is not an exception. The paper will first outline the arguments that have been put forward for the development of small contractors in the construction industry in sub-Saharan Africa. The paper will then describe the problems and successes that have been experienced in Swaziland in relation to small contractor development programme. The paper will conclude with recommendations for the future which will enhance the success of small contractors in Swaziland

Keywords: Contractor, Construction, Development, Employment, Programme, Small Businesses, Swaziland.

1. Introduction

In Swaziland and other countries there seem a general consensus that small enterprises are the mainstay of economic growth and prosperity. Small contractors can be powerful instruments of generating job opportunities; small contractors can perform small projects at different and remote geographical locations that might be unattractive to big firms or too costly using the big firms; low overheads enable small contractors to work at more competitive prices; large number of functional small and medium scale black contractors can help to decentralise the construction industry dominated by established large contractors; the relatively low skills and resources required at this scale can easily lower the entry point for the small and medium size owners to begin to participate in the industry; and a large number of functional Swazi owned contractors can develop a platform for growth and redistribution of wealth in Swaziland.

At a time when the public sector and big business are shedding jobs, small businesses are maintaining real employment growth. The small contractor development programme falls under the Ministry of Public Works and Transport. The main mandate of the ministry is to ensure the provision and maintenance of a sustainable public infrastructure, an efficient and effective seamless transport system and network, regulation for a vibrant construction and transport industry, management of public service accommodation and the provision of meteorological services. In carrying out its mission, the Ministry is committed to upholding safety and environmental standards for socio-economic development by making the best use of the country's available resources. The following are the responsibilities of the ministry: construction and maintenance of Government buildings; construction and maintenance of public roads; administration of the Road and Outspan Act; planning and Regulation of Road Transport Services; Government Transport Administration; administration of the Road Traffic Act; administration of the Road Safety Act; Road Transportation Act; Government Housing; Royal Swazi National Airways Corporation; Civil Aviation; Meteorological Services; Regulation of Air Transport Services; and Regulation of Rail Transportation Services

2. Emerging Contractors in South Africa

In South Africa, the contractors enter the market at the lower end and in the general building contracting category, making the sector extremely competitive and unsustainable[1] and the emerging contractor policies intended for black economic empowerment (BEE) are being used as job creation opportunities, which contributes to the over crowding of the emerging market. It is common for black businesses to be based on technical skills which are based on technical skills, which are used to satisfy needs of the community. However, technical competence is no guarantee of business success. Operational (e.g. scheduling and ordering) and business (e.g. planning, financial control and budgeting) skills are vital to the success of any enterprise. It is precisely these skills which are often lacking in the black business and it is thus imperative that these are developed if the industry is to expand to accommodate the meaningful black presence that is necessary for economic growth.

Small enterprises contribute positively to the economics of the country and to the survival of large numbers of people. However, the success of small enterprise is impaired by the common weakness from which many enterprises suffer. South Africa is faced with a large challenge of developing infrastructure in the communities which were previously disadvantaged, and also upgrading the existing infrastructure to cope with the high demand. This category of contractors is the preferred vehicle of delivery of infrastructure to communities [2].

3. Financial Constraints

The high competition among emerging contractors has contributed to increase financial failures of the emerging market, making the market unsustainable. The (CIDB: 2005) states that the large numbers of emerging contractors have moved into higher value public tendering in the 0.5m to 2m market, which is also becoming overly competitive. In a study which looks at the construction industry in South Africa [1]. Emerging contractors should not tender for higher contract values until they have gained enough experience and have financial capacity to handle the larger contracts.

The CIDB [3] states that from 1995 to 2005, about 5907 construction companies were formally liquidated. The CIDB [4] states that much more than 90% of the emerging black contractors survive the first five years. The CIDB further highlight that 1,400 construction companies were liquidated over the past three years. Emerging contractors feel that the banks are reluctant to deal with them unless exorbitant interest rates and through compulsory business management services. Complexity, risks involved in the construction industry have led to enormous failures especially in small contractors and those small emerging contractors harboring the wrong impression that there is quick money to be made are the mostly affected [2]. Lack of access to finance both during pre-construction which disqualifies emerging contractors from meeting guarantee and performance bond requirements and during construction which leads to cash-flow problems, incomplete work and even liquidation are financial constraints facing emerging contractors.

4. Relationships between Emerging Contractors and Suppliers

Emerging contractors do not have good relationships with their suppliers. In a functioning relationship, the material supplier provides credit to the contractor (30-90 day term), contractor pays on time and the cycle gets repeated. In an emerging supplier relationship, the supplier requires cash upfront and will not deliver the material until payment is made in full. The reason for this is if the supplier provides credit to the emerging contractor, the contractor is often unable to pay on time due to capacity or performance constraints. The reluctance by suppliers in the relationship with emerging contractors is caused by the following risk factors:

- History of emerging contractor’s failure to complete projects which is very high
- Systematic contractor payment processing delays, especially for construction works commissioned by the public sector.
- The potential for material losses due to theft, lack of appropriate storage and mismanagement by emerging contractor

5. Late Payment by Clients

Emerging contractors run into problems due to late payments by the clients. A problem arises when the local council run into budget difficulties and be unable to pay. The emerging contractor does everything right, his work is of good quality but the local council doesn’t pay on time and the contractor ends up owing the bank and defaulting. In one case, the contractor built 400 houses, but the town councilor had used the money for other pressing needs. On a different project, the same contractor built 150 of 300 houses; only to discover that the town council had forgotten to register the houses and this caused a delay in the payment for over a year. The unlucky contractor, failing to repay loans in a timely fashion had his business put into liquidation.

6. Difficulties when Running a Business

The Construction Industry Development Board (CIDB) [1] has presently concluded a reform measure whereby it used certain criteria to grade/ categorizes / register the contractors, which are to a certain extent being contested at some quarters. All these reform measures tend to concentrate on how to make projects accessible to the black contractors. They do not change the complex conditions of the contract performance procedure; they do not equip the contractors with the required capacity/ competency that can achieve success.

In South Africa, problems facing small emerging contractors in the contractor development programs (CIDB, DPW, CETA (2005) are as follows: [4] usually open adverts are placed in the media calling on people to come out and participate; it is very difficult for a selection process to capture those with the proper drive, passion and ability to work as contractors; this brings wrong people in the programs and drives them easily on the way; the required academic qualification is usually matric or less; no prior technical and managerial skills/experience in construction related fields as prerequisites; few matric holders make rare success; most successful contractors have degree or diploma in construction related field, with 5-10 years technical and managerial work experience; inadequate training done at short period's in-between projects; unsuitable for the contractor's time and project need; inappropriate trainers; clear-cut grading criteria had been elusive; recently CIDB graded/categorized the contractors using some contested criteria; core tech and management staff not stated, this may still lead to contractors getting projects they do not have capacity for; the contractors do not seem to understand the nature of complexity and risk in contracting; do not seem to be adequately informed of how to deal with them properly; the contractors lack skill, experience and tools to win profitable contract; they either win a grossly under-priced bid, or lose a grossly over-priced one; they lack own ready finance and access to affordable loan.

Due to lack of collateral, any one that gets credit from banks is subjected to high interest and financial risk management charges that make contracts unprofitable; in the ambition to grow big and make big profit, most of them take projects they do not have the necessary skills and financial resources to execute; the contractors tend not to employ qualified worker; they consider them expensive, but they fail while doing things all by themselves or with cheap, incompetent workers; they lack skills to properly program projects resources in monthly segments for healthy cash flow; they are not allowed front load due to lack of trust; they do not know how to prepare documents for timely payment; delayed payment; they do not seem to understand terms of contract conditions; do not know how to use applicable contract performance procedure to deal with client; they do not get properly trained in this. they are usually considered incapable of doing competent work, which imperils their relationship with the client's agent; they do not seem to know how to use applicable contractual instruments regarding instruction, demand for specific performance, and payment; they are not properly taught; where they know these rules they fail to use them due to fear of being 'red listed'; in attempt to make huge profit they cut specified quality, do bad work that falls short of the design standards/specification. Rejection of such works usually leads to none payment, conflict and most times failure of the contractors; and those that manage to win profitable contracts get only 2% profit if they are able to successfully complete the project; it seems discouraging.

7. International Experience with regard to Small and Medium Enterprise

In order to get an overall perspective of the environment and conditions within which we operate, it is imperative that we look at similar situations of small enterprise development in other countries. Bangladesh, Singapore and Malaysia have grappled with similar situations as far back as the post Second World War reconstruction period. These countries in different ways have a longer history and applied experience with regard to the development of a small business strategy. We do however recognise that different circumstances supported their initiatives, despite common experiences of the war devastation. In spite of positive circumstances in the above economies for Small Medium Micro Enterprises (SMMEs) to prosper, the strategies took at least ten years to unfold. This provides us with the opportunity to learn from other countries experiences, both useful and harmful, for Swaziland’s unfolding small business strategy.

All three countries add a different perspective about 'international best practice'. International best practice in these countries suggests that a strong institutional framework displays the following characteristics: a combination of financial and non financial services delivered by separate institutions in close co-operation as part of a national strategy; targeted finance programmes i.e. broad based, industry based and sector based schemes with focused assistance e.g. machinery, factory premises, raw materials, training programmes and technology; a detailed and comprehensive 'economic umbrella plan' with targets i.e. an overall vision and the inputs to be invested with clear detailed outputs within particular time frames; avoidance of ad hoc and disconnected programmes. Programmes are part of the larger strategy or plan [5]. A rapid delivery of programmes and an ability to rapidly shift programme focus and resources; ease of access to user; demand driven support; and a platform for interaction between public and private sectors with a strong emphasis on the planning role of the state.

8. Contractor Accreditation Process in Swaziland

A registration of accredited construction enterprises in Swaziland constitutes an essential tool for the industry transformation, for monitoring the performance of enabling environment programmes, and for ensuring compliance with the performance of public-sector projects. All construction enterprises engaged in public sector work, or in receipt of State funding training or support functions, will be required to be registered in a manner that will reflect their capacity and performance. The registration process must address the following: the operation of a preference scheme, or approved public tender list, which would reduce industry and public sector cost associated with an all out open tender process at the same time supporting risk management; performance monitoring to enable the promotion of improved contractors and to ensure compliance where standards are violated; and; the targeting of resources to the emerging contractors which are demonstrating progress and the withdrawal of support from those which have graduated or have failed to progress [6].

8.1 Category 1

Project Category 1 is eligible to tender for:

1. Locally and internationally funded construction projects above R20 million.
2. Specialist Projects of any value in areas where there is little or no expertise in the other categories to generate interest and competition.
3. Will Have 5% disadvantage on the tendered price on all locally funded projects when compared to the prices tendered by category two contractors.
4. Will have 10% disadvantage on the tendered price on all locally funded projects when compared to the prices tendered by category three contractors.
5. Will have to manage 25% of relevant portions subcontracted to category 3, 4, 5&6 contractors.
   (These will be sub-contracts, tendered for by registered local sub-contractors as part of the main contractor's bid in line with the percentage sub-contracts specified as shown below).
   - 15% to category 3 and 4 contractors.
   - 10% to category 5AND 6 contractors.

8.2 Category 2

Project Category 2 is eligible to tender for:

1. Local and internationally funded construction projects above E10 million.

2. Specialists' projects of any value in areas where there is little or no expertise in the lower categories to generate interest and competition.

3. Will have 10% disadvantage on the tendered price on all locally and internationally funded projects, when compared to the prices tendered by category 3 contractors.

4. Will have to manage the 25% of relevant portions sub-contracted to category 3, 4 5, and 6.
(These will be sub-contracts, tendered for by registered local sub-contractors as part of the main contractor's bid with the percentage sub-contracts specified as shown below.)

- 15% to category 3 and 4 contractors.
- 10% to category 5 and 6 contractors.

8.3 Category 3

Project Category 3 is eligible to tender for:

1. Local and internationally funded construction projects above E5 million.

2. Specialists' projects of any value in areas where there is little or no expertise in the lower categories to generate interest and competition.

3. Maintenance projects above E1million

4. Entitled to a portion of the 15% sub-contract works to category 1 and 2 contractors.

6. Will not be eligible to tender for routine maintenance works such as vegetable control, porthole patching, fencing etc.

7. Will have 10% advantage on the tendered price on all locally funded projects when compared to prices tendered by category 2 contractors.

8. Will have 5% disadvantage on the tendered price for sub-contract work, when compared to the prices tendered by category 4 contractors.

9. Will have to manage 25% of relevant portions sub-contracted to category 4, 5, and 6.
(These will be sub-contracts, tendered for by registered local sub-contractors as part of the main contractor's bid with the percentage sub-contracts specified as shown below.)

- 10% to category 4 contractors.
- 15% to category 5 and 6 contractors.

8.4 Category 4

Project Category 4 is eligible to tender for:

1. Local and internationally funded construction projects above E1million.

2. Specialists' projects of any value in areas where he has sufficient expertise and experience.

3. Maintenance projects above E1million.

4. Will not be eligible to tender for routine maintenance works such as vegetable control, porthole patching, fencing etc.

5. Will have 5% advantage on the tendered price on projects when compared to the prices tendered by category 3 contractors.

6. Will have to manage the 25% of relevant portions sub-contracted to category 5, and 6 contractors.
(These will be sub-contracts, tendered for by registered local sub-contractors as part of the main contractor's bid with the percentage sub-contracts specified as shown below.)

- 15% to category 5 contractors.
- 10% to category 6 contractors.

8.5 Category 5

Project Category 5 is eligible to tender for:

1. Local and internationally funded construction projects above E500, 000.00 but below E3million.

2. Specialists' projects between E500, 000.00 and E1million in areas where he has sufficient expertise and experience.

3. Maintenance projects between E500, 000.00 and E3million.

4. Will be eligible to tender for all road reserve maintenance contracts.

5. Will have a 2% disadvantage on the tendered price on all sub-contract works when compared to the prices tendered by category 6 contractors.

6. No sub-contract works.

8.6 Category 6

Project Category 6 is eligible to tender for:

1. Local and internationally funded construction projects below E500, 000.00.

2. Specialists' projects between E500, 000.00 in areas where he has sufficient expertise and experience.

3. Maintenance projects below E500, 000.00.

4. Will have a 2% disadvantage on the tendered price on all sub-contract works when compared to the prices tendered by category 5 contractors.

9. Problems Facing Small and Medium Size Contractors in Swaziland

The problems facing small contractors are not unique to Swaziland. The vast majority of construction firms are small enterprises that rely on outsourcing personnel as required. This has severely affected skills training and the retention of expertise in the industry as construction workers become highly mobile, walking in and out of the industry, depending on performance in other sectors of the economy. The impact can be seen in the rigid adherence to management techniques and construction practices handed down from colonial times which, as a result of inadequate skills and capacity. Delays with interim and final payments, as well as onerous contract conditions faced by construction firms, can also impose huge constraints on the industry. Many construction firms have suffered financial ruin and bankruptcy because of delays in payment, which are common with government contracts. Contemporary research that was conducted in 2007 by the authors revealed the current reasons for the failure of small and medium size contractors in Swaziland. 87 owners of the small and medium size contractors were interviewed. 68% of the contractors are less than four years; 20% are between 5 and 9 years; and 12 % had operated for more than 10 years. There was no contractor that had operated more than 15 years. 63% of the respondents believe that the four major banks in Swaziland have proper systems in place to support small and medium size contractors once they have secured work. On the other hand 37% of the respondents do not believe that the four major banks in Swaziland have proper systems in place to support small and medium size contractors. 33.4% of the respondents think that the current environment within the construction industry in Swaziland is favourable for small and medium size contractors to be successful. On the other hand 66.6% of the respondents believe that the construction industry environment is not favourable for the success of the small and medium size contractors.

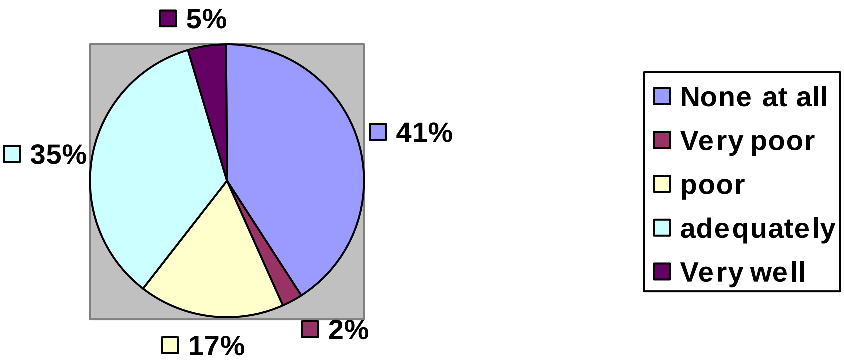

Figure 1 - Develop Business Skills

From the above figure 40% of the respondents are satisfied with business skill development and 60% of the respondents were not satisfied. The figure above shows that the respondents are not satisfied with regard to the development of business skills.

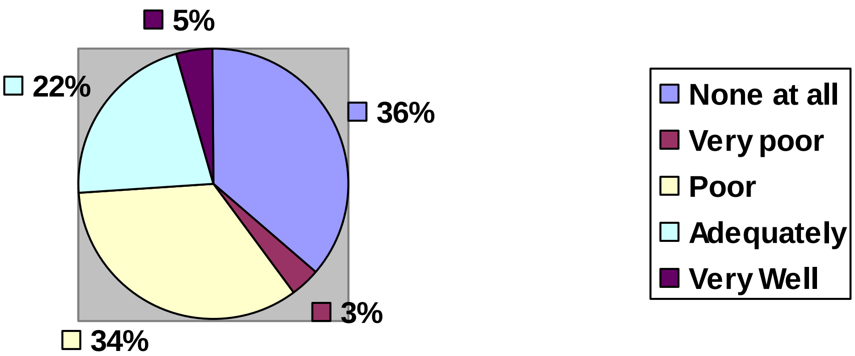

Figure 2 - Develop Management Skills

From the above figure 27% of the respondents are satisfied with the development of managerial skills. 73% of the respondents are not satisfied with the development of managerial skills. It is clear from the above figure that respondents had not been trained.

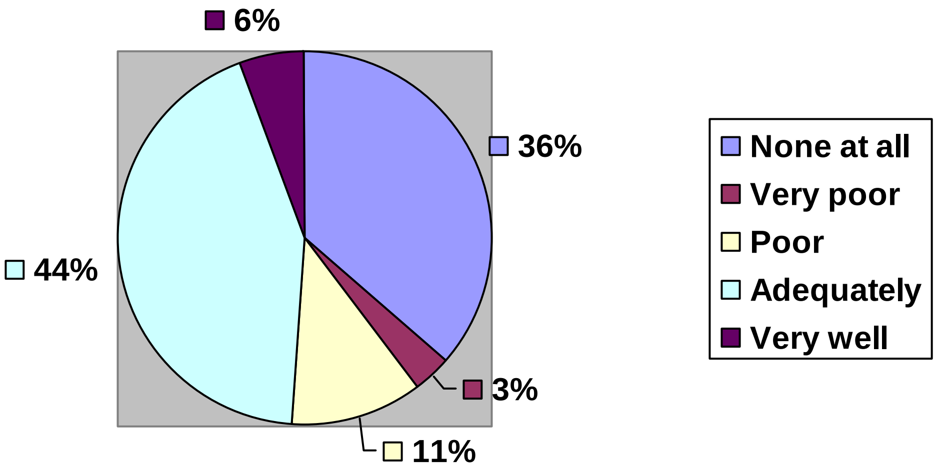

Figure 3 - Develop Technical Skills

From the above figure 47% of the respondents are satisfied with the development of technical skills. 53% of the respondents are not satisfied with the development of technical skills.

From the research conducted it can be concluded that the relative lack of success among the small and medium size contractors in Swaziland is a results of the following problems which must be addressed in order for the contractors to be successful:

- A lack of resources for either large or complex construction work.
- An inability to provide securities, raise insurance and obtain professional indemnity.
- The contracts were inevitably packaged in such a way as to exclude small contractors.
- Inadequacy in technical and managerial skills required in project implementation.
- Lack of continuity in relation to type, scale and location of work
- An inadequate approach and insufficient knowledge, time and experience required for the whole process of finding work, once found, insufficient understanding of the contract documentation and the preparation and submission of tenders.
- Slow and non-payment by government after completing a government project

10. Lessons and Recommendations

The planning processes in Singapore and Malaysia are comprehensive, detailed and act as a guide for different Ministries to set quantitative and qualitative targets for delivery institutions. The planning process involves extensive consultations and input by a broad range of stakeholders, which is then co-ordinated and submitted to cabinet and finally parliament as the Industrial Master Plan. These plans tend to unite society around a common purpose and vision.

Integral to economic planning in Singapore and Malaysia is targeted financial assistance for broad based, industry based and sector based schemes with focused assistance programmes e.g. machinery, factory premises, raw materials, training programmes, industrial linkages, technology and research and development. The interest rates for the contractor programmes are generally lower than bank loans. The overall plan identifies certain industries and sectors as crucial to the economic development of the country. Holistic support programmes including financial incentives are introduced for identified sectors and industries. The growth of these industries and sectors act as a catalyst in the development of other sectors. It is seen as an investment by government with spill off effects. The government financial assistance is not ad hoc but part of a broader strategy.

None financial support programmes cover a focused and wide range of issues including targeted training, quality circles, research, mentoring, design and product development, skills development, Local Enterprise Upgrading Centre, infrastructure development, export development, technology development and technical assistance. These support programmes are closely linked to the financial packages e.g. the buying of machinery requires, optimal training in the use of such equipment. Support programmes are not seen in isolation to the broader strategy and guides entrepreneurs in fulfilling the targets set. The programmes are able to rapidly shift focus and resources. The Singapore Local Enterprise Upgrading Centre acts as a first stop for SMMEs giving assistance in technical consultancy and financing. It co-ordinates government programmes administered by a range of institutions. The first stop centre avoids bureaucracy for the entrepreneur and increases delivery efficiency. Government procurement is clearly an important mechanism in redistributing resources and opportunities in society. In Malaysia the government has actively used procurement as a means to empower, skill and redirect resources to the Bumiputeras.

11. Conclusion

The small and medium size contractors in Swaziland is relatively underdeveloped, mainly constrained by limited access and high cost of capital and weak support programmes from government. There is also lack of skills. The most important deciding factors in the development of small contractors in Swaziland are to address the issue of access to finance, shortage of skills and adequate support from government must be a priority. Survival, growth and expansion of the small business sector are essential for economic growth and job creation in Swaziland. Small businesses represent over 95% of the total number of business organizations in the United States of America [7]. Thompson [8] points out that small businesses employ six out of every ten people and have been responsible for more than half of all the innovations developed during the 20th century. Haswell & Holmes [9] they attribute small business failures to the following: managerial inadequacy, incompetence, inefficiency and inexperience in running a business venture.

DISASTER MITIGATION

Gender mainstreaming in disaster reduction: why and how?

Abstract

The significant losses in human life and livelihoods, the destruction of economic and social infrastructure and damage to the environment caused by disasters in the past decade has increased the necessity for proper disaster reduction and risk management strategies. A disaster is shown as a combination of a trigger agent and vulnerabilities. Since vulnerabilities are the dependant component of a disaster, they should be managed and minimised in order to reduce disasters. Disaster reduction policies and measures, which ensure a decrease in vulnerabilities, need to be formed and implemented to achieve a sustainable and consistent plan of disaster management. Since women are more vulnerable in a disaster, their needs and concerns should be widely integrated into risk reduction plans and procedures from both perspectives of women as beneficiaries and decision makers. Gender mainstreaming is considered an important element in disaster reduction policy making to integrate a gender equality perspective in all policies at all levels. Gender mainstreaming in disaster reduction refers to promoting awareness about gender equity and equality, to help reduce the impact of disasters and to incorporate gender analysis in disaster management, risk reduction and sustainable development to decrease vulnerability. This paper reviews literature on disaster reduction and gender mainstreaming to emphasise why gender mainstreaming has become a necessity in disaster reduction attempts and to highlight the ways in which it can be achieved.

Keywords: Disaster reduction, Gender mainstreaming, Women.

1. Background

1.1 Introduction

"Disasters, one of man's oldest concerns, reach back to periods of pre-history and myth, yet strangely enough, are hardly an area of critical scrutiny" [14] (p. 66). Disasters are known as sudden events, which bring serious disruption to society with massive human, material and environmental losses and these losses always go beyond the capacity of the affected society to cope with its own resources [15],[27]. According to McEntire [17], any disaster is a combination of a triggering agent and a set of vulnerabilities – and it is these vulnerabilities, the conditions, which affect the capacity of a society to respond to the triggering agent which is the controllable component of a disaster. Since disasters cause large-scale damage to human life, their livelihoods, economic and social infrastructure and environment [11],[28] and these damages have shown a significant increase in the last one and a half decades [28], the world is in serious need of a sustained and comprehensive disaster reduction strategy. In achieving this, the needs and concerns of all social groups such as poor, rich, men, women, young, old, indigenous or non-indigenous must be necessarily integrated into the disaster reduction policies and measures because the level of vulnerability depends on these social aspects [11]. The Secretariat of the United Nations International Strategy for Disaster Reduction [8] emphasises that the vulnerability of women to disasters is greater mainly because of the social values.

The main aims of this paper are to highlight the importance of gender mainstreaming in disaster reduction policymaking and to discuss ways of mainstreaming gender. In order to make the path of achieving this aim clearer, this paper gives an account of the nature and types of disasters and the world's movement towards disaster reduction in its early sections. The next section characterises and classifies disasters as a preface to the disaster reduction trend and practices, which are described later. The third section focuses on gender mainstreaming, its importance and proposed means of integrating it into disaster reduction policies and measures. This paper is based on a review of academic literature, papers and reports produced by the United Nations International Strategy for Disaster Reduction (UN/ISDR) and various other institutions.

1.2 The way disasters are seen

1.2.1 Defining disasters

Historically, disasters were known as acts of god, or events outside human control, which brought massive disruption to society [17]. However, subsequently, with the expansion of scientific knowledge, disasters became synonymous with disaster agents or more specifically, they were seen as natural hazards [17]. UN/ISDR defines a disaster as a serious disruption of the functioning of a community or society causing widespread human, material, economic or environmental losses, which exceed the ability of the affected community or society to cope using its own resources [15]. However, disasters are interpreted in different ways by scholars and institutions. Weichselgartner [33] argues that natural disasters are a social phenomena because the overall damage due to natural hazards is the result both of natural events that act as a "trigger" and a series of societal factors. According to Jaya Kumar [14], the term is used to indicate a whole range of distress situations both individual and communal and that disasters are events in time, which have distinct phases of onset, climax and withdrawal. Ariyabandu and Wickramasinghe [1] view disasters as sudden events, which require immediate, emergency relief. McEntire [17] puts forward a different perspective by indicating that disasters as the disruptive outcome or human-induced triggering agents when they interact with and are exacerbated by vulnerabilities from diverse but overlapping environments. Apropos, as Shaluf et al. [28] indicates none of these definitions of disasters are universally accepted yet. The way that the disasters are explained varies according to the discipline in which they have been defined. Generally, there are four main bases for defining disasters as technical, sociological, political and medicinal [29]. However, almost all the definitions describe a disaster as an event, which disturbs the social structure or the environment, causes a significant loss and needs external assistance in recovery.

1.2.2 Types of disasters

Disasters are often divided into two main categories - as natural or man-made according to their cause [28],[15],[23],[27]. Figure 1 illustrates this. In addition to the two main categories of disaster, Shaluf [28] and Shaluf and Ahmadun [27] indicate that there can be a third category of disasters as hybrid disasters, which occur as a combination of natural and man-made disasters. Further, Shaluf and Ahmadun [27] show that natural and/or man-made disasters can trigger subsequent disasters as well.

Disasters are classified into three groups by Jaya Kumar [14] referring to the spatial dimensions of disasters as small, localised or large and regional disasters. On the other hand, disasters can be categorized into two, based on their spatial and socio economic characteristics as exogenous disasters and endogenous disasters [14] (p.75).

- Exogenous disasters- which relates to an energy that is external to society and which injure, destroy and affect everyone trapped within the spatial or temporal dimension. This can be defined as an event concentrated in time and space in which a community or a society experiences and shares severe danger, injury and destruction or disruption of the social structure and essential function of the society.
- Endogenous disasters- which emerge from forces within society and which injure one group while enrich other or which distress is suffered by one section of the community while material gains and social satisfaction accrue to another.

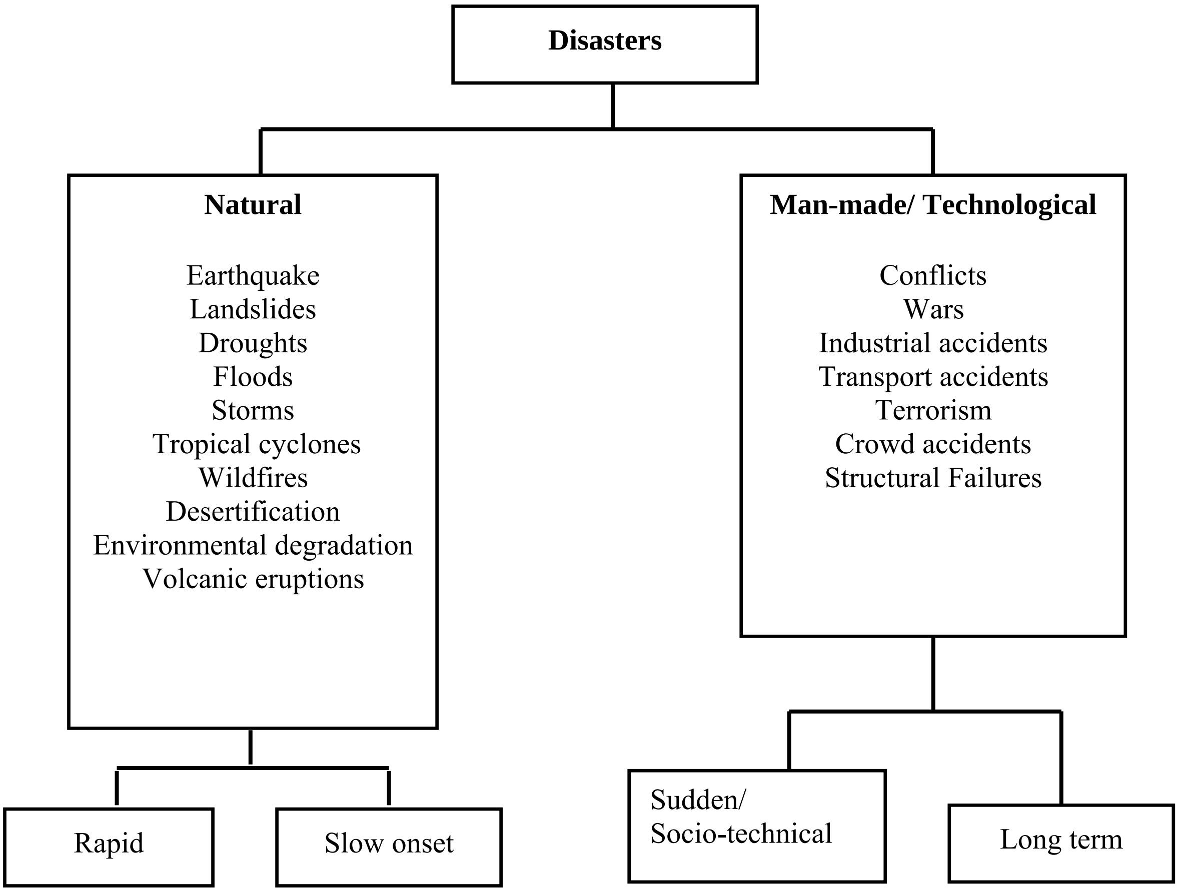

Figure 1: Categorization of disasters according to their cause

1.2.3 Occurrence of disasters

Initially, scholars and policy makers gave attention to disasters concentrating mainly on hazards giving an implication that the hazard agent was the disaster [19]. UN/ISDR [12] describes hazard as a potentially damaging physical event, phenomenon or human activity that may cause the loss of life or injury, property damage, social and economic disruption or environmental degradation. Furthermore, hazards can include latent conditions that may represent future threats and can have different origins: natural (geological, hydro-meteorological and biological) or induced by human processes (environmental degradation and technological hazards) [12]. However, this initial perspective on disasters was problematic because natural occurrences such as tornados in uninhabited plains may not be seen as a disaster and some hazards such as floods and fires can even be beneficial for the environment (e.g. providing rich, fertile soils for farming and forest rejuvenation) [19]. Therefore, the subsequent viewpoint that all disasters irrespective of whether they are natural or man made emerge as a combination of a triggering agent/hazard and vulnerabilities [17],[24] is more rational. With the establishment of the latter view, the emphasis on vulnerabilities in the context of disasters was raised gradually.

1.2.4 Vulnerabilities

Vulnerability is known as a set of conditions that affect the ability of countries, communities and individuals to prevent, mitigate, prepare for and respond to hazards [1]. It is seen that all individuals and communities are to varying degrees vulnerable to hazards and all have intrinsic capacities to reduce their vulnerability [34]. Apropos, vulnerability is given various definitions in disaster research since 1980 [33]. Similarly the disaster definitions vary according to the discipline they are based on and the way in which vulnerability is seen depends on the respective discipline [19]. UN/ISDR [12] defines vulnerability as the conditions determined by physical, social, economic, and environmental factors or processes which increase the susceptibility of a community to the impact of hazards. Based on the above explanation, the Working Group on climate change and disaster risk reduction of the Inter Agency Task Force on Disaster Reduction [34] illustrates the different dimensions of vulnerabilities as follows.

- Physical vulnerability refers to susceptibilities of the built environment and may be described as "exposure".
- Social factors of vulnerability include levels of literacy and education, health infrastructure, the existence of peace and security, access to basic human rights, systems of good governance, social equity, traditional values, customs and ideological beliefs and overall collective organisational systems.
- Economic vulnerability characterises people less privileged in class or caste, ethnic minorities, the very young and old, the disadvantaged, and often women who are primarily responsible for providing essential shelter and basic needs.
- Environmental vulnerability refers to the extent of natural resource degradation.

On the other hand, McEntire [17] categorizes the variables, which interact to produce a future of increased vulnerabilities under physical, social, cultural, political, economic, and technological headings as given in the following list. This classification splits the social vulnerability in the earlier categorization into three separate groups as social, cultural and political dimensions of vulnerabilities. In addition, the environmental dimensions are brought under the physical variables here in contrast to the earlier division.

- Physical
    - the proximity of people and property to triggering agents
    - improper construction of buildings
    - inadequate foresight relating to the infrastructure
    - degradation of the environment.
- Social
    - limited education (including insufficient knowledge about disasters)
    - inadequate routine and emergency health care
    - massive and unplanned migration to urban areas
    - marginalisation of specific groups and individuals
- Cultural
    - public apathy towards disaster
    - defiance of safety precautions and regulations
    - loss of traditional coping measures

    - dependency and an absence of personal responsibility.
- Political
    - minimal support for disaster programmes amongst elected officials
    - inability to enforce or encourage steps for mitigation
    - over-centralisation of decision making
    - isolated or weak disaster related institutions
- Economic
    - growing divergence in the distribution of wealth
    - the pursuit of profit with little regard for consequences
    - failure to purchase insurance
    - sparse resources for disaster prevention, planning and management
- Technological
    - lack of structural mitigation devices
    - over-reliance upon or ineffective warning systems
    - carelessness in industrial production
    - lack of foresight regarding computer equipment/programmes

McEntire [17] explains that vulnerability acts as the dependant component while the triggering agent stands as the independent component of a disaster. This dependant component is determined by the degree of risk, susceptibility, resistance and resilience [17]. Therefore, vulnerabilities should be managed in order to mitigate disasters. McEntire [17] shows invulnerable development or vulnerability management as a process whereby decisions and activities are intentionally designed and implemented to take into account and eliminate disaster to the fullest extent possible.

2. An overview of disaster reduction

Disaster preparedness through minimising vulnerabilities has been identified as a better approach to face disasters than post-disaster responsiveness [9],[24]. According to Goodyear [6], creating a culture of prevention is essential to address everyday hazards and the consequences of a disaster. Disaster risk reduction is defined as the conceptual framework of elements considered with the possibilities to minimise vulnerabilities and disaster risks throughout society, to avoid (prevention) or to limit (mitigation and preparedness) the adverse impacts of hazards, within the broad context of sustainable development [12]. Therefore, disaster risk reduction must be more decisively incorporated as an essential component of all development strategies, policies, programmes and investments for national and local governments [26]. In other words, disaster reduction incorporates taking measures in advance, addressing risk reduction, involving environmental protection, social equity and economic growth, the three cornerstones of sustainable development, to ensure that development efforts do not increase the vulnerability to hazards [11].

The United Nations International Strategy for Disaster Reduction (UN/ISDR) is a pioneer in disaster reduction movement in the international context. ISDR aims at building disaster resilient communities by promoting increased awareness of the importance of disaster reduction as an integral component of sustainable development and it promotes following four objectives for disaster reduction.

- Increase public awareness to understand risk, vulnerability and disaster reduction globally.
- Obtain commitment from public authorities to implement disaster reduction policies and actions.
- Stimulate interdisciplinary and intersectoral partnerships, including the risk reduction networks.
- Improve scientific knowledge about disaster reduction.

A close inter-relationship is shown between disaster reduction and sustainable development in disaster management research. Stenchion [31] determines that a number of development activities have a great responsibility and inter-relationship with disaster risk reduction because both development and disaster management are aimed at vulnerability reduction. Further, it is indicated that development can increase and/or decrease disaster vulnerability [18]. It is essential, therefore, to take measures of disaster risk reduction into consideration in all development activities. The framework for Action 2005-2015: Building the Resilience of Nations and Communities to Disasters states, "there is now international acknowledgement that efforts to reduce disaster risks must be systematically integrated into policies, plans and programmes for sustainable development and poverty reduction, and supported through bilateral, regional and international cooperation, including partnerships. Sustainable development, poverty reduction, good governance and disaster risk reduction are mutually supportive objectives. In order to meet the challenges ahead, accelerated efforts must be made to build the necessary capacities at the community and national levels to manage and reduce risk" [13].

3. Gender mainstreaming and disaster reduction

3.1 Gender and disasters

"Disasters affect women and men differently because of the distinct roles they occupy and the different responsibilities given to them in life and because of the differences in their capacities, needs and vulnerabilities" [1] (p.51). UN/ISDR [8] indicates that women are more vulnerable in disasters and they are the most affected. The poor and predominantly female and elderly populations are characterised by higher economic vulnerability as they suffer proportionally larger losses in disasters and have limited capacity to recover [34]. Enarson [4] identifies the following points as the reasons for women's higher vulnerability in disasters.

- Women have less access to resources.
- Women are victims of the gendered division of labour.

- Women are primarily responsible for domestic duties such as childcare and care for the elderly or disabled and they do not have the liberty of migrating to look for work following a disaster.
- As housing is often destroyed in the disaster, many families are forced to relocate to shelters.
- When women's economic resources are taken away, their bargaining position in the household is adversely affected.

In addition to the above factors, Enarson [4] points out that disasters themselves can increase women's vulnerability not only because they increase female headed households but sexual and domestic violence are also increased following a disaster.

According to, Enarson [4] and Khatun [16], although women are at greater risk than men in disasters, it is the women who make it possible for the community to cope with disasters because their social role is central to the management of a disaster coping strategy. However, women's abilities to mitigate hazards and prevent disasters and to cope with and recover from the effects of disasters have not sufficiently been taken into account or developed [1]. As Ariyabandu and Wickramasinghe [1] indicate, in current practice of disaster reduction women are seen as helpless victims and their capacities, knowledge and skills in each stage of the disaster cycle are not recognised. The gender differences in the disaster mitigation have been discussed primarily in the context of vulnerability or community involvement. The absence of women in decision making positions in emergency and recovery planning is not effectively addressed. Therefore, a gender perspective should be integrated into all disaster reduction policies and measures in order to decrease women's susceptibility in disasters. However, gender equality in disaster reduction requires empowering women to have an increasing role in leadership, management and decision making positions because women are not only victims of disasters but they can act as agents of change in disaster reduction planning [8],[11].

3.2 Gender mainstreaming

The Platform for Action (PfA) at the Fourth World Conference on Women in Beijing in 1995 brought up the concept of gender mainstreaming, the commitment to integrate gender perspective in all forms of development and political processes of governments [22]. UN/ISDR [11] elaborates gender mainstreaming as the process of bringing a gendered perspective into the mainstream activities of governments at all levels, as a means of promoting the role of women in the field of development and integrating women's values into development work. Although, the ultimate aim of gender mainstreaming is to achieve gender equality, it is not for promoting equality to the implementation of specific measures to help women; it is to achieve equality in all general policies and measures by actively and openly taking the possible effects on the respective situation of men and women into account at the planning stage [5].

According to the Employment and European Social Fund [3], gender mainstreaming means a partnership between women and men to ensure both participate fully in society's development and benefit equally from society's resources. Gender mainstreaming covers the following aspects.

- Policy design
- Decision-making
- Access to resources
- Procedures and practices
- Methodology
- Implementation
- Monitoring and evaluation

Therefore, gender mainstreaming is necessary to incorporate in the policies and programmes related to disaster reduction mainly because “gender shapes capacity and vulnerability to disasters” [2] as discussed earlier. As the United Nations Office of the Special Adviser on Gender Issues and Advancement of Women [22] explains, gender mainstreaming can promote gender equality and women's empowerment, particularly where there are glaring instances of persistent discrimination of women and inequality between women and men. Gender mainstreaming can be used as an effective tool to reduce the vulnerability of women, which arise due to various factors including less access to resources and to bring more women in to disaster reduction policy making process.

However, promoting gender mainstreaming is a long, slow process requiring inputs on many fronts over a long period of time, including advocacy, advice and support, competence development, development of methods and tools and vigilance in following up and evaluating progress [22].

3.3 Gender mainstreaming in disaster reduction

According to the definition given by the International Labour Organisation [7] for gender mainstreaming, it is bringing the experience, knowledge, and interests of women and men to bear on the development agenda and identifying the need for changes in that agenda in a way which both women and men can influence, participate in, and benefit from development processes. Accordingly, mainstreaming gender perspectives into disaster risk reduction should concern women in development processes as equal partners to men as both decision makers and beneficiaries [1].

According to Carolyn Hannan, Director of the UN Division for the Advancement of Women [7], the following basic principles should be set up for mainstreaming gender.

- Adequate accountability mechanisms for monitoring progress need to be established.
- The initial identification of issues and problems across all area(s) of activity should be such that gender differences and disparities can be diagnosed.
- Assumptions that issues or problems are neutral from a gender-equality perspective should never be made.
- Gender analysis should always be carried out.

- Clear political will and allocation of adequate resources for mainstreaming, including additional financial and human resources if necessary, are important for translation of the concept into practice.
- Efforts to broaden women's equitable participation at all levels of decision-making should be taken.

Therefore, mainstreaming gender in to disaster reduction policies and measures translates into identifying the ways in which women and men are positioned in society [11]. In other words, in the context of disaster risk reduction, gender mainstreaming refers to fostering awareness about gender equity and equality, etc, to help reduce the impact of disasters, and to incorporate gender analysis in disaster management, risk reduction and sustainable development to decrease vulnerability [11]. Gender mainstreaming can be used to bring equality into disaster management through considering the specific needs and interests of vulnerable women before, during and after disasters.

The United Nations International Strategy for Disaster Reduction [11] shows gender mainstreaming in disaster reduction as a parallel but inter-linked process to the mainstreaming of disaster reduction into sustainable development policies and activities while recommending to integrate gender, development and environmental management and disaster risk reduction both in research and practice. It further recommends that efforts should be made to increase a gender balance in decision-making positions to deal with disaster risk management. There is a need for a focus on the disaster and sustainable development planning processes and ensure a participatory approach and involvement of non-traditional/non-conventional ideas and partners.

4. Conclusions

Disasters, which disrupt society with enormous damage to the human life, environment and economic resources treat women and men differently. Women are more vulnerable to the consequences of disasters because of their social role. This emphasises the need to achieve gender equality in disaster reduction and integrate a gendered perspective to all policies and measures implemented in disaster management context.

Gender mainstreaming in disaster reduction allows women to decrease their vulnerability through identifying their specific needs at the disaster management planning stage. Women are empowered by gender mainstreaming to reach equality in decision making roles in disaster reduction and to utilise their skills in planning and implementation of policies and measures. After identifying the existing roles of men and women through gender analysis, gender mainstreaming helps to achieve equality in disaster reduction by giving a comprehensive understanding of the possible effects of policies and measures developed for disaster reduction on gender roles. However, since disaster reduction and development have a close inter relationship, gender mainstreaming in disaster reduction is a parallel and inter-linked process to mainstreaming disaster reduction into sustainable development policies.

5. The way forward

This paper focused to give an account for the importance of gender mainstreaming in disaster reduction through a discussion of literature findings on disasters, the types of disasters, different categories of disaster vulnerabilities and gender mainstreaming and its role in disaster reduction process. Apropos, gender mainstreaming in disaster reduction facilitates non-traditional ideas and parties to participate in disaster reduction and sustainable development planning while empowering women to develop their leadership qualities and other special skills in the decision making process.

Therefore, the study which was the basis for this paper aims to continue researching in the future on:

- establishing a relationship among disaster reduction, construction and gender,
- demonstrating the importance of gender in the context of disaster reduction construction,
- understanding the need for mainstreaming women in construction in disaster reduction,
- identifying the ways of mainstreaming women in construction in the disaster reduction decision making process.

Abstract

Recent catastrophic events demonstrate the importance of the post-disaster interventions, where the management of rescue operations and recovery assistance to citizens, the coordination of several organizations and the allocation of proper resources are truly critical issues. Many Civil Defence Systems have developed the knowledge and the experience to understand in “real time” the actual situation of the disaster context (e.g. through GPS tools for continuous monitoring or using ICT infrastructures to communicate with field forces); nevertheless, due to the complexity of the situation and the amount of information to process, specific decision support tools are needed that allow the decision maker to provide prompt responses and effective coordination of all the actors of the Civil Defence System. The paper describes a decision support tool, based on Bayesian Belief Network (BBN), for rescue and recovery operations during a rock fall disaster; the variables in the model allows both the representation of the causal chain of physical phenomenon and the assessment of other context factors affecting the emergency planning and management. The quantification of this advanced Decision Support System (DSS) is based on data gathered from available monitoring system and on experts’ judgements. The paper starts describing the Bayesian-based approach, showing the ability of the model to integrate different data-sets in different steps of the analysis (from the preliminary definition of the hydro-geological phenomenon to the integration of expert’s observation into the model). Finally, a brief case study is presented, referring to a rock fall event in an urban area, where the capability of the BBN to incorporate direct observations and describe a real case of rock fall is shown.

Keywords: Disaster management, Rock fall, Bayesian Network, Decision Support System, Civil Defence

1. Background

Landslides are one of the greatest natural hazards, causing considerable damage and claiming a large number of victims in several areas of the world. The consequences of landslide phenomena in Italy are so significant that they represent a genuine socio-economic problem, of an extent which is unique on a European scale and in the Mediterranean basin, and second only to Japan amongst the technologically advanced nations [1]. Managing natural risks therefore constitutes a fundamental problem for society [2] and is likely to play an increasingly important role in the future. It must be said that this type of event shows no sign of decreasing, despite the heavy investments being borne by public and private bodies. All this must be related to the fact that the large part of interventions have been directed towards remedying damage already caused by landslides and flooding rather than preventing such phenomena with systematic planning, based primarily on in-depth geological, morphological and climatic studies. The analysis and assessment of landslide risk is a complex task, due to: 1) the specific characteristics and hydrogeological properties of the area under assessment (landslide susceptibility), 2) the interactions between the natural environment, the built environment and the social environment, 3) the organization and management of rescue operations. What is clear, however, is the importance of an accurate knowledge of hydrological phenomena to be able to prepare efficient forecasting and planning intervention. There are various strategies a community can adopt in order to manage the risk of landslides, that can be grouped into three main categories: the first type of intervention consists of planning checks, to reduce high risk elements; the second category comprises engineering solutions, to reduce the probability of occurrence and the probability of a landslide having an impact on targets to be protected; the third category entails monitoring and warning systems, to reduce the number or vulnerability of elements at high risk. In order to manage risk correctly (Figure 1) it is therefore necessary to move to an initial phase of risk analysis, in the traditional terms of danger, vulnerability and value of the elements at risk, followed by a phase of risk assessment. Risk assessment consists of determining whether or not the calculated risk is acceptable to the community, and to what extent [3].

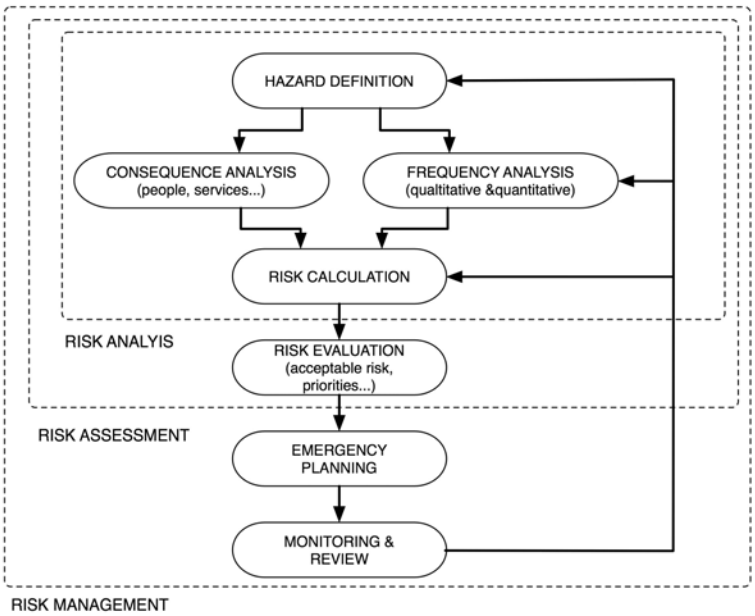

Figure 1: A model of landslide Risk Management

1.1 Rock fall: description of the phenomenon

Rock fall represents one of the highest risks in mountain area. A recent bibliographical study [4] outlines that rock fall is one of the most dangerous phenomenon for people safety. A rock fall consists in blocks fall due to slope traction or shear joints and the phenomenon can be divided in different steps, that are detachment, free falling, impact, bouncing, and sliding. Number of events that may cause a fall is wide and almost unpredictable. Historical data shows that such events are really common in Lombardy [5][6], mainly due to hydrogeological characteristics, geological local circumstances (essentially lithological-structural), pluviometric phenomenology and climate (characterized by frequent froze-unfroze cycles). According to the latest researches the highest risk areas are Sondrio and Lecco province and Garda lake area (INTERREG II C) [7]. In Lecco Province rock falls are 28.4% of overall censed landslides in Lombardy, while in Sondrio province this percentage rises to 30%. One must notice that risk of infrastructure and built up areas damaging is really high, and local public administrations have to evaluate large areas of dangerousness. As previously mentioned, detachment is due to a critical combination of intrinsic factors [8], described in the proposed model by means of a Bayesian Network (BBN) that represents the complex causal chain of the phenomenon [9] [10].

2. The Hydrogeological Network

2.1 Definition of the structure

The construction of a Bayesian Network [11] is made up of two fundamental steps: 1) the definition of the variables and of the links between variables, 2) the quantification of the links in terms of conditional probabilities. In both steps the contribution of experts is required to define the knowledge space, both in qualitative terms (topology of the network) and quantitative terms (estimation of the conditional probabilities). The logic of procedure is comparable to the construction of a cognitive map [12], since it is possible to proceed by identifying which causes may lead to some effects or, vice versa, given certain effects, which causes they may be attributable to. The adoption of a coherent inductive or deductive reasoning has the advantage of making the expert more confident in formalising the knowledge space. In this first step three fundamental basic structures (Figure 2) may be identified to which it is possible to relate every other subset of a graph [13]. Recognizing such structures is very important for studying the dependence of the variables and in general the capacity of the network to transmit the so-called causal flows generated by inserting the observations and experts' judgments. Indeed, in the case studied the typical phenomenology of a rock fall was translated, thanks to the contribution of some experts who identified the main hydrogeological variables and the dependent relationships between the phenomena. The use of BBN in the hydrogeological field is in any case well-known in the study of similar phenomena [14] [15]. The inductive process, followed in the topological definition of the network, uses the logic of identifying the phenomena capable of influencing the chosen target variable "rock fall": a set of relevant factors and observable phenomena exists whose correlation with the rock fall is proven by literature. Following on from these considerations in the first step of the procedure the experts defined the variables as well as the links, obtaining the hydrogeological BBN shown in Figure 2.

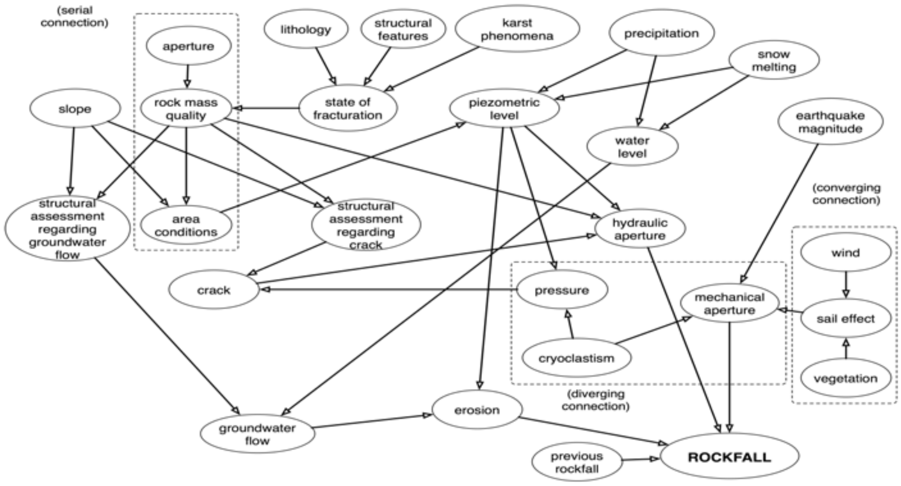

Figure 2: The hydrogeological BBN for forecasting rock fall (and basic cognitive structures: serial, diverging and converging connections)

In the second step all the links between variables were quantified: the method adopted for the quantification of the Conditional Probability Tables (CPT; Table 1), is largely based on the elicitation of experts' judgments, due to the lack of direct observations or consistent data from literature. The chosen approach required a strict validation process in order to assure the consistency of the knowledge incorporated into the network.

Table 1: Example of a Conditional Probability Table (CPT) for computing $P(X_3|X_1,X_2)$

X_3	X_1			
	y		n	
	X_2		X_2	
	y	n	y	n
y	p1	p2	p3	p4
n	1-p1	1-p2	1-p3	1-p4

2.2 Quantification of the variables: elicitation of experts' judgments and observations

The qualitative topology of the network is translated into a quantitative model of relationships between variables by the CPTs, which are generated for each variable in the network that has input nodes. To do this an elicitation process of expert's judgments is required which leads to the links between the variables being expressed in terms of conditional probability and finally the definition of the conditions surrounding the problem, i.e the definition of the states of the prior variables. Getting the analysis underway therefore requires the experts to fill in a questionnaire; such an instrument is capable of translating qualitative (verbal) estimations on the nature of the links, into probabilities of a conditional nature (Figure 3) [16] [17]. The expert is asked to quantify all the links in the network answering to questions like: "What is the probability that the state of fracturation is absent, knowing that there is a good lithology and an absence of Karsist phenomena?” where the answer should be: “Is expected with a very high probability (0,85-0,9) that the state of fracturation is absent”.

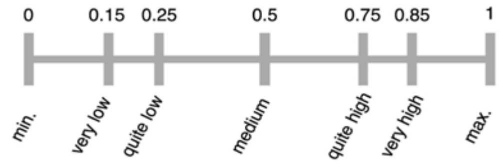

Figure 3: Example of comparative judgments scale for quantifying BBN variables

3. Using the Hydrogeological Network as a DSS for Emergency Management

The BBN is now capable of returning the probability of a generic rock fall in the reference geographical area, via the conditional probability of the target variable “Rockfall”, and based on the conditions defined by the prior variables. In addition we can improve the knowledge space of the hydrogeological phenomenon each time it is possible to gather direct observations of the variables [18] to partially replace experts’ estimations. Indeed the opportunity for updating the knowledge about the phenomenon may come from inspections by geologists at the rock fall front: through direct observations or the use of instruments on the ground (e.g. distometers) they are able to gather more data and return information back to the control room. New data can be translated into the BBN updating the values into the CPTs (i.e. filling in the fields represented in Table 2 and Table 3). The joint exploitation of on-site inspections or monitoring and the proposed BBN allows to organize appropriate countermeasures (evacuation, structural reinforcement etc.) [19]. The present version of the BBN does not incorporate any decision model for selecting suitable measures for risk mitigation or emergency management, nevertheless and updated estimate of rock fall probability is an important factor for the decision makers.

4. Case study: The Varenna rock fall

4.1 Rock fall event

On the 13th of November 2004, at around 17:30, 15.000 m^3 of rock broke loose from the slopes of the Foppe mountain at an altitude of 600 m above sea level, and tumbled down the slope below, reaching the village of Fiumelatte, in the commune of Varenna, completely destroying two residential properties and damaging a further 5. The masses of rock also hit the Milan-Lecco-Sondrio-Tirano railway line causing it to be disrupted and damaged two medium and high-voltage power lines. The mass, which was of immense dimensions (110 m^3, 300 tonn.), claimed two victims and left one injured before coming to rest against a large building some 10-15 meters away from the provincial road [20].

4.1.1 Observations on the hydrogeological characteristics predisposing the rock fall

What follows (Table 2) is a summary of the geological characteristics, taken from geological studies of the area, which must be considered in the model (prior variables) and their corresponding values which have been included in order to calculate the probability of rock fall: these values have been quantified with a probability equal to 1, since they are assumed as deterministic observations: the incline, for example, is very steep (in certain stretches the slope exceeds a 70° gradient with respect to the reference plane) and is formed of cemented debris often covered with arboreal and shrub vegetation (vegetation). A further cause can be identified in the morphology and in the several discontinuities observable in the rock, due to erosion, cryoclastism and pressure induced by run-off water.

Table 2: Synthesis of the variables, and the relative states, predisposing rock fall in the area of Varenna

Variable	**Description**	**State and assigned value**
Lithology	Densely stratified black limestone, occasionally bituminous, with isolated flint nodules and pyrite smearing produced by a process of sedimentation occurring in the past	sedimentary = 1
Karst phenomena	The mountain is affected by Karst phenomenology of the dissolving type	deep = 1
Structural features	From a structural point of view they often exhibit folds and faults and the strata predominantly lie horizontally deposited in opposite direction to the sloping soil	fault = 1
Slope (°)	The slope is sheer	> 70 = 1
State of fracturation	Dolomite light pink-grey limestone rocks, massive, locally stratified and intensely fractured along the joints in direction E-W, NNW-SSE & NW-SE and with open vertical fractures, and one higher up, even more massive in appearance, of almost entirely dolomitic composition	very fractured with Karst phenomena = 1
Aperture	The discontinuities are predominantly lacking filling material	open, empty = 1
Vegetation	The mountain side is characterized by tall, leafy trees	tall & leafy = 1

4.1.2 Observations on triggering factors

The event that has just been described and examined appeared unpredictable, even with the observed conditions: there was none of the typical predisposing and triggering factors of rock fall in the days leading up to the event itself and therefore no warning signal allowed the rock fall to be forecast. On the other hand, further environmental observations allow the conditions of the rocky mass to be defined better: the rock fall phenomenon, predominant in the area in question, is linked to triggering factors such as freeze-thaw cycles, thermal cycles, and seismic stresses for example. On the day the rock fall occurred wind speeds exceeding 60 km/h were recorded: given the presence of tall, leafy vegetation, it is possible to state that one cause triggering the event may be the sail effect created by the combination of the two factors. All these causes that are intrinsic to the area, coupled with the freeze-thaw cycles and the steep incline of the mountainside, facilitate the manifestation of the phenomenon. The BBN is capable of incorporating the above-mentioned observations thanks to the definition of the states of the corresponding variables listed in Table 3.

Table 3: Synthesis of the variables, and relative states, corresponding to the environmental observations in the area of Varenna

Variable	**Description**	**State and assigned value**
Cryoclastism	Along the rock faces there is cemented colluvium forming carbonatic breccias with blocks of considerable dimensions, interspersed with incoherent sandy horizons, with thicknesses of a few decimeters up to about ten meters (crumbling effect due to the freeze-thaw cycle, known as cryoclastism)	yes = 1
Precipitation (mm/gg)	Scarce during the period prior to the rock fall and irrelevant to the rock fall phenomenon	< 40 = 1
Snow melting	Winter month so harsh temperatures wich do not cause snow melting	no = 1
Previous rock fall	The area affected by the rock fall event had already been classified for some time as an unstable area of the Province of Lecco. The area is frequently affected by rock fall phenomena	yes = 1
Wind (km/h)	On the day of the rock fall the recorded wind speed exceeded 60 km/h	> 60 = 1
Earthquake magnitude (Richter)	Although it is an earthquake zone, no relevant phenomena showed up prior to the rock fall	< 2 = 1

4.2 Results

With the predisposing conditions quantified above and with the addition of the values corresponding to the environmental conditions (triggering factors), the BBN returns a very high value for the probability of rock fall (P (Rock fall) = 95,15%). In particular the contribution of the environmental conditions observed is about 30%. Similarly to what has been described previously, the observations on the predisposing factors alone are not sufficient to determine a high probability of collapse. The observations carried out do indeed have a great impact on the variables “mechanical aperture of discontinuities” and “hydraulic aperture of discontinuities”. For example, a fissure increase in the order of centimetres per day (or week), measured by a fissure gauge (Figure 4), is an extremely important warning signal, so much so that it would prompt the evacuation of the surrounding urban areas in case of imminent rock fall.

Figure 4: Aperture monitoring using a fissure gauge

The case study brings out the fact that the combination of the strong wind recorded on the 13th of November, and the presence of tall, leafy trees (conifers), generated a strong sail effect destabilizing the mountainside and producing the rock fall. In addition to the external mechanical stress due to the sail effect, the case under analysis reveals the presence of an area which is intrinsically predisposed to landslide and rock fall. The sedimentary lithology, the presence of numerous discontinuities and the steep gradient are characteristics which can strongly predispose the detachment of material. In short, when the observations carried out in the simulation lead to a value in the order of millimeters being associated to the daily variation of the apertures, the network returns P(Rock fall) = 68%, whereas if (for example with monitoring instruments) an evolution of the phenomenon in the order of centimeters is observed, the BBN returns an extremely high probability value, that is to say an almost certain occurrence of the rock fall. The simulation run using the BBN therefore proves to be consistent with the true evolution of the phenomenon as described on the basis of the data available for the Varenna rock fall.

5. Conclusions

The results obtained following the simulations, although still in the preliminary stages, have allowed the following objectives to be met: 1) to obtain an initial validation of the model and 2) to provide the first set of information which can be used to support the decision making process in the early stages of emergency. The preliminary results provided by case study do quantitatively confirm the validity of the knowledge space of the BBN: marginal probabilities, returned by the model are consistent with the qualitative description of the real event. Finally, what is more interesting from an operational point of view, the BBN model of a rock fall demonstrated a good sensitivity with respect to the type and amount of available information. Indeed, the analysis pointed out that the simple observation of the predisposing environmental conditions leads to a limited variation of the probability of occurrence of the rock fall – information that is marginal in decision making terms –, but also demonstrated that the improvement of the BBN knowledge about rock fall phenomenology (e.g. aperture discontinuity), either direct or via network computation, returns clear and unambiguous assessments (in the case study the rock fall probability increased over 95%). This leads to the conclusion that the BBN is able to exploit all the knowledge made available by the experts on the ground and by monitoring devices. In the case of environmental conditions favouring rock fall (persistent rain, seismic phenomena, steep slope of mountainside etc.) the proposed model can be jointly used with predefined threshold values to identify critical situations or areas and to release early warnings and alerts. Thanks to early warnings, anticipated inspections can be scheduled, obtaining more precise information and observations on the actual site conditions, which can be used to update the corresponding variables in the BBN, as shown. The process can be managed directly by the analyst on-site or by operators at the control room, which receives verbal communications from the site. Further steps of the research project will be focused on the development of a fully integrated system for monitoring, improved situational awareness and decision making, during emergency management [21][22].

Raising Preparedness by Risk Analysis of Post-disaster Homelessness and Improvement of Emergency Shelters

Nicole Henerichs,
Institut für Tragwerksplanung, Technical University of Braunschweig
(email: n.henerichs@tu-bs.de)

Abstract

A central element of disaster response is the provision of adequate emergency shelters for those who have been made homeless by a disaster. In order to raise the preparedness for the disaster case and thereby improve the disaster response it is necessary to first of all analyse the risk of post-disaster homelessness and secondly to develop adequate shelters. Therefore, a risk analysis has been undertaken investigating the distribution and the reasons for post-disaster homelessness. Furthermore, in order to improve the available emergency shelters different options of an insulated floor for tents in cold climate regions were developed.

Keywords: Preparedness, Risk analysis, Emergency shelter, Reconstruction, Disaster management

1. Background

Due to natural disasters every year hundreds of thousands of residential buildings are destroyed leaving their inhabitants for a certain period of time homeless and in need of both intermediate shelters (such as emergency and temporary shelters) and long term housing reconstruction. Especially in cold climate regions it is important to provide adequate emergency shelters quickly, in order to prevent post-disaster illnesses or even death from the cold. However, the Pakistan earthquake in 2005 with its 3.1 million (mio.) homeless showed once more that appropriate tents for cold climate regions are not available. With no other emergency shelter option than tents feasible this earthquake underlined again the necessity to develop winterised tents.

2. Risk Analysis of Post-disaster Homelessness

For the undertaken risk analysis the data on post-disaster homelessness of the database EM-DAT was used [1]. It was shown that the distribution of homelessness over disaster types varies with the largest number of homeless generated by floods (672 homeless per year per mio. inhabitants), followed by windstorms (266) and earthquakes (71). Analysing the reasons for the observed homelessness it was found out that for earthquakes the number of homeless increases with higher Richter scale magnitude while, considering the human development index (HDI), the highest homelessness is registered for medium human development (Figure 1). This can be explained by an increase in vulnerability in the transition from low to medium human development e.g. by rural exodus and the formation of large urban slums while for high human development the vulnerability decreases e.g. due to larger financial means for preventive measures. Finally, assigning to each country a risk class depending on its Mercalli scale zoning and combining this with the human development status a risk index for earthquakes was formulated [2].

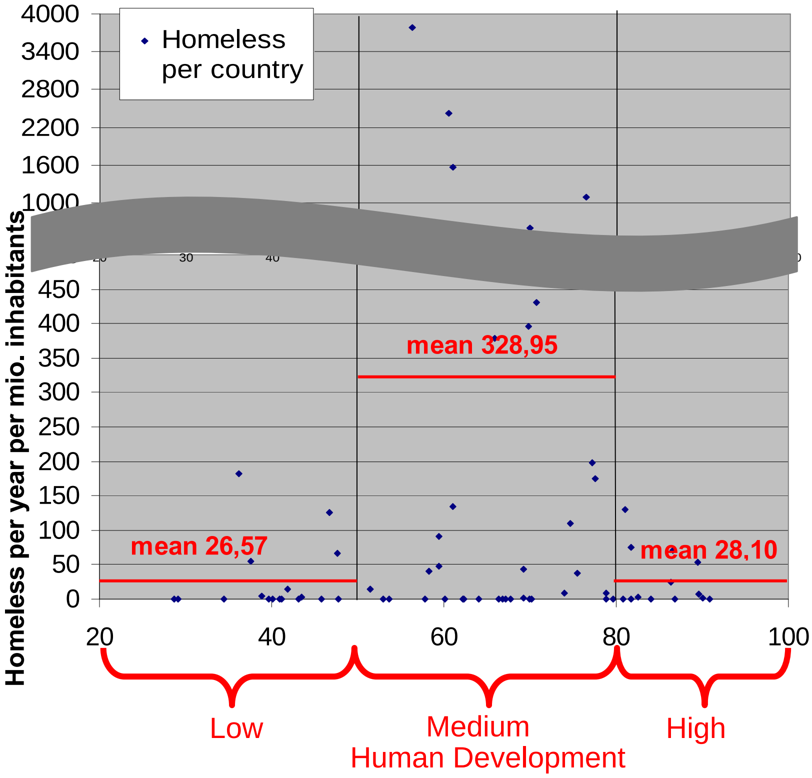

Figure 1: Homelessness by earthquakes depending on Human Development Index

Analysing the post-disaster shelter situation the dependency between socio-economic boundary conditions, vulnerability and shelter need could be identified (Figure 2). In each of the 3 parts of the diagram the different options which exist depending on the socio-economic boundary conditions are depicted with an increase in vulnerability from the left to the right. Initially the socio-economic conditions such as building quality and site location influence the structural vulnerability of the individual's home e.g. poor people settling on endangered land (part I of Figure 2). In this way the socio-economic conditions affect the total number of homeless which corresponds with the above demonstrated relation between human development status and the number of homeless due to earthquakes.

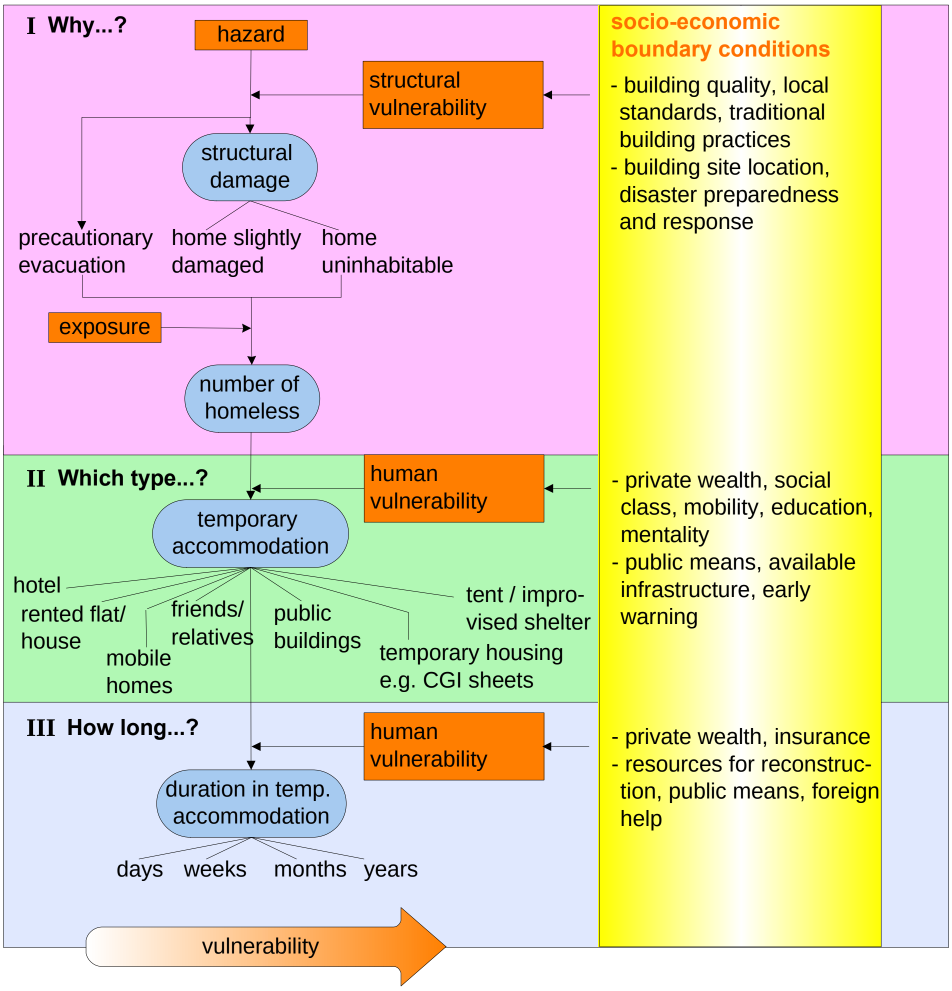

Figure 2: Influence of vulnerability on post-disaster shelter situation

Furthermore, the socio-economic conditions contribute to human vulnerability which influences the availability of emergency shelter options (part II of Figure 2) as well as the duration in temporary housing until reconstruction is finished (part III of Figure 2). For example a wealthy person in a highly developed country can rent a hotel room and quickly return to a reconstructed home paid for by insurance whereas a poor person in a developing country will be compelled to wait for the delivery of tents and external help for reconstruction. From past disasters it can be shown how with increasing human vulnerability the emergency shelter options change from renting a hotel room over mass accommodation in schools towards tents. This signifies that the availability of emergency shelter options is not arbitrary but depends on the socio-economic context. At the same time this means that adequate shelter can only be provided if it is designed in correspondence with the given socio-economic situation.

3. Winterisation of Emergency Shelter Tents

Due to the observed lack of sufficient winterisation of emergency shelter tents the UNHCR (United Nations High Commissioner for Refugees) defined the development of cold climate tents as a pressing task. Within this task the provision of an insulated tent floor is of major importance as it not only restricts the overall heat loss from the tent but reduces the heat loss of the occupants while they are sitting or sleeping on the ground [3]. Especially during the night the heat loss from the body is critical as less heat is produced and hence freezing is more likely. Therefore, different options for the floor insulation have been investigated using insulation materials from the building industry like Expanded Polystyrene (EPS) as well as locally available materials such as straw. Beside the conformity with the specific requirements from the use as emergency shelter material e.g. low cost, ease of transport the thermal properties of the solutions were evaluated using calculation methods from the building codes.

Table 1: Thermal properties of different options for tent floor

Type	**Basic win-terisation**	**Solid system**	**Air layer system**
Standard	2 tarpaulins, 3 blankets p.p.		
Additions		2cm EPS / XPS, stove	2cm air layer, stove
R_{tot}	0.21 m^2K/W	0.78 m^2K/W	0.80 m^2K/W
$Q_{sleeping}$	157 W	59 W	59 W
Q_{floor}	2273 W (heated)	613 W	603 W
T_{si}	-4.1 °C (heated)	13.5 °C	13.6 °C

In Table 1 the heat loss of an uninsulated tent floor consisting of two layers of plastic sheeting is compared with two insulated options. The solid system is formed by 2 cm of rigid Styropor or Styrodur lying between two plastic sheetings. For the second option a 2 cm air layer is constructed by a rectangular grid of supporting beams and a top tile both of High Density Polypropylene (HDPP). The thermal properties of the air layer are additionally improved by an infrared reflecting coating on the underside of the top tiles. Table 1 shows for a ground temperature of -10 °C how the heat loss during sleeping can be reduced from 157 W to 59 W by the installation of a stove and the provision of an insulated floor. The achieved value is well below the heat produced by the body during sleeping (85 W) so that the occupants do not chill. Similarly the overall heat loss for an internal tent temperature of 20 °C can be reduced drastically. This is important for the heating up of the tent as the heat produced by a standard stove is restricted to 5–7 kW. Furthermore, the thermal comfort which depends largely on the radiation of the surrounding surfaces is raised by a significant increase in the inner surface temperature of the floor (T_{si}).

Summarising the results of the research on insulated tent floors, an easy to apply tool for the shelter aid sector has been developed indicating adequate floor insulations options depending on the local climate (Table 2). All depicted options beside the air layer system are designed with two plastic sheetings: one on top of the insulating layer to protect from daily wear and tear and one underneath to protect against water etc. Beside the two options discussed above the specifications of the options are as follows:

- **Acoustic floor mat:** Quiet Zone Acoustic Floor Mat of 9.5 mm closed cell, extruded polyethylene foam

- **Pallet with/without IR-reflec.:** Standard wooden pallet with min. height of 134 mm; area between top boards of pallets filled with additional boards to form a closed wooden cover of min. 18 mm wood; with IR-reflection: aluminium foil fixed to underside of wooden cover

- **Straw:** ~10 cm thick layers from bales of dried straw

Table 2: Options for insulated tent floor depending on local climate

Min temperature	10 °C	5 °C	0 °C	-5 °C	-10 °C
EPS / XPS	✓	✓	✓	(✓)	(✓)
Air layer	✓	✓	✓	(✓)	(✓)
Acoustic floor mat	✓	(✓)			
Pallet without IR-reflec.	✓	✓	(✓)		
Pallet with IR-reflec.	✓	✓	✓	✓	✓
Straw	✓	✓	✓	✓	✓

The applicability of the different options depends on the inner surface temperature as this is the most critical requirement for thermal comfort. The minimum acceptable inner surface temperature was set to 15 °C (case ✓) or providing less thermal comfort to 13.5 °C (case (✓)). With these temperatures as boundary conditions the following other thermal properties are fulfilled:

- Q_{floor} < 485 W resp. 631 W (i.e. overall heat loss through floor)

- $Q_{sleep,down}$ < 34.1 W resp. 33.2 W (i.e. heat loss from body downwards during sleeping for bed clothing + 1 layer of medium thermal resistance blankets resp. 2 layers of medium thermal resistance blankets)

It can be summarised that an insulation of the tent floor is possible both with imported or locally available materials and that thermal comfort can be achieved even under severely cold conditions.

4. Conclusions

Much work has been undertaken to identify the risk of death or monetary damage due to natural disasters. However, the significance of shelter for a fast recovery of the affected population and the large financial expense for both temporary shelter and reconstruction necessitate as well an analysis of the risk of post-disaster homelessness. The undertaken risk analysis shows how a risk index can be developed using the endangerment and the human development status as indicators.

With respect to an improvement of the disaster response the presented options for an insulated tent floor demonstrate that an enhancement of the thermal properties of emergency shelter tents is possible. This will not only raise the immediate post-disaster living conditions of the affected but as well enhance the overall sheltering process. With adequate emergency shelters to hand and a thereby raised preparedness for the disaster case, more time for good reconstruction becomes available and potentially temporary shelters become abundant leaving additional money for a better reconstruction. However, much effort is still required to ensure the completion of fully winterised tents.

Abstract

In the UK, extreme weather events (EWEs) such as floods, heat waves and storms are increasing in frequency and severity. The ability of local communities to cope with the immediate impact and recover from the aftermath is critical to the continued well-being of the community that is affected. As part of Engineering and Physical Sciences Research Council (EPSRC) funded projects we investigate how Small and medium-scale Enterprises (SMEs), prepare themselves for the effects of EWEs. SMEs constitute a substantial proportion of the community that is affected as a result of these events. They need to prepare themselves for the effects of EWEs in a way that minimises disruption to them and allows them to return to near normal working conditions as soon as possible after an event. Very few studies have examined how SMEs respond to EWEs. Policy makers and theorists in this field have proposed various models and frameworks to improve the adaptive capacities of SMEs by concentrating on identification of risks and opportunities coupled with strategy development and implementation. Their individual and collective attitudes influence the activities that SMEs perform towards preparation of disaster preparedness plans and post disaster recovery measures. The paper argues that this continuous process of engaging SMEs will develop their adaptive capacities and enhance their coping measures in facing up to the risk of extreme weather events. The paper provides a literature review and a synthesis and a methodological vehicle to guide this research.

Keywords: SME, extreme weather events, coping skills, adaptive capacity, built environment

1. Introduction and main focus

The World Bank estimates that, in 1998, various natural disasters killed over 50,000 people and destroyed $65 billion worth of property and infrastructure [1]. This number significantly increased in 2004 due to the tsunami. South Asia Disaster Report [2] states that 2004 – 05 period was the ‘most appalling’ period in the history of South Asia. In the UK, extreme weather events (EWEs) such as floods, heat waves and storms are increasing in frequency and severity. For instance, according to UKCIP [3] climate change is likely to impact on winter peak river flows to rise up to 20% by 2050. Further, insurance industry reports specify that this will double the likelihood of flooding in certain areas [4]. The ability of local communities to cope with the immediate impact and recover from the aftermath of a disaster is critical to the continued well-being of the community that is affected. Small and medium-scale Enterprises (SMEs) constitute a substantial proportion of the community that is affected as a result of these events. They need to prepare themselves for the effects of EWEs in a way that minimises disruption to them and allows them to return to near normal working conditions as soon as possible after an event. Most of the natural disasters affect many organisations and are difficult to predict or prevent. SMEs in particular are often affected directly and indirectly from the very same disasters faced by large companies. However, the former tend to have fewer resources than their larger counterparts with which to plan, respond and recover. As part of UK’s Engineering and Physical Science Research Council (EPSRC) ideas factory project titled “community resilience to extreme weather events through improved local decision making”, we investigate the role of SME’s within a community in response to extreme weather events in the UK. The three year research project commences in February 2008.

The objective of the paper is to conduct a literature review on unique characteristics of SMEs, their general behaviours and decision making. These will inform the investigation of the various coping mechanisms and the importance of SME resilience and disaster risk management (DRM) plans. The literature review and synthesis of the paper will serve as the foundation for research. This paper will also inform policy making in the area of building resilience and coping strategies for SMEs when facing up to EWEs.

The paper is organised as follows. First, it provides insights into the unique behaviour of SMEs and how this behaviour is aligned with improving their coping strategies against extreme weather events. Then, the paper focuses on disaster risk management and discuss cases from various countries on the importance of disaster risk management planning to SMEs. The third section of the paper provides insights into participatory approaches as a potential tool to engage SMEs into generate solutions for them to effectively and efficiently face up to challenges of extreme weather events. The paper then sets out the research problem and the methodology. Finally the conclusions are drawn.

2. Literature review and synthesis

2.1 SMEs and their unique behaviour

Burk [5] presents the European Union based definition for an SME by considering its number of employees and annual turnover. Accordingly an SME could have 1 – 250 employees and a turnover of up to Euro 50 million. This size is relevant to the particular sector in which the SME operates. For example an SME in the oil sector, where there are a number of extremely large corporations, may be classified as small as a comparative measure. A similar size firm in the fashion design industry may be classified as large as the fashion design industry consists of many large firms [5]. SMEs are socially and economically important to society, "since they typically represent 99% of all enterprises in Europe and America" [5: 14]. According to Robbins et al [6] SMEs are important to the economic vitality of cities, states and the countries due to their significant number and employees. However, they tend to display vulnerability in facing up to various conditions prevailing in a country's economy resulting in business failure. Ability of SMEs to turnaround their companies is constrained due to their limited access to financial resources and capital [7]. It is therefore pertinent to investigate unique SME behaviour, their coping skills, resilience in facing up to both direct effects of extreme weather events as well as the various indirect economic effects of extreme weather.

Historically, it has been recognised that the SME sector poses various challenges for implementing policies, transfer of good practice and various Government agendas. For instance, studies conducted by researchers at University of Salford [see 8, 9, 10] identified that strategic horizons and organisational capabilities of SMEs did not allow sufficient 'organisational slack' to conduct activities outside their main business activities. Therefore for an appropriate SME resilience agenda to emerge it is of strategic importance that mitigating measures against EWE's are conceptualised as closely associated with the mainstream business activities of these companies. This notion will further strengthen the processes followed for effective engagement, identification of SME coping strategies, role of intermediaries and preparation of interface toolkits and other support material.

SMEs' ability to effectively react to various EWEs are often affected due to lack of planning, vulnerability to cash flow interruptions, lack of capital for recovery, ineffectual interactions with national agencies, infra-structure problems [11], individual attitudes and organisational culture [12], access to expertise, business sector and perceived exposure to risk [13]. Collectively these factors determine the adaptive capacities and the overall behaviour of SMEs. For SMEs one also needs to consider the general attitudes towards disaster recovery and business continuity planning (BCP). Even though guidance exists for BCP [14], most SMEs do not consider it, or are under-insured against the potential risks [15].

2.2 Disaster risk management (DRM) and SMEs

The severity of extreme weather events has impacted many businesses and individuals and the effect has spread over to various regions in the world. The main risks to any business of EWEs are increased costs and loss of revenue. According to Canadian Chamber of Commerce [16] the risks (within the context of Canada) could include risks of blackouts and damage to property and inventory from floods and high winds as a result of extreme weather events. In addition crop failures from drought will affect farmers, and lack of snow in winter will affect ski resorts. In the UK, Bosher et al [4] identified that most significant threats to the built environment in the UK were considered to be floods, climate change, ageing/inadequate infrastructure, and inadequate urban planning. Figure 1 identifies the perceived threat to the built environment through the multi-sectorial study conducted by Bosher et al [4].

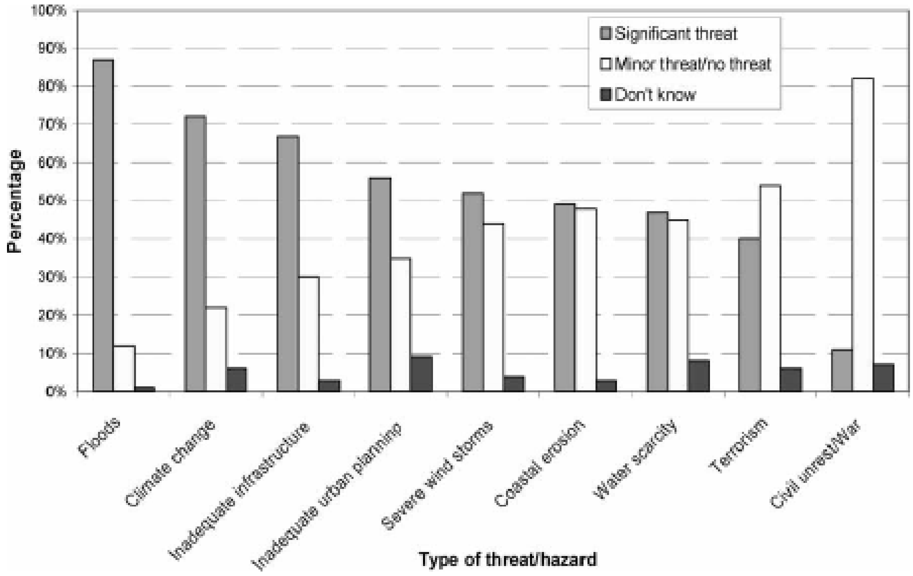

Figure 1: Perceived threats to the built environment through a Multi-sectorial study (Source: [4])

The ability of companies and individuals to insure these losses vary to a large extent. SMEs in particular find it very difficult to insure against EWEs due to the funding restrictions that they have. According to Dunn and Flavin [17], who studied results from the insurance industry, found that losses caused by various extreme weather events have multiplied several times as indicated in Figure 2.

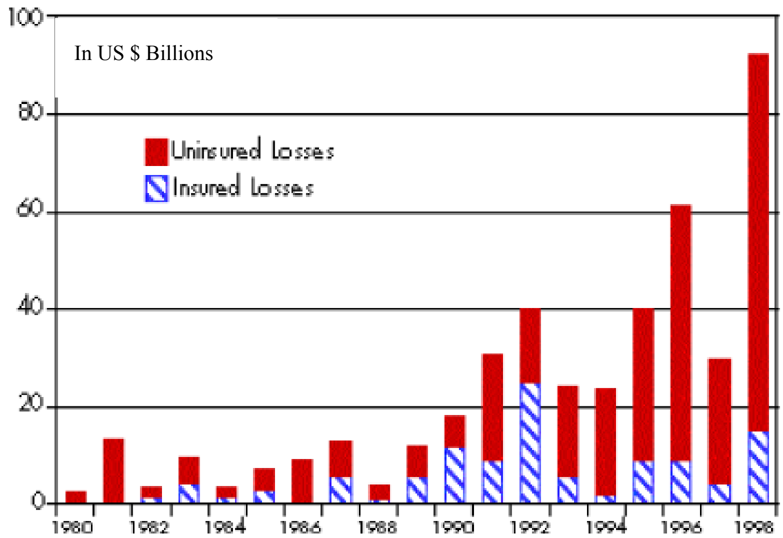

Figure 2: Losses from weather related disasters in the world (Source: [18])

As stated by Raksakulthai [18] insurance companies paid US $91.8 billion in losses from weather-related natural disasters around the world in the 1990s. This was a significant increase from the previous decade. This report further states that, "as developing nations attempt to build infrastructure and a tourism industry, some may find insurance rates prohibitive because of their vulnerability to extreme weather events" [18: 25]. Many insurers have already raised the premium rates for islands like Jamaica following the destructive hurricane Hugo of the late 1980s, while others have completely withdrawn property insurance". To a large extent, this phenomenon also applies to SMEs in developed countries. For instance, in the UK, Overall buildings insurance increased by 3% to cover estimated £3 billion flood damage in June and July 2007 and the Association of British Insurers (ABI) in the UK have stressed that £800 million per year additional funding pledged by the UK Government is insufficient and they may conduct a review of providing buildings insurance in the light of these heavy losses [19]. This might result in either significant increases in insurance premium or complete withdrawal of buildings insurance cover for areas subjected to extreme flooding. This was proven within the context of the Caribbean Islands in the 1980's when they suffered from the effect of hurricanes. This effect will further constrain SMEs in pursuing the insurance route and strengthen calls by policy makers of various other risk management planning, resilience measures and strengthening their coping mechanisms. Due to possible non-availability of insurance schemes in the future to cover business premises in areas of severe flood risk, several opportunities may arise where we can apply case studies and good practices from developing countries in the area of disaster risk management (in developing countries some of the insurance schemes found in developed countries are not available). In contrast to non-availability of insurance schemes, in the recent past, certain countries have witnessed the introduction of new insurance schemes in areas which are prone to various extreme weather events. For instance, according to Raksakulthai [18], the skiing industry is so vulnerable to climatic changes that some resorts protect themselves from decreased snow cover by purchasing 'snow insurance'. This indicates that some companies are developing or expanding coverage for loss of business due to various weather-related events, which are likely to increase around the world. For the insurance industry, therefore, new opportunities might arise for new products to be introduced.

According to Schneider [20] DRM has often been viewed as a reactive measure because activities such as risk reduction and hazard mitigation are rarely seen as urgent. To reduce risks, Bosher et al [4] suggests various forms of mitigation measures. Some of the non-structural measures address the development of coping mechanisms and consist of various behavioural changes that the companies can make in either avoiding or reducing the impact of risk in facing up to extreme weather events. Within the hotel sector, Raksakulthai [18] lists out various indigenous strategies that large resort hotels adopt such as when the meteorological department predicts high winds making swimming for children dangerous, alternative activities are planned at the man-made lakes located within their resorts. However, small businesses (small hoteliers) do not have adequate resources to adopt the requisite behavioural changes due to unfavourable weather conditions. They face financial, manpower and other resource constraints. For instance, guides working for small hotels who takes tourists on diving excursions or trips to nearby islands such as 'Phi Phi' also receives the weather report each day (like large hotels). When rain is forecasted (or when it starts raining), the guides have no choice but to cancel the trip as they are unable to organize any alternative trips due to constraints in funding.

Jackson [21] studied various stakeholders in the tourism sector, in Caribbean Islands and found that their level of concern about the vulnerability of building in coastal areas despite the damages and economic setbacks caused by hurricanes in recent years was very low. Part of the challenge therefore was to convince the various stakeholder groups who believed that there are no viable alternatives to beach tourism of the risks involved in pursuing existing land use polices without adjustments. Large hotel owners (resorts) on the other hand who construct their premises using multi storied buildings, have a number of advantages such as small building foot prints to guestroom floor space ratio that reduced the number of guest units that are vulnerable to storm surge related flooding. But it was found that the SME hotel owners built their hotels with a larger footprint within the coastal areas, thus increasing their vulnerability to the effects of extreme weather. The degree both SMEs and large companies are affected due to extreme weather and the emphasis on risk management can be assessed through various impact assessment tools. As part of disaster risk management, UKCIP [3] proposes a holistic impacts assessment tool for organizations to assess the potential impacts of various EWEs on their business. This tool emphasizes that the scope of risk assessment should not be limited to one particular company and it should be broadened to cover other SMEs that are involved in the supply chain. For instance, it recommends several focus areas for risk assessment such as understanding the vulnerability of the supply chain companies to EWEs, which is important as any delays on scheduled deliveries, power outages and the effect to the transport infrastructure can cause severe problems to another company's operations although it is not directly affected by an EWE.

Aside from some of the above risk assessment tools recommended for businesses, DRM strategies are usually prepared for communities at large and are often conducted by International Non-Governmental Organisations and various agencies in developing countries (Shook, [22]) and local councils and Government policy makers in developed countries. In addition, large multinational companies which have access to financial and other resources conduct their own DRM plans. Sometimes, DRM becomes a mandatory process that large companies have to undertake due to the potential hazard that could be created to the society at large. For example, severe flooding in the area of Surrey in the UK could have caused the recent spread of the "foot and mouth disease" in the area. Investigations into the cause of the epidemic revealed that appropriate measures were not put in place within an animal health laboratory in the area [23]. This is indicative of the inadequate DRM conducted by the private laboratory, mainly against the effect of severe flooding due to the perceived remoteness of such an effect. DRM, therefore is relatively common at the level of the communities and large companies, but SMEs usually do not consider DRM activities as a priority area within their businesses due to the perceived misalignment between the opportunity costs of DRM and potential future profitability of their businesses. As pointed out earlier, SMEs are not usually receptive to Government policy making. Governments, SME associations, supply chain companies should therefore work with the SMEs to facilitate behavioural changes so that SMEs could develop their coping measures and decision making skills. One approach that might benefit is known as adopting of participatory approaches. Adopting participatory approaches could ensure continuous SME engagement in DRM by understanding of existing SME coping strategies and their adaptive capacities and changing their behaviours by building up their resilience in facing up to EWEs.

The objective of adopting participatory approaches is to facilitate a process of knowledge transfer between the Government policy makers, SME associations, supply chain associates and the targeted SMEs. The key challenge of good practice knowledge transfer is how easily it is absorbed by the transferee. This depends on the absorptive capacity (Cohen and Leventhal, [24]) of the recipient and the appropriateness of the new context to receive the new knowledge. According to Lillrank [25] the transfer process involves three variables. They are; the level of abstraction used in the process, the approach of actors involved in the process and the type of managerial content transferred. Further, Goh [26] citing Zulzanski [27] focuses on transferee characteristics and points out that a recipient's lack of motivation, absorptive capacity and retentive capacity can result in poor transfer of knowledge. Therefore a participatory approach should aim at achieving the above outcomes for SMEs to successfully develop their adaptive capacities.

2.3 Participatory approaches for effective engagement of SMEs and synthesis

The objective of participatory approaches is to gain some of the subtle dynamics of the SME community that is affected due to the EWEs and gaining a thorough knowledge on how their coping skills, BCP measures and their decision making aspects are influenced. This knowledge is gained through a continuous process of engagement between the various elements of the SME network. The continuous process of engagement through adopting of participatory approaches ensures the fulfilment of the three variables cited by [25]. Any disconnection between these elements would result in possible failure of the SME engagement process. A significant part of this knowledge is not available in explicit fashion (as documents). This knowledge exists mainly as tacit knowledge and is embedded and grounded within the SMEs and their actions. (both individual as well as within networks). For example Empson [28] refers to explicit knowledge as the 'tip of the iceberg', because a substantial part of the knowledge is tacit and hidden below the surface. Practical action [29] suggests various tools for participatory assessments as good practice information. Some of the participatory tools are observation, semi-structured interviews, drama, role play, diagrams and visual tools, mapping, modelling of various scenarios. (for a full list of participatory tools – see [29]). The Practical action infopack is tailor-made for individual households and has a community emphasis. We attempt to customise some of these tools to cater for SME engagement. Moving from community to encapsulate companies, is a major step forward considering the change in the unit of analysis.

Several other participatory tools exist in practice. One of the techniques that can be combined with SME engagement in coping with EWEs is to visually model various EWE scenarios to understand SME behaviour, their adaptive capacity, coping skills and the overall resilience. First, this technique can be utilised to present SMEs with different scenarios utilising a very user friendly interface and then it can also be used to capture the different perspectives of the SMEs.

According to Doduras and James [30] fuzzy modelling techniques can also encourage participation and improve communication between different SME groups. Soft systems modeling technique can be used to build up these EWE scenarios. Soft systems modelling utilises the rich picture diagram technique. Sutrisna and Barrett [31] adopted the rich picture diagram (RPD) technique to map a construction process. The rationale for the RPD here was to "acknowledge the complexity and specific characteristics of each construction project in trying to congregate evidences to tell the storyline of the construction project being studied" [31]. Within the context of SME engagement in facing up to EWEs, RPD can be utilised both to transfer the knowledge relating to various EWEs to the SMEs as well as to understand SME coping mechanisms and their decision making processes. Therefore RPD can be used both as a data gathering as well as a data analysis tool.

Further, Brown-Gaddis et al, [32] adopted computer based participatory modeling technique to engage various stakeholders. This has become an important means by which stakeholders are engaged in the scientific process. There are many stages in the modeling process in which stakeholders can engage including model development, data collection, model assumptions, scenario development, interpretation of results, and development of policy alternatives based on model results [32].

The above discussion indicates that simply raising awareness of the problems with the SMEs will not result in behavioural changes. Although large companies will be to a certain extent be receptive to various Government policy making and regulations towards DRMs and improving their adaptive capacities, SMEs perceive such strategies as too remotely connected and misaligned with their business objectives. Therefore, a possible way of making effective changes to SME work practices and behaviour, might be to effectively engage them through a formalized way that is sympathetic to their specific working conditions and needs. Through the literature review and synthesis the paper then sets out the broad research problem so that SMEs are informed of ways and means of improving their adaptive capacity and coping strategies in facing up to extreme weather events.

3. Problem identification and research focus

SMEs as a group constitute an important element in a country's economy. Due to the lack of access to financial resources and capital, they are unable to survive against volatility of markets and adverse economic conditions. Therefore as EWEs can create devastating effects on the economy of a country, they can exert undesirable consequences against the survival of SMEs. Although this effect is well documented in literature (Canadian Chamber of Commerce, [16]; UKCIP, [3]), very few studies have examined the existing coping strategies, adaptive capacities and the SMEs' overall resilience in response to the effect of EWEs. Also it is important to further extend the study to include sector based comparison of how SMEs cope with EWEs. For example, how different would a SME type firm of solicitors and a SME type construction company react to an EWE? The non existence of such studies pertaining to SMEs has also been pointed out by Runyan [11] who studied the area of crisis management.

Policy makers and theorists in the field have proposed various models and frameworks to improve the adaptive capacities of SMEs by concentrating on identification of risks and opportunities coupled with strategy development and implementation. However, the effectiveness of these models and frameworks in practice and how the SMEs' individual and collective attitudes influence their activities have not received adequate attention. This research focuses on this broad area of understanding the SME decision making processes, their coping strategies and their adaptive capacities in facing up to various extreme weather events. The research also tests and validates various solutions that will enhance the overall resilience of SMEs against EWEs.

4. Methodology

The research considers a broad array of approaches to investigate, the current scoping mechanisms and adaptive capacities of SMEs and finding solutions. Engaging SMEs via participatory approaches is the overall guiding methodology for this research. As a first step, a UK wide cross-sectoral survey will be conducted to identify the current coping mechanisms and adaptive capacities of SMEs. The preparation of the survey instruments will be informed by a an extended review of literature, gathering existing weather generator data and assembling of documented cases of SMEs and policymaking related to EWEs from other countries. The initial survey sample will include SMEs (in excess of 500) from areas having a very high risk and a low risk of various extreme weather events such as flooding. Then participatory action research is conducted with a target sample of fewer SMEs (about 50) focusing on the coping measures and solutions. The solutions will also be disseminated towards a wider body of SMEs through various networks and supply chain partners. A re-survey is then undertaken of the same initial sample of SMEs to identify any improvements achieved during the course of the research. This methodology integrates with other methodologies of this research and runs parallel with other workpackages of the programme investigating into how various stakeholder groups such as SMEs, individual households and Government policy makers cope with extreme weather events.

5. Conclusions

SME sector is renowned for suffering the most in times of crises such as extreme weather events and prepared the least for such events. The paper provides a literature review and a synthesis on generating various methodologies, frameworks and models for improving adaptive capacities and enhancing coping measures of SMEs. The paper draws upon experiences of other countries in dealing with SME engagement and argues that this continuous process of engaging SMEs will develop their adaptive capacities and enhance their coping measures in facing up to the risk of extreme weather events. It proposes a high level abstraction of the core principles of SME engagement through various participatory techniques associated with appropriate capacity and capability building techniques that will enable the various stakeholders such as SME networks, supply chain partners and policy makers to create a new application to suit the appropriate context of the transferee SMEs.

This research is currently at a very early stage in the developmental life cycle. The key emphasis at this stage is to gather information pertaining to similar initiatives from other countries. The paper through a literature review and synthesis sets out some of the guiding principles and the overall methodology to conduct the research programme. The problem identification and the methodology will enable the various stakeholders of this project to delve into some of the finer details of the research agenda, which will further inform the development of key milestones and tasks.

Children as Actors in Disaster Management: Insights from a South Asia Regional Research Study

Bala Raju Nikku
Head of Academics, Department of Social Work, Kadambari Memorial College of Science and Management, Purbanchal University, Nepal
(email: nikku21@yahoo.com)

Abstract

Disasters around the world disrupted the lives of millions of people, especially children pushing many of them in to prostitution, armed conflict, drug trafficking and other dangerous occupations leading to violation of their rights. At the same time, approaches to disaster management continue to be largely technology centered, top down and isolated from human development processes. This paper is focused on disasters that took place during 2004-2005 in South Asia region. The paper is divided in to four sections. First section discusses various approaches to disaster management. The second section discusses whether and how Children's needs and rights have been addressed by the duty bearers during various disasters in the selected countries. Section three briefly discusses various policies and legal frameworks related to disaster management. The paper concluded in the fourth section. The paper is based on a larger regional study conducted during 2005-2006 supported by Save the Children Sweden Regional office situated in Nepal.

Key words: Child Rights, Disaster Management, Legislation, Policy, South Asia

1. Background

1.1 Approaches to Disaster Management

Historically, approaches to disaster management were *technology-centred, top-down* and isolated from the development process. They relied heavily on outside 'experts'. However, over the past two decades, increasing emphasis has been placed on, on the one hand, *community-based approaches,* and on the other, pre-emptive approaches that focus on the root causes of vulnerability rather than isolated disaster events (Blaikie et al., 1994). Particular stress has been put on local capacity-building (Alexander, 1997; Benson et al, 2001; Christie and Hanlon, 2000; Rocha and Christoplos, 2001) as a means of increasing resilience to natural hazard events, preventing disaster and adapting to environmental and climatic change (Allen 2005:83 cited in Asian Disaster Management News 1997).

The growing evidence that the top down approaches to disaster management resulted in inequitable, unsustainable and inappropriate results. There is a paradigm shift – humanitarian agencies moving away the traditional relief and response focus disaster preparedness to a developmental approach incorporating hazard mitigation and vulnerability reduction in their strategies [[1]] . However, in the recent decades new approaches to disaster management have been evolved.

Many development practitioners now support *Community Based Disaster Management* (CBDM) approach. This approach has been discussed, debated and adopted in the World Conference on Natural Disaster Reduction held in 1994 at Yokohama, Japan.

Community Managed Disaster Risk Reduction (CMDRR) is another approach that seeks to bridge the gap between disaster and development. It refers to a process of reducing disaster risks in which communities actively engage in identifying, analysing, addressing, monitoring and evaluating their disaster risks to reduce their vulnerabilities and to enhance their capacities to overcome a disaster situation [2]. Community Managed Disaster Risk Reduction paradigm warrants facilitation from the development practitioners. However, currently there is a significant capacity gap that constrains the application of CMDRR in practice.[3]

Right based humanitarian approaches to Disaster Management are based on the belief that the humanitarian imperative comes first and that people affected by conflict and calamity have right to protection and assistance[4]. They seek to alleviate human suffering without offending the affected people's dignity or undermining the local capacities. Generally, they apply a *rescue-relief-rehabilitation* model of interventions. In practice, excepting in few cases, they fail to pay attention to children's particular needs, women's personal hygiene and care of people with special needs[5]. The findings of several studies suggest 'disaster interventions rarely consider children holistically as the UNCRC indicates they should'[6].

Furthermore, every new disaster brings renewed demands for a swifter response. However, the danger is that such requests strengthen and centralise the power and authority of the technical and sectoral agencies, which in turn strengthen fast-moving, non-participatory practices that undermine the ability of communities to respond. Studies on children, women and minorities in disaster shed light on the role of class, race, gender and age in different societies. There is a serious need to find a place for children and youths on the disaster research agenda.

1.2 Children Rights and Natural Disasters

The history of Children Rights movement dates back to 17th century in countries like USA, contrary to a number of writings. For example 'The Bodies of Liberties (1640)' established first code in the world to offer legal protection to the children. On the one hand, the children under this law could be 'putt to death' for insubordination against their parents [7] .n the other hand, under this law, children could voice to the state authorities whether or not they were subjected to abuse by their parents (cited from Jones 1992). Against this back of legal histories, the Children's

Rights movement comes of age when the United Nations Convention on the Rights of the Child (UNCRC) ratified by as many as 192 state parties in 1989[8]. The declaration of UNCRC is truly a milestone in the history of evolution of Children Rights movement across the globe. The convention[9] draws attention to four sets of rights namely: the right to survival; the right to protection; the right to participation; and the right to development.

The (UNCRC) sets principal standards for the well-being and development of children. It is based on the premise of the child as a subject and bearer of his/her own rights. The Convention provides a comprehensive framework for action on and by children. It is the first human rights treaty combining civil, cultural, economic, political and social rights of children, overcoming ideological debates on "who goes first". A child rights-based approach challenges the existing societal role models and perceptions of the child detrimental to its well-being and development and promotes a new culture of respect towards young people.

> *"A century that began with children having virtually no rights is ending with children having the most powerful legal instrument that not only recognizes but protects their human rights."*
>
> – **Carol Bellamy**, UNICEF Executive Director

In addition to the conventions and laws, various academic disciplines like Psychology and Social Work have been influencing the Children Right's movement in different countries. Today we can conclude that children are better off as a result of years of child advocacy, yet there are areas like disasters in which children are largely treated as passive beneficiaries. An estimated 77 million children under 15, on average, had their lives severely disrupted by a natural disaster or an armed conflict, each year, between 1991 and 2000. Millions of children were made homeless, lost loved ones, received injuries, witnessed or experienced violence and suffered scarring psychological traumas.

Anderson (2005) argues that 'significant progress has been made in the social science disaster research held since its inception several decades ago. Despite the advances in knowledge, important areas of research have been seriously understudied, including the impact of hazards and disasters on children and youths' (p.159). Anderson highlights that the knowledge base on children and disasters is so thin that studies related to children in this context are needed across the entire mitigation, preparedness, and response and recovery spectrum[10].

Drabek's systematic survey of disaster research findings mainly refers to children in a mental health context reflecting a dearth of information on the topic of children and disaster[11]. Thus there is a serious need to find a place for children and youths on the disaster research agenda and to advance knowledge about this segment of the population. Such knowledge would provide a more complete understanding of the impact of hazards and disasters on society across the board and result in a firmer basis for policy and practice[12].

In the following section, I present the field evidence on whether and how children's rights have been addressed by the duty bearers during disaster relief and rehabilitation? How have child rights concepts been incorporated in the program designs? Are systems and polices inclusive of children rights in disaster management?

2. Insights from Country Case Studies

2.1 Research coverage and Method

The research focused on and was restricted to earthquakes in Pakistan and India in 2005 and Kuchch (India) in 2001, Tsunami 2004 (India and Sri Lanka), and floods of 2004 in *Tarai* Nepal. A desk research was conducted to collect the secondary information on the subject matter. A large amount of web based literature was collected and analysed. A brief policy literature was conducted in order to strengthen the analysis. Further, to supplement the secondary information using an exploratory and descriptive research design, primary data was collected by administering a questionnaire. Key Informant interviews were conducted with policy makers, bureaucrats and NGO and media representatives. Focus Group Discussions were carried out with children and members of Child Clubs involved and affected by disasters. Some case studies were collected to provide the evidence of the situation and interventions as best practices and learning for the future.

2.2 Child Rights and Floods: Nepal Tarai

Nepal Terai region is prone to flood, due to accelerated deforestation and the construction of dams on the rivers on the Indian side. As such, today a large number of people are exposed to seasonal floods.[13]

The floods and landslides in 2004 have affected the lives of approximately 360,243 persons of 62,357 families in 25 districts of the Nepal.[14] The most affected districts were concentrated in Terai region and few in mid hills.[15]

The government approach/activities were focused only on disaster relief and often directed by the Chief District Officer (CDO), who heads District Administration Office. The District administration follow the *Natural Disaster (Relief) Act (NDRA), 1982* to implement the disaster related activities.[16] The Act has provisions for formation of the disaster relief committees at the central, district and local levels. At the district level, a District Natural Disaster Relief Committee functions under the Chairmanship of the CDO and the Local Development Officer as its member secretary. The committee is responsible for policymaking and implementation of disaster activities. It was evident from the field material and from the discussions with the district level bureaucrats that the Act does not mention about children and their rights and hence there was no special focus on children while delivering the government relief activities.

We conclude that the central approach of the government related to flood/disaster management remained or restricted to using the army and police for emergency operations and sending packages of relief material along with the rescue teams. After the situation has been normalized, there were no clear follow-up actions. There at least six government departments that are involved in disaster related activities. None of them have a child centric plans and coordination among them is often missing.[17]

From the field evidence, it has become evident that due to the lack of co-operation and coordination among the government departments and other agencies involved in Tarai flood disaster management in 2004, most of the disaster victims/families did not received the necessary help in time. In cases of delayed relief assistance and co ordination, the children and elder citizens were the most affected.

In contrast to the government approach, some Non-Governmental and Relief organizations like Nepal Red Cross Society, Dhanusha Branch mentioned that their Junior Red Cross Circle members not only received relief benefits but also participated in data collection, distribution of food and other materials. The organization staff consulted children to decide the actual victims (and to avoid political influences) from flood affected villages. Partner NGOs of Save the Children (like ASMAN Nepal) have implemented child related projects with a focus on Child Rights of varying degrees and understanding.

Some NGO leaders (for example Dr. Ajaya Kant from RCDSC, Mahottari district) claimed that though they did not implement their relief activities from a child point of view but family as a unit. The NGO staff claimed that helping a family means reaching not only adult men, women but also children and old age members.

We came across few other NGOs that implemented the relief activities as designed by their donors. In this case, the NGOs rather acted as delivery agents by signing contracts with their respective donors. However, the NGO leaders expressed that though they did not want to function like a contractors, ultimately they want to help communities in some ways.

In addition to the above observations, we found that the NGOs activities were mainly focused on school going children, leaving a large section of non-school going children in the villages. In many cases the NGO activities were also time bound and funding based. Few local NGOs did implemented some activities during the floods that were child focused, but overall understanding or implementing the activities from a child rights perspectives was missing. There was no evidence that the implementing NGOs have had a long term plan and understanding on children rights.

Focus Group Discussion with *Bal Committee* (Child Committee) members at Shree Rashtriys Prayhamik Vidhyalaya Dholbaja, Kiratpur and other students[18] suggest that children were involved in the process of finding out other children and families who were severely affected and needed a support. According to the students the flood level was above their neck levels. Some of them were protected by Nepal Army. Some of them lost their house and stayed for about a month in the relief camp located in the same school. Some of them mentioned that they received cloths and school bag with books and other materials.

From the evidence, I conclude that the children affected by the floods were neither consulted nor represented in the program plans of implementing agencies. The survival needs of children only received some attention. Disaster management policies in Nepal are still based on the emergency-relief- rescue approach.

2.3 Child Rights and Earth Quakes Disasters: Pakistan and India

On January 26, 2001 a massive earthquake with 6.9 on the Ritchter Scale struck western state of Gujarat, India at 08:46 a.m local time. The tremors were felt in Delhi, Bombay and neighboring Pakistan. The epicenter of the quake was 20 km north-east of the town of Bhuj, the district headquarters of Gujarat's Kuchchh district[19] while, at the same time, seriously affecting all the area within the range 100 km from the epicenter.[20] The result was catastrophic total 7906 villages from 182 blocks from 21 districts were affected taking death toll of 20,005. About 166,000 people were reportedly injured out of which 20,000 were seriously injured[21]-[22].

On 8th October 2005 another powerful earthquake (also known as South Asia earthquake) occurred at 08:50:38 Pakistan Standard Time (09:20:38 Indian Standard Time) stuck (7.6 on the Richter scale) causing widespread damage in Pakistan, India and Afghanistan. Over 70,000 were killed (about 17,000 students were killed when their schools collapsed) with as many injured and approximately 3 million were rendered homeless. More than 50 percent of the homeless were children[23]-[24].

In both the country cases response came from various sources. In addition to governmental efforts many international organisations especially focusing on children and local NGOs were involved in rescue, relief and rehabilitation activities. Presence of International Save the Children Alliance, Red Cross and other organisations were visible in both the cases.

In the case of Gujarat Earth Quake (2001) *Child based emergency response* programs were implemented. Save the Children and *Kutch Nav Nirman Abhiyan* (Abhiyan), a network of NGOs jointly implemented Semi Permanent Shelter (SPS) programme. The objective of the programme was to help substantial number of families through selected group of NGOs, to build interim shelters while they continue to rebuild their lives and homes and thus enable them to protect themselves and their children against severe weather conditions before the onset of monsoon in the Western part of India. The SPS programme was conceived as an alternative to both, temporary and permanent shelter programmes.[25]

Child to Child (CtC) groups have been formed by NGOs. Each child group has a support of teacher and is comprised of boys and girls in about the same proportion as their school enrolment rates. With support from Save the Children and the NGOs, these groups have developed an identity, momentum and an agenda of their own and have been able to undertake several difficult tasks such as the cancellation of a transfer order of their school teacher (Fathegarh village). Exposure visits to Ahmedabad and other NGOs working with children have had a significant impact on CtC members as many of them had never travelled outside their Taluka in their lives. Socially relevant activities such as abolition of chewing tobacco (*gutka)* – a known cause of cancer in India, improved solid waste management in the villages etc. have been initiated by the children.

A Child Help Line was established and the telephone based service was supplemented by a set of trained volunteers from partner agencies who established contact with vulnerable children – orphans, children of single parent, physically and mentally disabled children and established their linkage with other agencies that could provide the necessary support.

Like the Bhuj Earthquake, the Earthquake disaster of 2005 in Pakistan, also focused on bringing normalcy back into children's lives affected by the earthquake and to mobilize families and e community support to help children.

The other focus areas have been reconstruction and restarting of government schools, reconstruction of integrated child development service (ICDS) centres, establishing Adolescent Girls Drop-in Centres, creating Safe Play Areas, formation of Cricket Clubs, capacitating the teachers and ICDS workers on Child Rights and child protection issues. The evidence suggests that children can play an active role in disaster management. It was clear that the local communities if mobilised are the best judges of protection needs of children and vulnerable families.

2.4 Child Rights and Tsunami : India and Sri Lanka

A massive underwater earthquake with M 9 struck Indian Ocean near Sumatra at 06:28:53 a.m. IST on December 26, 2004, and triggered a series of lethal tsunamis that spread throughout the Indian Ocean, killing large number of people and devastating coastal communities in Indonesia, Sri Lanka, India, Thailand, and Maldives. The result was catastrophic with 186,983 people dead and 42,883 missing, 125,000 injured and almost 1.68 million displaced. More than 500,000 houses were totally or partially damaged. Road and railway networks were torn apart in large parts of Indonesia, Sri Lanka, Maldives, and in some parts of India (Andaman Islands). The direct damage caused by this earthquake was more than $7 billion.

In India, the State government provided immediate relief support very quickly. The government's supports were mainly focusing to food and non-food items, clearing of debris, setting up temporary shelters and providing assistance to the families who lost their family members. International Non Governmental Organisations (INGOs) also did provide support to meet the gap. The focus of the INGOs relief support (for example of Save the Children) was to meet the survival, development and protection needs and requirements of children along with their family members. It supported with foods including high energy foods for infant, pregnant and lactating mothers, cooking utensils, clothes for women, men and children, sleeping mats, medical and hygiene kits, notebooks and pencils, toys and other play materials and play areas.

In Sri Lanka, the government and NGOs have been involved in relief, rehabilitation and preparedness program for the Tsunami affected population. Since some of the regions have been severely affected by the Government-LTTE war, many organizations have also been involved in relief and rehabilitation programs. Further, few organizations have already integrated the issues related to child rights and child protection in their long term development plans. The field material suggests that, rescue, relief and rehabilitation are the major approaches taken to respond to the Tsunami affected communities in the country. But in the later period, many of the organizations have also paid attention to the disaster preparedness and disaster risk reduction. Organizations (such as SCiSL, World Vision Sri Lanka) have also integrated a long term plan on disaster preparedness and disaster risk reduction (DRR) especially focusing to community based awareness raising and preparedness as well as influencing at policy level.

Sri Lanka banned adoption of child orphaned by Tsunami, which is a firm step to protect children from sexual exploitation and trafficking. There is a separate department of rehabilitation, relief and disaster management formed recently. The staffs in the department are yet to be equipped well with knowledge and skills on child rights and child participation.

3. Disaster Policies and Legislation

In Nepal before 1981, there were no organized relief and rehabilitation activities for victims of natural disasters. The relief activities were based on social welfare activities of local institution and individuals. It was in 1982 that Natural Disaster Relief Act of 1982 has been enforced and amended in 1992. According to this Act, Home Ministry and Department for Disaster Management are responsible for relief activities, where as Ministry for Physical Planning and Housing is responsible to implement a long term solution for the displaced. Central, regional, district and local relief committees are formed to channelise the implementation of relief activities. National Disaster Relief Regulations (NDRR) could not yet be formulated which is very essential, due to which the Act could not be fully effective. Ironically the Local Governance Act is silent on natural disaster management and relief. It has created vacuum on effective implementation of relief activities at local level.

In Sri Lanka *the National Disaster Management Act No.13 of 2005 is* formulated and passed by the Parliament of Sri Lanka in May 2005. *The* Disaster Management Council is a statutory institution responsible for policy formulation and the Disaster Management Centre (DMC) is responsible for implementation. The Ministry of Rehabilitation, Reconstruction and Refugees is the nodal ministry to address issues relating to the conflict in North and East regions in the country.

Under the Indian Constitution, disaster management is the responsibility of state governments. For example, the Gujarat Disaster Management Act 2003 provides scope for capacity building of groups in local communities to cope with any disaster. At the national level, there is a National Crisis Management group headed by the cabinet secretary to assess the impact of major disasters. The group consists of various nodal ministries. In India, the new approach adopted by the government translated in to a National Disaster Framework covering institutional mechanisms, disaster prevention strategy, early warning system, disaster mitigation, preparedness and response and human resource development. For example, disaster management as a subject in social sciences has been introduced in the school curriculum for class 8th and 9th in schools run under CBSE system. The state governments have been advised to take similar steps vis-à-vis their school boards.

A brief analysis of legal frameworks and policies in the South Asian countries suggest that there are policy gaps in the implementation. The disaster policies are mostly relief centered. As more then one government agency is responsible for disaster management, evolution of better co ordination strategies is essential. None of the legal frame works recognized children as the actors and provided scope for their participation and consultation in decision-making.

4. Conclusions

Research on Children in disasters is relatively young and needs much more attention from all the quarters. Researchers and Social Workers should give the subject the attention it deserves, so that much can be learned about the outcomes of these disasters for children and how children can be actors in the management of the disasters rather as passive beneficiaries.

Children are the most photographed but least consulted, while making disaster management polices and programs. The rescue- relief-rehabilitation model of interventions resulted in treating children as passive beneficiaries and not as actors. These models fail to pay attention to the special needs and rights of the children.

Policies related to natural disaster preparedness, relief and response are adult focus and there is much less consideration of children's needs and rights. Hence, children who are most vulnerable in disasters are always left behind and suffer a lot. Hence, such polices and guidelines need to be child focus and sensitive. The specific survival, development and protection needs of children need to be addressed in emergency response, rehabilitation and preparedness.

Children rights perspectives were often talked about but seldom implemented. However, in some cases (the Save the Children work in Pakistan Earthquake for example) there is evidence of children participation ensuring their right to participate in decision making.

There is acute need of consideration of children's participation in rescue, relief and rehabilitation and preparedness phases of disaster including situation assessment and decision making. Evidence from the field has shown that children's participation is possible in all stages and has enriched the quality of response and support and enhanced the ownership and sustainability of the program.

The paper concludes that there is an urgent need for increased focus on the child centred preparedness and risk reduction policies and co ordination between the governments, donors and NGO in the region.

[25]The programme initially targeted to provide earthquake safe technology and material assistance to about 22,000 families, which eventually grew to about 24,000 families living in 253 villages of eight out of ten talukas of Kutch district. The programme was implemented by a group of 13 NGOs.

Tsunami Disaster Risk Reduction- Practical Guidelines for the Indonesian Context

Regan Potangaroa,
School of Architecture Unitec Auckland New Zealand
(email: rpotangaroa@unitec.ac.nz)

Abstract

Much of the practical advice and certainly the theoretical position of those trained in disaster management fall short of what is encountered in Indonesia. Based on the development of tsunami guidelines for Aceh this paper outlines the particular differences that make Indonesia a special case. The proximity of tsunami generation and consequent lack of warning time, a large coastal population, large areas of flat coastal land and the lack of escape options particularly for those returning to previously tsunami hit areas puts Indonesia unfortunately outside much of the experience of neighbouring countries such as Sri Lanka and India. And consequently, there is the need for specific guidance for the Indonesian context.

This paper documents the basis for the tsunami disaster risk reduction measures that were developed to provide some rational grounding on which to plan an evacuation from village rebuilding projects located back in tsunami affected areas of Aceh.

The paper addresses issues of escape times, safe havens, widths of escape paths and most importantly the decision between a horizontal or vertical evacuation. The development of the guidelines utilized video footage from the tsunami disaster, fire evacuation data, surveys from survivors, risk theory and "common sense" to arrive at its final recommendations. Unfortunately, those recommendations, given that people were opting to return to at risk areas, expose the harsh reality of the decisions that the community would need to make.

Keywords: Disaster risk reduction, tsunami, guidelines, planning

1. Background

1.1 Methodology

There is a lack of design guidance on exactly how one physically builds disaster risk reduction into communities. And this was the situation that faced many NGO's in terms of developing meaning village plans as required by BRR in Aceh , Indonesia as part of their post disaster reconstruction work following the Asian Tsunami of 2004 [1]. In response, engineers, architects and planners on the ground developed their own rational approaches for this design one of which is now outlined in this paper. The standard approach consisted of marking exit routes on to a masterplan of the village under study that would have been sufficient given adequate warning. However, the Indonesian reality of between 10-20 minutes of warning time meant that exit (or evacuation) distances were in reality severely limited and consequently design teams had to determine a suitable design approach. And hence the topic of this paper.

This approach was developed based on the following 4 pieces of research:

1. A tsunami report by Wilkinson [2]
2. Interviews of survivors of the tsunami
3. A desktop review of past lessons learnt based around work by the US Geographical Service [3]
4. The development of practical guidelines based on speeds of people observed in fire situations and video footage of the actual disaster.

And in particular, the work by Wilkinson.

1.2 The Wilkinson Report

Wilkinson studied the tsunami context in Aceh and confirmed that for "..for areas close to the fault zone such as west Aceh, it is unlikely that the planned Indian Ocean tsunami warning system can respond quickly enough to save lives. From the end of the earthquake, it was only 5 minutes before the first indication (the withdrawal of the water from the shore) of the tsunami was observed at Calang. This time was insufficient and 90% of the population died. This highlights how little time is available for warnings to be given to areas that are closest to the epicentre."[4]. He goes on to recommend that "…The planning….must assume virtually no warning of any future tsunami and plans should be based on reacting immediately to large earthquakes. Access to safe refuges should take no longer than 10 minutes to reach safely. Many survivors stated that it was not possible to move far during the earthquake and that they could only run after the earthquake finished. In Calang there was only 10 minutes between the earthquake stopping and the first wave arriving. It should be noted that what happened at Calang could happen to any point along the West Sumatran coast that is close to an earthquake epicentre." And straight away it is evident that the tsunami context in Indonesia is different from that observed elsewhere. Unfortunately, this difference was not readily appreciated by Agencies on the ground.

Figure 1: Map of Aceh and its West Coast Area Studied by Wilkinson(locations of interest are underlined)

Moreover, Wilkinson went on and suggested that rather then being a rare event the Asian Tsunami was more common than appreciated "…In effect, major tsunami causing earthquakes that occur about every 200 years at different sections of the fault zone [and they] are out of phase by about 40 years. Hence, the average return period of a disastrous tsunami is of the order of 100 years but the present probability of a it occurring now is 3% per annum based on it occurring in the next 20 to 50 years. In addition, the average occurrence of smaller tsunamis (less than 5 or 6 metres) over the last 170 years is 30 years and these events will continue to occur." And more specifically "…these frequencies [are] well within the time frame for determining design forces for important buildings and should be of major importance for the design of future planning and construction. However and more importantly these frequencies are of major concern because it is within the lifetime of the people living in the area and moving back into their devastated housing sites. It must be recognised by Government that there will be a massive loss of life again if action is not taken to have people living in safe areas." He concludes that "…despite the information above it is considered at this stage that there is insufficient data to undertake a numerical analyse of these previous tsunamis to determine the wave tsunami height distribution along the Sumatra west coast. However based on the frequency of tsunamis over the last 170 years and on geotechnical advice provided to the author in Australia the best estimate of reoccurrence of a 10-metre tsunami, is of the order of a 100-years and it is not a rare one off event. This height is less that the maximum height of 13-metre at Lhoknga and along much of the coast between Banda Aceh and Calang." (Underlining added)

Thus, in summary he was stating the following:

- Early warning tsunami systems are not an option for much/most of the West coast of Sumatra with 10 minutes being the probable evacuation time after an earthquake before the arrival of a tsunami.

- The Asian Tsunami was not a rare event and that a 10 metre wave height should be the standard design tsunami with a return period of 100 years (meaning that there could be expected to be one such event every 100 years). But with a 3% chance (3 times that of the 100 year event at 1%) of it occurring in the next 20-50 years.
- Other smaller tsunami of less than 5 to 6 metres would have a return period of 30 years.

His work immediately puts the tsunami risk into context.

1.3 Interviews of Survivors

Given such a background, how did anyone survive? Earlier research work by Potangaroa had created a database of 404 eye witness accounts of survivors of the Asian Tsunami in Aceh using a questionnaire developed at the Cambridge University Centre for Risk in the Built Environment [5]. These interviews were later analysed in collaboration with Cambridge University [6] and given that there were (at least they were perceived to be at the start of this process) critical villages in the city of Banda Aceh (the Provincial capital) those respondents from Banda Aceh (91 in all) were analysed separately to find the following:

1) What was their sense of the earthquake?
2) What was their immediate response to the earthquake?
3) When were they first aware of the tsunami and what warning did they have?
4) Where did they go in response to the tsunami? And how did they go?
5) Was their first choice exit route available?

The results from this are summarised next.

1.3.1 Sense of the Earthquake?

The majority of those surveyed experienced a violent or strong earthquake. (80% of respondents indicated that it was a violent while 19% indicated that they felt a strong earthquake with the remaining 1% being a fisherman at sea at the time). This is significant as it indicates that despite experiencing a violent seismic event the possibility of a resulting tsunami did not occur. Moreover, Wilkinson reports that he found one person from the last tsunami in 1941 during his review of the tsunami affected areas along the west coast of Aceh and that despite there being songs (that formed part of the local culture) about a large wave no one understood what the song meant or the potential for a tsunami. Thus, despite a history and culture associated with tsunami, the potential risk and warnings of a tsunami are unfortunately not recognised within the community.

1.3.2 Immediate Response?

Most people ran outside (74%) with only a small percentage electing to stay inside their houses or the buildings they were in (6%). The remainder of people were already outside and moved to where others were congregating (20%). Such a response (running outside) is not surprising but does underline the need to ensure exit ways out of the house are protected or structurally secured.

1.3.3 What Warning?

Most of these survivors were warned by others of the pending tsunami (51%). However, 44% had no warning and were only aware of the tsunami when it arrived. Thus, there is a need for a fundamental warning system possibly based around ground shaking intensity and community socialisation of such a system possibly through schools.

1.3.4 Where And How Did They Go?

Perhaps the most interesting information is where did people go in response to the tsunami? Most people moved on to the road (24%). The next popular choice was to be with other family members (16%), the neighbour's house (15%), a shop or café (14%) and then the mosque (11%). Interestingly, these were all horizontal evacuations and relatively smaller numbers elected for a vertical evacuation with only 7% climbing trees and 5% climbing on to roofs. Fortuitously, 5% of people managed to survive being in the water.

In terms of mode of travel 46%of people walked while only 11% were able to evacuate by private vehicle and 18% (strangely) by bus. 2% were carried out because of injuries.

1.3.5 Blocked Route?

Finally, it is also interesting that 66% of the survivors reported that their usual route was blocked. Clearly, they were able to go around or take an alternative route but plainly there is a need for substitute routes through communities and villages. Nonetheless, such routes would be under pressure given the essentially horizontal evacuation options taken earlier

Thus, in summary significant numbers had no warning of the pending tsunami, had there preferred exit routes blocked and elected to walk out once they were aware of the danger.

1.4. Lessons for Surviving a Tsunami: Desktop review.

Other countries are (like Indonesia) subjected to tsunami. And the aim of the desk review was to ascertain what survival strategies worked in other countries and what should/ could be used in Indonesia. Much of this work in other countries had been gathered by the US Geological Service. The lessons are tabulated below with the lesson learnt in italics and its relevance to Aceh reviewed.

Thus, while many of the lessons learnt in other tsunami affected countries did apply in Aceh there were several that did not. Significant among these were the ineffectiveness of any early warning system for Indonesia (raised earlier by Wilkinson) and the consequent need to evacuate vertically rather than horizontally. This need requires the identification and tsunami design of designated buildings within the immediate community as safe havens. Obvious buildings would be mosques, schools, health clinics and most public buildings.

Table 1: Lessons Learnt from Other Countries

Many Will Survive the Earthquake	*Lesson: In coastal areas, the largest subduction zone earthquake may kill fewer people than the tsunami that follows.* This was also true for Aceh with many surviving a 8.9 Richter scale earthquake but dying in the resulting tsunami.
Heed Natural Warnings	*Lesson: An earthquake may serve as a warning that a tsunami is coming, and so may a rapid fall or rise in coastal waters.* There are various natural warnings from the environment and nature of an impending tsunami. Some are well recorded while others are more folklore. The most known is the sudden recession of coastal water below usually tidal levels. But others such as falling water levels in wells and unusual animal behaviour were apparently seen in Aceh.
Heed Official Warnings	*Lesson: Play it safe, even if warnings seem ambiguous or you think the danger has passed.* No warnings were able to be issued.
Expect Many Waves	*Lesson: The next wave may be bigger, and the tsunami may last for hours.* Most people in Aceh that did see the tsunami wave saw a wave train consisting of 3 wave fronts. The first was a small wave with a larger 2nd wave not far behind. The big wave was the third wave and many observed that it was also a breaking wave. However, countries distant from the source of the tsunami usually experience more than one such wave train with the perhaps hours between the different water level peaks. This did not appear to be the case in Aceh.
Head for High Ground and Stay There	*Lesson: Move uphill or at least inland, away from the coast.* This is universal but the big difference for Aceh was the lack of time to get any warning sent out. This shortage of time means that people in the tsunami affected area could only move within a 600-900 metre radius once the earthquake shaking stopped.
Abandon Belongings	*Lesson: Save your life, not your possessions.* There are several instances where people returned to pick up possessions.
Don't Count on the Roads	*Lesson: When fleeing a tsunami caused by a nearby earthquake, you may find roads broken or blocked.* This was also experienced in Aceh as indicated earlier (66% had their exit route blocked). And video footage immediately after the earthquake but before the tsunami clearly show the extent of traffic jams even when the roads were not apparently broken or damaged.
Go to an Upper Floor or Roof of a Building	*Lesson: Only if trapped and unable to reach high ground, go to an upper story of a sturdy building or get on its roof.* This did not or could not occur in Aceh. The decision to change from a horizontal evacuation to a vertical evacuation was one of the major issues of the evacuation in Aceh, and Banda Aceh in particular..
Climb a Tree	*Lesson: As a last resort, climb up a strong tree if trapped on low ground.* This did not occur as noted earlier. This may have been due to there being predominantly coconut palms that can be only climbed by the fit.
Climb onto Something that Floats	*Lesson: If swept up by a tsunami, look for something to use as a raft.* Seemed to be anecdotal evidence of this amongst those that survived being in the tsunami water.
Expect the Waves to Leave Debris	*Lesson: A tsunami will leave behind sand, the remains of houses, and bodies.* This was certainly the case in Aceh.
Expect Earth quakes to Lower Coastal Land	*Lesson: A large earthquake can leave nearby coastal areas lowered, allowing tidal water to flood them.* This was generally true for Aceh. The port area of Banda Aceh sunk but parts of Simeulue Island were lifted.
Expect Company	*Lesson: Shelter your neighbours.* This occurred in Aceh as shown in earlier statistics.

2. The Design Details

The work so far set the basis of the design process in Aceh but the process had to assume the following:

- People individually knew where to go (the horizon and vertical evacuation plan)
- Families collectively knew where to go (if they were not at home at the time of the tsunami)
- And safe havens (either hill tops or designated buildings) besides being identified were open and accessible.

Consequently, there was also a significant community and socialisation component required to make such a plan effective.

2.1 Safe Havens

For a hill top to be suitable as a safe haven required additional height above the design height of the tsunami (the so called run up height). This will vary depending on the distance from the shoreline and Wilkinson [7] below suggests the follows design clearance heights (modelled using a flat ground profile). And it is only that area of the hill beyond and the building area above the heights given in table 2 below that can be counted as a safe haven.

Table 2: Estimated Safe Heights for Hills and Clearance Heights for Buildings

	500m inland (metres)	**1000m inland (metres)**	**2000m inland (metres)**	**3000m inland (metres)**
Safe Height for Hills	22	17	10	6
Minimum Building Height Required on Level Ground	10	9	6.5	4

2.2 Tsunami Design Loads

In addition, where a building is designated as a safe have it must be designed for the appropriate tsunami loads Again, Wilkinson [8] in table 3 below suggests water speeds from which the dynamic pressure could be calculated and added to the static water pressure for the design loading on the building. Wilkinson notes that " … In many cases, the impact wave will cause the more severe design loading condition for housing, buildings, and structures. The maximum wave, which arrives shortly after the impact wave, has lower velocities, but it is the design condition for larger buildings and structures…" An alternative design approach to that suggested by Wilkinson is given by the proposed Japanese Code [9] which suggests simply tripling the height of the inundation level and applying the resultant pressure to the building. Whichever approach is adopted, it should be noted that any debri generated by the tsunami will typically double the density of the water (and hence double the tsunami loading) but debri will also block any localised panel collapse subjecting the building to even further loading. Timber debri in particularly, should be controlled.

Table 3: Estimated Wave Heights, above Ground Level, and Velocities for a 10 metre Tsunami

Distance from Shoreline (Metres)	**Impact or Front Wave**		**Maximum Wave**	
	Wave Height (metres)	**Water Velocity (m/sec)**	**Wave Height (metres)**	**Water Velocity (m/sec)**
At shoreline	4.5	5.5	10.0	5.5
500	5.0	6.0	8.0	5.5
1000	4.5	5.5	7.0	5.0
1500	4.0	5.0	6.0	4.5
2000	3.5	4.5	5.0	4.0
2500	2.5	4.0	4.0	3.0
3000	2.0	3.0	3.0	2.5
3500	1.0	2.0	2.5	2.0

As a rough comparison, Indonesian seismic load levels are equivalent to 1.7 to 2.5 metres of static water pressure and therefore tsunami loading will be significantly larger than any seismic requirement

Therefore, based on the distance to the shore line the wave height at a particular site can be calculated from table 1 above. And the design tsunami height can then be approximated by taking off the site elevation above sea level from that wave height. This will be used later to ascertain the evacuation line for natural havens and the suitability of built safe havens.

2.3 Evacuation Distances

How fast do people evacuate following a tsunami warning disaster? There are no guidelines in the literature for tsunami and the closest comparison is with fire evacuations of buildings. Typical figures are given in table 4 below for such evacuation walking speeds [10].

These figures were verified against video footage from the tsunami and an example of that is shown in figure 2 below. It is of a dependent elderly person being assisted to a nearby roof. In 4.5 seconds they are able to move 10 to 12 metres, an average walking/running speed of 2.7 metres (compared to 0.948 for an independent elderly person).Thus, the observed evacuation speeds can be significantly higher than those suggested for fire evacuation albeit on a tar sealed road in good weather during the day. Given that such an evacuation could be in bad weather, could be at night and in the dark and/or over broken or blocked roads suggests that lower evacuation speeds should be used and the figures on the right of table 4 were selected by the shelter team as being reasonable. Therefore, the evacuation line or limit based on 1 to 1.5

metres/sec for 10 minutes is a radius of between 600 to 900 metres. Thus, any safe haven would need to be within that radius.

Table 4: Evacuation Speeds used for Fire Safety Design

Walking Condition	Design Fire Evacuation Speeds* (metres/sec)	Suggested Tsunami Evacuation Speeds** (metres/sec)
A person with a child	1.02	1.5+
An independent elder person	0.948	1.0-1.5
A dependent elderly person	-	1.0
A group of elderly people	0.751	-

*based on Fire Safety & Disaster Preparedness 1987. ** based on video during the tsunami

2.4 Bottle Necks

These evacuation distances can only be achieved where there is sufficient space for people to walk. And many in Banda Aceh and in particular Calang reported being caught in traffic jams such as the one shown in figure 3 below taken from video footage in Banda Aceh. It shows both motor bikes and vehicles locked up and unable to move.

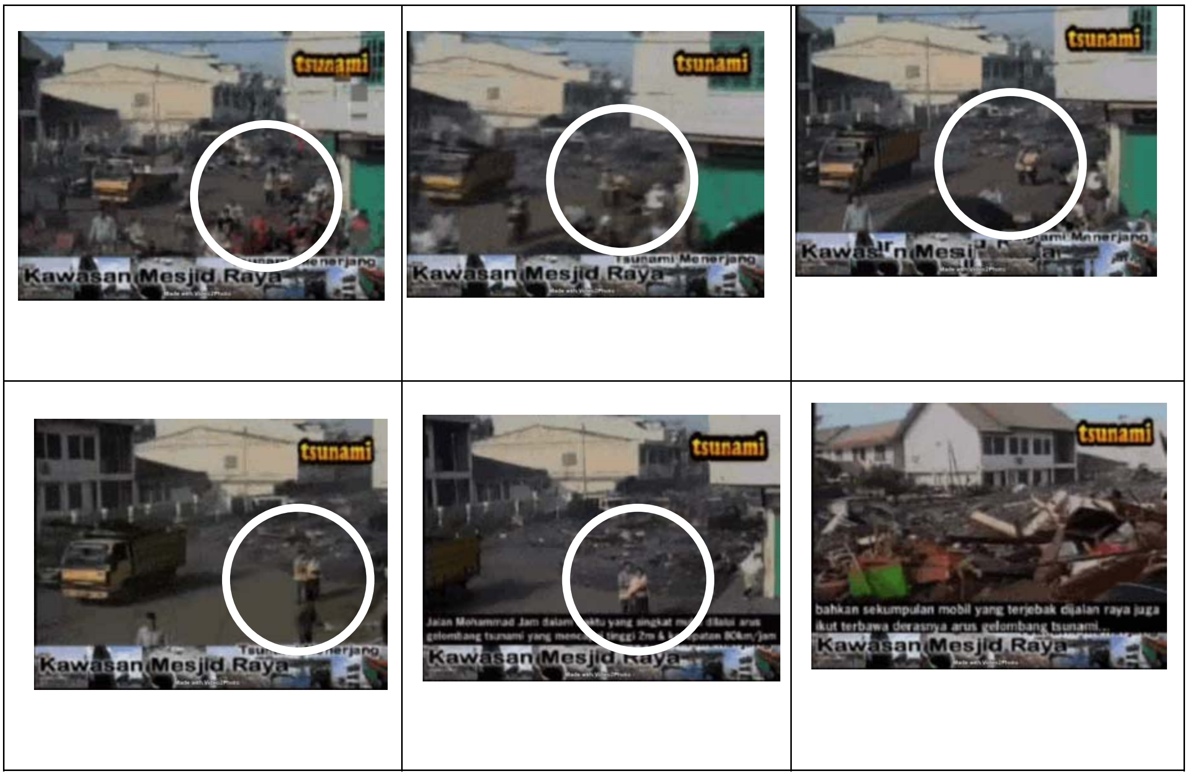

Figure 2: A dependent elderly person evacuating in the face of the tsunami

People should evacuate on foot (as the outlined in the earlier research) and not by car or motor bike. And to check that there will be sufficient walking space an arbitrary road lane of 2.5

metres was assumed with any remainder being potentially a walking lane of 800mm width. And based on the evacuation speeds each lane would have a minimal capacity of 1.5 persons/sec. For example, if the road width (drain to drain) was 6 metres then there would 2 traffic lanes of 2.5 metres = 5.0 metres and 1 metre leftover which would sufficient for one lane of foot traffic; 7 metres would be 2 traffic lanes and two walking lanes while 8 metres would be 3 traffic lanes and no walking lanes. And consequently would require alternative walking options potentially outside the side drains of the road.

2.5 The Design Process: Step by Step

Thus, the design process consisted of the following procedure:

1. Calculate the distance from the shore line and ascertain the site elevation.
2. Read off table 2 for the tsunami height and from table 3 for the safe haven height criteria.
3. Identify potential natural and building safe havens on a topographical map of the village/ community.
4. Mark on the map the area of the village/ community those areas within the evacuation limits of 600-900 metres of these safe havens.
5. Based there being 5 people per household calculate the evacuation network numbers
6. Based on say 3 people per m^2 calculate the people capacity of the haven.
7. Starting from the safe haven and working out wards check the capacity of the people lanes. Assume people can “short cut” across house sections.
8. Check the capacity of the haven to take these expected numbers of people.
9. Identify those areas of the village that do not have an evacuation option and engage community facilitators to ensure that these people are aware of the risk.
10. Concurrently, present findings and discuss overall situation with village/community.

Figure 3:Traffic Grid Lock Prior to the Tsunami.

3. Conclusion

The development of the above design process was welcomed by the design team and applied to the 17 village master plans that were being developed. While the results of all 17 could not be confirmed there were responses reported for the two villages in Banda Aceh where the above procedure was applied. These two villages had been badly destroyed by the Asian Tsunami but despite that people had elected to move back to their original sites. The process identified that they were too distant from any natural features and consequently people would have to seek refuge in buildings and adopt a vertical evacuation quickly. Suitable buildings were then located within the evacuation radius (and assuming that the buildings were able to with stand the tsunami loads) were treated as safe havens. The network analysis was completed and access ways checked. And thus, the approach seemed to be working. However, when the floor area of the safe haven was checked it became clear that there would be insufficient room and that one half of the village would potentially witness the other half being swept away by the tsunami. And quite suddenly, the realisation that someone was going to have the terrible job of shutting the door (as it were) on the other half of the village that the full gravity of the situation of the villagers was realised. The sense was that despite having developed a well grounded design procedure we had some how failed, badly, and unfortunately there was no conclusion.

Abstract

This paper will present a new methodology for the assessment and monitoring of rockfalls through an integrated multi-disciplinary approach. Current solutions include classical surveying instruments (e.g. total stations, GPS) integrated to sensors for monitoring local deformations (e.g. strain-gauges, deformometers), which are used to achieve information about a limited number of critical points of a rock slope, complemented by geological inspection and qualitative analysis. The innovation of this approach is firstly based on the use of some new sensors which allow to increase the achievable information: terrestrial remote sensors – laser scanner and ground-based interferometric SAR – would allow the measurement of deformations of whole surfaces instead of single points, ground penetrating radar the exploration of rock sub-surface, digital photogrammetry the automatic measurement of crack deformations, seismic and acoustic sensors the detection of vibrations and sounds which could be pre-signal of a rockfall. The second stage of the research involves the integration of different techniques to exploit the full achievable data. This means either the integrated use of sensors and the development of expert systems to integrate different measurements and to make decisions. All activities will be carried out through the setup of some test fields in the Alpine area, where all investigation techniques will be tested.

Keywords: Engineering Geology, Natural Hazards, Rockfall, Georadar, Ground-Based InSAR, Seismic Sensors, Terrestrial Laser Scanning

1. Introduction

1.1 Relevance and impact of rockfall disasters

The investigation of potentially unstable mountain slopes is today a primary need to increase natural and anthropic risk prevention and forecasting. The continuous expansion of human habitats, the presence of transport routes in valleys, melting of alpine permafrost as a consequence of global warming, and exceptional climatic events are amplifying the risk of catastrophic mountain-slope failures, landslides and, more in general, hydro-geological instability. Among the many natural hazards in mountainous regions, *rockfalls* are frequently occurring processes that are characterized by their suddenness and difficulty of prediction [5].

The most part of worldwide countries are interested by this concern, that involves areas with major and minor relieves, with a manifold impact at social level, on national and regional economy, and on the environment. These grounds show somehow this research topic is nowadays relevant, and operational solutions to cope with it might have a great direct and indirect fall-down on the whole society.

Figure 1: A case of rockfall happened at Fiumelatte di Varenna (Northern Italy); on the left is shown the rock face where in november 2004 several big masses fell and hit a railway station and a house

1.2 State-of-the-art of rockfall prevention

The problem of preventing or reducing damages consequent to rockfalls is complex, due to the very large number of feasible scenarios, with the local morphology of the site providing an additional degree of freedom. Due to this complexity, several competences are needed to address at the best methods and investigation techniques.

The state-of-the-art on analysis, prevention, and monitoring of rockfalls accounts for several studies which mostly concern only a limited aspect of the whole problem. Solutions applied for deep-seated landslides, based on either terrestrial and aerial observations [4], cannot be easily extended to rock face investigations, due to the presence of vertical and sub-vertical faces. Here the main role is currently played by classical surveying and monitoring instruments (e.g. robotic total stations, deformation and displacement sensors) with results complemented by geological inspection and qualitative analysis, as well as the weather observation and forecasting. On the other hand, measurements are registered at predefined times, according to the magnitude of the rock displacements and to the acquisition rate of the adopted instrument. In case of permanent monitoring systems, some measurements per hour could be taken, while in case the instrument needs to be periodically repositioned, the frequency might become weekly or monthly. Moreover, traditional monitoring techniques are based on the definition of a safety threshold for every measurement. When this is not respected, an alarm will be activated and emergency procedures will be called for. By this approach the data integration is seldom exploited.

The complexity of rockfall assessment and monitoring requires not only to focus on specific issues, but to establish a close cooperation between experts skilled in several research fields. Indeed, only a multi-disciplinary environment would allow a real integration between different technologies and methods. Unfortunately, until now the cooperation has been generally limited to geologists and geotechnical engineers, with very few openings to expertises in measurement and data acquisition systems. Thus it’s possible to state that a multi-disciplinary approach represents the real new frontier of this research field.

1.3 The GPE-PROMETEO project at Polimi

In 2005 the Politecnico di Milano (Italy) university launched an internal project (PROMETEO) focusing on 6 different frontier research fields on the theme of hazard management and public protection (see the website of PROMETEO for information about all involved topics – [16]). The basic aim was to establish some multi-disciplinary investigation teams collecting different resources (instruments, knowledge and people) working inside the university. Here we limit ourselves to deal with one of the sub-projects (GPE), where the problem of rockfall is concerned, among others. The acronym GPE means "first emergency management" ("Gestione della Prima Emergenza", in Italian), and is focused on establishing criteria for optimizing aid actions just after disasters due to the hidro-geological desease (or to other reasons, e.g. earthquakes) resulting in the destruction of buldings and human artifacts, and involving buried people. One of the specific tasks of this project is to establish the safety conditions for intervention of the emergency teams, based on the evaluation of the so-called *residual risk*. In case of a landslide or a rockfall, this means the capability of understanding in a quick time and possibly with limited resources, if the happened phaenomenum is not completely ended and might occur again. This issue becomes even more complex when dealing with rockfalls, subject that has only been partially investigated till now, as reported in subsection 1.2. This goal generated the need for a wider investigation about rockfall in GPE, which is focused to open new frontiers in this research field based on a multi-disciplinary approach, called IMARF ("Integrated Monitoring and Assessment of RockFall").

On-going research activities under GPE are organized in two main sections. The first one concerns testing and development of new technologies, sensors, and data processing techniques for rock face monitoring. This aspect will be the specific subject of the paper and it will be dealt with in section 2. The second one is based on establishing a methodology to apply different investigation and monitoring instruments and method by an integrated approach, which can be summarized by the following items:

1) Considering in a given region all sites possibly interested by rockfalls, in each of them different investigation tools are applied to locate *sensible areas* where rocks might fall down.

2) Relationships should be found between observed processes (cracks, deformations, vibrations, sounds,…), morphology and rockfall triggering. This goal can be reached by the analysis of several cases, either from literature and past experiences, and from new testing activities.

3) Criteria to define which sites should be monitored and which techniques should be applied have to be set up.

4) Different sensing techniques need to be tested in on-the-field labs (see next section 4 for more detail).

5) Some risk-based operational guidelines for setting an effective monitoring strategy and for emergency management and rescue related to a given rock face have to be written.

As it can be seen by the listed items, the IMARF research program requires several activities and specializations to be continuously applied for a period of at least 5 years. In the following pages of this paper we would like to deal with the problem of monitoring the rock face stability, being this task already on-going at our university.

2. Overview of adopted monitoring techniques

In recent years new instruments and techniques for deformation monitoring based on ground remote sensors have appeared (Terrestrial Laser Scanning and Ground-Based Interferometric SAR), whose application to rockfall monitoring represent a current challenge. On the other hand, the development of Ground Penetrating Radar and related data analysis methods offers powerful tools to investigate about sub-surfaces. This could be successfully exploited to detect discontinuities under a rock face, and then to locate areas of possible mass detachments. Similarly, digital photogrammetry is expected to allow monitoring of deformations on the surface of the rock (e.g. in case of cracks). Eventually, distributed sensors (microseismic or acoustic) could allow to sense small sounds or vibrations which might be a signal of an upcoming rockfall.

New techniques need to be widely tested on sites really interested by rockfalls, in order to evaluate their potential and operational effectiveness. On the other hand, these are expected to be integrated both mutually among them as well as to traditional monitoring systems.

2.1 Terrestrial Laser Scanning

Terrestrial Laser Scanning (TLS) is a quite recent technique (first instruments appeared about 10 years ago) able to directly acquire in a quick time 3-D unspecific points describing the surface of a given object, with an accuracy lower than ±1 cm [15]. The availability of Long-Range sensors, capable to realistically operate up to a range of 500 m, and the possibility of integrating data acquired from different points of view, allow the geometric survey of geological sites of big dimensions [1]. For this reason, this tool is ideal for the determination of the local morphology of a slope (see item 1, sub-sec. 1.4), considering the possibility to integrate also LiDAR data as well as terrestrial and aerial imagery, extending the achievable information.

However, the most challenging task concerning the use of TLS for rock face analysis is monitoring. Indeed, this technique allows to measure a huge number of points with a very high spatial resolution (also 1 point every few square cm) which is not comparable to that of any other instruments (also Ground-Based Interferometric SAR), as presented in the following sub-sec. 2.2). On the other hand, considering the intrinsic precision of range measurements by laser scanners, summed up to the accuracy of georeferencing (task needed to transform all data acquired from different positions and epochs into the same reference system), the accuracy of the acquired 3-D points of a rock face is not enough to forecast rockfalls. Indeed, these might occur also after displacements of a few mm, which cannot be observed by directly comparing TLS measurements. In recent years, several papers were published dealing with the monitoring of buildings by TLS (see e.g. [12]), the most of these overcoming the problem of low accuracy by exploiting the regularity that surfaces of structures generally present. Thus they interpolate the georeferenced point-cloud captured by TLS by geometric shape (planes, cylinders, polynomial surfaces,…) so that the acquisition noise can be strongly filtered and deformations detected from the comparison of interpolating surfaces taken at different epochs.

Unfortunately, the application of the same strategy to rock face monitoring is not trivial, first because regular surfaces seldom exist here, secondly because the complexity of sites and the long-ranges involved make very critical the georeferencing. In the activities of IMARF, some results achieved during a parallel research on dam monitoring will be translated to the case of rock faces [2]. These are based on 2 main solutions, whose effectiveness is to be tried during on-going tests:

1. to improve the georeferencing, the laser scanner is accurately repositioned over a fixed removeable pillar, locked to a stable permanent foundation on the ground (see Figure 2);

2. to reduce the measurement noise, small (the size depending on the rock face regularity) portions of the rock face are interpolated by simple surfaces (flat or parabolic).

Moreover, the application of *change-detection* [20] based on TLS data will be adopted for measurement of the total mass of rock which has detached from a given face between two different epochs.

During this project, further investigations are carried out in order to evaluate parameters influencing the accuracy of TLS measurement, and in particular: roughness and colour of the surface, angle of incidence laser beam, intensity of sun lighting. Similarly to somewhat was carried out by other researchers on the sensor calibration of some TLS models, the scanner adopted in our testing is under experimental calibration [11].

*Figure 2: On the left a GB-In SAR system IBIS-L by IDS (Pisa, Italy); on the right a long-range terrestrial laser scanner Riegl LMS-Z429*i *mounted over a steel pillar for precise repositioning.*

2.2 Ground-Based SAR Interferometry (GB-InSAR)

Synthetic Aperture Radar (SAR) interferometry is a methodology that has been used for a wide range of applications among which the measurement of ground displacements. The combination of the SAR technique, exploiting the movement of the physical radar antenna along a straight trajectory, and differential interferometric analysis, comparing phase information of reflected waves collected in different time periods, provides high resolution radar images allowing displacements evaluation with a sub-millimetre accuracy.

In recent years, satellite, airborne, and Ground-Based Interferometric SAR (GB-InSAR) techniques have been successfully employed for terrain monitoring (landslides, glaciers, subsidences, and volcanic slopes deformations [19]) and for civil engineering concerns (bridges, dams, towers and buildings monitoring). Both systems can be used in all weather conditions, and they allow to obtain information from all the region covered by the antenna beam, to perform measurements during night and without the need to access the area undergoing examination. Nevertheless, ground-based investigation offers some benefits when compared to satellite-borne platforms: a remarkable flexibility in the acquisition design can be achieved (i.e. suitable to almost any application) and the system can usually be deployed in a straightforward and time-effective way.

The possibility to analyse nearly vertical instable rock faces (very steep slopes are not visible in satellite images) and the capability to perform fast and frequent measurements (satellites pass over the same ground area after a time period related to their orbits) make GB-InSAR a very promising technique for addressing rockfall monitoring and management of the first emergency. In Figure 2 an example of a GB-InSAR system is shown.

Moreover, the acquisition of TLS scans concerning the same rock face monitored by GB-InSAR is expected to improve the results which can be obtained from both techniques separately. Indeed, precise deformation measurements carried out by GB-InSAR will be used to refine TLS data. On the other hand, laser scanning measurements will allow to solve for phase ambiguities of the radar system or to explain the consequent loss of coherence. Eventually, integration of these remote sensors would improve the localization of controlled points on the rock face and should make possible the repositioning of GB-InSAR instrument to carry out periodic measurement at different epochs, without the need of its permanent installation.

2.3 Image-based techniques for monitoring of crack deformations

Enlargement of cracks in rock faces is one of the more evident signal of failure, thus their monitoring is a useful tool of prevention. Different methods are currently available to perform this task, all of them capable of a precision better than that needed to detect mass detachment. This could be evaluated in the order of ±0.1 mm, even though it depends on local conditions. An important classification can be made according the automation degree of the adopted method: (i) several sensors (e.g. *deformometers*, *comparators*) require to be handled in correspondence of a pair of reference point across the crack, then they are able to measure the variation with respect to a previous epoch; (ii) *automatic systems* (e.g. *strain-gauges* or *fiber-optic deformometers* – see [14]) based on sensors which are permanently positioned over each crack and linked to an acquisition/energy supply unit via a serial or parallel cable connection. The use of (i) or (ii) approach presents evident advantages and drawbacks, and the selection is mainly based on the possibility to access the slope in safe conditions. In IMARF a solution has been already developed which is based on the analysis of a sequence of images captured by a digital camera at different epochs (see [3] for details). Either deformations across and along the crack direction can be measured, thank to a pair of targeted plastic labels which are permanently fixed on both sides of the existing (or foreseen) fissure. Images can be acquired periodically by a digital camera, but also a continuous monitoring by a videocamera is feasible, according to the local geometry of the site.

2.4 Ground Penetrating Radar

Dip, shape, filling, orientation and penetration depth of fractures in a rock-mass are important parameters in geomechanical modelling as well as for slope-stability analysis. Ground Penetrating Radar (GPR) is indeed a powerful non-destructive tool to image the presence of discontinuities in the sub-surface. Many studies involving GPR investigations have already been carried out on rock faces and very steep slopes ([8], [10], [17]). Multi-frequency and multi-polarization surveys were performed to assess sub-surface rock conditions in order to delineate and locate internal fractures.

To overcome the fact that surface-based georadar method is not appropriate for the reflection imaging of steep-dipping features (this is primarily due to the unfavourable radiation patterns of most georadar antennas), borehole data were also collected but final results showed little significance because of azimuthal invariance of borehole antennas.

Rather complex processing algorithms have been developed to deal with data collected in presence of rugged terrain, undulating topography and big boulders [6].

Data collection in such difficult contexts (rough terrain, steep and uneven slopes) is definitely demanding, thus improvements and customizations (e.g. wireless technology to move the instruments efficiently on the slope) to the acquisition system are essential. For instance, data from GPR could be coupled with TLS techniques to position the GPR traces on a numerical model of the rock face and to define the 3-D geometry of potentially unstable blocks.

Previous experiences of our research group with GPR applied to the investigations on limestone rock quarries have been very encouraging [13]. Preliminary experiments in different test-sites with high frequency antennas were performed to evaluate the propagation of the radar signal inside a limestone rock mass and its ability to resolve thin discontinuities. The achieved results were positive.

Finally a new acquisition configuration with a low frequency antenna has been tested to explore the possibility of collecting data with an air gap between the antenna and the investigated rock mass. However, this solution still requires further study.

2.5 Seismic/Acoustic techniques

Seismic investigation of an unstable slope may involve passive short-to-long term monitoring of microseismic events and refraction seismic experiments [18].

There is usually a good correlation between fracture propagation inside the rock mass as well as slope displacement and the rate of the microseismic activity. The monitoring strategy basically foresees the installation of a permanent seismic network (surface and borehole sensors) to develop a site history and to provide a predictive capability based on temporal changes in the rate of the microseismic activity and/or on temporal changes in the recorded waveform characteristics.

On the other hand, the purpose of 3-D tomographic seismic surveys is to determine the broad scale distribution of highly fractured rocks (dry cracks, fracture zones, and faults on a wide variety of scales), which is expected to be represented by low P-wave velocities [7]. The 3-D velocity model has a great importance when incorporated in the microseismic events localization procedure. It has been shown that the quality of the velocity model dramatically affects localization errors [9].

At present our researches are addressing lab and on site tests for the evaluation of different data acquisition and inspection solutions, e.g. seismic sensors able to detect microseismic events (geophones, piezoelectric and MEMS - Micro Electric Mechanical System - accelerometers), and devices tailored to the detection of acoustic emissions generated inside the rock mass.

The final goal would be developing a wireless seismic network able to operate autonomously in a challenging environment (harsh weather conditions, difficult access and constraints for power supply), allowing an efficient, low-cost gathering and transfer of acquired information that will be handled with brand new dedicated and power-aware software for a fast and efficient data processing (e.g. filtering, detection, pattern recognition and localization algorithms).

3. Analysis and integration of multi-source data

The integration of different data is the core of IMARF project and concerns two different levels. The first one is related to the use of multisource data during the data processing stage, in order to improve the quality of achievable information. Example of this have been already reported at sub-sections 2.2 (TLS and GB-InSAR) and 2.4 (TLS and GPR).

The second one concerns the integration of different final results that are obtained from every monitoring system, in order to recognize and to predict cases when the risk of rockfall is too high and decisions must be taken (e.g. evacuation of population which could be hit). Typically, monitoring sensors work through the definition of thresholds: when a signal or a measurement goes out the safety field, an alarm is activated. This concept still holds for integrated monitoring as well, even though the setup of suitable values for every threshold is an open problem (see sub-sec. 1.4). However, the added-value derived from the IMARF approach is not only limited to the availability of several systems sensible to processes which might address to possible rockfalls (deformations, sounds, etc.), because this also accounts for correlations between different signals. This extension would allow to detect high risk situations which might occur also in case every of the single sensors' alarm thresholds is still satisfied. Strategy will involve pre-alarm thresholds which could be activated by different monitoring systems, each of them triggering a specific emergency procedure. These might consists in analysing data acquired by other systems to look for correlations, or to start new investigations by adopting techniques for remote deformation measurement (GB-InSAR and/or TLS) or GPR measurement. The integrated analysis of all collected data after a pre-alarm status will give a final risk evaluation based on the estimation of the possible total volume of detached rock mass. At this stage an external alarm procedure involving Civil Protection forces will be called for.

4. On-the-field testing

The IMARF's approach requires to experiment different innovative technologies to the aim of assessing and monitoring the stability of a rock face. Moreover, also already known monitoring and investigation instruments need to be tested in this context, in order to optimize, improve and possibly standardize their use. The testing stage will involve test-sites of different size and complexity, which will be dedicated to experiments concerning specific sensors only, or to the whole integrated monitoring system. In this case, tests will be not limited to assess performances and capabilities of each technique, but will extend to the full IMARF procedure.

Currently some initial test fields have been selected in the Lecco mountain area, in the nearby of a county road which is continuously affected by rock falls in different areas. In a second stage, three different rock faces which have been recently affected by rockfalls (see Figure 1) or which are likely to be (see Figure 3) will be equipped by an integrated monitoring system.

Figure 3 - Two test-sites for on-the-field experimentation of integrated monitoring, located in the nearby of Lecco town (Northern Italy): on the left the Navegno rock face, on the right the Rialba Tower.

5. Conclusions and future activities

As a first follow-up of the research, we expect the assessment of innovative technologies requiring both a metrological analysis and further investigation and improvement to grant effectiveness in the envisaged application. The second main objective of the research is to develop risk-based operational guidelines for emergency management and rescue under specific site conditions. This activity will be based on innovative modeling and analysis approaches, such as: definition of a quantitative method for the evaluation of the contribution of the new monitoring systems to the effectiveness of emergency management plans and, in general, to improve the safety of population; development of a decision support system for real-time emergency management, specifically to assess the stability of a given site, integrating experts' judgements and observed data.

Acknowledgements

Acknowledgements are addressed to all researchers involved in the PROMETEO project who are cooperating to this activity (especially Proff. C. Alippi, P. Trucco, and O. Grande), and the technical personnel of Polo Regionale di Lecco (Politecnico di Milano) for supporting on-the-field measurement campaigns.

SECTION VII

LEGAL SCHOLARSHIP AND RESEARCH WITHIN THE BUILT ENVIRONMENT DISCIPLINE

The rule in Hadley v Baxendale (1854) and its place in the standard form of contract[1]

John Adriaanse,
Department of Property, Surveying and Construction, London South Bank University
(email:adriaajs@lsbu.ac.uk)

Abstract

The English Standard forms of Building and Engineering Contracts make complex provisions for dealing with delay and the management of its financial consequences. Similar provisions are found in many countries where the general structure of these contracts has been adopted. Analyses of these indicate that by approaching their application from the common law rules concerning damages for breach of contract provide a clearer rationale for explaining what these clauses set out to do. This enables users in countries outside the common law jurisdictions to gain a clearer means of adapting or using them.

Research into the earlier versions of the standard forms indicates that the relationship between the common law and the standard forms appear to be drafting accidents. Later judicial analyses of the common law identified the relationship between primary and secondary obligations. Clauses in the standard forms allocate these expressly. Only by examining the scope of the rule in *Hadley v Baxendale* (1854) in a construction setting, is it possible to identify the practical solutions the standard forms provide.

By analysing a variety of clauses in different standard forms of contract, it is possible to identify a common thread running through these clauses. These indicate that in order to understand the drafting, a clear appreciation of the rules about the right to damages at common law is essential. Only then is it possible to understand why these clauses were drafted and how they may be adapted and used in other jurisdictions.

Keywords: Risks, damages, secondary obligations, delay, liquidated damages, direct and indirect loss.

1. Introduction

There is wide range of contractual provisions dealing with delay and its consequence in the English Standard form of construction contracts. The paper analyses the legal interpretation of a number of such contractual provisions. The wording of earlier forms reflect their history, and in

[1] My thanks to Andre De Wet (Quantity Surveyor and Project Manager for Transnet South Africa) for the idea of this paper

the older forms, by the manner in which the courts have interpreted them. Newer forms contain different wording but their aims are the same; to allocate the risk arising in these contracts in a clear and efficient manner. Contractors can as a result, price their tenders clearly knowing what their risks are. As a consequence price comparisons between tenders can be managed in a straight-forward manner. These principles were emphasised by the Privy Council in *Phillips HK Ltd v AG of HK* [1] that 'parties…should be able to know with a reasonable degree of certainty the extent of their liability and the risks which they run as a result of entering into contracts. This was 'particularly true in the case of building contracts and engineering contracts'. Quantifying delay in completion and its consequences is particularly important in situations where it is difficult for the employer to prove its actual losses. It then makes commercial sense for parties to agree the actual losses recoverable beforehand so as to reduce this uncertainty. This paper analyses these provisions in the context of JCT05 [2], the NEC3 [3] and the PFI4 [4] standard form contracts. Their relationship with the case law on damages for breach of contract is evaluated in the context of these.

2. The common law

2.1 The significance of Hadley v Baxendale in English Law

In *Photo Production Ltd v Securicor Transport Ltd* [5] Lord Diplock giving the opinion of the House of Lords, observed that it was a characteristic feature of commercial contracts that parties promise each other that things will be done. Two examples he gave are (a) that a building would be constructed in accordance to plans agreed and (b) that services of a particular kind would be provided. So where one party fails to deliver what has been promised, the 'promisor has failed to fulfil [its] own primary obligation'. This failure amounts to a breach of the contract. The main remedy under English law is damages i.e. monetary compensation which aims 'to put innocent party in the place they would have been had the contract been completed'. This is called its reliance loss. *Hadley v Baxendale* (1854) [6] established the rules for deciding whether the defaulting party was liable for <u>all</u> the damage caused by their breach. This is commonly described under the rules of 'remoteness of damage'. English law this rule to decide whether a particular loss in the circumstances of the case is too remote to be recovered. There are two limbs to the Rule (Anderson B):

'Where two parties have made a contract, which one of them has broken, the damages the other ought to receive in respect of such breach of such a contract should be such as may:

(a) fairly and reasonably be considered as either arising naturally, i.e., from the usual course of things, from the breach of contract itself, or

(b) such as may reasonably be supposed to have been in contemplation of both parties, at the time they made the contract, as the probable result of breach of it.'

Such is the importance of this case to Anglo-American Law that 26 academics contributed papers to the 150th anniversary of *Hadley v Baxendale* [7]. Now whether there are two rules or simply two different aspects of the same rule has caused much academic and judicial debate. Lord Hope in *Jackson v Royal Bank of Scotland* (2005) [8] observed that what was in the contemplation of the parties was in fact, the principle underlying both. Lord Walker of Gestingthor too, stressed the importance of that underlying principle of what the contract breaker knew or was taken to know, 'so as to bring the loss within the reasonable contemplation of the parties' (at para 48). From a strictly legal perspective therefore, there may well be only one rule but from the practical point of the clauses in contracts dealing with these, the courts treat it as of consisting of two different rules. In *Hotel Services Ltd v Hilton Int Hotels (UK) Ltd* [9], the Court of Appeal, in relation to the need for special knowledge [the what was in the contemplation of the parties] found that 'authority dictates that the line between direct and indirect and consequential losses is drawn along the boundary between the first and second limbs of *Hadley v Baxendale'* (at para. 18).

2.2 Remoteness of damage

The rules established *Hadley v Baxendale*, were explained by Lord Hope at para 26 in *Jackson* (2005), a case concerning the sale of dog chews. In the process he explained that the court of appeal misunderstood the effect of the case. In fact the crucial date for determining what 'may reasonably be supposed to have been in the contemplation of both parties' was the date of the contract, not the date of the breach. Why this matters is because it is then that the parties could limit their liability under the contract. So while the rules are 150 years old, three eminent Lord Justices misapplied them, which illustrates that applying them are in practice not at all easy. If the rules are so easily misunderstood, allocating damages through the contract itself is from any perspective, the better way to manage commercial relationships.

2.3 Application in construction contracts

Before the decision in *Balfour Beatty Construction (Scotland) Ltd v Scottish Power plc* [10], it was quite difficult to imagine a scenario where the rule would be applied in a construction context. Or that the point would be of such importance that it would reach the House of Lords. During construction of an aqueduct, the batching plant broke down due to the rupturing of the fuses provided by the supplier. Since watertight construction required a continuous pour of concrete, this came to at end with the power failure. Once it was restored, attempts were made to continue the work by cutting back the old concrete and adding fresh concrete. The contractor was unable to meet the specification for a watertight aqueduct and the engineer instructed the demolition and rebuilding of the structure. In an action against the supplier the contractor won damages for breach of contract. On appeal by the supplier against damages of £229,102.53 plus interest, the Lords confirmed that: damages should either arise naturally from the breach or have been in the contemplation of the parties at the time they made the contract. What one party knew about the other's business was a question of fact. The demolition and reconstruction of the aqueduct was not in the contemplation of the supplier [since they did not know, and were unlikely to know, that a continuous pour was required make the structure water-tight].

The answer is of course to ensure that the supplier is aware of the consequences of a breach. Note though that damages were awarded under the first limb of *Hadley v Baxendale* for the damages that arose naturally when the fuses failed. An example of this was the costs of cutting back unsuccessfully the concrete in an abortive attempt to restart the work. In *Stuart Pty Ltd v Condor Commercial Insulation Pty* Ltd [11] too, the court of appeal found that the event giving rise to the loss (a fire due to faulty workmanship of the sub-contractor) was not within reasonable contemplation of parties under the second limb. The relevance of the second limb is that the parties can limit their liability at the time of contracting for what would otherwise be a breach of contract. For instance, had the supplier known what damage might result, it could have stipulated that they were not liable for any damage resulting from a failure of their fuses. Would they not then also have raised the matter of a back-up generator if a continuous supply was so vital to the operation? After all, in *Hadley v Baxendale* itself, the claim for loss of profits caused by delay in the delivering of the broken mill shaft to the repairers, failed under the second limb precisely for that reason. How were the couriers to know that the mill would have no back-up shaft (which was after all central to their business)?

It should be borne in mind that even if the tests in *Hadley v Baxendale* are satisfied, the quantification of the loss has to be made. In this respect English law takes a reasonable approach. In *Electronics and Construction Ltd v Forsyth* [12] the House of Lords was held that where the costs of repair were disproportionate to the benefit to be gained, the winning party was only entitled to nominal damages. To demonstrate the difficulty of deciding damages at common law, it should be pointed out that 9 judges at three different judicial levels were eventually split 5:4 in the same case. Thus demonstrating that deciding whether a swimming pool had to be constructed to its specified depth, where there was no benefit to be gained by doing so, was no easy matter. The case was not a commercial one as it involved a builder and a home owner. The principle has however, been applied in commercial contracts. For an example see *Birse Construction Ltd v Eastern Telegraph Co Ltd* [13]. Damages of £2 were awarded to the winning party, because it was selling the defective premises without repairing it. A further illustration of the principle at work is *Shepherd Homes Ltd v Encia Remedation Ltd* [14]. It took a 5-week trial for the claimant to prove that a failure to carry out the work with reasonable care and skill had resulted in the damage. Even then though the claimant succeeded on all points of claim, for 40 of the 94 of the houses damaged by subsidence only nominal damages was awarded of £2 per house.

3. Contractual provisions

What these cases show is the difficulty, uncertainty and costs of successfully proving damages at common law. For this reason, avoiding the application of rule is a much the wiser option. Construction contracts therefore, make specific provisions for the payment of damages, to achieve the ‘certainty’ referred to in *Phillips*. These were emphasised in *Photo Production Ltd v Securicor Transport Ltd* [15] where the House of Lords distinguished between the primary and secondary obligations of the parties. Where there is a failure to perform those primary obligations (i.e., the performance obligations in the contract), there is a breach of contract. Lord Diplock observed that: ‘The secondary obligation on the part of the contract breaker…is to pay monetary compensation to the other party for the loss sustained by him as a consequence of the breach.’ Parties are free to decide for themselves how to allocate those secondary obligations. The approach of the courts to such allocation of risk was described by Chadwick LJ in *Watford*

Electronics Ltd v Sanderson [16] (with whom LJ Gibson and Mr Justice Buckley agreed) at 55 as accepting that:

> 'Where experienced businessmen [and women] representing substantial companies of equal bargaining power negotiate an agreement, they may be taken to have regard to matters known by them…They should be taken to be the best judge on the question whether the terms of the agreement are reasonable.'

Gibson LJ too went on to say that a court should not assume that either party is likely to commit their company to unfair or unreasonable terms. So where they have agreed the allocation of risk, the price must be taken as reflect that allocation and that therefore there would be little scope for a court to unmake the bargain of commercial people. He adopted the observation of Forbes J in the *Salvage Association v CAP Financial Services* [17] at p. 656 to the effect that: 'where a party well able to look after itself enters into a commercial contract and, with full knowledge of all relevant circumstances, willingly accepts the terms of the contract which provides for the apportionment of financial risks of that transaction, I think the court should be slow to interfere'.

The apportionment of financial risks include the provision of LD for delay, inserting exclusion or limiting clauses, and making provision for loss and/or expense to be paid in certain defined circumstances. Consequential losses are also excluded or limited to the value of the contract. Termination clauses too, fall in this category for they contain provisions that are in fact much wider than the position at common law. Again, what has to be borne in mind is that by so doing, the parties are in effect allocating risk between themselves.

The primary obligation of the contractor is to carry out the work required to prescribed standards in a specified time. That of the employer is to pay for the work. Provision is then made for a starting and a completion date. Any construction contract will contain other obligations, but the primary purpose of this paper is analyse the provision of secondary obligations only.

4. Secondary obligations

The early versions of the JCT standard form of contract had limited provisions for the payment of extra money (now called 'loss and/or expense'). It appears that before JCT 63, there was no provision for the payment of extra money arising out of a delay caused by the employer [18]. However, the contractor had at common law, a claim for damages arising out of the delay. Such a clause was introduced in JCT 63 contract but was limited scope. These were substantially expanded in subsequent editions in 1980 and in 1998. The latest version, the JCT 05 has simplified these clauses. This contract too introduces provisions dealing with consequential loss [19] as does the NEC3.

4.1 Liquidated Damages

The object of LD is to fix the compensation resulting from delay in completing the contract. The advantage of doing so is to escape the uncertainty and costs of suing at common law. The sum so fixed is a pre-estimate of damages. The figure consists of the estimated costs arising out of any delay. This will usually be direct costs only and falls into the first limb of *Hadley v Baxendale*. For commercial reasons, the resulting sum may not always amount to the true value of the loss. *Bath and Somerset* [20] provides an example of the kind of losses (or costs) that can be incurred. The employer successfully proved that the LD's was not the only damages it was likely to suffer if the project was delayed and that it was likely to incur other heads of damage too.

The actual sum need not be accurate as it is only an estimate at the time of the invitation to tender. In what circumstances if it was not 'correct' would it amount to a penalty? This question arose in *McAlpine Capital Projects Ltd v Tile Box Ltd* [21] where the law was extensively reviewed. Mr Justice Jackson proposed a test for discriminating between a LD clause and a penalty. It was his view was that: 'a pre-estimate of damages does not have to be right in order to be reasonable. There must be a substantial discrepancy between the level of damages stipulated in the contract and the level of damages which is likely to be suffered before it can be said that the agreed pre-estimate is unreasonable' (at para 20). Note that LD was £45,000 per week and at trial it was claimed that the work 2.5 years late (at para 25), however the employer was able to prove that its actual losses exceeded the sum allowed. The effect of this judgment is that is difficult to conceive of a situation where a sum expressed as LD will be held to be a penalty in a construction contract.

As always, the parties are free to choose whether or not their contract should make provision for fixed payments to be paid in the event of delay. Under NEC 3, Liquidated Damages are provided for in the optional clauses rather than in its core clauses. Option X7 requires the contractor to pay damages for delay from the completion date until the date the employer takes over the works. Should the option not be adopted, the employer is left to recover damage for delay at common law. In the light of the difficulties of proving loss at common law, this is not a particularly wise choice, especially since in a construction contract, the effect of delay is often difficult to quantify afterwards.

4.2 The relation between Liquidated Damages and extensions of time

Where the employer is wholly or partially responsible for an act of prevention that for prevents the contractor from completing on time, the employer cannot recover LD unless the contract provides otherwise. As Phillomere LJ observed in *Peak Construction (Liverpool) Ltd v McKinney Foundation Ltd* [22], 'a clause providing for LD are closely linked to one providing for an extension of time.' The parties agree that were delay is due to the employer; such a provision cures the default. Note though that where the employer issues a notice of intention to deduct LD, the sum crystallises at that date and the employer can deduct LD despite an extension of time being granted [23].

The JCT 05 calls these provisions ‘relevant events’: clause 2.29. In practice, these are risk allocating measures. As the contractor does not have to include a price in its tender for these possibilities, the tender price should reflect this. In addition the contract contains provisions for loss and expense: clause 4.29 (discussed below). There is not necessarily a connection between the two in JCT contracts: *H. Fairweather & Co Ltd v LB of Wandsworth* [24]. This is emphasised in the JCT 05 contract which widely separates a claim for an extension of time from a claim for loss and expense. The NEC3 by contrast, treats these together in clause 60 where they are called ‘compensation events’. Clause 61 requires the contractor to give notice of compensation events. Where the project manager accepts that’s such an event has occurred, the project manager may instruct the contractor under clause 62 to provide a quotation for extra time and compensation. Note that the NEC also uses a system of early warnings in clause 16.1. This requires the contractor and project manager to notify each other of matters that could increase prices, delay the works or the meeting of key dates.

The PFI 4 allows for Supervening events in clause 5. These are three kinds: 5.2.1: (a) Compensation events which are at the Authority’s risk and for which the contractor receives compensation (b) Relief events which the contractor is best able to manage, but receives no compensation and (c) Force Majeure events. These arise through neither party’s fault, but provide ground for the contractor to terminate its employment under the contract. Clause 5.1.3 provides that Compensation events entitle the contractor to more money and extra time and relief events only extra time to complete.

It is clear from precedent how the court will approach the meaning of the clauses in JCT 05. In *Beaufort Developments (NI) Ltd v Gilbert-Ash*, Lord Hoffman said of the process at p. 784 that legal documents often contain superfluous words. He gave two reasons for this: (i) clumsy draftsmanship and (ii) the lawyer’s desire to cover every conceivable point. Of the JCT standard form of contract he said that it is periodically renegotiated, amended, and added to over many years. It would be unreasonable to expect there to be no redundancies or loose ends. It was therefore important that that earlier judicial authority and practice on the construction of similar contracts be examined to discover the true meanings of the words used. He added that standard forms of contract evolve and reflect the interaction between the draftsmen and the court. These could not be understood without referring to the meanings the judges gave to previous versions of the contract.

The guidance notes to the NEC 3 make clear that this contract is radically different from other existing standard form contracts, and that in should be used in a different manner. Admirable as this view is, common law judges do not make decisions in isolation. In *Costain Ltd & Ors v Bechtel Ltd & Anor* (2005) [25], the court had to interpret the duty of the project manager in certifying payment where the contract required the exercise of good faith. The clause was similar to that contained in NEC 3 where clause 10.1 requires the employer, the contractor, the project manager and the supervisor to ‘act…in a spirit of mutual trust and co-operation’. To decide what the words meant the court looked at previous precedents dealing with the duties of a certifier. It concluded that in those cases involving other forms of contract, the certifying role required the exercise of fairness and impartiality. Having decided that, there was no need to decide what the clause actually meant in the context of the contract. It is therefore suggested that in interpreting expressions such as compensating events or relief events, the courts are likely to look at the interpretation of similar provisions in other contracts. It is therefore important when using new forms of contract to be aware of the way in which the courts have interpreted other contracts dealing with the same matters.

4.3 Direct loss and/or expense

Clause 4.23 of JCT 05 allows the contractor to claim 'loss and/or expense' caused by matters materially affecting the regular progress of the works. It requires the contractor to make written application to the Architect/Contract Administrator stating that it has incurred or is likely to incur direct loss and/or expense in the execution of this contract for which it would not be re-imbursed by payment under any other provision of this contract. This is an important proviso because the granting of an extension of time does not automatically trigger a claim for loss and expense. Only when 'the Architect is of the opinion that the direct loss and/or expense has been incurred…by matters referred to in clause 4.23…then the Architect shall ascertain or shall instruct the Quantity Surveyor to ascertain, the amount of such loss and/or expense.' Such claims for delay and disruption may include (apart from additional project specific costs: (a) loss of profit (b) finance charges such as interest on borrowed capital (c) head office overheads (d) loss of productivity or uneconomic working (e) idle plant or machinery and (f) increased costs resulting from inflation.

4.4 The meaning of direct loss and/or expense

The words direct loss and/or expense were considered in *Wraight Ltd v PH &T (Holdings) Ltd* [26]. It was held to mean that the sums recoverable are equivalent to damages at common law. Megaw J said at p 34 that there was no other meaning to be given to the phrase other than what it would have in relation to a breach of contract: see *Hadley v Baxendale*, thought it must be stressed that at no point does he refer to that case itself. The Court of Appeal in *FC Minter v WHTSO* [27] considered the phrase in relation to the JCT 1963 contract. It held that direct loss and/or expense is loss that arises naturally, and in the ordinary course of things, as stated in the first limb of *Hadley v Baxendale*. It defined 'direct damage' as 'that which flows naturally from the breach without any other intervening cause and independently of any special circumstances whereas indirect damage does not so flow.' Any claim put by a contractor is therefore subject to the question of whether it falls within the first limb of *Hadley v Baxendale*. Keating [28] considers that the use of other formulae by contractors does not displace or detract from this principle. These formulae are based on the theory that where the period of delay is uncertain and hence the contractor cannot take steps to reduce its head office expenditure or other overheads by obtaining additional work, an approximation of the damages supposedly incurred by the contractor can be made [29].

In *FC Minter* finance charges were claimed as direct loss and/or expense. In holding that the JCT terms contained an implied term to pay interest as a constituent part of direct loss and/or expense, Stephenson LJ added that in the context of the building contract involved and 'the accepted "cash flow" procedure and practice', he had no doubt that the sums claimed was direct loss and/ or expense. See also *Tate & Lyle Food & Distribution Ltd v GLC* [30] where it was decided that an interest claim for direct loss and /or expense should be calculated at a rate equivalent to the rate of borrowing.

A further detailed analyses of the phrase was carried out in *Robertson Group (Construction) Ltd v Amey-Miller (Edinburgh) JV* [31]. Lord Drummond Young had to construe the meaning of the phrase 'all direct costs and directly incurred losses' in a letter of intent. The employer argued that the expression limited the contractor to the cost of labour, plant and materials used on the contract. It excluded head office overheads and any profit element. The contractor claimed that it was entitled to recover not only the cost of labour and materials plus the cost of plant and sums paid to subcontractors but also an appropriate sum to cover their head office overheads plus an appropriate element of profit. The judge considered to the case law on the expression loss and/or expense in the JCT forms. These could 'be summarised in two propositions. First, the word "direct" in the expression "direct loss and/or expense" is concerned with remoteness of loss…Second, the word denotes that the loss or expense in question must flow naturally from the contractual event relied on by the claimant, in the sense of the first [limb] in *Hadley v Baxendale'*. It is worth remembering that in the JCT contract, the costs of disruption of the regular progress of the work is not a breach of contract but a specific contractual entitlement to compensation for loss and/expense. Hence it is an example of a secondary obligation fixing the likely damages and circumstances where it will arise. Lord Drummond Young concluded that the phrase included profit and overheads.

4.5 Provisions excluding indirect and consequential losses

Making provision in traditional contracts for contractor design elements has led to standard form contracts containing provisions dealing with consequential losses. JCT 05 now has such a provision in clause 2.19.3. This is due to the inclusion of a 'Contractor's Design Portion'. The clause limits the liability of the contractor for loss of use, loss of profit or other consequential loss arising from a design failure. This is limited to the amount stated in the appendix. The NEC 3 too in Option X18 'Limitation of liability' in Clause X18.1 states that 'the Contractor's liability to the Employer for the Employer's indirect and consequential loss is limited to the amount stated in the Contract Data.

Clauses of this type are commonly found in contracts for the supply and installation of goods and materials. In *British Sugar plc v NEI Power Projects Ltd* [32] for example the clause provided that: 'The Seller will be liable for any loss, damage, cost or expense incurred by the Purchaser arising from the supply by the Seller of any such faulty goods or materials …save that the Seller's liability for any consequential loss is limited to the value of the contract.'

The importance of the clause for the parties is shown in sharp relief when the facts of the case are considered. The contract between the parties was for the design, supply, delivery, testing and commissioning of electrical equipment at a final price of £106,585. The buyer claimed that the equipment was poorly designed and badly installed and caused the power supply to break down. Damages of over £5 million were claimed for the increase in production cost and the losses of profits resulting from the breakdown.

The recent case of *Shepherd Homes Ltd v Enica Remediation Ltd* (2007) [33] demonstrates principle in operation in a construction setting. The preliminary issue for the court was whether a limiting term had been incorporated into a piling sub-contract. The value of a contract for the design and installation of ground beams on a site where the underlying soil was peat was £100K. Within a year of completion properties on the site showed signs of cracking due to settlement with a potential liability of £10m. The sub-contractor had included a term clause with their offer stating that 'our maximum liability is limited to the Contract price; whether in contract or in tort, for any damage or loss whatsoever, including all direct, indirect or consequential loss' Clarke J decided that the clause was a fair and reasonable one in the circumstances.

The meaning of the phrase is much clearer by a series of cases. In *British Sugar* and also *Deepak Fertilisers & Petroleum Corp v. Davy McKee* (London) (1999) [34] the Court of Appeal had once again to consider the formulation adopted in pervious cases. This was that the phrase 'consequential loss' did not exclude losses arising naturally from the breach of contract. In each case the Court of Appeal concluded that 'consequential loss' and 'indirect and consequential loss' refer to damages falling into the second limb of *Hadley v Baxendale*. In *British Sugar* it also did two other things: (a) It adopted the view that once a court has in a similar context, authoritatively construed the phrase, the 'reasonable businessman' must intend the phase to bear that meaning and (b) it confirmed that the phrase is concerned with damages that are too remote unless they are within the actual contemplation of the parties at the time they made the contract. The result of this approach is that a party intending to exclude categories of foreseeable loss, would be better off specifying what is included rather than specifying what is excluded. Examples are loss of profit, overheads, additional costs required to bring the project back to the level contracted for and loss of revenue.

5. Termination clauses

Lubenham Fidelities & Investments Co Ltd v. South Pembrokeshire DC [35] illustrates clearly the difference and risks between termination clauses and the right to repudiate at common law. Termination clauses terminate the employment of the contractor and not the contract. In *Lubenham* the contractor abandoned the contract because of what it considered an under-valuation of an interim certificate of payment. The employer determined the employment of the contractor under an express provision. In leaving the site, the contractor was in breach of the obligation to proceed with work regularly and diligently. It was held that no right to suspend the work for underpayment existed at common law. The contractor had repudiated the contract and was liable in damages to the employer. The employer in following the procedures laid down by the contract had lawfully determined the contractor's employment.

Repudiating (and effectively terminating the contract) is therefore fraught with risk. This is because having done so, the party who has chosen to do this, will only later find out whether it was lawfully entitled to do so. In *Alkok v Grymek* [36] for example, the contractor having repudiated the contract was found by the Court of Appeal to have had no grounds for repudiating their contract. So too did the contractor in *Lubenham Fidelities*. The result was that in both cases the contractors were held liable for all the damage resulting from their breach of contract. Similarly in *Rheidwood* (2007) [23], the contractor thinking it had the right to determine its employment was found to have repudiated the contract instead.

The JCT 05 contains two types of termination clauses. One deals with the effect of insolvency (clause 8.1) and the other with defaults under the contract. Clause 8.4.1 deals with defaults by the contractor and clause 8.9.1 with those by the employer. These rights are wider than those at common law and in addition, the contract has accounting provisions dealing with the consequences. The NEC 3 deals with the right to terminate in clause 90. Clause 91.1 entitles either party to terminate on insolvency. Clause 91.2 deals with defaults by the contractor, clause 91.4 allows the contractor to terminate for non-payment and clause 91.5 allows either party to terminate. Clause 92 contains the procedures to be followed upon termination. The PF1 Contract in clause 21.1 allows the contractor to terminate on authority default and clause 21.2 allows for termination due to contractor defaults.

6. Conclusion

The primary interpretation of contractual clauses dealing with delay and its consequences have been made in the earlier cases on the JCT form of contract. It can therefore be concluded that in interpreting expressions such as compensating events or relief events, the courts are likely to look at the interpretation of similar provisions in other contracts.

By adopting the analyses made by the House of Lords in *Photo Production* it is possible to demonstrate the close relationship between the standard forms of contract and the common law. Construction contracts expressly allocate secondary obligations which arise as a consequence of a failure to carry out primary obligations. By doing so, contractual parties avoid the difficulty, costs and uncertainty of proving damages at common law. Where the courts have to decide what these clauses which allocate secondary obligations mean, they in fact, return to the common law principles to decide this. The question of how the parties have allocated risk then depends on whether the loss falls into the two limbs of *Hadley v Baxendale*. This is the very thing that secondary obligations are meant to avoid. The result is that contractual provisions such as liquidated damages fall into the first limb because it is a direct loss. The same applies to provisions for loss and/or expense (and probably for compensating events or relief events) as well. Consequential losses fall into the second limb unless they are in fact direct loss and for this reason the wording of the clause is crucial. Termination clauses, while not strictly within the rule, avoid the application of the rule, since they too eliminate the uncertainty of damages at common law and the further risks of unlawfully terminating a contract. What all these express secondary obligations do is to allocate risks between the parties, which ultimately is the purpose of a construction contract.

Therefore, in dealing with the English standard forms of contract and their meaning, it is vital to understand the relationship between the contractual provisions and the common law. Only then is it possible to decide how risk is allocated and how the clauses may in turn be modified to reflect the legal position in other jurisdictions.

Judicial Mediation Statements in the Technology and Construction Court: Appropriate Cases for Mediation

Penny Brooker
School of Legal Studies
University of Wolverhampton

Abstract

Many common law countries, which operate an adversarial system, promote the use of mediation to help reduce costs for the parties and minimize the pressure on courts. In the United Kingdom (UK), this has taken the form of the Civil Procedures Rules (CPR) and court protocols which encourage the parties and their lawyers to consider Alternative Dispute Resolution (ADR) or facilitate mediation use in appropriate cases. Under CPR, judges have the power to penalise unreasonable behaviour in litigation through costs sanctions and rejecting an offer to mediate has been found by the court to be unreasonable behaviour. [1] Case law provides that a successful party will not be deprived of their costs unless it is shown that they acted unreasonably in refusing to agree to mediation. Although the Court of Appeal in Halsey (2004) dispensed guidelines on when a case will be deemed 'appropriate' for mediation, it was emphasised that the list was not conclusive, thus disputing parties and their legal advisors cannot determine, with certainty, when a refusal will attract a cost sanction. [2] P4 Limited v. Unite Integrated Solutions PLC (2006) exemplifies the likely approach the Technology and Construction Court (TCC) will take to an unreasonable rejection of mediation and is a significant 'steer' on when construction cases are deemed appropriate for the process. [3] This paper examines the Halsey (2004) guidelines and reviews cases in the TCC to elicit how the specialist court is applying and developing mediation appropriateness criteria.

Keywords: Mediation, ADR, judges, Technology and Construction Court (TCC), Civil Procedure Rules (CPR), court protocols.

1. Background

1.1 Court encouragement of mediation: Civil Procedure Rules (CPR)

The CPR were introduced to reduce the costs of litigation, increase the efficacy of the courts and control increasing "combative" behaviour in the adversarial system. [4] [5] CPR implemented a new litigation 'landscape' where judges are under a duty to further the overriding objective of the court to deal justly with the cases by using case management. [4 Forward] Judges control litigation through case management meetings (CMC) by setting timetables and allocating trial dates. [5 para. 3] Court protocols set down detailed requirements for pre-action meetings, document disclosure and timing for responses and imparts a duty on the parties to consider alternative ways of settling their dispute. ADR is given a significant role within case management, as judges have a duty to encourage and facilitate settlement which might be through the use of alternative procedures in appropriate cases. [6] For example, at the request of one party, ADR may be endorsed by permitting a stay in the proceedings [6 at 26.4(1)] but stronger encouragement has been the inclusion of a cost sanction for unreasonable behaviour in litigation, which can take account of a party's rejection of an offer to mediate or use ADR. [6 at 26.4] An unsuccessful litigant generally has to pay the costs of the successful party but judges have discretion to take account of any circumstances', which may include consideration of the parties' efforts 'if any, before and during the proceedings in order to try to resolve the dispute'. [6 at 4.5(3)(a)(ii)] Cost sanctions have been made not only for non-compliance with court protocols [7] but also for unreasonable refusals to participate in ADR. [2][3] Additionally, judges have discretion to award costs at a higher indemnity basis rather than the standard rate. [6]

1.2 Definitions

Earlier explanations of ADR suggest the term involves the 'help of an independent third party' [8] but the TCC provides a broader definition in its guide by including 'any process that the parties enter into voluntarily'. TCC pre-action protocols also count 'formal inter-party negotiations' as an acceptable alternative [9 at 7.1.1] and contend that the protocol is a *'type of ADR, because it requires there to be at least one face-to-face meeting between the parties before the commencement of proceedings. At this meeting, there should be sufficient time to discuss and resolve the dispute"*. [9 at 7.2.2] The courts have accepted 'round table meetings', [10] and 'negotiation or attempts to use an honest broker' [11] when considering whether the parties' conduct in litigation has been reasonable, which is indicative of the importance placed on settlement by the CPR. [8]

The TCC pre-action protocol and the Court of Appeal in Halsey note that ADR is usually a 'form of mediation' with a neutral. [9] [2 at 5] Different 'variants' of mediation are described as 'facilitative' or 'interest based' where the mediator assists the parties to create their own settlement. A more recent phenomenon is the recognition of mediators taking an 'evaluative' role by providing a view on the merits of a case or by making suggestions for settlement outcomes. Some UK construction literature identifies this as 'evaluative mediation' but it is also referred to as 'conciliation' where the conciliator makes a recommendation at the end of the mediation phase if settlement has not been reached. [12]

Statutory adjudication is regulated by the Housing Grants, Construction and Regeneration Act 1996 (HGCRA), which provides a statutory right for parties to construction contracts to elect an adjudicator to give a decision which is binding on the parties until practical completion. The UK construction industry has a long history of using Arbitration, which is a confidential private tribunal where an arbitrator, selected by the parties, makes a legally enforceable binding decision as governed by the Arbitration Act 1996.

The UK construction industry also utilises Early Neutral Evaluation (ENE) where the parties jointly choose a neutral with specific expertise to give a non-binding decision. Judges offer a form of ENE [13] and recently the TCC piloted a Court Settlement Process (CSP) where judges offer to assist the parties reach settlement, 'in such manner as the Judge considers appropriate'. The Court Settlement Order prescribes a process resembling mediation where the mediator adopts 'evaluative' techniques rather 'than 'facilitative' techniques, where the parties are encouraged, rather than directed, to explore alternatives and create their own solutions. [15]

1.2 CPR in the TCC

The TCC is governed by the Construction and Engineering Court Protocol. [14] The parties are required to meet 28 days after the claimant has received a letter of response from the defendant and at this meeting consideration should be given to whether some form of ADR is 'more suitable than litigation' and if so try to agree the 'form to adopt'. [14] The TCC will in appropriate cases indicate what type of ADR this should take but emphasis this will be mediation in most cases.

At the first CMC meeting the parties are required to address the court on '*the likely efficacy of ADR, the appropriate timing of ADR, and the advantages and disadvantages of a short stay of proceedings to allow ADR to take place'*. [9] There are two important considerations lawyers and their clients need to evaluate. First, what criteria of a construction dispute make mediation a suitable alternative, and second, what conditions do the courts regard as appropriate for rejecting an offer to mediate in order to avoid a cost penalty. This paper is essentially concerned with the second consideration. It analyses evidence from cases to elicit court opinion on 'appropriate mediation criteria' and the existence, if any, of specific conditions where a refusal may be deemed acceptable or unacceptable. This paper considers the judgments from the civil appeal court, which are binding on the TCC.

The CPR rules are underpinned by the principle of directing 'appropriate' or 'suitable' cases to alternative procedures. Before considering the leading cases in the Court of Appeal, this paper will explore, briefly, the key findings from construction mediation studies on the effectiveness of mediating.

2. Appropriate criteria for mediation use

2.1 Empirical findings in the construction industry

There still exists a shortage of empirical data which identifies the suitability and effectiveness of mediation for construction disputes. One problem is that studies use different measures for establishing mediation effectiveness, for example determining mediation success in relation to party satisfaction or non-compliance with mediation agreements. [16][17] This paper is concerned with judges encouraging the parties to 'settle' cases through mediation and will therefore analyse survey findings relating to settlement outcome as the criteria for mediation effectiveness.

A leading study in the US found disputes involving delays, changes, job site administration, property damage, defective work, personnel injury or site conditions had little affect on mediation reaching full or partial settlement but a significant variable on outcome was the financial size of the dispute. The higher amount involved in the case the less often full settlement was achieved.` [16 at 107] The extent of discovery also influenced outcome, as mediations were twice as likely not to settle when this activity had not taken place. The duration of mediation was also significant because the longer the parties mediated the more likely the process settled. The quality of mediators also influences outcome as the more varied techniques used, such as caucusing, site visits or consulting experts, the more likely settlement was achieved. [16 at 144] The parties' perception of mediator quality was influential: Mediation was less likely to settle when the parties believed the mediator was weak. [16 at 145] However, the US research discovered that the most important factor was the rules adopted in mediation. When the parties created their own rules they were more likely to settle their dispute than when the mediator adopted regulations designed by the court or professional institutions. [16 at 144-145]

A study of construction mediation in the UK similarly found settlement outcomes were not affected by the type of dispute or the identity of the parties (contractor, sub-contractor, employer, or client). [18] However, analogous with US findings, the most critical factor for non-settlement was found to be the attitude of the parties. [16] [17] Mediation was often ineffective when one or more of the parties had unrealistic expectations, were intransigent or unwilling to compromise or when both parties were too far apart at the beginning of the process. Mediation outcomes in UK court schemes in the UK also indicate that *'case type, case value, party configuration, representation, case complexity*' are not determinative on settlement. Settlement is more likely to be a combination of factors including '*individual characteristics of the cases, attitude and motivation of the parties, skills and knowledge of the mediator.* [19]

A review undertaken by the TCC to determine when mediation provides a 'real alternative' to litigation, at what stage the TCC should encourage mediation and which mediation techniques are particularly successful reports that most disputes are still settling through 'conventional negotiation'. [20] The report suggests that statutory adjudication is dealing with cases involving payment, variation, delay and site conditions, leaving the court, and mediation if the parties are directed or encouraged to use it, with more difficult complex cases, which are often multiparty, involving defects, design and negligence. It has been suggested there is a trend for more difficult cases being taken to mediation, with the result that settlement is harder to achieve because of increasing familiarity and tactical use of the process by lawyers. [21][22] The TCC report advises mediation may fail if engaged in too early because of a lack of information about the case and if used too late substantial expenses may be incurred or the parties may be 'too entrenched' but, perhaps significant is the finding that mediation was most often undertaken voluntarily by the parties rather than through a court order or court pressure and that most mediations were conducted by a small cohort of experienced mediators, which confirms findings from other studies. [23]

The construction studies suggests the type of case and the relationship of the parties are unlikely to create barriers to settlement but that there are a number of significant determinants that may lead to failure, which centre on the skills and quality of mediators; the mediation rules; the uncompromising attitudes of the parties and the financial size in dispute.

2.1 Jurisprudence Case Review: Appropriate criteria

The Court of Appeal first sanctioned a party for unreasonably refusing an invitation to mediation in Dunnett. [1] The decision did not give guidelines on the appropriateness criteria but led the way to a number of cases eulogising on the ability of mediation and the skills of mediators to transform the dispute resolution environment. [1] [24] Lord Judge Brooke observed that many cases can be successfully settled by a 'skilled mediator', even those which appear unpromising because of the intransigent attitudes of the parties. Further, experienced mediators are able to achieve outcomes 'beyond' the scope of the court and lawyers. [1 at 14] This view was reiterated in Hurst v Leeming (2003) by Mr Justice Lightman, who affirmed that *'the mediation process itself can and does often bring about a more sensible and more conciliatory attitude on the parts of the parties than might otherwise be expected to prevail before the mediation'.* [25] Although the power of mediation to transform party relationships is well documented, [26] the empirical data reported above suggest that the parties' attitudes are one of the key factors contributing to non-settlement. None of the reasons given for not mediating in Hurst v Leeming, a 'watertight case', excessive costs already involved in litigation, defence of serious allegations or the lack of substance in the case, were found to 'necessarily' lead to a reasonable rejection. The test to apply was whether 'objectively viewed' there was an 'unrealistic prospect' that the process would achieve settlement. [25 at 12-19] The decision was criticised for failing to provide certainty on when it is safe to reject mediation in any given circumstances because a judge could decide there was a good prospect for mediation to achieve a settlement. [21][22]

The test in Hurst v Leeming was considered by the Court of Appeal in Halsey (2004). Lord Justice Dyson's judgement exhibited a change in emphasis on the virtues of mediation by acknowledging the merits of the process still need to be empirically demonstrated. [2] Nevertheless, the decision is founded on the belief mediation is 'suitable for many disputes'. Parties are encouraged to use mediation, not only because the court believes it is a less expensive option than litigation, but because it provides a wider range of outcomes 'including apologies, explanations, continuance of relationship and agreements without legal obligations'. [2 at 14] However, research in the UK castes doubt on the perception that creative outcomes or continuing relationships feature often in construction mediation. [18] [21] [22]

Following Halsey, the unsuccessful party has the burden of proving a party has acted unreasonably in refusing mediation. Six circumstances were identified that should be taken into consideration when determining this question but these are not limited:

(1) Nature of the Case: Halsey takes the view that most cases by their nature are suitable, but accepts the subject matter of some will be 'intrinsically unsuitable for ADR'. The court accepted there were a restricted number of situations where rejecting mediation might be considered safe. The recommendations given by a Commercial Court Working Party in 1999 were accepted: where a party requires a court determination on a point of law, where the issues have importance for future trade or commerce or where a case involves fraud or disreputable commercial conduct but two further examples were provided: when a party wants a resolution of law or injunctive relief.

(2) Merits of Case: The merits of a case are a more problematic and Halsey identifies only one 'clear cut criteria' where a party is likely to be exonerated for refusing mediation: When a party would have succeeded at summary judgement but had not made an application. A more difficult judgment relates to the belief a party has regarding the merits of their case. If a party believes that s/he has a strong case the court might find this relevant but warned future courts to take account of the susceptibility of large organisations and public bodies to cynical invitations to mediate from parties with unmeritorious claims, which force them to make 'nuisance-value' offers to avoid the cost of mediation. However, as Brooker and Lavers observe, smaller organisations, perhaps sub-contractors, with 'limited budgets and a good claim' are equally susceptible to tactical mediation strategies by large corporations, resulting in settlement on unfavourable terms in order to avoid what is an increasingly expensive ADR option. [22]

Border-line cases involve an even more difficult assessment, because courts are likely to view them as 'suitable' for mediation. Halsey advises that 'little weight' should be given to a rejection in these circumstance unless there are 'compelling countervailing factors', which the court does not specify but which are likely to derive from the other five circumstances. Making judgments on the balance of success at court is usually in the hands of legal advisors and it is recommended that the best line of action must be to accept an offer to mediate in borderline cases. However, where parties believe that they have a 'watertight case', in contrast to the decision in Hurst v Leeming, Halsey held that a refusal may be justified but only if it is reasonable: An unreasonable belief that a case is watertight will warrant a penalty for unreasonable behaviour.

(3) Other settlement methods: Another relevant factor is whether other 'settlement methods' have been attempted, which is translated in the judgment to mean 'settlement offers'. Refusing such offers may be evidence of a party's 'unrealistic understanding of the merits of their case'. Halsey highlights that mediation is often successful when other attempts have been made to settle but identifies involvement in settlement methods as 'no more than an aspect of factor'. Nevertheless it does indicate the importance of the dispute resolution strategy that litigants adopt. Parties should be advised to seriously consider any offer and to make counter offers in order to justify continuing litigation. It is also indicative of the importance settlement is given in CPR and the broad concept given to ADR to include negotiation. [8]

(4) Costs: The TCC protocols state ADR can lead to 'significant savings in costs and may result in a settlement which is satisfactory to all parties'. [9 at 7.1.2] However, the cost of mediation may justify rejecting the process where it is disproportionately high to the sums at stake. Halsey notes mediation can cost as much as a day in court and that significant costs can accrue when settlement is only achieved just before the court date. Studies suggest mediation is becoming expensive, particularly if the parties are well advanced in litigation and intend to employ legal representation and a leading mediator. [21] [22] if judges direct or facilitate the process in unsuitable cases then these costs become a direct cost of litigation although; the courts have shown willingness to award aborted mediation costs to the unsuccessful party. [27]

(5) Delay: Weight is given to the timing of mediation: If the offer is late and has the effect of delaying trial that may justify rejecting mediation. The TCC protocols do not enlighten the parties merely noting that ADR or mediation may be appropriate at any time. [9 at 7.2.1.] There may be a diminishing return on engaging in mediation close to trial, however there may be other benefits such as testing witnesses or evidence or narrowing issues which may make late mediation an attractive option. [21] [22]

(6) Prospect of success: The factor that is most difficult to assess with certainty is whether mediation has a reasonable prospect of success. Hurst v Leeming established this to be the critical factor [25 at 381] but Halsey (2004) views it as relevant but not determinative. The court illustrated a party's response to an invitation to mediate with two cases. First, when the opponent takes an intransigent position a party may 'reasonably decide mediation has no reasonable prospect of success because of the unlikelihood of reaching a reasonable compromise'. Second, if a party has been 'unreasonably obdurate' the court may decide that mediation has no reasonable prospect of success but a party is not allowed to rely on their own uncompromising approach, which would be unreasonable behaviour and could be penalised through costs. [2 at 25-26]

Halsey observed that some disputes are inherently more intractable than others (although crucially the decision does not specify which ones or, why) and that some mediators are more skilful that others, which may affect the outcome and the ability of the court to decide how reasonable a prospect there was for success. [2 at 27] Shipman argues that a party should not be allowed to cite mediator skills or competence as a relevant factor as it creates uncertainty in case management. [8 at 206] However, mediator skills have been found be a key factor to settlement. [17][18][23] Specialist courts and judges hearing complex construction cases have long been a feature of litigation and the parties in the building environment are now seeking subject-expert mediators. This is leading to construction mediation being in the hands of a few specialist well qualified, expensive mediators. [20] As mediation grows so too will the pool of experienced mediators but in the current climate a reasonable belief that there is a shortage of mediators with relevant experience might suffice when claiming it was not unreasonable to reject mediation. However, the likely success of such a claim in the TCC is weakened for a number of reasons. First, the TCC provides for judges to offer their services to help resolve the dispute through appropriate methods. Second, the court protocol directs the parties to where information can be found about mediation. [9 at 7.3.4] Finally, the TCC indicate that if the parties fail to agree a mediator when involved in an ADR order, the court may facilitate selection from lists provided by the parties. [9 at 7.3.3]

The Halsey guidelines indicate broad circumstances where the court may find that mediation was a suitable option. Although a party may wish to rely on their right to seek redress from a court they may find they have little support from judges who use their discretion when awarding a cost penalty. Shipman believes judges' discretion is influenced by their 'ideological attitudes' to the function of the court by either maintaining a pre-CPR approach of finding the correct legal outcome or adopting a post-CPR approach of allocating limited court resources to appropriate cases which increases the uncertainty of predicting how the court will view a rejection to use mediation. [8 at 194] The following section will evaluate how the TCC has interpreted the Halsey guidelines.

3. Appropriate Criteria in TCC

The court protocols require the parties to consider ADR but it is only when a party claims there has been an unreasonable rejection of mediation that the court uses its discretion as to whether costs should be awarded against the successful party on this basis which can be at the indemnity basis. [6 at Part 44] A search of the databases reporting TCC cases (BAILII, WESTLAW and LEXUSNEXUS) using the terms mediation, mediate, mediator and ADR since the decision in Halsey, returned twenty-nine cases. The data indicates three cases were determined involving costs which are relevant to an identification of mediation appropriateness criteria for construction disputes. Reference is made to other cases as the decisions indicate categories or circumstances of construction disputes where judges view mediation to be appropriate or inappropriate. It is also noted that in twelve cases mediation had been attempted but had not settled, which indicates a relatively high level of settlement failure.

Prior to Reid Minty v Taylor [2002], it was understood indemnity costs were awarded for behaviour 'lacking in moral probity' or 'deserving of moral condemnation', however it was found not to be necessary to reach this standard [28] but behaviour that is 'unreasonable to a high degree' will be penalised. [29] The TCC considered whether the conduct of the successful party had sufficiently reached this level when refusing to mediate in International Ltd & Orr v Styrene Packaging and Insulation & Ors [2005] [30] The court was unaware of any case where a rejection to mediate was the 'sole justification' for awarding indemnity costs but accepted that in 'exceptional circumstances' it may be 'wholly unjustified to reject an offer to mediate. [30 at 9] Having examined the facts, the judge declined the claim for indemnity costs because the successful party had not 'wholly refused' mediation and had agreed to mediate when the offer was first made but the parties were unable to agree the form to take. Further, the court determined that it was not unreasonable to refuse mediation because the parties were already preparing for trial on the directions of the judge.

There is little evidence available to help parties evaluate the optimum timing for mediation. Although the TCC protocols suggest ADR may be appropriate at any time, Halsey held that it is unlikely to be unreasonable to refuse a late offer to mediate, particularly when this would delay trial and add to litigation costs. [2] Following Dunnett, there were reports that some lawyers were using mediation offers as a 'cost terrorism' devise. [21] [22] The TCC condemned the tactics of 'belated offers' from solicitors who had got themselves into 'costs difficulties' in

Wates Construction Ltd v HGP [2005] because it is 'not a practice in accordance with the CPR' and because mediation in these circumstances is unlikely to settle. [31] In contrast, mediation was commended as an option for 'overall settlement' on costs after trial in Multiplex Construction (UK) Ltd v Cleveland Bridge UK [2006]. [32] The TCC had determined the preliminary issues of a complex construction case involving an interpretation of the Heads of Agreement, an interpretation of the Supplementary Agreement, a decision on the value of work completed and a resolution of who had repudiated the subcontract, which resulted in both parties winning some issues but no 'overall winner'. Mediation at this stage was deemed to offer the potential of saving costs and management time. [32 at 666]

Indemnity costs were considered in relation to the parties' conduct in litigation and an unreasonableness of refusal to use ADR in Tonkin & Anor. v UK Insurance Ltd (2) [2006]. [33] The TCC concurred that an award at the higher rate 'simply' because of a failure to mediate is not sufficient. The claimants' house had been destroyed by fire and they asserted that the defendant's scheme for reinstatement was undervalued. They failed to better the defendant's payment into court under a Part 36 offer and the judgement also found they had refused 'two sensible offers of mediation'; their scheme for reinstatement was 'wholly inadequate'; their case was 'weak' as they were found to be wrong on 'almost every issue' and further their conduct was 'unreasonable and at times reprehensible', particularly their unjustifiable attack on the bone fides of the defendant's expert witness. [33 at 42]

His Honour Judge Coulson, observed that indemnity costs need not always be awarded because a party maintained a weak case or because the losing party refused ADR [33 at 30] and had the claimants been reasonable 'in just one way' they would have avoided the higher rate. [33 at 40] On the issue of rejecting ADR, the court stated this was a 'grave mistake' because it was deemed to particularly appropriate 'in this <u>case</u>, for <u>these</u> disputes' of architectural detail'. [33 at 31(b)] Emphasis given in judgment]

The Halsey guidelines were considered in P4 Ltd v. Unite Integrated Solutions PLC [2006] in a case that Mr Justice Ramsey regarded as a 'classic example' of suitability for ADR. [3] P4 alleged that the defendant (Unite) had converted £70,000 of goods supplied by them to Unite's subcontractor, who became subsequently insolvent. P4 claimed Unite had notice of a Retention of Title clause in the goods but had gone on to install a significant number. P4 made several Part 36 offers but failed to better the amount awarded by the court, therefore under Rule 36.20(2), the court, unless unjust to do so, had to order the claimant to pay the costs up the date of the Part 36 offer. P4 claimed it was unjust and Unite were claiming their costs for the whole period of the litigation at the indemnity rate. In response, P4 submitted that no costs should be paid, first, because Unite had failed to provide requested information about the payment order made to the subcontractor and, second, because Unite had unreasonably refused mediation. Mr Justice Ramsey, in giving the judgement, reiterated that the Halsey guidelines are not limited to the six factors but Unite were found to have unreasonably refused P4's invitation to mediate for the following reasons:

Nature: The dispute was found to be suitable because, although not of significant value, it did cover a number of factual issues including; the number of unfixed goods on site at the time P4 gave notice of the Retention of Title clause and whether the subcontractor had been paid for the goods. The court refuted Unite's claim of an on-going relationship where a point of law needed to be determined and the assertion they needed to defend allegations of bona fides on the grounds that both issues emerge after P4 offered mediation.

Merits: Unite's claim of a 'watertight case' at the time of the first proposal to mediate was rejected because it only became stronger later during the proceedings. In the judgment of the court, they did not have a strong case when the first two offers of mediation were made. Further, the court contended mediation would have helped Unite's weak oral evidence on the number of fitting made, which with other evidence may have narrowed the dispute.

Other methods: Exchange of offers and information were not held to be evidence of other settlement methods but the court noted P4, during this phase, increased the Part 36 offers indicating an 'increasingly unrealistic view of the merits of its case'. [3 at 37] The court observed offers to settle might be relevant but only an 'aspect' of whether there is a reasonable prospect of success for mediation. Particular note was made that letters exchanging offers are not a 'proper substitute' for a process of ADR with a third party neutral, such as a mediator, which allows the parties to gain a more realistic understanding of their position and avoid 'increasingly unrealistic offers' being made.

Costs: The court disagreed with Unite's argument that the cost of mediation outweighed the amount in dispute because their analysis had failed to take into account the cost of proceeding to a hearing and the time spent on litigating, which should have been factored into the evaluation leading to a conclusion mediation would have been less expensive than going to trial.

Delay: Unite accepted that there was no delay in offering mediation, which the court confirmed but they were found to be unreasonable when they stated in correspondence at the beginning of the claim that P4 had not considered mediation when they had done so. This indicated Unite were not seriously considering ADR.

Prospect of success: Mr Justice Ramsey, took as the starting point 'the majority of cases are capable of settlement and are in fact settled in this way'. [3 at 41] Unite, had used Halsey's example that a party's intransigency might suggest little prospect for mediation success and submitted P4's obduracy was an indication that settlement was unlikely. However, the court stated Halsey had suggested success 'may not only depend on the willingness of the parties to compromise', implying mediation can be successful even under these conditions. The court was of the opinion not only would mediation have had a 'reasonable prospect' of success but a 'good prospect' and there was a good possibility P4 would have compromised if they had the opportunity to meet face to face or with a mediator.

P4 was suitable for mediation because it involved small sums compared to the cost of litigation and there were a number of 'uncertain factual and legal issues'. [3 at 45] The court were ‘persuaded’ that it was of ‘great importance’ that both parties had a long commercial relationship, albeit through the subcontractor, which P4 had been seeking to develop because this would have given mediation a good prospect of success. [3 at 45] Unite were found to have unreasonably refused mediation which prevented the parties from an early resolution of their dispute but only for the period up to the Part 36 in July 2005 when P4’s case became weaker, after that date Unite were awarded their costs but not at the indemnity rate because P4’s conduct was not found to be ‘out of the norm’. [3 at 51]

Construction cases are likely to be deemed appropriate when they involve disputed facts or legal issues because mediation might allow the parties to gain a better understanding of the dispute and bring about settlement, or allow the parties to narrow the issues. Certainly had the parties meet face to face at an earlier stage in P4, it may have shed light on the missing evidence of payment to the sub-contractor, which was crucial to the dispute. Settlement is undoubtedly the optimum outcome from mediation but an understanding by the TCC that other advantages can be gained is a factor parties are advised to take into consideration when reviewing dispute resolution strategy, particularly when the court make their judgments with the assistance of hindsight. [29] Research indicates other benefits can accrue with mediation such as clarifying or narrowing issues, assessing strengths and weaknesses or reality checking, all of which might stimulate a later settlement or help prepare for trial with the added bonus of reducing litigation costs. [21][22] Tactical benefits such as ‘feeling the financial muscle’ of the other side or ‘testing’ the evidence have been identified as incentives for mediating but some lawyers adopt a more cynical use by employing 'tactical games' and being ‘less open and more manipulative with the mediator’. [21 at 213] The parties are entitled to adopt any position they like in mediation and the court will not look behind the reasons settlement was not achieved as this compromises the confidentiality of the process. [2 at 14] It would be unfortunate if the TCC, in its efforts to encourage mediation, play into the hands of less scrupulous parties.

4. Conclusions

Mediation has been shown to offer benefits to disputing parties and it is irrefutable that many TCC judges, with personal experience and expertise in construction disputes believe it should be ‘routinely’ discussed and used by the parties. [2] A failure to do so may be sanctioned, although it is unlikely to be at the indemnity level unless there is other evidence of unreasonable behaviour in litigation. Construction parties should take into account that the court continues to emphasis the ability of mediation to deal with intractable parties and the importance of continuing commercial relationships despite evidence suggesting uncompromising attitudes are often a key factor for non-settlement and mediations rarely achieves creative outcomes enabling parties to continue their ongoing relationship. Although Halsey witnessed a retreat from the contention that nearly every case will acquiesce to mediation or the skills of experienced mediators, the personal experiences and perceptions of judges continue to drive appropriateness criteria in the TCC, which could in the long term work negatively against its true potential. The more construction parties experience mediation, or less experienced mediators, failing to work its ‘magic’ with intractable parties or not producing creative outcomes, the less confidence there is likely to be in the process. Developing a Conceptual Framework of Catastrophic Withdrawal Behaviour in Construction Dispute

Pui Ting Chow, Sai On Cheung
Construction Dispute Resolution Research Unit,
Department of Building and Construction,
City University of Hong Kong

Abstract

The voluminous reported studies on dispute management have engendered a need for sustainable improvement in negotiating skills because of its decisive effect on the success or otherwise of construction dispute negotiation (CDN). Earlier studies identified that performance of negotiators dictate and influence the outcomes of negotiation. Negotiators should also be responsive to their opponent's negotiating style and strategy as these would undoubtedly affect their own negotiating attitudes. The prospect of negotiation is doomed if negotiators lose the interest to continue. This phenomenon is described as withdrawal in this study. Withdrawal has been found to be influenced by a vast array of cognitive factors. Ignoring or undermining these cognitive obstacles to negotiation can be fatal as these can be the major hurdles against successful outcomes. This study aims to contribute to the study of CDN by analysing withdrawal phenomenon under a 3-variable catastrophe framework. Future research directions for the development of conceptual model of CDN withdrawal are also proposed.

Keywords: construction dispute negotiation, withdrawal management

1. Introduction

It has widely been accepted that conflict is inherent in all construction projects. If conflicts are not handled properly, they will escalate and turn into disputes. When this happens, the disputes need to be resolved. There is a range of resolution methods available for this purpose. Among these, negotiation is the most informal, thus, allows the disputants to take control of the resolution process. Furthermore, it offers high degree of confidentiality and is well recognised as a time- and cost-effective method. An effective negotiation involves heavy information exchange as well as meticulous trade off of values and interests. Negotiators are responsible in charting for successful outcomes. As such, it is imperative to keep the negotiators at the negotiation table. In other words, once negotiators withdraw, the disputes would likely have to be dealt with by other means like arbitration and litigation. This is an undesirable outcome as the possibility of future dealings and relationship among the contracting parties would very likely be tarnished. Moreover, several reviews of the construction industry reported that contracting environment remains adversarial and disputes are often not resolved promptly. It is further stated that practitioners often deal with small and uncomplicated construction disputes with reasonable efforts. Unfortunately, complicated disputes are intentionally ignored. In actual facts, construction professionals should instead be able to recognize and diagnose problems as they evolve and apply appropriate means to resolve them. Despite the complexity involved, negotiators should display their perseverance and patience to engineer a successful negotiation. In this connection, *"…an increasingly lean world which is saturated with uncertainty is that the future will be punctuated with unexpected, potent and cryptic events which will require a rapid response…"* [1]. To mitigate this impact, it is important that the construction industry can react accordingly. In this study, withdrawal is defined as situations when negotiators decide not to continue with the negotiation [2]. Withdrawal behaviours (WB) are therefore those happenings that would lead to withdrawal if not controlled. Withdrawal behaviours will foster the growth of an uncooperative working environment. As such, productivity erosion, and profitability reduction as well as an adversarial and mistrust environment among contracting parties will surface. In view of the importance of withdrawal in construction dispute negotiation (CDN), a conceptual framework on withdrawal is developed by examining (i) what phenomena characterize withdrawal behaviours in CDN?; (ii) how can a model of withdrawal in CDN be formulated?; and (iii) which factors trigger withdrawal?

2. Characterizing withdrawal behaviour by catastrophe theory

Negotiation breakdown occurs when one of the negotiating parties withdraws. It is resulted from psychological struggles experienced during the course of negotiation [3]. Resolution becomes impossible once withdrawal happens [4]. Furthermore, it will also lead to destructive outcomes that have damaging effects on later interactions. When withdrawal tendency is high, the associated feeling of uneasiness and insecurity would ultimately cause collapse. Withdrawal does not sit comfortably with the rational models that predict negotiators would pursue their goals and maximize joint profit. Retreating and leaving the dispute unresolved is thus simply a suboptimal outcome. Neale and Bazerman [5] stated that "… *a great deal of sub-optimality in negotiated outcomes is attributable to deviations from rationality in negotiators' cognitive processes…* ". Negotiation often involves mixed-motive interactions in which disputants face particular cognitive problems. In those circumstances, these disputants continue to experience high degree of cognitive dissonance, losing face, negative self-image, disrespectfulness and unfairness, and misunderstanding that lead to withdraw. Indeed, research has revealed that once withdrawal happens, it can affect the way people think and act, as well as repetitive withdrawal behaviours. Bluedorn [6] described withdrawal as a reduction in the socio-psychological attraction to or interest in organization. Herzberg *et al*. [7] suggested that ultimate withdrawal is predisposed by a series of dysfunctional behaviours progressing from declining performance, frequent lateness, and absenteeism to withdrawal.

Withdrawal may also be a sensible tactic when negotiator feels being excessively exploited by an opportunistic opponent. It can be triggered by the number of counterparts' non-compliance to negotiated agreements. In addition, Surra and Longstreth [8] demonstrated that people, who felt tension with others, were more likely to withdraw from negotiation than those who didn't. These interpersonal problems often drive anxiety and fear. Negotiators may also experience frustration, strain, and uneasiness when they dislike each other. The likely responses in these circumstances will be psychological or physical withdrawals from the negotiation processes [4], [9]. Rise in withdrawal tendency will fester in an organization, grow in proportions and ultimately cause collapse [10].

In most negotiation models, negotiators are regarded as rational utility maximizers. As such, these models typically suggest that negotiations would end in resolution at the point that utilities of each party are enhanced [11]. This proposition suggests that continuing the negotiation process is more beneficial than withdrawing [12], [13]. However, negotiators often fail to reach an agreement even when there are mutually acceptable solutions within the positive contract zones described by Walton and McKersie [14]. This proposition suggests that there exists a threshold of level beyond which withdrawal will suddenly occur. Some of the social science studies [14] reported similar findings in that human behaviours exhibit a continuous change of behaviour often display a discontinuous lapse; a classical phenomena described by Catastrophe Theory (CT) [15]. In this study, withdrawal in construction dispute negotiation (CDN) is taken as the behaviour whereby a negotiator loses the interest to continue with the negotiation. It is further suggested that such change is dynamically associated with the underlying factors of disputes and can be characterized by a catastrophic discontinuous lapse.

CT has widely been used in a number of science based research fields such as physics, chemistry and biology. More recently, it has been used in social science and finance. The simplest catastrophe model, cusp, is a 3-variable framework that includes one dependent behavioural variable (represented by Z-axis) and two independent control variables (represented by X- and Y-axes). The dependent variable shall have polarized discrete forms, whereas the two control variables are known as normal and splitting factors respectively [16]. The horizontal plane formed by axes X and Y is called the control surface, while the respective value of Z forms the behaviour surface. Negotiation is an argument across value and interest. It involves multi-emotional mood of various status. In a professional negotiation context, the withdrawal behaviour axis may run as shown in Figure 1 as described by Zeeman [17]. At one end, negotiation can be brought to a successful conclusion only when the disputants remain at the negotiation table with hopeful manner or either party's impending proposal is more desirable than the previous one [2]. On the other hand, once negotiators lose their interest to continue, the negotiation probably would collapse – withdrawal occurs. Figure 2 illustrates the hypothesized catastrophe model of negotiator's withdrawal tendency. The withdrawal tendency as shown in the figure is a result of the interaction between the normal and splitting factors. The behaviours of withdrawal ranging from continue to withdraw as depicted in the behaviour surface (B) are governed by the withdrawal tendency as shown in the vertical axis.

Emotional mood		Withdrawal behaviours
	Withdraw	Withdraw
		Abuse
		Irrational argument
		Rational discussion
	Continue	Concessions
		Apologies

Figure 1 The behaviour axis model describing the emotional mood of a negotiator in an negotiation (Modified from Zeeman [17])

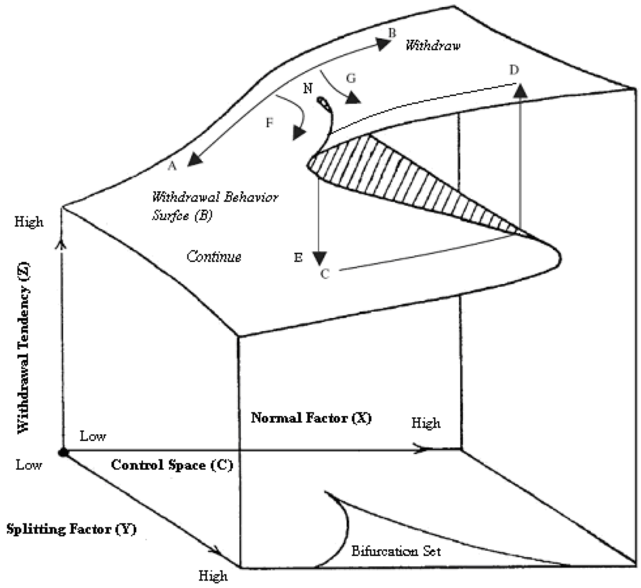

Figure 2 A 3-variable cusp CDN withdrawal framework (Modified from Zeeman [17])

3. Models development

Figure 2 shows a typical 3-variable cusp catastrophe CDN withdrawal model. In this, a set of respective values of X and Y defining the edges of the pleat represents the singularity set. Once the intensities of the normal and splitting factors reach the critical value of the singularity set, the behavioural variable undergoes a catastrophic change. It is visualized as the arrows D and E in Figure 2. There is one likely form of behaviour in any given combination of the two control factors except within the bifurcation set. In other words, there are two stable equilibriums for some combinations of values of control variables inside the bifurcation set [18]. The pleat of the behaviour surface runs smoothly without crease and there is a middle fold that completes the pleat of the cusp behavioural surface giving the representative feature of the "S" shape of cusp model. This shadow region in Figure 2 represents an area having an unstable equilibrium and of least potential. At the point N, marginal change in path causing major change in behaviour and it is represented as the neutral point. The pleat in the behaviour surface diverges from the neutral point and enlarges along the splitting factor. It is represented by the path F and G in Figure 2. Once a transition from the upper surface to the lower surface is made or vice versa, a return of its original behaviour value will not occur even if the same magnitude differential in the control variables values are reached as shown by the path CD and DE. They are called the hysteresis paths.

4. Model descriptions – Control variables

Several researchers have admitted that there are cognitive frames that individuals use to understand negotiation situations and react correspondingly [19]. Pinkley and Northcraft [20] further described the three orthogonal dimensions of frames: (1) relationship level versus task level, (2) emotional level versus intellectual level, and (3) cooperate level versus win level. As these forces in CDN co-exist and are in dichotomy, these forces fit nicely with the requirements of the 3-variable cusp catastrophe framework. Therefore, the application of CT to analyze the relationship between withdrawal behaviour and its drives in dichotomy is considered probable. These three dimensions are identified as pragmatism, intelligence and interdependence in the study.

4.1 Pragmatism (Task level versus Relationship level)

The first dimension, pragmatism, refers to the variation in the extent to which a disputant focuses on ongoing relationships and the conflict itself with the other party. Disputant with a high relationship orientation focuses on interpersonal concern; disputant with a high task orientation instead concentrates on the substantive aspects of a dispute, such as money or property settlements. Harold [21] stated a model focusing on the tension between relationships and goals in conflict handling. When a negotiator is engaged in a conflict there are two major concerns to deal with: (a) achieving goals of the task and (b) preserving the relationship. The importance of goals and relationships affect how negotiator acts in a conflict situation. Framed with these two concerns, the arrangement of the five styles of managing conflict is as shown in Figure 3.

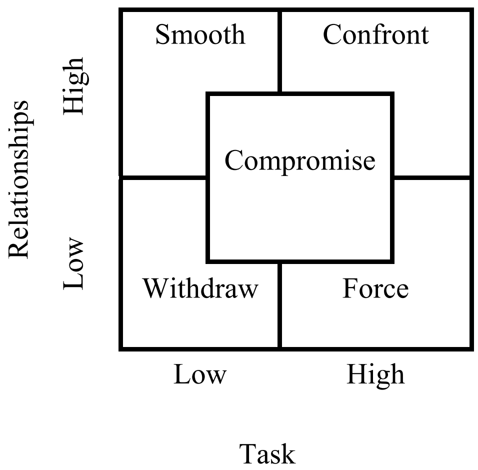

Figure 3 Task versus Relationship model (Adopted from Harold [21])

4.2 Intelligence (Emotional level versus Intellectual level)

The second dimension, intelligence, reflects the degree of attention a disputant pays to the affective components and substances of a dispute. A disputant in one way focuses on feelings involved, such as jealousy, hatred, anger, and frustration, and in other way on actions and behaviours. Bazerman *et al*. [22] stated that positive moods tend to increase negotiators' tendencies to select cooperative strategies and enhance their ability to communicate for integrative gains. An angry negotiator who is less accurate in judging the interests of his opponent would achieve lower joint gains. Thus, it advocates move such as deception in negotiation. Simultaneously, Radford [23] characterized that a negotiator can be accommodating or coercive from an intellectual perspective. An accommodating move is one that strives for an agreement. A coercive move, on the other hand, is to seek a favourable outcome for one's own. In Figure 4, the four styles model in the emotion/intellectual perspective is proposed.

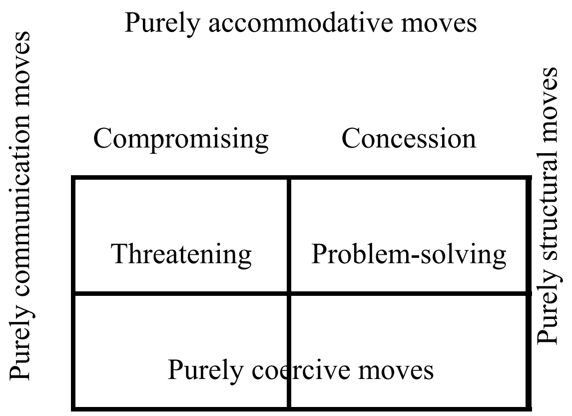

Figure 4 Emotional versus intellectual model (Adopted from Fraser and Hipel [24])

4.3 Interdependence (Cooperative level versus Win level)

The final dimension, interdependence, suggests that negotiation involves a fundamental tension between whether parties feel they need to cooperate or compete in order to achieve their goals. Deutsch *et al*. [25] distinguishes between two key dimensions, i.e. assertiveness in the pursuit of one's own goals, and cooperativeness in pursuit of mutual goals. Thomas and Kilmann [15] elaborated this conception by using two orthogonal dimensions that include cooperativeness and assertiveness. Carnevale *et al*. [26] stated that "…*Bargainers will make pressure statements only if they can accompany them with efforts to stare the other side down.…* ". In other words, parties who perceive the other parties as dominant lead the arousal of dominant behavioural responses among parties. Actions involving either attack or retreat are viewed as their walk-away option as a source of power. As such, the intention to cooperate or to win may be related to individual's withdrawal tendency. For the purpose of this study, Thomas-Kilmann model [27] on conflict handling style is used (Figure 5).

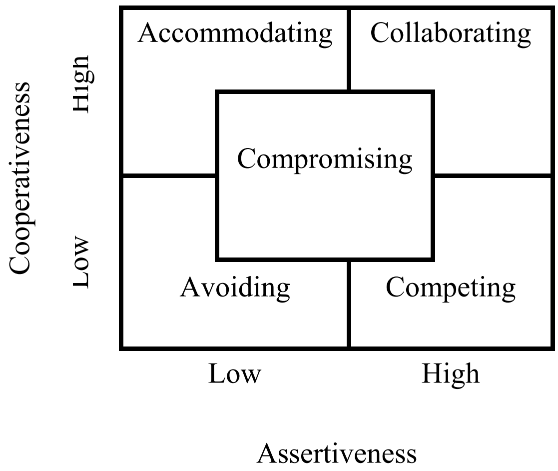

Figure 5 Cooperative versus win model (Adopted from Thomas and Kilmann [27])

To sum up, the measurement frameworks of the three conflict frames are adopted into the control factor models as represented in Figure 6.

Level		Control factor model		
		Pragmatism	Intelligence	Interdependence
High	↕	Force	Problem-solving	Collaborating
		Withdraw	Compromising	Avoiding
		Compromising	Concession	Compromising
		Confront	Threatening	Accommodating
Low		Smooth		Competing

Figure 6 Control factor models for the three negotiation dimensions

5. Catastrophe CDN Withdrawal Model

Having introduced the model components, this section gives the implications suggested by the CT. According to the model in Figure 2, the changes in the withdrawal tendency as a result of the moderating effect of the splitting factor on control factor influence the withdrawal behaviour. To illustrate the working by way of an example, hypothesized cases with low, moderate and high degree of pragmatism (as splitting variable) level are elaborated (Figure 7). When the level of pragmatism is low, the parties emphasize the areas of agreement to preserve their relationship. At this position, the situation can be described as either smoothing or confront, i.e. change from continue to withdraw is relatively unlikely. The parties are more accommodating and willing to adjust their responses to situational demands. This situation is reflected in Figure 7 as the path movement between A and B. It is noted that the changes in intelligence are approximately proportion to that of withdrawal tendency. Thus, if an abrupt change in the withdrawal behaviour under a low pragmatism, a fairly large increase in intelligence is necessary. On the other hand, when the degree of pragmatism becomes moderate, the parties become less adaptive as they concentrate on the materials. The capability of matching the intelligence demands becomes weaker across intelligence level from high to low. A small change in the intelligence level can result in substantial change in withdrawal tendency as indicated by the path movements of CD and DE (Figure 8). With reference to the study of Blau [28], it is suggested that current behaviour is a response to the previous behaviour of the others. If pragmatism and intelligence levels are moderate, it is possible for the party to withdraw or continue as indicated by the point H and J in Figure 8, where point I is the least possible form of behaviour.

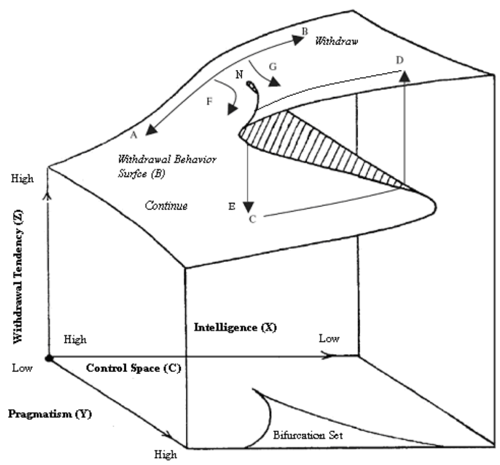

Figure 7 A hypothesized cusp catastrophe CDN withdrawal model with pragmatism as splitting factor (Y) and as intelligence normal factor (X)

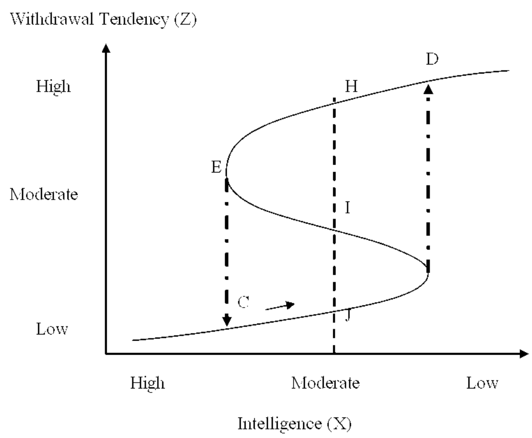

Figure 8 Withdrawal tendency movements at middle level of Pragmatism (Y)

6. Concluding Remarks

Most construction disputes are firstly negotiated for a resolution. A negotiation can be considered doomed if a negotiator withdraws from the process. Once negotiation fails, conflict may escalate. It may have to resort to lengthy and costly legal actions. In this study, withdrawal is defined as situations where negotiators lose the interest to continue with the negotiation. This study suggests the use of cusp model to describe the dynamics of withdrawal behaviour. This conceptual framework is subject to empirical testing currently being conducted by the authors to confirm the appropriateness of employing the three dimensions of negotiation frames – pragmatism, intelligence and interdependence as control and splitting factors of a 3-variable cusp catastrophe CDN withdrawal framework. Six such frameworks are proposed through different combinations of these frames. Testing of these models shall provide invaluable insight to enhance the understanding of CDN.

Legal research in the built environment: a methodological framework

Paul Chynoweth,
Research Institute for the Built and Human Environment, University of Salford
(email: p.chynoweth@salford.ac.uk)

Abstract

The methodological basis of legal research has traditionally not been explained by its practitioners and this has led to misunderstandings between researchers in interdisciplinary fields, including the built environment. The paper therefore develops a methodological framework as a mechanism for communicating the implicit, often subconscious, methodologies employed by legal scholars to other researchers within the built environment. It distinguishes legal research from scientific research and defines it as a normative process which is undertaken within the humanities research tradition. The approaches adopted by researchers are explained primarily in terms of deductive, analogical and inductive reasoning although it is noted that the term "methodology" is more suited to research in the sciences than in the humanities.

Keywords: Disciplines, Epistemology, Jurisprudence, Knowledge, Law, Methodology, Research, Theory.

1. Introduction

Legal research is a comparatively recent phenomenon within the built environment research community. Its academic methods have traditionally been regarded with suspicion by other built environment researchers who have struggled to recognise its outputs as credible research contributions [1]. In particular, legal researchers have arguably been insufficiently reflective as to the methodologies employed in their work and, as a consequence, have found difficulty in explaining these to researchers from other disciplines.

The underlying reasons for this phenomenon are to be found in the traditional approach to legal education which conditions students to "think like a lawyer" [2] without providing any theoretical grounding in the methods actually being employed. As a consequence legal researchers have always struggled to define their work in terms that their academic peers in other disciplines can understand [3].

The present paper therefore reflects on the techniques actually employed by legal researchers at a subconscious level and attempts to make these explicit. It presents these in the form of a methodological framework for possible adoption by the built environment legal community as a mechanism for more effectively describing its work to researchers in other disciplines within the field

2. Epistemological considerations

2.1 The nature of legal scholarship

Before considering the methodologies employed by legal researchers (or legal scholars, as they are more usually described) it is first necessary to understand the epistemological nature of the process being undertaken by them, and to appreciate how this differs from other research in the built environment.

There is a dearth of theoretical literature on the nature of legal scholarship and a consequent lack of awareness about what legal scholars actually do. Nevertheless, Arthurs proposed a useful taxonomy of legal research styles in his report on legal education and research in Canada [4]. This has informed the analysis in this paper and is represented as a matrix in Figure 1.

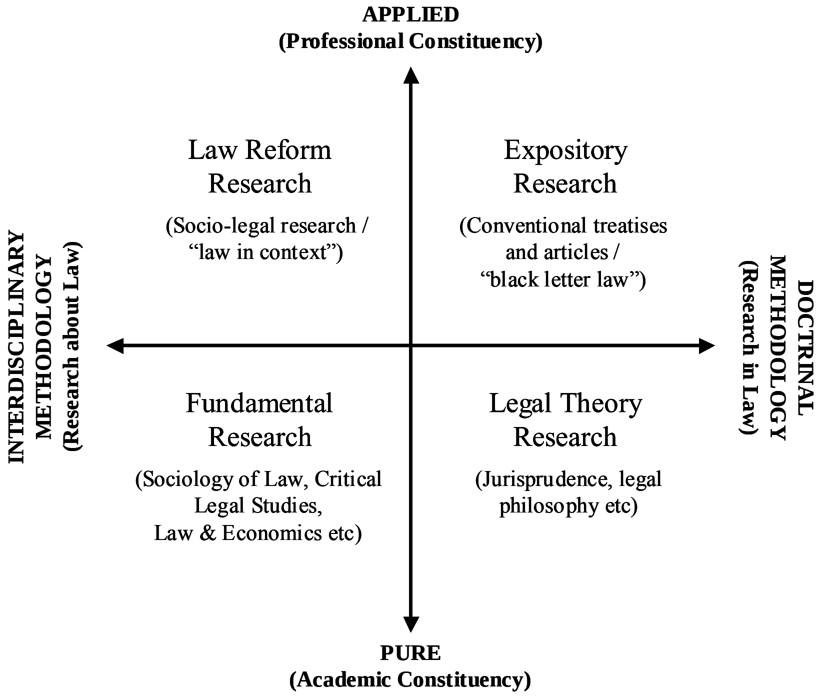

Figure 1: Legal Research Styles (after Arthurs 1983)

It will be seen that the vertical axis of the matrix represents the familiar distinction between pure research which is undertaken for a predominantly academic constituency, and applied work which generally serves the professional needs of practitioners and policy makers. This has been explored in some detail elsewhere [5]. In the present context, the more interesting distinction is that between doctrinal and interdisciplinary research which is represented by the horizontal axis and the present paper considers only this aspect of Arthurs' model.

2.2 The meaning of 'doctrinal' research

Doctrinal research (on the right in Figure 1) is concerned with the formulation of legal "doctrines" through the analysis of legal rules. Within the common law jurisdictions legal rules are to be found within statutes and cases (the sources of law) but it is important to appreciate that they cannot, in themselves, provide a complete statement of the law in any given situation. This can only be ascertained by applying the relevant legal rules to the particular facts of the situation under consideration.

As will be discussed below, deciding on which rules to apply in a particular situation is made easier by the existence of legal doctrines (for example, the doctrine of consideration within the law of contract). These are systematic formulations of the law in particular contexts. They clarify ambiguities within rules, place them in a logical and coherent structure and describe their relationship to other rules. The methods of doctrinal research are characterised by the study of legal texts and, for this reason, it is often described colloquially as "black-letter law".

2.3 Contrast with scientific research

Doctrinal research is therefore concerned with the discovery and development of legal doctrines for publication in textbooks or journal articles and its research questions take the form of asking "what is the law?" in particular contexts. This form of scholarship has always been the dominant form of academic legal research [6].

At an epistemological level it differs from the questions asked by empirical investigators in most other areas of built environment research. Scientific research, in both the natural and social sciences, relies on the collection of empirical data, either as a basis for its theories, or as a means of testing them. In either case, therefore, the validity of the research findings is determined by a process of empirical investigation. In contrast, the validity of doctrinal research findings is unaffected by the empirical world.

Legal rules are *normative* in character as they dictate how individuals *ought* to behave [7]. They make no attempt either to explain, predict, or even to understand human behaviour. Their sole function is to prescribe it. In short, doctrinal research is not therefore research *about* law at all. In asking "what is the law?" it takes an internal, participant-orientated epistemological approach to its object of study [8] and, for this reason, is sometimes described as research *in* law [4].

As will be described below, the actual process of analysis by which doctrines are formulated owes more to the subjective, argument-based methodologies of the humanities than to the more detached data-based analysis of the natural and social sciences. The normative character of the law also means that the validity of doctrinal research must inevitably rest upon developing a consensus within the scholastic community, rather than on an appeal to any external reality.

2.4 External factors and interdisciplinary research

In practice, even doctrinal analysis usually makes at least some reference to other, external, factors as well as seeking answers that are consistent with the existing body of rules. For example, an uncertain or ambiguous legal ruling can often be more easily interpreted when viewed in its proper historical or social context, or when the interpreter has an adequate understanding of the industry or technology to which it relates. As the researcher begins to take these extraneous matters into account the enquiry begins to move leftwards along the horizontal axis in Figure 1, in the direction of interdisciplinary research.

There comes a point, towards the left hand side of the matrix, when the epistemological nature of the research changes from that of internal enquiry into the meaning of the law, to that of external enquiry into the law as a social entity. This might involve, for example, an evaluation of the effectiveness of a particular piece of legislation in achieving particular social goals, or an examination of the extent to which it is being complied with.

3. Methodological framework

3.1 Dominance of the doctrinal tradition

The dominance of the doctrinal tradition in legal scholarship has already been noted [6]. However, it is important to understand that this is not simply a single, isolated category of scholarship. Some element of doctrinal analysis will be found in all but the most radical forms of legal research and it was once suggested within a socio-legal studies context, that social scientists should be regarded as "intellectual sub-contractors" who should be kept "on tap, not on top" [9]. Doctrinal analysis therefore remains the defining characteristics of academic legal research and the account which follows represents an attempt to describe the nature of the methodologies employed within it.

3.2 Role of deductive reasoning

The starting point is to recognise that there is no fundamental distinction between the process of academic doctrinal analysis and the legal analysis undertaken by practising lawyers or judges. As already described, the aim, in each case, is to answer the question "what is the law?" in a particular situation. In the case of practising lawyers or judges this will be a real and well-defined situation requiring an immediate answer to the question. For the legal scholar, the situation, or more likely the class of situations being considered, will be hypothetical and the purpose is to undertake a more in depth analysis which is capable of informing the deliberations of practitioners and judges in future cases.

In either case, the initial process of applying a rule of law to a factual situation can be understood as an exercise in deductive logic. Most readers will need no explanation of this form of reasoning which, of course, also forms the basis of the scientific method. However, in a legal context, the familiar syllogism, comprising major premise, minor premise and conclusion, takes the following form:

- Major premise – identifies a general rule of law which requires a specified legal outcome when particular facts are present in a situation.
- Minor premise – describes a particular factual situation.
- Conclusion – states whether the rule in the major premise therefore applies to the facts in the minor premise, and whether the specified legal outcome therefore takes effect.

By way of example, in English law, section 108 of the Housing Grants, Construction and Regeneration Act 1996 contains a general rule of law (the major premise) that a party to a construction contract is entitled to refer a dispute under the contract to adjudication. Therefore, where a particular dispute arises in a particular construction contract between a particular employer and a particular contractor (the minor premise) we can conclude, as a matter of deductive logic, that either party is entitled to refer that dispute to adjudication (conclusion).

3.3 Dealing with the hard cases

This, of course, is an idealised account of the process of legal reasoning. If the process were as simple, and as mechanistic as this, society would have no need for lawyers, and still less for legal scholarship. In reality, in almost all cases, the deductive model will fail, without further analysis, to produce a definitive answer to the question of what the law is in a given situation.

Legal rules, of necessity, have to be expressed in general terms and were famously described by Hart [8] as having an "open texture", and therefore capable of interpretation in more then one sense. In the context of the above example, there has, for instance, been considerable judicial and academic discussion over the meaning of "dispute" in relation to construction adjudication. There will, therefore, often be an element of doubt as to whether a rule applies to a particular factual situation and this characteristic will, of course, be manipulated by the opposing parties and their lawyers in an attempt to achieve the outcome that is most favourable to their interests.

Although Hart [8] concluded that judges exercise discretion in these so-called "hard cases", their decisions are actually based on recognised patterns of reasoning employed within the legal community which are used to supplement the deductive model described above. Lawyers and legal scholars are therefore often able to predict the outcomes of future cases by employing, however subconsciously, the same patterns of reasoning that will eventually be used by the judiciary.

3.4 Role of analogical reasoning

The most widely used technique is undoubtedly the process of analogical reasoning. In contrast to deductive reasoning, which entails reasoning from a general rule to a specific case, analogy involves a process of reasoning from one specific case to another specific case. In those many situations where it is unclear whether a particular factual situation falls within the ambit of a rule, it can often be helpful to examine apparently similar cases which have previously come before the courts. If, upon examination, the facts of these cases are found to be sufficiently similar to the facts of the subject case then it can be concluded that the facts of the subject case should be treated by the courts in the same way. Most readers will be familiar with this process in the context of the operation of the common law doctrine of precedent.

The decision as to whether a case is sufficiently similar to another is ultimately a subjective one as no two cases are ever completely identical. Judges therefore have considerable scope to distinguish the facts of a subject case from those in an established precedent if they choose not to follow it. Nevertheless, this scope is not unlimited and Bell [10] has highlighted how judicial decision making in these circumstances is constrained by social conventions within the legal community which he describes as the "rules of legal discourse". He describes how these "provide a framework lying outside the power of the reasoner within which he has to operate if his arguments are to count as legal justifications". Judges are subject to these rules but so, of course, are lawyers and legal scholars who all participate in the same legal discourse, and who all desire their arguments to be taken seriously.

3.5 Role of inductive reasoning

A third technique involves the use of inductive reasoning which can be described as the reasoning from specific cases to a general rule. This can be of particular assistance when a particular factual situation does not appear to be addressed directly by a legal rule at all and it therefore becomes necessary to "fill the gap" in the law. As with inductive reasoning in the sciences a general proposition can sometimes be derived from a number of specific instances.

In the case of legal reasoning this involves the recognition of a new general rule which emerges from a number of earlier authorities which are then regarded simply as particular instances of the new rule. *Donoghue v Stevenson* [1932] AC 562 is the best known example of this technique. Particular instances of negligence had been recognised by the courts for years before the famous snail in the ginger beer case came before the courts. However, it was not until Lord Atkin proposed his now well-known neighbour principle in this case that the tort of negligence was recognised as a more general rule, capable of being applied to novel fact situations which were not already described in the individual authorities then available. Once again, the capacity for developing new rules in this way will be regulated and limited by the recognised rules of legal discourse described above.

A variety of other techniques is available which, like those already described, also allow the available body of legal rules to be marshalled into coherent patterns (or "doctrines") and applied to new factual situations in an apparently logical and consistent manner. Indeed most legal discourse revolves around the verbal manipulation of the available sources of law in the belief that the answer to most legal problems can be found in the underlying logic and structure of the rules if only this can be discovered [11]. This approach is usually described as legal formalism [2] and, despite numerous academic criticisms of its assumptions (for example, Fitzpatrick &

Hunt [12]), continues to represent the dominant paradigm within legal practice and within legal scholarship, at least in terms of external appearances.

3.6 Role of policy judgments

Nevertheless, there is now a widespread recognition that, in some cases, the law cannot be determined with certainty from an analysis of the rules alone. Although judges will justify their decisions by reference to the existing rules [13] there is a growing realisation that the rules (in the so-called "hard cases") can sometimes be used to justify a number of possible, and opposing, legal outcomes. This is, once again, a function of the open texture of legal rules and, where this occurs, the law is said to be indeterminate [14].

If law is indeterminate, and some cases are decided according to a value judgment made by the judge on the day, there are of course implications for democracy, and for the rule of law. This has unsurprisingly generated criticisms of the political role of the judiciary (for example, Griffith [15]) which remains beyond the scope of this chapter. However, the judges' political role is usually described more charitably in terms of making decisions according to "policy considerations" and this is now widely accepted as a legitimate part of the judicial function.

The challenge for the legal scholar (or practising lawyer) trying to predict the likely outcome of future cases is to understand the nature of the policy considerations that are likely to influence the judiciary. Dworkin's [16] influential writings provide a wealth of guidance in this respect and remind us that policy decisions are far from the arbitrary and unpredictable exercise of judicial power that some would suggest. Rather, he argues that legal systems consist of underlying principles, as well as rules, and that judges are bound to follow these when deciding the outcomes of hard cases. As with Bell's [10] rules of legal discourse described above, these can be seen to provide a constraint on judicial action, and at least some assistance in attempting to anticipate the likely outcome of cases. Bell's [17] empirical work on policy matters also identifies the particular forms of policy argument used by the courts and this can also assist the scholar in trying to anticipate judicial decision making in this context.

3.7 Summary

In summary, therefore, it is probably incorrect to describe the process of legal analysis as being dictated by a "methodology", at least in the sense in which that term is used in the sciences. The process involves an exercise in reasoning and a variety of techniques are used, often at a subconscious level, with the aim of constructing an argument which is convincing according to accepted, and instinctive, conventions of discourse within the discipline.

Although the discourse is apparently conducted according to formalistic conventions it is also influenced by shared value (or policy) judgments which often remain unspoken. The "methods" employed in legal scholarship are therefore neither consciously learned, nor consciously employed as is the case with scientific methods. The skills and conventions of legal analysis are instead learned at an instinctive level through exposure to the process, and they are then employed on the same basis in the development of legal argument. In much the same way that the use of an explicit methodology confers legitimacy in scientific research, credibility within legal scholarship is therefore dependent on the researcher's work demonstrating an understanding and adherence to the accepted conventions and norms of its discourse.

4. Relationship of law to other disciplines

This lack of a formal research methodology, and the reliance on analysis and the development of argument within a prevailing academic discourse, is of course a particular feature of the arts and humanities family of disciplines to which law belongs. This places law at the "soft" end of the familiar disciplinary spectrum and (in common with design), law therefore differs from the dominant built environment research specialisms in this respect. Unlike law and design, the other built environment disciplines of technology, economics and management all belong either to the natural, or to the social sciences.

The science / arts & humanities distinction reflects genuine epistemological and methodological differences between the families of disciplines about the nature of knowledge, and about the manner of its production. Becher [18] has described knowledge production in the sciences in terms of the cumulative and piecemeal accumulation of individual segments of knowledge which, over time, contribute to a comprehensive explanation of particular phenomena. He contrasts this with humanities disciplines like law. These, he describes, as being concerned with the organic development of knowledge through an ongoing process of reiterative enquiry. They address multifaceted, rather than discrete, problems and attempt, not to explain the individual components of phenomena, but to develop a holistic understanding of their overall complexity.

The dominance of the scientific disciplines within the built environment inevitably influences prevailing views about knowledge and knowledge production within the field. Indeed, the language of built environment research is often dominated by the rhetoric of the social sciences in particular. This is characterised by a concern with the traditional social science methodologies (see, for example, Fellows & Liu [19]) and with an emphasis on empirical investigations rather than the development of theoretical perspectives (Betts & Lansley [20]; Brandon [21]).

5. Conclusion

The paper has shown that the normative process of doctrinal analysis is the defining characteristic of most legal scholarship. It has demonstrated how this places it within the humanities tradition with corresponding methodologies and cultural norms. As the built environment research community operates overwhelmingly within a scientific paradigm it embraces different methodologies and cultural norms from those traditionally associated with legal scholarship with consequent difficulties for communication.

In common with other humanities disciplines most legal scholarship is not concerned with empirical investigation, but with the analysis and manipulation of theoretical concepts. The methodologies employed therefore differ from those of the sciences and are probably more accurately categorised, in social science terms, as techniques of qualitative analysis. As has been seen, deductive and inductive logic, the use of analogical reasoning and policy analysis all feature strongly within this process.

Crucially however, as the process is one of analysis rather than data collection, no purpose would be served by including a methodology section within a doctrinal research publication and one is never likely to find one. This is perhaps the most striking difference between the appearance of research outputs in the two traditions, and the one which has historically caused most difficulty for legal scholars when subject to peer review by other built environment researchers.

This paper began by highlighting the failure of the legal research community to adequately explain itself to its peers in other disciplines and in this sense it can hardly complain if those peers then judge it by standards other than its own. Communication between disciplines is one of the great challenges to achieving genuine interdisciplinary and that challenge is never greater then when trying to bridge the gulf between the humanities and the sciences.

Nevertheless, it is surely incumbent on all of us within the built environment research community to do precisely that. This involves developing at least an awareness of practices within the field's various disciplines. But it also involves a willingness to reflect upon our own previously unquestioned assumptions about the practices in our own discipline, and to articulate these for the benefit of others within the field. It is hoped that the methodological framework presented in this paper might provide a vehicle for communicating the nature of legal research to other built environment researchers, and thereby assist the process of communication within the wider discipline.

An analysis of dispute resolution literature in construction management journals

Deniz Ilter,
Project Management Center, Istanbul Technical University
(email: artande@itu.edu.tr)
Attila Dikbas,
Project Management Center, Istanbul Technical University
(email: dikbas@itu.edu.tr)

Abstract

Dispute resolution has become an established part of construction management discipline, both with respect to the academic research undertaken and to its wide application in practice. This paper analyses the recent literature on construction dispute resolution as published in the mainstream construction management journals, aiming to identify those aspects of dispute resolution that have been studied by the researchers and chosen for publication. Peer reviewed articles published in the selected mainstream construction management journals are analysed and classified in terms of research stream, level of analysis, sector, definitions of dispute, sources of information, contribution of the articles and backgrounds of the authors within a meta-classification framework proposed. Based on the findings, the paper presents research trends, neglected areas and future research suggestions for the discipline.

Keywords: Dispute resolution, Construction management, Meta-Analysis, Research Trends

1. Introduction

Academic journals are platforms where communication of research findings and scholarly debate take place. In the academic world, communication is central to the promotion of knowledge and while there are many forms of communication channels, the most permanent and durable are the published literature, especially refereed academic journals. An established refereed journal is a repository of good and novel insights gained from data-based research, scholarly enquiry, rigorous analysis of experience and careful logical debate about an issue or phenomenon [1].

The analysis of mainstream journals is well established [2] and occurs not just in the core scientific and social scientific disciplines. The analysis of a single journal as a case study provide a historical record, describe the information characteristics of a journal and give an opportunity to assess the editorial policies or develop recommendations for future policies and publication gaps to be filled [1]. On the other hand, analysing a broader sample can provide a map of a discipline reflecting important patterns and is seen as vital for research policy making at national and institutional levels. Jacobs [3] also suggests that the studies of publication patterns are useful indicators of scientific productivity, trends, emphasis of research in various disciplines, and of researchers' preferences for publication outputs. Results of such studies may be very useful in decision making in research administration and planning, in collection development and use in libraries. These results further enable policy makers in different organisations and funding agencies to evaluate their decisions on the awarding of grants to individuals and institutions. Within all fields of study, it is needed to know the ways in which an academic discipline develops, the main dimensions of the subject matter and the ways relevant research methods and tools are used. These studies are called meta-analyses and concern, in general, the characteristics of the papers and the nature of the authors in various aspects.

This paper sets out to reflect upon the most recent research in the field of dispute resolution in construction and gives an overview of what aspects of it have been studied in the papers published in five main stream refereed construction management journals; Construction Management and Economics, Journal of Professional Issues In Engineering Education and Practice, Journal of Management in Engineering, Journal of Construction Engineering and Management and International Journal of Project Management in the last decade. With this study on the recent research in the field, a more holistic view of the subject area can be obtained to identify trends and knowledge gaps. This integration of the recent research is expected to contribute to generating new agendas for future research and to the debate on the development of the field.

The objectives of the analysis are:

- Identify the content in the recent studies of dispute resolution in construction, including research stream, level of analysis, sector and definitions of dispute.
- Identify the style including sources of information and contribution of the article.
- Identify the author background.

Dispute resolution in construction has been subject to considerable scrutiny in recent years. Although there have been some studies of the previous research undertaken in this field, these reviews have not considered patterns of published output from academic research. This review is deemed timely since the international community of researchers in the field of dispute resolution in construction, represented by CIB Working Commission W113 on Law & Dispute Resolution introduced new Task Groups, TG-67 Statutory Adjudication in Construction and TG-68 Construction Mediation with a mission of fostering the development of legal scholarship across a broad range of legal subject areas within the field of construction. With the constitution of these task groups, the Commission also encourages the formation of groupings of specialists in particular areas that are able to address individual topics in greater depth [4]. Both task groups aim to produce bibliographies and international reviews as their first outputs, showing the importance of the studies of previous research in navigating future research.

2. Method

A wide variety of sources are available on dispute resolution in construction including journal articles, conference papers, reports, presentations and thesis. To ensure the academic standard of the literature analysed in this study, only peer reviewed articles were decided to be included. For this purpose a core of international refereed journals that had a construction and project management perspective were designated and the keyword "dispute" was searched for amongst the title and the keywords sections of the articles in the selected journals. In order to obtain the most recent research in the field, the study was limited to a ten year period (1997-2006) of publication.

2.1 Journals Analysed

The articles that are analysed in the study were obtained from a group of international refereed journals selected in tune with the aims of the paper. These journals are Construction Management and Economics, Journal of Professional Issues in Engineering Education and Practice, Journal of Management in Engineering, Journal of Construction Engineering and Management and International Journal of Project Management. These journals aim to provide a home for serious articles which recognize and reflect the fundamental changes in construction and project management and its sub-disciplines. Although there are several journals more specialized in dispute resolution in construction, the journals above were chosen to understand how the subject acquires a niche in the mainstream construction management journals. All articles published between 1997 and 2006 in the journals listed were included in this study but book reviews and editorials were excluded.

2.2 The framework

Betts and Lansley [1] suggest that the meta-models are important for the analysis and classification of a discipline, inter-relating different areas of study and identifying emerging or neglected themes. The rationale for the use of meta-models arises out of a theoretical understanding that the main determinants of the nature of construction management research come from the multi-disciplinary background of its knowledge bases, the many organisational levels within the industry, the multiple stages through which construction projects move in their life-cycle, the professional differentiation that exists between parts of the sector and the distinctions within different types of research process.

The design of a meta-classification framework for the articles analysed has been the core issue of the study. Many classifications including the ones proposed by Betts and Lansley [1], Dickinson et al. [5] and Wolfe [6] were studied. The meta-classification framework adopted in this paper is based on independent classifications of the content, style and author background of the papers in many factors. The framework, the factors and their attributes examined are given in Table 1. The journal articles were analysed against this framework and categorized by one of the attributes of each factor.

Table 1 The meta-classification framework that the articles were analysed against

	Factors	**Attributes**
Content	**Research Stream**	Analysis of a Dispute Resolution (DR) Method Method Selection Models Factors Affecting DR Causes of Disputes DR Approaches Alternative Dispute Resolution (ADR) Policy Making
	Level of Analysis*	Global / Industry (Glo/Ind) National / Industry (Nat/Ind) Profession Group (Prof's Group) Firm/Organisation (Firm/Org) Project Professionals/Individuals (Prof's/Indiv's)
	Sector	Public (Pub) Private (Priv) General (Gen)
	Definition Dispute**	Yes (Y) or No (N)
Style	**Sources of Information***	Reviews Case Studies Empirical Data (Emp Data)
	Contribution of Article*	General Insights Statistical Results (Statistical Res) Model Building System Building
Author	**Author(s) Background****	Academic, Practitioner or Government (A, P or G) & Construction Related, Law Related (C or L)
	Author(s) Country	

** Adapted from Betts and Lansley [1]*

*** Adapted from Dickinson et al [2]*

The framework adopted in this study has three groups of dimensions, one concerned with content and the second style, following the proposal of Betts and Lansley [1] who imply these are the two principal means of characterizing research. The final dimension analysed is the author background to understand the contribution of researcher groups in the field.

In content dimension, the first factor examined is the research stream which defines the main subject of the article. This is an important means of gathering the body of knowledge in a discipline and determining the frequently published or neglected themes. The attributes for this content are analysis of a dispute resolution method, method selection models, factors affecting dispute resolution, causes of disputes, dispute resolution approaches, Alternative Dispute Resolution (ADR) and policy making. The second factor examined is level of analysis which determines the organisational level at which the research was done. Within the construction proper there are organisations that operate at different levels. The construction project is a dominant level for many but enterprises and national bodies are examples of other potential levels of application. The attributes are therefore determined as global/industry, national/industry, profession group, firm/organisation, project and professionals/individuals. The third factor examined is the sector at which the research was done. Although there are common attributes like building, housing, civil engineering etc in the literature for this factor, the attributes are determined as government, private and general in this study due to the characteristics of the discipline studied. The final factor of the content dimension is whether the article contains a definition for dispute or not, since defining the subjects and issues investigated by research provides precision and clarity in the discipline [5].

In style dimension of the meta-classification framework, the first factor is the sources of information of the articles which are the inputs of the research. The attributes for this factor are reviews, case studies and empirical data. The second is related to contribution of the article as the outputs of the research where the attributes are general insights, statistical results, model building and system building.

The final dimension is the author background where the articles are analysed against the attributes academician, practitioner, government, construction related and law related. The country where the research was undertaken was also noted to gain insight into levels of contribution from different countries. Beside analysing the articles against these eight factors that constitute the meta-classification framework, the relations between the factors were also examined in quest for providing a map of the discipline of dispute resolution in construction.

3. Analysis and Results

The results show the analysis of forty-two journal articles published on the subject of dispute resolution in construction in the chosen mainstream construction management journals between 1997 and 2006. Table 2 shows the number of articles from each journal according to their publication years analysed in the study.

Table 2 Publication years of the journal articles

Journals	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	Total
Construction Management and Economics	4		2	2		1			1	1	11
Journal of Professional Issues In Engineering Education and Practice							3	3	2	5	13
Journal of Management in Engineering				2			2	1			5
Journal of Construction Engineering and Management				1	1	1	2	1		4	10
International Journal of Project Management		1	1	1							3
Total	4	1	3	6	1	2	7	5	3	10	42

The distribution of the number of articles show that there is a continuous interest in the subject of dispute resolution in the mainstream construction management journals. The results do not show a general decrease or increase in the number of articles but rather a wave of rise and falls indicating that dispute resolution is a well-established sub-discipline in construction management.

The forty-two papers analysed involved 61 different authors from only 8 different countries. This analysis generates one of the most remarkable results showing that the research on dispute resolution in the construction industry is still undertaken by the authors from a very limited number of countries. The majority of the research in the field is done in the USA, the UK and Hong Kong.

Of the 42 papers, 12 were authored by single authors, 15 by two authors, 12 by three authors and 3 by four authors. Only 2 papers involved the collaboration of authors from different countries namely the UK and Hong Kong. This is another remarkable result showing that international collaboration is limited although benchmarking the practices and lessons learnt from cases prove very useful in advancing the discipline. Strengthening the relations between the researchers from different countries and backgrounds is needed to bring in new perspectives. The formation of the new task groups TG-67 Statutory Adjudication in Construction and TG-68 Construction Mediation by CIB Working Commission W113 on Law & Dispute Resolution is important in this regard as well, providing a platform for more vigorous international collaboration and a forum to facilitate exchange and synthesis of research internationally.

Results from the analysis of the journal articles against the meta-classification framework proposed are presented in Table 3. A discussion of the findings for each factor in content, style and author dimensions follows.

Table 3 Results from the analysis of the journal articles against the meta-classification framework proposed

3.1 Content

The first factor analysed in content section is research stream, which is the most diversified factor analysed in this study. In the meta-classification framework proposed, the attributes for this factor are defined as analysis of a dispute resolution method, method selection models, factors affecting dispute resolution, causes of disputes, dispute resolution approaches, Alternative Dispute Resolution (ADR) and policy making. As the results in Figure 1 reveal, a remarkable portion of construction dispute resolution research is most closely related to analysis of a dispute resolution method. The seventeen articles in this research stream involve the analysis of different ADR methods as well as the combination of various dispute resolution methods with organisational dispute prevention methods and tools developed with the aid of new technologies. It is remarkable that only two papers are about e-applications of these methods. The dispute resolution methods adopted by the statutory adjudication acts and standard forms of contracts such as FIDIC or NEC and their consequences are largely discussed as well. The contribution of the vast majority of research in this stream is general insights with the main source of information being the reviews and case studies. ADR and DR Approaches, each in six of the articles, are the following most frequent research streams. In ADR stream, the studies of the identification of key features of ADR (for ADR process design) and the studies on the current use of ADR constitute the main areas. The source of information is generally empirical data (mostly surveys) and the contribution of the articles are statistical results or general insights. Articles in the DR Approaches research stream generally deal with the behavioural aspects at the organizational level and trends at the national level. The rest of the attributes of research stream attracted less attention.

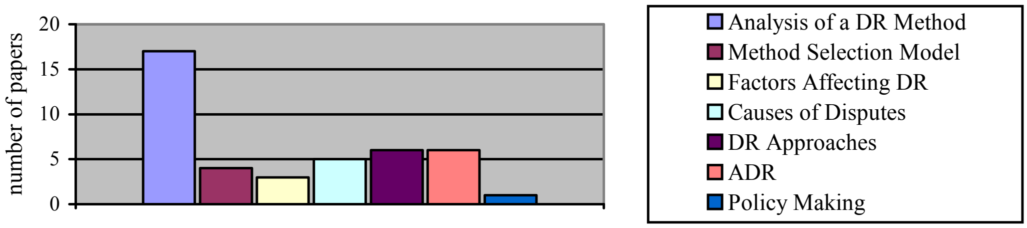

Figure 1: Articles by research stream

The attributes of the second factor, levels of analysis, were determined following the classification of Betts and Lansley [1]. At least one journal article was identified at each level of analysis in this review and national / industry level has received the most attention. This is possibly due to the unity of acts and regulations at a national level. The firm / organisation and professionals / individuals attributes received the least attention in which the research undertaken was about the dispute resolution approaches of organisations and individuals respectively.

In terms of sector, there is a lack of specific focus on public and private sectors. With the exception of a few authors, most do not make reference to their research concerning the sectors although the contexts are markedly different for dispute resolution in public and private construction sectors.

As for the last factor in the content dimension, articles were analysed for definitions of dispute. Although all journals analysed contained the word dispute in the title of the article or as an article keyword, only two of the articles actually define dispute. The failure of journal articles to clarify the content and dimensions of a subject does not assist comparing and generalising between studies [5]. More definitions are necessary especially for the resolution of the debate and frequent confusion concerning the definitions of conflict and dispute and moreover the debate concerning the scope of Alternative Dispute Resolution (ADR) methods.

3.2 Style

In the style dimension of the meta-classification framework, the articles were firstly analysed for their sources of information. The attributes were designated as empirical data, reviews and case studies for this factor. More than half of the articles used empirical data as their source of information. A variety of research techniques were used to collect data that include surveys, interviews and historical analysis. Case studies were classified as a separate attribute and six of the articles were determined as case studies. Fourteen articles, on the other hand, were classified as review-based articles. These review contributions demonstrate that non-empirical articles can offer value and indispensable insight to this research field.

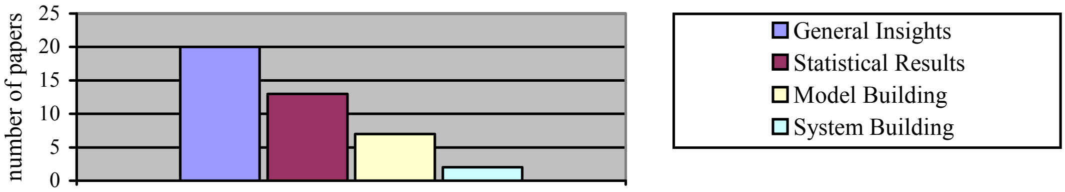

Figure 2: Articles by contribution

A further research aspect of the articles analysed was the contribution of the articles to the field (Figure 2). There were twenty articles offering general insights most of which were reviews, whereas thirteen articles offered statistical results arising from the empirical data used. One remarkable result is that there were only seven model building contributions and only two system building contributions among the articles analysed. The research stream in model building articles were diversified. The lack of model building articles might be explained by the difficulties associated with making generalisations in the field, however the existing examples show they prove valuable with the right techniques in advancing the knowledge base in the field. This way, the insight and results that have been collected in the field can be tested and organised to become more useful for the development of the theoretical base of the research field.

3.3 Author

The last dimension of the meta-classification model proposed is the author background. One of the most striking results reached in the analysis of the dispute resolution in construction literature is the publication dominance of academic authors. There are only four articles without any academic authorship. In addition, of forty-two articles, there are only six articles that include collaboration in authorship between academic and non-academic authors. Only two of these include authors from government which is consistent with the small number of public sector articles. However, dispute resolution is largely under the influence of government regulations and there is a need for more studies on pubic sector dispute resolution including collaboration of the authors from the government to derive benefits from the accumulated data and actually advance the public practices.

Another aspect of the author factor is the distinction between construction related and law related backgrounds. Out of forty-two articles, four involve authors with a law background and five with construction and law backgrounds in collaboration. This does not imply that authors with construction background do more research, but it is rather due to the peculiar design of this study that attempts to look at dispute resolution field from the perspective of construction management mainstream journals. However, it is clear that more collaboration between authors from different backgrounds would bring in different perspectives and contribute to the improvement of the research in the field.

4. Conclusion

The recent dispute resolution literature in construction management journals was analysed against a meta-classification framework proposed in this study. The articles in selected mainstream construction management journals published between 1997 and 2006 were searched with a keyword “dispute” in title and keywords section. In total, forty-two articles were analysed against several factors including research stream, level of analysis, sector, definition of dispute, sources of information, contribution of the article and author background. Due to the limitations of the paper, academic books, reports, conference papers and journal articles published prior to the specified ten year period were not included in the analysis.

Remarkable findings have been reached regarding some of the factors. First of all, nearly half of the construction dispute resolution research is most closely related to the analysis of a dispute resolution method as a research stream. The seventeen articles in this research stream involve the analysis of different ADR methods as well as the combination of various dispute resolution methods with organisational dispute prevention methods and tools developed with the aid of new technologies. In terms of level of analysis, national/industry has received the most attention in the literature analysed possibly due to the unity of acts and regulations at a national level. The identified shortcomings include the lack of specific focus on public and private sectors, the failure of most of the articles to define dispute, the lack of articles contributing to model building in the discipline, the limited practitioner and government employee authorship and the limited collaboration between academic and non-academic authors resulting in the publication dominance of academic authors. Future research directions are suggested in the study in order to address the identified shortcomings and improve the knowledge base in dispute resolution in construction field.

Critical Factors for Insurance Premium Computation in Construction

Imriyas Kamardeen
Faculty of the Built Environment, University of New South Wales, Sydney, NSW 2052, Australia

Abstract

Workers' compensation insurance is imperative for construction projects to safeguard the interests of workers and contractors. The commitment of insurers under this insurance is extremely broad. They must therefore accomplish rigorous risk and market assessments to decide optimal premiums. General insurers in Singapore have been experiencing detrimental loss-ratios in this business due to the lack of a proper framework that encompasses all the critical variables. The purpose of this study is to identify and explore the critical variables for premium-rating of construction workers' compensation insurance. An extensive literature review helped identify 17 variables that may influence premium rates. An interview questionnaire survey and subsequently a statistical analysis of the survey data were carried out to identify the critical variables. Eight variables were found significant for insurers for premium-rating including: wage roll, project hazards, project safety, contractor's claims history, insurer's overhead costs, insurer's corporate objectives, competition, and investment income from underwritten premiums. The findings of this study can be used by insurance companies in their risk assessment and premium-rating exercises.

Keywords: *Occupational injuries, Construction safety, Workers' compensation insurance, Premium, Singapore*

1. Introduction

Construction is one of the most dangerous and risky occupations. Insurance is a keystone to eliminate most of the financial threats in construction business [7]. Bunni [3] identified five types of insurance that are available for contractors for different risk nature: contractors' all risk insurance, general liability insurance, worker's compensation insurance, motor insurance , and marine transport insurance. Contractors' all risk insurance covers physical losses or damages to works, plant, equipment and materials during the course of construction that are resulted by crises such as natural disasters, fire/explosion or collapse. General liability insurance indemnifies the contractor in respect of legal liability for damages arising from death or injury to non-contracting entity or damage to non-contracting entity's property due to a project. For example, damage to adjacent property, injury to any third party due to an excavation work or damage to underground utilities may be indemnified under this insurance. According to the Workers' Compensation Act, cost of all the injuries/fatalities to workers resulting from construction activities should be borne by the contractor, irrespective of fault. Worker's compensation insurance (WCI) is purchased to transfer this financial risk to a professional insurer. Motor insurance provides liability coverage for over-the-road hazards for self-propelled motor vehicles used for the sole purpose of providing mobility to construction equipment such as pumps, cranes, air compressors, generators, etc. In international construction, marine transport insurance is required to protect from any losses resulting from ship crises when travelling by the sea.

Out of these five classes of insurance, the significance of the WCI in construction is overwhelming because the construction industry is well-known for poor safety performance globally. In Singapore, the construction industry accounted for 29% of the total number of industrial workers but accounted for 40% of worksite accidents [5]. Moreover, the latest analysis as of year 2006 on worksite accidents by the Ministry of Manpower, Singapore revealed that the construction industry recorded the highest accident frequency and injury severity rates among all the industries in Singapore [18]. Providing adequate WCI covers is therefore mandatory by the law of Singapore for employers to engage workers under a contract of service. It is enforced to safeguard the interests of occupational injury victims and to ease their employers' financial burden of compensating. On the other hand, insurance companies who issue the WCI for construction projects are forced to assume abundant financial risks. This implies that the construction WCI is a critical class of insurance in the whole portfolio of any insurer's business. Hence, the utilisation of an effective premium-rating technique is essential for insurers to perform rigorous risk assessments for construction WCI.

In the Singapore insurance industry, WCI premiums are traditionally computed by applying a rate on the wage roll of construction projects. There has been a collective agreement among general insurers that the preferable WCI premium rate for construction projects is 1% of the wage roll. This rate is merely a benchmark. Individual insurers set competitive rates around the benchmark considering other important variables. However, no strong theory supports this benchmark norm and therefore lacking of an effective framework for insurers to perform structured analyses on project risk and market factors. In the face of keen competition in Singapore's insurance market, underwriters tend to compromise the technical factors such as the risk profile of a project and the contractor's safety management system, due to the lack of a well-balanced framework. This brings about riskier projects that are being covered by insurers at lower premiums, which ultimately result in adverse loss ratios. Most of the general insurance companies in Singapore have been encountering undesirable loss-ratios in the construction WCI due to inadequate premiums; some have given up issuing the WCI altogether and a few other companies have bankrupted [13]. The industry statistics for year 2006 of the General Insurance Association of Singapore reinforced that the WCI is the third largest class of insurance in Singapore. It continued to struggle in 2005 with an underwriting loss of S$7 million in the first half of 2005 compared to the same period in 2004, when it lost S$1 million. The incurred loss-ratio has climbed from 72% to 80%. The WCI business has sustained poor underwriting results over the years. This is mainly due to unrealistic pricing, under declaration of wages by some companies as well as aggravated and fraudulent injury claims by some foreign workers [10]. Hence, there is an intense need for developing a new methodology for WCI premium-rating of construction projects. The prime task towards developing a new model is to identify the critical variables that influence WCI premiums for construction projects. Hence, the aim of this paper is to explore and critically analyse the variables pertinent to WCI premium-rating.

The paper is presented in various parts. Firstly, a general view of workers' compensation insurance is given followed by an account on the literature review findings on variables pertinent to WCI premium-rating. Then, the research method and the findings are described followed by a conclusion.

2. Background of WCI

During the industrial revolution, injured workers had to prove employers' negligence to recover medical expenses, lost wages and other damages caused by accidents. Employers had three primary defences for them to avoid liabilities for injuries. The first was the concept of *contributory negligence,* which prevented the employee from recovering any damage if he/she contributed to even in a small way to the cause of the accident. Another defence was the *fellow-servant doctrine.* If the injury resulted from contributory actions of fellow employees, the employer was not considered liable. The third defence was the *assumption of risk doctrine.* It could limit a worker's recovery of damages if he/she knew of the workplace hazard and assumed those risks by going to work [6].

Besides overcoming common law defences, injured workers faced other problems in filing lawsuits against the employer: (1) filing lawsuits often resulted in injured workers losing their jobs, (2) the lawsuits were expensive and time-consuming thus workers had difficulty finding lawyers to represent them, and (3) there was no guarantee that the employee would win the suit and collect damages [17]. Thus, injured workers received no compensation, lost the current job or faced difficulty finding other jobs due to disability. To overcome this unfair situation, the workers' compensation system was designed as a trade-off between employers and employees. The underlying principle behind the system is that the cost of on-the-job injuries, regardless of fault, should be borne by employers. In exchange, the injured workers forfeit the right to sue employers. The basic objectives of the workers' compensation are to: (1) provide sure, prompt and reasonable benefits to work accident victims or their dependents, (2) provide a single remedy and eliminate time-consuming and costly trials, (3) encourage maximum employer interest in safety and rehabilitation, and (4) promote frank study of accidents' causes and reducing preventable accidents [9].

According to Singapore's Workers' Compensation Act, the compensation to a victim can be as high as S$147, 000. Thus, all contractors are required by law to procure the WCI for all their projects to eliminate such financial burden in the event of any worksite injuries/fatalities. Failure to do so is an offence punishable with a fine of up to S$10,000, a jail term of up to 1 year or both [16]. Hence, the WCI is an integral part of the insurance business.

3. Premium-rating variables for construction WCI

In insurance, unlike other industries, the cost of the production is unknown when the contract is sold, and it will be unknown until the policy expires. Therefore, the pricing for insurance must be based on predictions of losses, expenses and incomes in future. Under the WCI, the commitment of an insurer is extremely broad; there are no exclusions, and there is no maximum limit on the insurer's liability [20]. Setting an appropriate cost for some future contingency of unpredictable timing, frequency and size requires the estimates of future claims, investment income, administrative expenses, profit and tax. In addition, the price can profoundly influence the volume of the business attracted [2]. Hence, WCI premium-rating is a critical management function for any insurer, which should decide premiums that are high enough to cover all the future costs, yet low enough to meet the market competition. The premium-rating is regarded as a two-stage process [2]:

1. The costing exercise – this is a scientific method that calculates the cost of future claims from the insured risks and all associated expenses.

2. The pricing exercise – this is a commercial adjustment to technical costs that considers broader corporate and market factors.

4. Predicting future claims in construction WCI

The scientific approach to determine the cost of future claims of a WCI policy entails an assessment of project and contractor related variables. Under the project-related variables, the following were identified by various authors:

- Worrall & Buttler [21] noted that the wage roll, project duration and the expected workers' compensation liability per wage roll unit need to be accounted for predicting claims.
- The Canadian Wood Council [4] reported that base rates are influenced by the: (1) location of the project, (2) type of construction, and (3) general industry experience on loss history for projects of similar type and location.
- Lott [15] added that an assessment of the workers' risk management programme will lead to an effective prediction of the costs to be incurred. This assessment should scrutinise the following aspects:
    1. Management commitment and employees participation in workers' risk control;
    2. Workplace hazards, population demographics and previous incident rates;
    3. Implementation of a pertinent risk/safety programmes; and
    4. Training of supervisors and workers.

As for the contractor-related variables, Groth [12] commented that WCI premium-rating must consider contractors' past claim history. Coble [8] noticed that the contractor's size has a bearing on premium rates. The Canadian Wood Council [4] suggested that insurers must consider the following variables:

1. Contractors' knowledge, experience and safety-consciousness;
2. Compliance with loss control and underwriting recommendations by the insurer;
3. Acceptance of deductible, that is, a retention of part of the claims cost by the contractor;
4. Potential future business; and
5. Placement of multiple policies with the same insurer.

5. Determining the mark-up for construction WCI

The adjustment of the technical costs of risks for commercial interests necessitates the consideration of insurers' corporate factors and market factors. The variables, pertinent to insurers, were recognised by many authors in the literature, viz:

- Vaughan [20] identified three variables that influence the mark-up:
    1. The expenses of acquiring and administering the business (overhead costs);
    2. The profit required by the insurer; and
    3. The return from the investment of premiums by the insurer.

- Young [22] quoted that premium-rates are adjusted on account of the profit/loss experience of the insurer in the past, and the outstanding claims to the insurer from all projects. The competition and the volume of business in the market also influence the mark-up.
- Booth [2] reported that corporate objectives of insurers will have a significant bearing on mark-ups.
- Phifer [19] observed that the reinsurance premium, which insurance companies pay for risk sharing with re-insurers do influence the pricing.

6. Research method

From the literature review above, 17 variables pertinent to WCI premium-rating of construction projects were identified and classified into four categories as shown in Table 1. Subsequently, a questionnaire was designed with the objective of determining the most significant variables. The questions in the questionnaire assessed the significance of the 17 variables for deriving the optimal premium rate on a 10-point Likert scale, whereby 1= “Low important” and 10= “High important”. The field survey was conducted during November and December 2005 in the Singapore insurance industry, which encompasses a population of 23 general insurers. An interview questionnaire survey was conducted to collect data because having a questionnaire administered face-to-face by an interviewer can attain higher response rates than mail surveys [1].

All the 23 companies were covered in the survey. At every interview session, the questionnaire was presented to the interviewee for his/her response. Additional explanations were rendered when needed. Moreover, interviewees were invited to elaborate on the rationale for their answers.

Table 1: Premium-rating variables

Variable category	Pertinent variable
1. Project factor	• Wage roll • Project duration • Project hazard level • Effectiveness of the safety management system on site
2. Contractor factor	• Contractor’s claims history • Placement of multiple policies by the contractor • Expectation of potential business from the contractor • Co-operation by the contractor • Contractor’s size
3. Insurer factor	• Corporate objectives of the insurer • Investment income from underwritten premiums • Overhead costs of insurance • Amount of outstanding claims to the insurer • Profit/loss experience in WCI business • Reinsurance cost
4. Market factor	• Competition • Volume of business in the market

7. Profile of the respondents

As shown in Figure 1, the designations of the interviewees were top management (48%) and middle management (52%). The top management interviewees comprised of managing directors, general managers, senior managers and managers. The middle management interviewees were assistant general managers, deputy managers and assistant managers. The mean working experience of the interviewees was 21 years. The minimum and maximum working experiences were 8 and 35 years, respectively. Also, more than 75% of the interviewees had experience of above 10 years. From the interviewees' profile, it is understood that all of them are well-qualified and well-experienced in the subject matter. Hence, the data collection is perceived to be reliable.

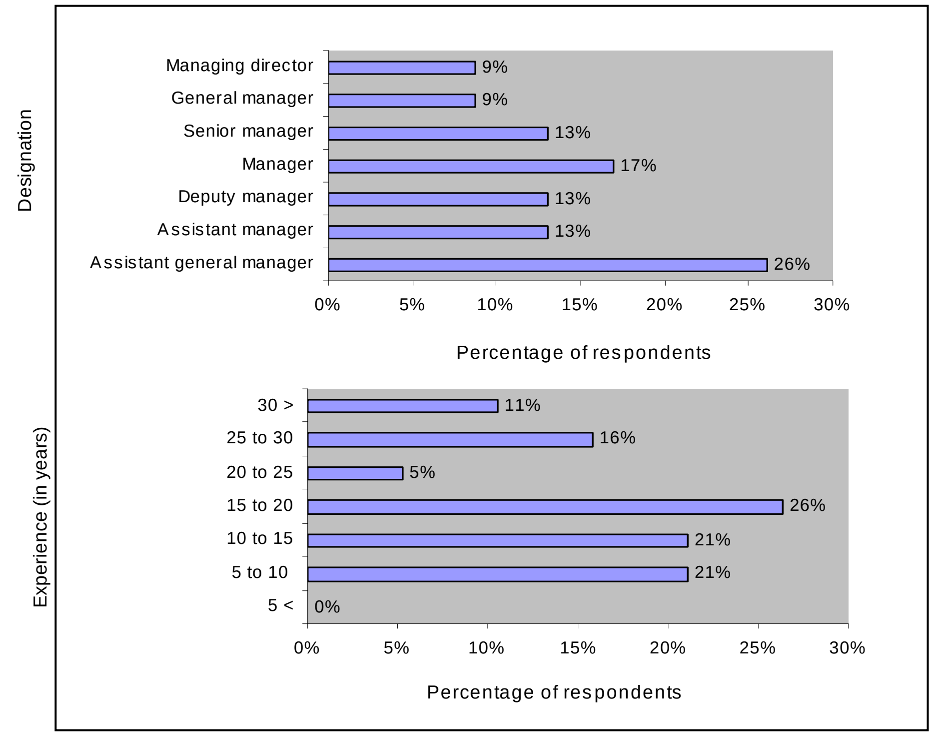

Figure 1. Profile of the respondents

8. Data analysis and discussion

A statistical analysis was accomplished to identify the most important variables according to the Pareto's 80/20 rule for WCI premium-rating. Descriptive statistics were computed for each category of variables as shown in Table 2. The 17 variables were re-organised, as illustrated in Table 3, into 3 groups namely, important variables, less important variables and unimportant variables, based on their mean importance ratings. Unimportant variables have mean importance ratings < 4.00, important variables possess mean importance ratings > 7.00, and the rest are less important variables. The above grouping notion was adapted from the medical industry of Singapore where Goh [11] proposed a pain scale, as shown in Figure 2a, to measure cancer pain intensity in patients. Based on that scale, the 9 equal intervals in the 10-point Likert scale were re-arranged into 3 equal intervals as illustrated in Figure 2b.

Table 2: Descriptive statistics of industry survey findings

Variables	Descriptive statistics							
	Mean	Standard deviation	Median	Mode	Kurtosis	Skewness	$X_{Min.}$	X_{Max}
Project factor								
• Wage roll	8.33	1.32	9	9	0.41	-0.81	5	10
• Project duration	5.10	3.10	6	3	-1.30	-0.12	0	10
• Project hazard level	9.33	0.71	9	10	-0.76	-0.63	8	10
• Effectiveness of the safety management system on site	7.67	2.17	8	8	3.67	-1.74	1	10
Contractor factor								
• Contractor's claims history	8.33	1.21	9	9	-1.18	-0.19	6	10
• Placement of multiple policies by the contractor	5.00	2.56	5	8	-0.66	-0.66	0	8
• Expectation of potential business from the contractor	3.76	2.60	4	0	-1.09	0.00	0	8
• Co-operation by the contractor	4.90	3.15	5	2	-1.34	0.01	0	10
• Contractor's size	3.38	2.92	3	0	-1.26	0.37	0	9
Insurer factor								
• Corporate objectives of the insurer	8.05	1.13	8	7	-0.80	0.32	6	10
• Investment income from underwritten premiums	7.24	1.23	7	8	-0.34	0.33	5	10
• Overhead costs of insurance	7.10	1.34	7	8	-1.22	-0.06	5	9
• Amount of outstanding claims to the insurer	6.62	2.15	7	7	0.14	-0.92	2	9
• Profit/loss experience in WCI business	6.76	2.51	7	10	-1.10	-0.34	2	10
• Reinsurance cost	6.71	1.91	7	9	0.05	-0.67	2	9
Market factor								
• Competition	7.38	1.68	7	7	-1.23	-0.14	5	10
• Volume of business in the market	4.52	2.52	5	6	-0.72	0.09	0	9

Table 3: Re-organisation of variables

Variables group	Pertinent variable
1. Important variables	• Wage roll • Project hazard level • Effectiveness of the safety management system on site

	• Contractor's claims history • Competition • Corporate objectives of the insurer • Overhead costs of insurance • Investment income from underwritten premiums
2. Less important variables	• Profit/loss experience in WCI business • Reinsurance cost • Amount of outstanding claims to the insurer • Project duration • Placement of multiple policies by the contractor • Co-operation by the contractor • Volume of business in the market
3. Unimportant variables	• Expectation of potential business from the contractor • Contractor's size

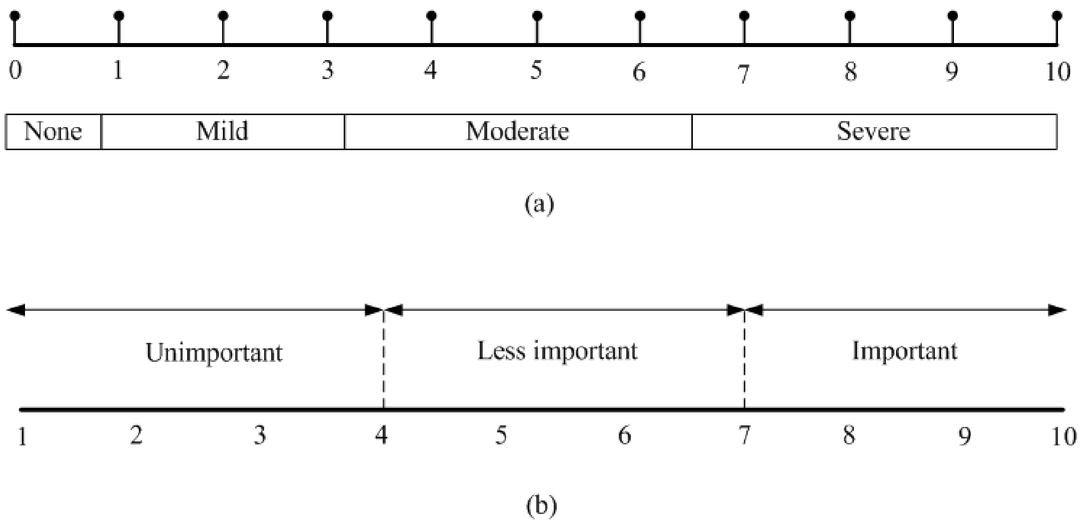

Figure 2: (a) Pain scale (Goh, 2004); (b) Intervals of rating

9. Important variables for premium-rating

Eight important variables for premium-rating were identified out of the 17 variables (See Table 3). A brief discussion on each variable is provided below, based on the qualitative explanation rendered by the interviewees.

1. Wage roll:

In the Singapore insurance industry, WCI premiums are traditionally computed by applying a rate on wage rolls of construction projects. There has been a collective agreement among the insurers that the preferable WCI premium rate for construction projects is 1% of the wage roll. This rate, however, is merely a benchmark. Individual insurers set competitive rates around the benchmark heuristically considering other important variables. The wage roll is also considered as a representation of the project duration since both are positively correlated.

On another perspective, when the wage roll is high, the premium amount is high though the premium rate is low. But, claims and administrative costs will be proportionately less, making it possible for insurers to earn more money by insuring bigger projects. Thus, large projects drive keen competition.

2. *Project hazard level:*

The project hazard is directly correlated with the frequency and severity accidents and thereby the amount of compensation to be paid by the insurer. Therefore, the higher the project hazard, the higher the premium rate. The project hazard has to be assessed in line with project's scope. The assessment should peruse if the project involves demolition works, explosive works, excavation works, works at heights, works involving lifting and cranes and/or confined space works. The hazard in each type of work has to be assessed via a rigorous analysis of relevant attributes. For example, the hazard in works at heights can be deduced by the total height of the building. Moreover, the characteristics of the project location/vicinity should also be assessed. Among the attributes to be scrutinized for project locality are: soil condition, site congestion level, and/or presence of any chemical/manufacturing factory or combustible source.

3. *Effectiveness of the safety management system on site:*

Presence of an effective safety management system on site is significant in reducing claims; thus, the better the safety management system, the lower the premium rate. All the insurers recognised that inspecting the safety management system of the project is essential in inferring potential claims. However, they encountered two constraints, viz:

- Lack of guidelines to assess the effectiveness of the safety management system; and
- Although a contractor can produce a well-documented safety plan for a project, its implementation on site is still uncertain as it is inherent to the attitude of the site management team.

4. *Contractor's claims history:*

Insurers examine a contractor's claims records for the past five years to deduce the contractor's safety performance as an alternative to assessing the safety management system. From the survey, it would appear that records with low severity and high frequency infuse higher premiums than records with high severity and low frequency.

5. *Competition:*

Triumphing competition is crucial in any business. A well-thought out strategy is necessary to assess the competition level by considering the number of competitors, regional economic condition, prestige in the project and the project size. This can subsequently be used to adjust the mark-up that the higher the competition the lower the mark-up.

6. *Corporate objectives of the insurer:*

The mark-up in a premium coheres with an insurer's corporate objective(s). The corporate objective of a Singapore's insurer at any given time can be one or more of the following:

i) Ensuring the survival of the company;

ii) To write a given premium volume;

iii) Achieving an overall operating ratio across the whole portfolio;

iv) Achieving an adequate level of profitability or return on equity; and

v) Achieving a target premium growth rate.

For objectives i to iii, an insurer may intentionally quote a low premium while for objectives iv and v, the same insurer may wish to quote an average premium.

7. Overhead costs of insurance:

Overhead costs are key components of a mark-up; the higher the overhead costs, the higher the mark-up. Overhead costs for the WCI includes brokerage fees and administrative costs for underwriting and claims management. The brokerage fee is a fixed percentage in the Singapore's market; 10% of the premium. Administrative costs vary from company to company, which are estimated to be in the range of 15% to 35 % of the underwritten premium. In total, overhead costs amount to 25% to 45% of the premium in Singapore.

8. Investment income from underwritten premiums:

The underwritten premium can be invested by the insurer on shares, subsidiary companies, real estate, etc. The returns on these investments influence the premium significantly. If the investment returns are high, the insurer can quote attractive premiums as the insurer's reserve is stable.

10. Less important variables for premium-rating

Seven variables seem less important for WCI premium-rating of construction projects.

1. Profit/loss experience in WCI business:

When an insurer experiences a remarkable profit/loss over a period of time, it is acceptable to adjust the premium rate for new undertakings. If there is a profit growth, the insurer may wish to reduce the premium so as to win more projects, as there is a buffer to assume the risk and to develop the business. In contrast, if the experience is bad, premiums for new projects could be increased with consideration of market trends because losing business is preferred to suffering from loss. However, such adjustments in the WCI's context are not encouraged by most of the Singapore insurers because profitable years will have to be balanced with less profitable years.

2. Reinsurance cost:

Reinsurance is the principal mechanism that insurance companies use to transfer part or all of the risks assumed through their own underwriting activities. The reasons for reinsuring are as follows:

- For balance sheet protection – reinsurance is purchased to protect the solvency of the insurance company.
- To increase the capacity – the risk exposure that an insurer can reasonably accept is restricted by the size of its capital base. Reinsurance allows taking larger risks, which makes the company more attractive to insurance brokers and their clients.

Risk of an insurer can be ceded to a re-insurer via facultative reinsurance and treaty reinsurance. Under the facultative arrangement, each risk is underwritten by the re-insurer on its own merits with a separate reinsurance contract. Under the treaty system, reinsurance is underwritten for a class of insurance, annually. The treaty reinsurance is further categorised into proportionate treaty and non-proportionate treaty. The subsets of the proportionate treaty are quota share reinsurance and surplus reinsurance while the subsets of the non-proportionate reinsurance are excess-of-loss (XOL) reinsurance and stop-loss reinsurance. The WCI in Singapore adopts the XOL treaty reinsurance.

A re-insurer decides the XOL treaty premium for an insurer based on the estimated premium income, loss-ratio, risk profile of the business covered and the excess point of the treaty. Insurers can decide upon attractive premiums for their policies, depending on their treaty premiums. However, reinsurance cost is usually less than 10% of the premium. Hence, it is not a major concern for premium-rating. Most of the companies incorporate the reinsurance cost into the overhead costs.

3. Amount of outstanding claims to the insurer:

When a particular class of insurance, like the WCI, experiences too many claims, the insurer prefers to increase the premium for new projects so as to recover losses. Nevertheless, market competition restrains such adjustments. On the other hand, decreasing the premium rate to attract more business for cash flow purposes is also unfeasible because the WCI is the riskiest insurance class in Singapore.

4. Project duration:

When the project duration is longer, the risk exposure of an insurer is longer and the earned premium, along with the net profit for the year, is reduced. Project duration is therefore a moderate consideration for some insurers in Singapore. However, the other insurers perceive that the duration is built into the wage roll; thus, it can be negligible for premium-rating.

5. Placement of multiple policies by the contractor:

When contractors take multiple policies for projects, discounts may be considered as the risks can be spread among policies. Contractor's all risk (CAR) insurance and the WCI are the main construction insurances. The WCI is ranked as the worse policy by insurers, which earns small premiums but large claims. Meanwhile, the CAR insurance has been contrary in this aspect. Mostly, the loss in the WCI is covered by the total premium from both policies. Most of the insurers prefer selling insurance packages rather than individual policies. Hence, the placement of multiple policies is more of a prerequisite than a discounting factor in Singapore.

6. Co-operation by the contractor:

The Singapore's construction industry is heavily reliant on foreign workers from neighbouring developing nations such as India, China, Bangladesh, Thailand and the Philippines. The objective of these workers is to earn money as fast as possible to return to their home countries for a comfortable life. There were incidents in Singapore whereby: (1) some of the injured workers chose to claim by common law to reap greater compensation and (2) some workers injured themselves or acted recklessly in order to claim compensation [14]. It is therefore important for insurers to scrutinise the root cause(s) of accident(s) and any fraudulent action(s) of workers to diminish their risks. Contractors' support is paramount in such situations, which could be a consideration in premium-rating. Nonetheless, it is a weak factor because there could still be claims although the contractor is supportive.

7. Volume of business in the market:

It is acceptable to increase premium rates when the construction industry undergoes an economic boom. Nonetheless, more insurers enter the market when the demand is high. This makes the Singapore's market constantly competitive.

11. Unimportant variables for premium-rating

Two insignificant variables for premium-rating are identified below.

1. Expectation of potential business from the contractor:

The expectation of potential business from contractors are irrelevant for premium-rating because construction projects are secured through competitive-bidding, thus the prediction of potential projects for contractors is difficult

2. Contractor's size:

Large contractors with good safety records demonstrate their capacity to use sophisticated and less hazardous construction methods. It is therefore beneficial for insurers to favour large contractors. However, all main contractors employ subcontractors. Thus, subcontractors' experience, operation methods and records become key factors. As per insurers' experience, reported accidents mostly involved subcontractors' workers whereby the main contractor provided the WCI.

12. Conclusion

Providing an adequate WCI is mandatory for a Singapore contractor to employ workers in construction projects. It is enforced to safeguard the interests of occupational injury victims and to ease contractors' financial burden of compensating. Under the WCI, the commitment of an insurer is extremely broad unlike other classes of insurance; there are no exclusions and there is no maximum limit on the insurer's liability. Hence, WCI premium-rating is a critical management function for any insurer who should decide premiums that are high enough to cover all the future costs, yet low enough to meet the market competition. Nevertheless, general insurers in Singapore seem to be reluctant to issue the WCI for construction projects as they have been experiencing undesirable loss-ratios. These losses occurred mainly due to underestimating of potential risks in construction projects. This is, in turn, the result of the ineffectiveness of the premium-rating framework as used by the general insurance industry in Singapore. Hence, an effective WCI premium-rating framework is imperative for Singapore insurers to address this dilemma. Identification of the critical variables for such a framework is crucial and fundamental.

Seventeen variables pertinent to WCI premium-rating for construction projects were identified in a literature review. An interview questionnaire survey was conducted in the Singapore general insurance industry to identify the most significant variables that fit in the Pareto's 80/20 rule. Statistical analyses results of the survey data indicate that eight variables are important for WCI premium-rating: (1) wage roll, (2) project hazard level, (3) effectiveness of the safety management system on site, (4) contractor's claims history, (5) overhead costs of insurance, (6) competition, (7) corporate objectives of the insurer, and (8) investment income from underwritten premiums. The finding may be utilised by insurance companies in Singapore to re-engineer their premium-rating approach. The study may be extended to develop a premium-rating model for workers' compensation insurance incorporating these significant variables.

Contracting in Good Faith – Giving the Parties What They Want

Jim Mason
Faculty of the Built Environment, University of the West of England, Bristol

Abstract

Examines the duty of good faith as an express obligation contained in the newer standard forms of construction contracts. Describes good faith provisions in other jurisdictions and the seeming hostility of the English judiciary. Discusses the benefits that might arise from "concretising" the duty of good faith in English law and encourages developments in this area.

Keywords: Good faith, Construction contracts, Standard form contracts, contractual innovation.

1. Introduction

Partnering promotes a co-operative approach to contract management with a view to improving performance and reducing disputes. The relationship between a contractor and a client in a partnering contract contains firm elements of trust and reliance. In so far as partnering is delivered through the medium of contracts, those contracts more often than not contain an obligation that the parties act in good faith to facilitate delivery of those aims.

Partnering contracts pose a problem for contract advisors containing as they do "hard" and "soft" obligations. Whilst all conditions of contract are equal, some, to misquote George Orwell, are more equal than others. Clients can be advised and terms drafted stipulating hard obligations such as payment and quality standards. But what of the soft obligations – and in particular the duty of good faith – what are we to make of them? As one leading commentator put it:

We in England find it difficult to adopt a general concept of good faith…we do not know quite what it means." [1]

The resulting situation is that "soft" obligations are often overlooked and not given any particular importance. This sentiment was picked up by a report expressing the consensus of construction lawyers as being that duties of good faith are not likely to be newly recognised in law by reason of their introduction into partnering contracts.[2]

This consensus of opinion invites the question whether this is what the users of construction contracts want. Parties having taken the trouble of entering into a partnering contract may feel disappointed to learn that their voluntarily assumed mutual obligations are not enforceable. This paper seeks to open a discussion around this point and recommends the "concretising" of the duty of good faith by judiciary and/or parliament to deliver what the parties have chosen for themselves.

2. The Newer Contract Forms

By far and away the most popular forms of contract are those which make no mention of partnering obligations.3 The dominance of the JCT lump sum and design and build forms remains intact. However, the growing trend is to use contracts which move away from formal legal "black letter" contracts to contracts fulfilling a different role which includes seeing the contract as a management tool and a stimulus for collaboration. The challenge for these newer contract forms is to capture this new role whilst providing sufficient contractual certainty in the event that disputes arise.

The link between contracts, partnering and good faith was initially made by organisations such as Associated General Contractors of America making statements such as:

"Partnering is recognition that every contract includes an implied covenant of good faith." [4]

These connections are relatively straightforward in the United States, a legal system that recognises the duty of good faith in contracting. The principles of partnering are congruent with the doctrine; trust, open communication, shared objectives and keeping disputes to a minimum. Making the connections in the English context is more challenging given the absence of the general duty of good faith. In its absence it is the partnering contracts themselves which fill the gap.

In the thirteen years since the Latham Report partnering contracts have become significantly more sophisticated in terms of the wording of partnering obligations and the conduct expected. The duty to act in good faith is a common thread.

There are variations on the exact imposition of the duty to act in good faith in partnering contracts. A distinction can be drawn between those which are intended to regulate the parties' behaviour through the contractual terms and conditions (binding) and those which place a non-contractual partnering framework over the top of another contract (non-binding). The latter have been described as seeking to influence rather than mandate certain behaviour [5].

The parties to the JCT Non-Binding Partnering Charter agree to "act in good faith; in an open and trusting manner, in a co-operative way in a way to avoid disputes by adopting a no blame culture". The binding multi-party PPC 2000 requires that the parties "agree to work together and individually in the spirit of trust, fairness and mutual co-operation". The NEC x12 Partnering Option calls the parties "partners", and requires that partnering team members shall "work together to achieve each other's objectives."

The latest contract to enter the fray is the JCT Be Collaborative Constructing Excellence Form. The contract goes further than the other partnering contracts in introducing an over-riding principle which includes a duty of good faith and stipulates that this principle takes precedence over all other terms.

This contract completes the transition of good faith-type provisions from being somewhere on the under-card of contractual terms to being the main event. A significant proportion of the standard forms of contracts now available to the construction industry expressly impose an increasingly onerous duty on the parties to act in good faith. This paper will briefly review the history of the duty of good faith before examining the reasons why the consensus of rejection of the legal significance of this development exists.

3. The Duty of Good Faith

The attraction for contract draftsmen to use the phrase "the parties owe each other a duty of good faith" is understandable. The phrase resonates with the reader who has an instinctive grasp of what it is the contract is trying to do. This resonance is, due in part, to the long history and high esteem in which the duty is steeped.

The concept of good faith has great normative appeal. It is the aspiration of every mature legal system to be able to do justice and do it according to law[6]. The duty of good faith is a means of delivery.

Good faith has an ancient philosophical lineage and is referred to in the writings of Aristotle and Aquinas[7] . They were concerned with the problems of buying/selling and faced the dilemma of how to achieve fairness while not stifling enterprise in commerce. This dilemma is still an issue today and its successful resolution is a major challenge for those seeking to (re-) establish a duty of good faith.

The ancient concept of good faith in a revived form went around Europe, England and United States like wildfire at the end of the 18th century. Lord Mansfield described the principle of good faith in 1766 as the governing principle applicable to all contracts and dealings[8].

The duty of good faith subsequently fell into disuse in England in favour of encroaching statute law and the emphasis on the promotion of trade. Emphasis shifted onto contractual certainty in contracting instead [9]. Contractual certainty has remained the cornerstone of standard form construction contracts since their inception at the start of the 20^{th} century. Procurement and contracting in the 21^{st} century however is different. The role of the contract is changing and the re-emergence of the duty of good faith is an important element in this development. The advantages of recognising the legal enforceability of the duty have been presented as [10]:

- Safeguarding the expectations of contracting parties by respecting and promoting the spirit of their agreement instead of insisting upon the observance of the literal wording of the contract
- Regulating self-interested dealings
- Reducing costs and promoting economic efficiency
- Filling unforeseen contractual gaps
- Providing a sound theoretical basis to unite what would otherwise appear to be merely a series of disparate rights and obligations

The support for introducing the duty of good faith amongst industry commentators has not to date been overwhelming. Academic studies in this area tend towards mild encouragement for the judiciary or parliament to take action and introduce a general duty [11]:

Making the case for the imposition of a general duty of good faith is as challenging as attempting a definition. Despite its beguiling simplicity it has proved to be an elusive term. The attempts to define good faith at best replace it with equally vague and nebulous terms. The danger, as one commentator put it, is that any definition would "either spiral into the charybdis of vacuous generality or collide with the scylla of restrictive specificity" [12].

The difficulty of defining "good faith" is not necessarily a problem for partnering contracts which tend to evoke the spirit rather than the letter of the law. However, progress has been made in defining the term, particularly by the Australian judiciary. The parallels here are striking – a common law jurisdiction grappling with the issue of how best to "concretise" the duty of good faith.

The Australian Judge Paul Finn made the following useful contribution towards definition in the common law tradition:

"good faith occupies the middle ground between the principle of unconscionability and fiduciary obligations. Good faith, while permitting a party to act self-interestedly nonetheless qualifies this by positively requiring that party, in his decision and action, to have regard to the legitimate interests therein of the other." [13]

Thus far the English Courts have denied themselves the opportunity to engage in this shaping of the meaning of good faith in the modern construction context despite its historical relevance, its resonance with the public and even in light of other recent stimuli to its introduction.

4. Other Stimuli towards Introduction of a Duty of Good Faith

As mentioned above, English law made a choice to promote trade through contractual certainty rather than through widely drawn concepts. In Europe the duty of good faith has flourished to the extent that its existence of otherwise in contract law is one of the major divisions between the Civilian and Common Law systems[14]. The great continental civil codes all contain some explicit provision to the effect that contracts must be performed and interpreted in accordance with the requirements of good faith. For example, article 1134 of the French Code Civil and Section 242 of the German Code.

In France, the rather vague concept of good faith or “bonne foi” has been given clarity and definition by judicial decisions, which cumulatively have produced a number of “rules” relating to the performance of contractual obligations and, possibly more importantly, to the obligations of parties before a formal contractual relationship is entered into. For example, good faith is the legal basis for the rules relating to the French doctrine of abuse of rights (l’abus de droit). This is where the court adds a further qualification to the specific express contractual obligations to prevent the purpose of the contract being thwarted by a manifestly unfair attempt to rely on a contractual right.

The development of the doctrine in France has also been determined by the nature of the contract being considered. The courts have developed different types of duties based on the general obligation of good faith that are specific to certain categories of contract. In the context of engineering and construction contracts, there is authority that the developer must provide all relevant data that are necessary to the proper completion of the project by the engineer.

German law has adopted a even more positive approach to the doctrine of good faith than the French. Good faith creates positive extra-contractual obligations and is used as a justification to facilitate performance of the contract. The doctrine is contained in sections 157 and 242 of the German civil code, the Burgerliches Gesetsbuch, which provides that:

S157 – Contracts shall be interpreted according to the requirements of good faith

S242 - The debtor is bound to perform according to the requirements of good faith

The wider statutory basis extending the application of the doctrine from performance to the definition of contractual obligations which explains the different approach of the German Courts, which has been used to create a positive duty of co-operation from one party to the other. For example, in one case where German long-term contracts were adversely affected by inflation after the First World War, it was held that the principle of good faith allowed the judge to re-allocate contractually agreed risk pursuant to section 157.

In summary of this point, the experience in France and Germany has been that that through the duty of good faith the German and Court have had the freedom to develop its doctrines without incurring the reproach of pure judicial decision law making. This has enabled the identification and solution of problems which the existing rules do not or seem unable to reach. Whether or not either of these models could be successfully adopted in England and Wales is not a question that can be easily answered. A “bolting on” by domestic law makers of a French or German type duty is extremely unlikely step in any event. The move contemplated by this paper is much more modest in scope: where the parties have expressly contracted in good faith there ought to be a detectable legal meaning to give some weight to their undertaking.

It is unsurprising, given the establishment of the good faith doctrine into continental legal systems, to discover the duty is enshrined within European law. For example, the Unfair Terms in Consumer Contracts Directive 1993 may strike down consumer contract if they are contrary to the requirements of good faith. The Commercial Agents Directive 1986 also makes reference to good faith.

Moves towards the harmonisation of European Contract law by the European Contract Commission stopped short of outright commitment to the duty of good faith but did state that regard is to be had to the observance of good faith in international trade.

Neither is good faith a concept unknown to English Law. The obvious example is in insurance contracts which are subject to a duty of utmost good faith owed by the assured to disclose material facts and refrain from making untrue statements while negotiating the contract.[15]

The duty of good faith is also apparent in areas of law where there is a special relationship such as family arrangements and partnerships.

A pattern is discernible towards the re-emergence of the duty of good faith in English law. Despite this encroachment (or possibly because of it) suspicion and hostility abound, in the words of one commentator *“(the duty of good faith) is a vague concept of fairness which makes judicial decisions unpredictable.”[16]*

Another argument against the imposition of a general duty of good faith is the preference given to ad hoc solutions in response to demonstrated problems of unfairness. In other words, good faith outcomes are already being achieved through other means. Examples of these outcomes have been given [17] as the contractor’s duty to progress the works regularly and diligently and the Employer’s duty not to obstruct and to co-operate. However, ad hoc solutions can lead to unsatisfactory results. Contract draftsmen have given the judiciary a unique opportunity to create new law based around the key concept of good faith. This paper now examines judicial attitudes in this area.

5. Judicial Hostility?

The grounds for the seeming hostility (with one notable of exception) of the judiciary to the concept of good faith has already been stated – suspicion of broad concepts. The approach is, to paraphrase Lord Bingham in Interfoto Picture Library v Stilleto Visual Programme Ltd [18] to avoid any commitment to over-riding principle in favour of piecemeal solutions in response to demonstrated problems of unfairness.

The judgment of Lord Ackner in the case of Walford v Miles [19] sums up the prevailing sentiment: "the duty to carry on negotiations in good faith is inherently repugnant to the adversarial position of the parties involved….how is the court to police such an "agreement?"

From time to time the courts have, at least, entertained submissions about the more general application for the duty of good faith [20]. A trilogy of cases [21]in the Court of Appeal suggested a move towards a more general principle. Lord Bingham was at the time dropping heavy hints such as: "we would, were it material, imply a term that [x] should act in good faith in the performance of this contract. But it is not material." In the second case "the court would then have wished to consider whether it was not subject to a duty of good faith substantially more demanding than that customarily recognised in English Contract Law". In the third "I am for my part by no means sure that the classical approach to the implication of terms is appropriate here".

The impact of these judgments on the Technology and Construction Court appears to have been minimal. The initiative towards the introduction of a general duty of good faith has not found support here. His Honour Judge Lloyd Q.C. in the case of Francois Abballe (t/a GFA) v Alstom UK Limited [22] "the proposition that "good faith" may be used as a fall back device tellingly shows why it is wrong but tempting to consider with the advantage of hindsight whether a term should be implied. I do not consider I should be a hero and permit the Claimant to advance this term."

The door seemed to be more firmly closed on the introduction of a general duty of good faith by His Honour Judge Seymour "the development of the law in the direction anticipated by Sir Thomas Bingham would, it seems to me, be fraught with difficulty….. I should not be prepared to venture into these treacherous waters…" [23]

There has only been one case where a specific duty to act collaboratively has been considered by the judiciary. The case of Birse Construction Limited v St David Limited [24] has been poured over in great detail in other articles. For the purposes of this paper the relevant considerations of the case are that a) it features a non-binding partnering charter and b) the Judge specifically highlighted that the parties had entered into a partnering arrangement.

His Honour Judge Humphrey Lloyd recognised that the terms of the partnering charter were important in providing the standards of conduct of the parties. Although such terms may not have been otherwise legally binding, the charter was taken seriously as a declaration of assurance. In short, the parties were not allowed to interpret their relationship in a manner which would have been inconsistent with their stated intention to deal with each other collaboratively.

It is possible to discern support from this judgment for the parties' expressed desire to operate in good faith in their dealings with one another. This support fulfils the role of meeting the expectations of the contract users. Increasing numbers of contract draftsmen have been bold enough to include good faith provisions in their contracts. The contracts have been welcomed by their users. If they find themselves into difficulties then the users have a reasonable expectation to be bound by their promises to one another. The challenge for the judiciary is to decide on the appropriate level of support to be given to the more prescriptive and onerous terms of contract now employed in the latest construction contracts.

6. How best to deliver what the parties want?

It is beyond the aims of this paper to provide a blue-print for how a general duty of good faith might operate. One commentator has pointed out that if good faith is to be of any practical utility it needs to provide a few clearly understandable action-guiding principles of conduct [25]. The small print solution of listing every possible potential misconduct on the part of any party is not suitable given the complexity of construction contracts and the move away from voluminous forms. One approach would be to allow the judge/arbitrator/adjudicator a wide discretion so that they might "concretise" the duty in line with the principles of conduct as they see fit or in line with experiences in other jurisdictions.

Good faith in negotiations could mean an inquiry into the reasons for breaking off negotiations. Examples of bad faith might include negotiating without serious intention to contract, non-disclosure of known defects, abusing superior bargaining position, arbitrarily disputing facts and adopting weaselling interpretations of contracts and willingly failing to mitigate your own and other parties' losses and abusing a privilege to terminate contractual arrangements.

The effect of the court recognising the duty of good faith as a hard obligation has been likened to recognising the general duty of care in negligence or the principle of undue enrichment [26]. As a result the principle may remain relatively latent or continue to be stated in extremely general terms without doing too much damage to the important virtues of certainty and predictability in the law. The principle could also provide a basis on which existing rules can be criticised and reformed.

The alternative way of introducing a duty of good faith is to set down guidelines in a statute. A statutory obligation to act in good faith was recommended by Latham as a measure which would lead to the improvement of the performance of the construction industry. The government of the time chose not to move in this direction. The time may have come to revisit this decision.

7. Conclusion

Good faith has been described as "repugnant to the adversarial position of the parties". The duty is surely not so repugnant to an industry currently characterised and actively pursuing an agenda not of adversarial relations but of collaboration.

The industry would benefit from some clear messages from the judiciary as to the enforceability of their collaborative arrangements. The positive stance taken in the Birse v St David case is encouraging in terms of direction but further concretising of the exact meaning of such obligations on the particular facts of any case would be helpful. Re-ordering the structure of construction contracts by introducing the sound theoretical basis presented by the duty of good faith is an achievable and laudable aim. The expression of this underlying principle with its uncluttered simplicity may serve to bring clarity to the dense contractual conditions for which the industry is renowned.

The optimization of regulations that guarantee housing quality

Abstract

All countries have sets of public building regulations to guarantee a minimum technical quality of buildings. Major goals are safety, health, energy saving, practicability and environmental aspects. To assure that the regulations are met enforcement regulations like permit procedures are laid down in laws. Tasks and responsibilities for building control bodies and other actors in the building process are defined. The reasons to set up national regulations vary per subject and change in the course of time because of societal changes and a changing view of the role of government. The goals and approaches in most countries are similar on the headlines. A closer look at the way things are worked out shows a broad spectrum of differences. There is some influence of the European union, e.g. the European Construction Products Directive, the Euro Codes and the European Performance of Buildings Directive. In the Netherlands there is an ongoing debate about the minimization of the administrative burden caused by regulations at one hand, and the improvement of the enforcement at the other hand. Also in other countries like England and Germany discussions are going on about the building regulations. Environmental aspects like energy conservation are dominating the policy agenda; this might request an innovation of the role of building regulations. Part of the discussion is the form the regulations take. This paper presents some societal developments and examples that influence the way one can look to the role of the government in safeguarding a minimum quality of houses. This is illustrated with examples of the systems of building regulations and building control of various European countries based on the outcome of ongoing international comparative research.

Keywords: Building regulations, Europe, Technical requirements Deregulation, Privatization.

1. Introduction

The protection of safety and health was the primary reason for governments to draw up technical regulations for the built environment. In the course of time other goals, such as utility, accessibility and energy saving have come to play a part. Although the necessity of some set of public building regulations is undisputable, in the Netherlands, as well as in other countries, the scope, level and system are a constant subject of discussion since there is a permanent urge for deregulation. The administrative burden for all parties in the building sector caused by building regulations is the reason for a constant process of minimization and optimization of the building regulations in a way that they facilitate an effective and efficient building process. A reference to the scope, level and organisation of the building regulations in other countries is considered to provide a good basis for this process.

The OTB Research Institute for Housing, Urban and Mobility Studies undertakes comparative studies of systems of building regulations since the mid nineteen-nineteen's. A few years ago we finished a study commissioned by the Dutch Ministry of Housing, Physical Planning and Environment. It was a comparative study of the building regulations in eight European countries focussed on technical requirements for dwellings and the systems of building control. The project resulted in two publications Meijer et all [1] and Sheridan et all [2]. Recently we have started a new initiative to collect information of the systems of building regulations in all European countries. In another project the systems of enforcement of building regulations in Australia and Canada are investigated. The projects generate much insight that contributes to the ongoing policy debate about the urge for deregulation on the one hand and on the other hand a rising sense of necessity of a proper functioning system of building regulations and building control. Recently the Dutch government has launched a project in which it wants to fundamentally reconsider the system of regulations. It fact it is considered to be a "green field study". There is a strong feeling in Dutch politics that the whole system is too complex, too detailed and goes far beyond what should be the core of government responsibility. One thinks that the optimization of the current system would only lead to minor improvements. Therefore it is considered that one should start from scratch again: first develop a vision on the way the government should interfere in the building process. When that is clear a new system can be build. It seems that the vision on the role of the government is clear yet. The government sets up the framework of the regulations and wants to hand over responsibilities and tasks for the implementation and control to the private parties. The government is responsible for the system and the private parties are responsible for the quality of building. It is unknown yet what this means for the further transformation of the system. In this paper we take this dilemma as a starting point. We use the characteristics of the current system with its pro's and con's in combination with examples of other countries and some societal developments to create some basic elements for a terms of reference for a future system of building regulations. In section 2 we go into the societal circumstances that define the need of building regulations. Section 3 deals with the systems of formulations of the technical regulations. In section 4 the organization of building control and the ways tasks and responsibilities are divided over parties in the building process is worked out. In section 5 we discuss the basic elements of a system of building regulations.

2. Reasons and goals for building regulations and building control

The Dutch Building Decree has the following mayor goals: safety, health, practicability, energy saving and environmental protection. This last goal however has not yet resulted in concrete regulations (it is still an empty chapter), although it has already been introduced in the Housing Law several years ago. In Sheridan et all [2] we compared the starting points (goals) and the subjects that were covered by the building regulations in eight European countries. The conclusion was that there are many similarities in de European countries in the mayor goals and subjects that are covered. However the formulations and the level of detail vary quite a lot. This makes it also difficult to be quite sure about the exact scope of the regulations in the various countries. Structural safety and fire safety are the most basic requirements and are well covered in regulations in all countries. For these regulations it is also most likely that there might be some convergence of the regulations within Europe. The development of the Euro Codes, containing calculation methods will contribute to this development.

1. DEFINITIONS 2. SAFETY - Structure - Moving in and around the building (Floor guarding, Staircase, Ramp) - Power supply (Electricity, Gas, Lighting) - Fire safety (Fire and Smoke development, Escape) - Burglary safety 3. HEALTH - Sound (From outside, installations, between rooms) - Moisture - Discharge of water - Ventilation - Harmful materials, substances and radiation - Harmful small animals - Water supply - Daylight	4. PRACTICABILITY - Dimensions of corridors and rooms (Accessibility for wheelchairs to the building, Minimum dimensions Door openings, length and width of living room and sleeping rooms, Minimum ceiling height) - Dimensions of toilet and bathroom - Kitchen (Sink unit and cooking appliance installation place, Dimensions of cooking place) - Other rooms and spaces (storage room for bicycles, Garden or balcony, places for services) 5. ENERGY SAVING - Thermal insulation - Reduction of air permeability - Energy performance 6. ENVIRONMENT (sustainability) (empty)

Fig 1 Main subjects of the Dutch Building Decree 2003

The public debate in the Netherlands about the burden caused by building regulations always starts with the proposal to eliminate regulations from the Building Decree. In fact the existences of more or fewer of these technical requirements have little influence on the whole of administrative procedures, processing time and costs. The planning regulations are much more dominating the process. It must be said that the politicians that are responsible for this, seem not always be informed well enough. Within the scope of regulations the subjects regulated under ‘practicability’ are more and more considered not to belong to the core of government responsibility. Developers would be smart enough to have dwellings designed and build that meet the preferences of buyers or tenants. In fact the housing market is far from perfect yet. The shortages in the stock and the big distance between the user (the occupant) and the developer of a house frustrate this. In 2003 the requirement for a balcony (for apartments) and a storage room for bicycles were removed from the Building Decree. It was thought that developers would realise these elements anyway. It turned out to be quite different. In 2007 the mayors of the four largest Dutch cities wrote a letter to the minister to ask for a reintroduction of these regulations.

In their cities quite large shares of the new developed housing stock do not have balconies nor storage rooms for bikes. These flats are not really wanted (even on a tight market).

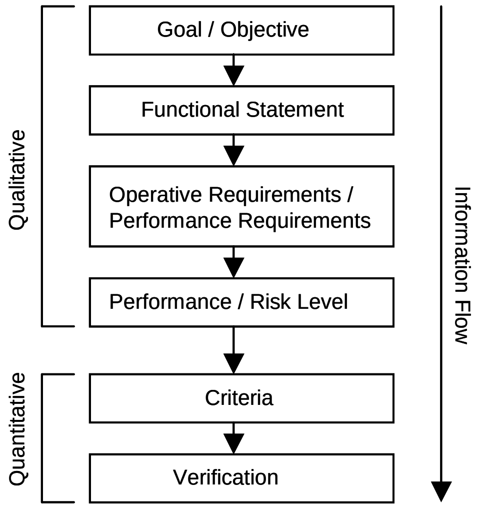
In 2007 the Building Decree existed 15 years. During a conference many representatives of Building Decree discussed about the pro's and con's of the current regulations. One quite clear conclusion could be drawn from the debate: no one wants to eliminate more requirements from the Building Decree. Even developers, builders and home owners are in favour of a good functioning national system of building regulations. When elements are removed from the regulations at national level there is a 'danger' that pseudo regulations are going to be developed at local levels or that some quality topics have to be defined at project basis. Public building regulations in fact serve a series of goals of which the guarantee basic qualities for its users is only one. Also the rights of third parties (e.g. fire safety for neighbours) and the contribution to societal goals at a much higher level (e.g. the reduction of CO2 emissions) have to be covered by the regulations. Houses have a much longer life span than its first users. It is a responsibility of a government that for economical and environmental (use of materials) reasons, new build houses have basic qualities that are contribute to the possibilities of a long life span (future value). Furthermore the national regulations provide equal legal rights to developers. Common used definitions and calculation methods facilitate communication in the building process. A growing concern of the contribution of the building stock to environmental pollution (energy use, CO2 emission, use of scare materials and many more environmental parameters) will lead to more regulations in next years. So if it is not likely or desirable to narrow the scope of the regulations, then what is the key to deregulation? In section 3 we look to the system of formulation of the regulations and in section 4 to the organisation of building control.

3. Systems of formulation of technical building regulations

The formulation of technical requirements has been discussed for many years. For instance, the Building Research Station of the Department of the Environment in England conducted comparative analyses of building control from 1969-74 [3] [4] [5] [6]. The move away from prescriptive specifications towards functional requirements started over 40 years ago, offering a clear explanation of specifications, functional requirements, and performance standards, together with the use of deemed-to-satisfy clauses, codes of practice, the system of agréements, and information for guidance. In 1978 the Nordic Committee on Building Regulations developed a five-level model of technical requirements [7]. Almost 20 years later, Bowen compared this with the structure of the first version of the Dutch Building Decree [8].

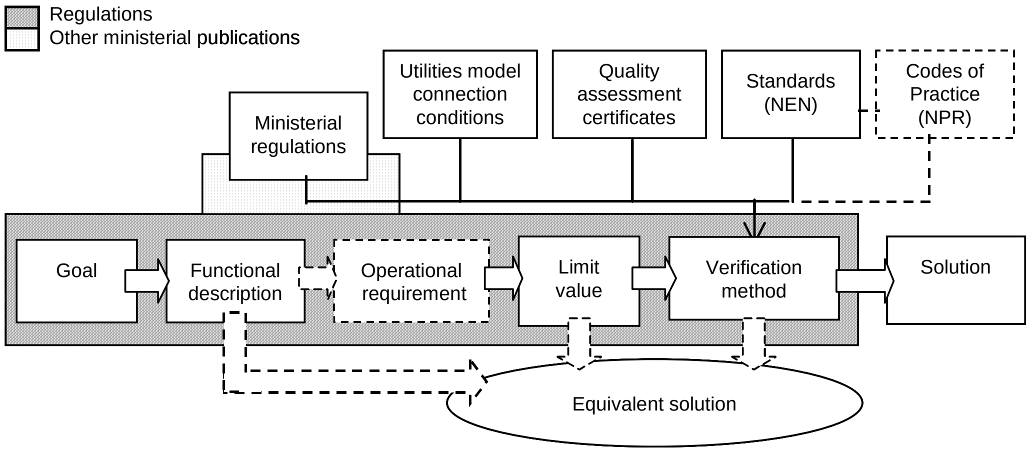
The CIB Taskgroup 37 'Performance based building regulatory systems' developed a model to analyse and describe the various systems of performance based requirements. In 2004 the Taskgroup held their final meeting at the CIB-world conference in Toronto and the final report was presented [9]. The concept of the 'Performance System Model (PSM)' was formalized.

Fig 2 Performance system model CIB-TG 37



The PSM moves on from the Nordic five level system, introducing a 'Performance risk level', which determines the application of requirements, and a further level of 'criteria' which can be worked out into of objectives like health and safety, fire safety, structure, and sustainability. It also combines levels four and five into a single verification level, which includes design guides as well as testing or modelling techniques and can also refer to acceptable solutions.

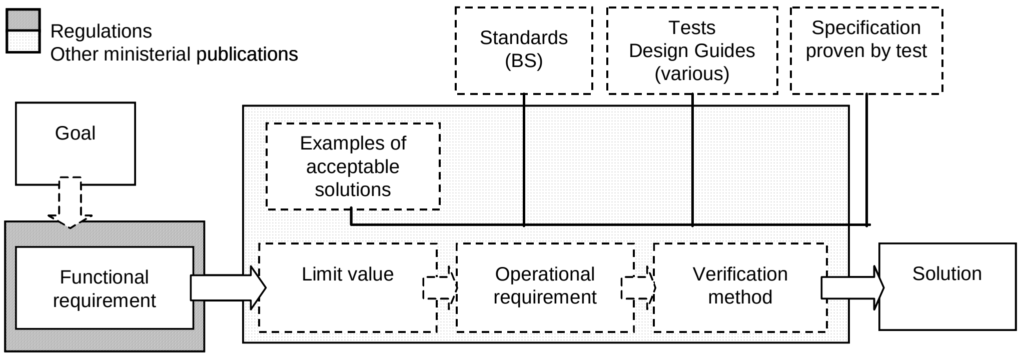
Fig 3 The Dutch Building Decree



We have used this model to analyse the formulation of requirements in different countries. Some countries, including the Netherlands, have consciously attempted to follow such a model.

Others have devised their own performance-based systems. The analysis is difficult, even for those countries that have adopted some form of performance-based system, firstly because commentators vary in their understanding of these terms and secondly because there is inconsistency within the specific systems of regulations in the countries used for different subjects. As other commentators have pointed out [10] [11] the term ‘performance requirement’ is interpreted in different ways. Although it is understood by CIB to mean the qualitative formulation of requirements or goals, as opposed to prescriptive regulations with mandatory design solutions, some countries understand it to constitute a description of desired levels of performance. In The Netherlands the formulation of regulations in the Building Decree was the result of a deregulation program in the nineteen-eighties which used the following criteria: a regulation must be legally explicit and equitable, unambiguous and thereby measurable and verifiable, and a regulation should present only a minimal restriction on freedom and innovation in design. These criteria have been interpreted very strictly and led to a system of performance requirements that conforms to the CIB-TG 37 model. In 2003 a revision of the Decree was introduced [12].

Fig 4 The Building Regulations of England and Wales



In England and Wales, the structure of the Building Act, the Building Regulations, and the associated advisory Approved Documents is relatively clear, in terms of a hierarchy of components. However, there are some inconsistencies between different subjects, which are partly the result of a rolling programme of review and amendment, but also reflect the nature of the subjects. The Building Act 1984 is the enabling legislation for the Building Regulations 2000. Schedule 1 to the Building Regulations sets out functional requirements, grouped in themes, termed ‘Parts’. Each functional requirement is brief. Approved Documents (ADs) are issued for each of the themes, which elaborate the requirements, discuss the underlying issues, and describe strategies that can be used to comply with the functional requirements. The ADs include: guidance on operative strategies and tactics (advisory equivalent to operative requirements); and various forms of verification: description of methods of measurement and verification, often by reference to British Standards; direct examples of acceptable solutions. Building control bodies can also accept alternative strategies and tactics, provided the developer demonstrates that they comply with the functional standards.

The Dutch Building Decree is quite abstract and difficult to read. Only the higher educated in the construction industry can work with it on a proper way. During the years more and more documents have been developed that should serve laymen. Most professionals are quite satisfied with the system. They can work with it and are used to it. The biggest advantage of the system is considered to be its clearness. For most topics, in most cases the required performance can exactly be defined. It seems that for reasons of deregulation a system like the English Building Regulations might be somewhat better, although the advantages are not really obvious. A transformation of the system will be very expensive and lead to a long time of transformation in the building industry. The further development of interpretive documents and software seems to be a better choice.

4. The organization of building control

Another element of the system of building regulations is the whole organization of building control, including the definition of permit procedures, and the division of tasks and responsibilities over public and private parties in the building sector. In most European countries (local or regional), authorities have traditionally been responsible for controlling and checking building plans and for granting permits. Figure 5 classifies the systems of eight countries according to the allocation of responsibility for exercising building control. Three categories are distinguished: public responsibility for building control, private responsibility for building control and private responsibility for granting permits. A fourth possible category – public responsibility for granting permits – has been omitted, as this remains the archetype in all European countries.

Fig. 5 Responsibility for control.

Public responsibility for control	**Private responsibility for control**	**Private responsibility for granting permits**
A. Local authority carries out control (Netherlands, Denmark, England & Wales)	C. Local authority contracts out, private organisation is responsible (Germany)	G. Private organisations are qualified to issue building permits (England & Wales)
B. Local authority contracts out but remains responsible (Netherlands, Denmark)	D. Legal liability for private control based on building regulations (France)	
	E. Private inspection because of liability and insurance requirements (Belgium, France)	
	F. Full private responsibility (Norway, Sweden, Germany)	

Our studies show that administrative procedures in Europe vary widely. Although building permit procedures are determined at the national level, developments indicate a trend towards convergence across the Europe member states. This trend is best described as ‘procedural (or administrative) deregulation'. Within these countries, the category of construction works that require building permits is diminishing. Authorities are trying to improve both the effectiveness and the efficiency of their procedures through such initiatives as making a procedural distinction between simple and regular procedures. Actions being taken to streamline regular procedures even further include introducing online facilities for acquiring information and applying for permits, allowing exceptions for certain frequent construction works (i.e., Type Approval) and dividing the regular procedure into phases [13].

The future of building control (and especially the way it is best organized and executed) are high on the agenda in many European countries. In almost all cases deregulation and privatisation are important themes. The way one can look at solutions however differs. Below we give a short impression of the actual situation (and discussions that take place) in the Netherlands, England & Wales and Germany.

Netherlands

In the Netherlands municipalities are required to check permit applications for new developments against the Building Decree, issue building permits, and supervise the construction work. However the current enforcement system does not function as well as it should [14]. Local authorities often lack the manpower to check all building plans and to conduct site inspections in a satisfactory manner. The smaller authorities in particular are unable to cope with fluctuations in the number of applications received. The quality of the building inspection departments, particularly among smaller authorities, leaves something to be desired. The small departments have difficulty in achieving the required level of specialization and to provide the necessary ongoing training. The local authorities do not apply uniform assessment protocols. Accordingly, not all building applications are subject to the same evaluation methods. Local authorities have limited liability for injury, loss or damage due to negligence in the control and inspection procedures. This is to the detriment of the quality and completeness of those procedures. Finally there is a risk that local political interests will stand in the way of objective enforcement of the regulations.

To improve the situation various ideas and instruments have been developed. A first step was taken in the direction towards more privatisation. In the early 2000's the idea was worked out to certify engineering companies and architect firms to check the integral (or one or more parts of the) Building Decree. In the past years this new system has been tested. Although the results are positive, the possibility for a private control is not yet incorporate in the Housing Act. However many stakeholders within the construction have recently (October 2007) signed a declaration of intent with the Dutch ministry of housing to develop the private building decree further. The organizations involved want to stimulate local authorities and market parties in the building industry to use the private building decree control possibility in practice. Other instruments that have recently been developed are aimed at the harmonization of plan check and site inspection procedures. A uniform assessment protocol has been developed to establish priorities for the checks and inspections. As stated in the introduction paragraph the Dutch government has recently started a study to fundamentally reconsider the building regulatory system. It remains to be seen what effects this project will have on the deregulation and privatization of building control in the Netherlands.

England & Wales

Since the 1980s, private bodies in England and Wales can be certified as Approved Inspectors, who determine whether the design and construction of projects meet the demands, and they are authorised to issue building permits. The approved inspectors operate side by side with local authority building control. Most of the construction works in England and Wales are still controlled by local authorities. In time, the English regulations may change some more. In addition to the self-certification schemes for the installation of specified equipment and for the replacement of windows, England is considering the development of self-certification for entire buildings by enterprises or individuals who have been deemed 'competent' by accrediting bodies.

The Department for Communities and Local Government recently made a start to review the English building control system. Not because there is something serious wrong with the system but there are some weaknesses that needs to be addressed. The department has bundled the first ideas and suggestions that involved stakeholders have came up with [15]. Six key areas have been identified for which attention and action is needed:

- What should be the vision and strategy for future building control? The public in particular has little sense of the purpose of building control or who is responsible for what.
- The levels of inspection and compliance are sometimes lower than they should be. Potential future ways are to develop an effective risk-based approach to inspection and enforcement and a wider range of sanctions and greater powers of enforcement.
- Building control processes are generally paper based and need updating and e-enabling. Alternative routes to compliance should be encouraged and developed further, particularly where self-certification is possible, so that cost and delay can be taken out of the system.
- Approved Documents are too technical and complex for most small building contractors to follow. The distinction between Approved Documents and Building Regulations needs clarification. Guidance needs to be simplified and targeted to take account of the different needs of different types of projects and different types of users.
- All parties involved with construction works are subjected to frequent change and have difficulty keeping up. Regulations are sometimes updated before previous changes have been fully applied. This makes it difficult for the industry to plan and therefore harder to prepare or innovate. This could be prevented by the introduction of fixed cycles of building regulation review and stakeholder engagement procedures to make better regulations.
- Building control is being considered as an ageing profession in which it is increasingly hard to recruit and retain staff. Resources which are intended to support training and development tend to be used for other purposes.

These proposals will be further developed. The results will be incorporated in a full consultation paper that should be published before the end of 2007.

Germany

In Germany privatization always has been an important feature of building control. Since the 1920s, local building control authorities in Germany have contracted out much of the control work to specialised engineering firms. These inspection *engineers*, who are certified, must meet strict requirements, and they are liable for their work. During the 1990's and early 2000's the German system has been severely deregulated. Most German states have enlarged the category of exemptions substantially Also a distinction has been introduced between an elementary and a regular permit procedure. The elementary procedure (e.g. dwellings with limit and moderate heights) consist of a check of the stability, durability and fire safety of the constructions. During the last decade the German system has made a sizable further step towards further privatisation. Construction works that are subject to the elementary procedure must be checked by certified inspection experts. The levels of education, experience and similar qualifications that are demanded of these experts are lower than those that are demanded of inspection engineers.

The main driver behind these developments seems to be to bring back the administrative costs for principals and applicants of building permits. These effects have indeed been realized. We give an example from one of the German states. In Bayern for instance the regulatory system was changed in 1994. Between 1994 en 2003 about one third of all house construction has been built without a permit. Roughly eighty percent of the construction works that needed a permit in that period have passed the elementary procedure, which took on average five weeks. The average duration of the regular period took around eleven weeks. All in all it is estimated that Bayern building owners have saved themselves some 132 million euro's on fees in the period 1994-2003 [16]. There is however a serious downside to this. The deregulation of building control also has caused negative effects. Especially the organisation of inspection engineers and the chambers of architects in various German states have warned about the effect before the deregulation took place and are now still criticizing it. The states and local authorities hardly check building plans and carry out site inspections. Research after the collapse of an ice skating hall (in 2006) learned that more than half of the similar construction works that were inspected had shortcomings. Also in the residential sector the financial loss of damage because of defects has grown with 30 percent in the past five years. It is expected that in the next five years many owners of one family and two family houses in Germany will be confronted with damages caused by building defects. The savings of administrative costs (through deregulation) and the transfer of the responsibility to the proprietor/owner has had serious consequences. The organization of inspection engineers states that: "who wants to deregulate should ascertain that the few regulations that are left are being met" [17] [18].

It is not known in which direction the German building regulatory system will develop in the near future. What is evident is that privatization and deregulation per se can have serious negative side effects. The situation after the deregulation and privatization operation seems to be very clear. The owner/applicant is responsible for control and the quality of their construction works. What happens when the owner/principal (for lots of reasons) does not effectuate this responsibility?

5. Discussion

Building regulations are an essential tool in planning and building processes. The government takes responsibility in defining a bottom quality for buildings. The complexity of design, construction and the organisation on the development procedures bring along many risks of failures. One may not expect that the primary processes of design and construction will lead to buildings that meet the defined requirements without strict quality assurance procedures. Therefore building permit procedures based on procedures of plan checking and site inspections are essential elements of the building regulatory systems. Time and again initiatives are started in the European countries to reduce the administrative burden and to improve the actual enforcement of the regulations. This can be worked out at several levels: the scope of the regulations, the system of formulation of the regulations and the system of enforcement. The expectation is that the scope of public regulations will not become narrower. The growing importance of environmental issues and reduction of energy use in buildings will lead to more regulations. Also, we believe that the existence of technical requirements is not the main reason of administrative burden. More can be gained by an easy use of the regulations in the building practice and an effective and efficient quality control process. The move towards more privatisation seems to be a sensible move. But do not consider it as a panacea for (serious) failures and weaknesses of current building control systems. Look at the German experiences. We think the Dutch and (especially) English are good 'process examples' to try to develop a sound future building control system. Current problems and barriers are addressed without the exclusion of possible solutions beforehand. Developments and solutions found in one country can inspire other countries in their strife for a better building regulatory system. However solutions for one country can not be automatically implemented in another country. Tailor-made solutions for certain problems/barriers still are needed.

Abstract

The continuing incidence of costly disputes in the construction industry has led to a common interest of researchers in different countries to identify the generic aspects of conflicts, claims, disputes and their resolution. This paper undertakes a comprehensive review of literature in the field of construction disputes and identifies the relationship between procurement selection (with the inherent risk allocation) and the behavioural attitudes of key stakeholders as critical factors in the incidence of disputes. It conceptualises the research area and identifies a proposal for further research based on case studies of construction projects in Lebanon which have encountered disputes and claims.

Keywords: Disputes, conflict, claims, risk, behavioural attitudes.

1. Introduction

1.1 Disputes and conflict

Unlike other types of industries where the development and manufacture of product can be standardised and tested before being purchased, the nature of projects in the construction industry is extremely diverse. Every project is unique. Even where identical buildings are under construction, the site conditions in each will differ and introduce new challenges. Moreover, it is a multi-party process where numerous specialist parties are involved due to the diversity of skills required and thus maintaining teamwork atmosphere and controlling potential conflicts is important. Also, the construction projects normally span for a long period between the decision to invest and the completion of works. This leads to instability of supply and demand and high sensitivity to economic fluctuation [1].

Maintaining a cooperative environment becomes a difficult task because conflicts are inherent in construction projects [2,3]. Where conflicts result in adversarial stances and mistrust, they have a detrimental effect on project performance [4]. Eliminating conflicts appears to be a daunting objective[5,6] and so efforts have been directed towards reducing their magnitude and/or keeping them under control [7].

The definition of dispute is itself a matter 'in dispute'. Some authors refer to disputes as simple disagreements, whilst others refer to disputes as the consequence of rejecting a claim [8, 9, 10]. Put in simple terms, and where it is referred to in what follows, a dispute is considered to be in existence where one party does not accept the rejection of the claim by the other party. Accordingly there has to be a claim, a rejection and a non-acceptance of the rejection. It is not considered to exist on the basis of a claim alone [11].

There appears to be a consensus in the literature that conflicts can be constructive or destructive. Accordingly, constructive conflicts should be encouraged whereas destructive conflicts that lead to disputes should be avoided [12, 5, 8, 4, 13]. Moreover, the sooner the destructive conflict is resolved the higher the percentage of resolution success and the lower the cost [4].

1.2 Causes of disputes

An extensive list of 56 causes of disputes over delay identified by Assaf *et al.* [14] includes: shortage of construction material, changes in types and specifications during construction, slow delivery of material, damage of material in storage, delay in the special manufacture of the building material, shortage of labour, labour skills, nationality of labourers, equipment failure, equipment shortage, unskilled operators, slow delivery of equipment, equipment productivity, financing by Contractor during construction, delays in Contractor's progress payment by Owner, cash problems during construction, design changes by Owner or his agent during construction, design errors made by designers, foundation conditions encountered in the field, mistake in soil investigation, water table conditions on site, geological problems on site, obtaining permits from municipality, obtaining permits for labourers, excessive bureaucracy in project Owner operation, building code used in the design of the project, preparation and approval of shop drawings, waiting for sample material approval, preparation of scheduling networks and revisions, lack of training personnel and management support, lack of database in estimating activity duration and resources, judgement of experience in estimating time and resources, project delivery systems used, hot weather effect on construction activities, insufficient available utilities on site, the relationship between different subcontractor's schedule, the conflict between the consultant and the Contractor, uncooperative Owners, slowness of the Owner decision making process, the joint ownership of the project, poor organization, insufficient communication between Owner and designer at the design phase, unavailability of professional construction management, inadequate early planning of the project, inspection and testing procedures used in the projects, errors committed during field, application of quality control based on foreign specification, controlling subcontractors by general Contractors in the execution of the works, the unavailability of financial incentives for Contractor to finish ahead of schedule, negotiations and obtaining of contracts, legal disputes between various parties, social and cultural factors, accidents during construction [14].

Through a questionnaire survey conducted on 61 contemporary construction projects in Hong Kong Kumaraswamy [8] attempts to better understand disputes; he identifies common root causes, proximate causes and confirms the need of further studies to isolate the real root causes of avoidable claims and disputes. A list of the root causes and the proximate causes is shown in Figure 1.

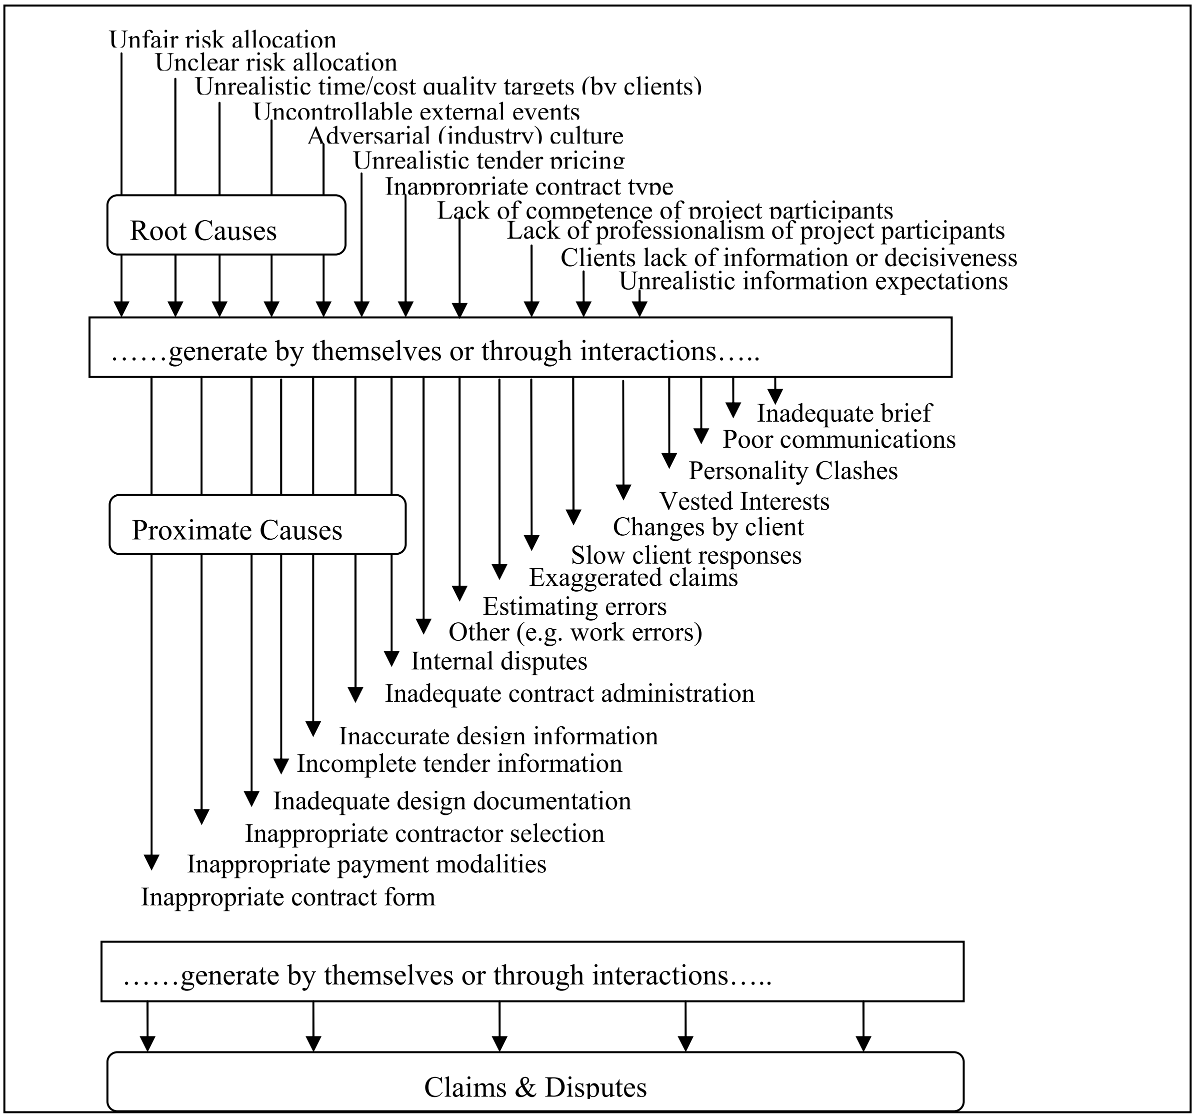

Figure 1- Root Causes and Proximate Causes (Kumaraswamy [8])

Other attempts to categorise the causes of disputes are shown in Table 1.

Table 1- Categorising Causes of Dispute (adapted from Fenn, [3] and Fenn, [60])

Al Momani [15]	Causes of delay: poor design, change orders, weather, site conditions, late delivery, economic conditions, and increase in quantity.
Alkass *et al.* [16]	Strikes, rework, poor organization, material shortage, equipment failure, change orders, act of God.
Bristow and Vasilopoulous [17]	Five areas unrealistic expectations: contract documents, communication lack of team spirit and change.
Colin *et al.*[18]	Six areas: payment, performance, delay, negligence, quality and administration.
Diekmann *et al.* [19]	Three areas: people, process and product.
Heath *et al.* [20]	Seven areas: contract terms, payment, variation, time nomination, re-nomination and information.
Hewit [21]	Six areas: change of scope change conditions, delay, disruption, acceleration and termination.
Kululanga *et al.* [22]	Four sources of dispute: (1) errors, defects and omissions in the contract documents, (2) underestimating the real cost of the project in the beginning, (3) changed conditions and (4) stakeholders involved in the project.
Madden [23]	Three categories: legal, technical and quantum.
Molenaar *et al.* [24]	Three categories: people issue, process issue and project issues.
Rhys Jones [25]	Ten areas: management, culture, communications, design, economics, tendering pressures, lay, unrealistic expectations, contracts and workmanship.
Semple *et al.* [26]	Four areas: acceleration, access, weather, and changes.
Sykes [27]	Two areas: misunderstandings and unpredictability.

Fenn [3, 60] conducted exhaustive studies of previous research into causes of disputes and the above table shows a sample from his studies of attempts to identify causes of disputes. However, it is evident from the sample that direct comparison of the results is, as expressed by Kumaraswamy [5], “neither possible nor useful, because of the diverse industry cultures and differing methodologies and terminologies used in data collection, analysis and outcome presentations.” However, all these factors as pointed out by Kumaraswamy [8] fall in the broader sense in three categories of external factors, contract and project teams. The same has been confirmed by the Dispute Prevention and Resolution Task Force of the Construction Industry Institute (CII) where the factors were described as project uncertainty, process problems including imperfect contracts and people issues [28, 29].

Mitropoulos and Howell [29] move beyond individual factors and study the effect of interaction of technical, contractual and behavioural factors on the development of disputes as proposed in a dispute development model. These authors again identify three basic factors that directly affect disputes: project uncertainty, contractual problems and opportunistic behaviour.

Fenn *et al.*'s [12] research proves that studies conducted to determine dispute causes do not identify the causes that produce the most expensive delays. He concludes that there is a need for research that would investigate the causes of general disputes. Kumaraswamy[5] again emphasizes the need for a deeper analysis of the causal linkage between conflicts, claims and disputes. Identifying common causes and consequences of unresolved conflicts and claims would allow for more effective dispute avoidance as well as more efficient resolution of 'unavoided and unavoidable disputes' [5]. In spite of abundant research in the area, the continuing emergence of costly disputes verifies that further studies are needed to identify the causes of these disputes.

2. Uncertainty, contracts and behaviour

2.1 Project uncertainty

Construction projects are sensitive to an extremely large matrix of hazards and risks due to some of the inherent characteristics of construction projects [1]. As with disputes, many attempts have been made in the literature to identify and categorise risks. Zack [30] presents an exhaustive list of risk allocated in standard construction contracts that includes: physical risks, acts of God, impractical/impossibility, latent site conditions, quantity variations, site access, weather, capability-related risks, defective works, labour forces, subcontractor, supplier failure, economic risks, bonding, contract termination, cost escalation, economic disasters, failure to pay, insurance, project funding, taxes, time-related risks, acceleration, delays and disruptions, early use of facility, suspension of works, untimely responses, union strike, engineering and construction risk, changes, Contractor furnished equipment/material, continuation of work, coordination, defective contract documents, interpretation of requirements, means and methods of construction, owner-furnished equipment materials, permits and licenses, productivity, site safety, and work quality. Comparing these risks factors with the causes of disputes mentioned above by Assaf *et al.* [14] it is noticed that these risks are included as causes of disputes. This suggests that where risks surface in a project and are not treated correctly a dispute will result. Previous literature has ascertained that the risk should be transferred to the party that has the competence and expertise for best assessing, managing, controlling and minimizing it [31, 32, 33]. Risk allocation may be achieved through any one or a combination of risk retention, risk transfer, risk reduction and risk avoidance [33]. Given the significance of risks on project success, construction practitioners have raised awareness to the importance of risk management.

2.2 Contractual issues

Choosing the appropriate procurement method is a vital preventive method which if not carried out effectively might increase the probability of dispute occurrence. For this reason many models have been devised for procurement selection including discriminate analysis approach, multivariate analysis, decision support system, knowledge-based systems, procurement rating systems, procurement path decision charts, the multi-attribute approach, the analytical hierarchical process, the project procurement system selection, the objective-subjective procurement method and the multicriteria / multiscreening model [34, 35, 36].

Some authors focus on the importance of proper contract documentation in avoiding and resolving disputes. Carnell [37] proposes that 'getting it right' requires successful negotiation of the contracting parties throughout the procurement and apportionment of risk, complying with contract requirements and monitoring delays. Jannadia *et al.* [38] conclude that, based on previous studies, waiting until the end of the project to resolve disputes makes the procedure more time and cost consuming. The authors investigate techniques that can be incorporated in preparing construction contracts for dispute avoidance and resolutions including: allocating fair contract risk, drafting dispute clauses, team building, and provision of a neutral arbitrator and binding arbitration. The authors conducted a survey in Saudi Arabia where results show that there was a common desire among the parties to draft dispute resolution clauses but they need to be better educated about the importance of 'fair risk allocation'. Other attempts in dispute prevention through contract procurement propose using alternative non-traditional procurement methods such as the design-build, EPC, PFI/PPP, Partnering, Concurrent Engineering, Incentive/Disincentive Contracts [39, 40, 41, 42, 43, 44, 45, 46].

Lowe and Leiringer [13] describe disputes as being the source of possible time and cost overrun and possible adversarial relationships between the different parties. This is not welcome to either the Owner or the Contractor. Cost overrun might lead to the project being unsuccessful, unfeasible or nullifying any benefits. Although avoiding disputes has been recommended, this is not usually possible and where disputes cannot be avoided efforts should be made to manage and contain the consequences. It is to the advantage of both the Employer and the Contractor to manage disputes towards a resolution as this will safeguard the success of the project.

2.3 Behaviour

The main causes of inter-organizational conflicts are identified as: conflict due to task interdependency, conflict due to differentiation, conflict due to differing values, interests and objectives, conflict due to communication obstacle, conflict due to tension, and conflict due to personality traits [47].

The resulting conflict leads to stereotyping and attitudes of low friendliness, low trust, and low respect which in turn has an adverse impact on performance [47]. In studying the dispute predictors: people, project and process criteria as likely sources of emanating disputes, the results showed that the people criteria had the most effect followed by the process criteria [10]. The team working approach on a project helps avoid opportunistic behaviour through promoting cooperation and establishing good relations [48, 49]. It is also important for the project team to establish effective problem solving mechanisms [29]. Jergeas and Hartman [50] propose approaches such as reference to facts and better understanding of contractual terms that could help the Contractor and the Owner to avoid protracted disputes as effective project management might be more successful than resorting to claim experts.

Zaccaro *et al.* [61] examined the theoretical framework for leadership where the two necessary qualities are identified to be social perceptiveness and behavioural flexibility. Self-monitoring includes three characteristics: a concern for social appropriateness, a sensitivity to social cues, and an ability to control one's behaviour in response to those cues [51, 52, 53].

Rahim [54] based his study on the conceptual scheme first presented by Blake and Mouton [55] to classify the modes for handling interpersonal conflicts into five types: problem-solving, smoothing, forcing, withdrawal, and sharing. He differentiated styles of handling interpersonal conflict on two basic dimensions, concern for self and concern for others as shown in Figure 2.

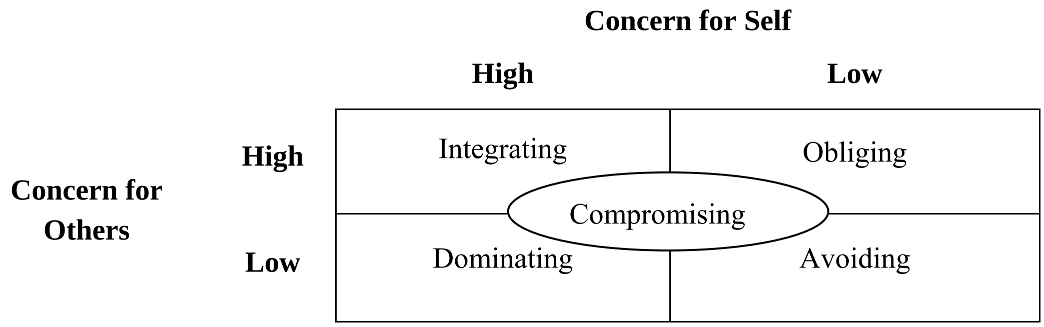

Figure 2- Styles of Handling Interpersonal Conflict (Rahim, [54])

In an attempt at studying the importance of behavioural attitudes of each party in dispute resolution, Loosemore *et al.* [56] highlights Latham’s recommendation to increase levels of trust as a means of reducing conflict. Based on previous surveys conducted by Rahim [54] and Likert and Likert [57], results show that there is a need for less reliance on prescribed rules and procedures, greater attention to lateral communication and a willingness to decentralize decision making authority. Conflict can also be minimized through enhancing the understanding of the other party’s perception, stimulating openness, reducing relational uncertainty, and analyzing problematic issues before escalating the tension [7]. The degree of open confrontation of differences, rather than smoothing them over or forcing decisions, will also encourage better cooperation and overall performance [58]. If qualified people are assigned by both parties of a contract, they will begin to know, understand, respect and trust each other. The work experience will build solid relationship and thus the effectiveness in negotiating settlements will increase and the time spent negotiating settlements will decrease [2, 7].

3. Research area conceptualisation and proposal

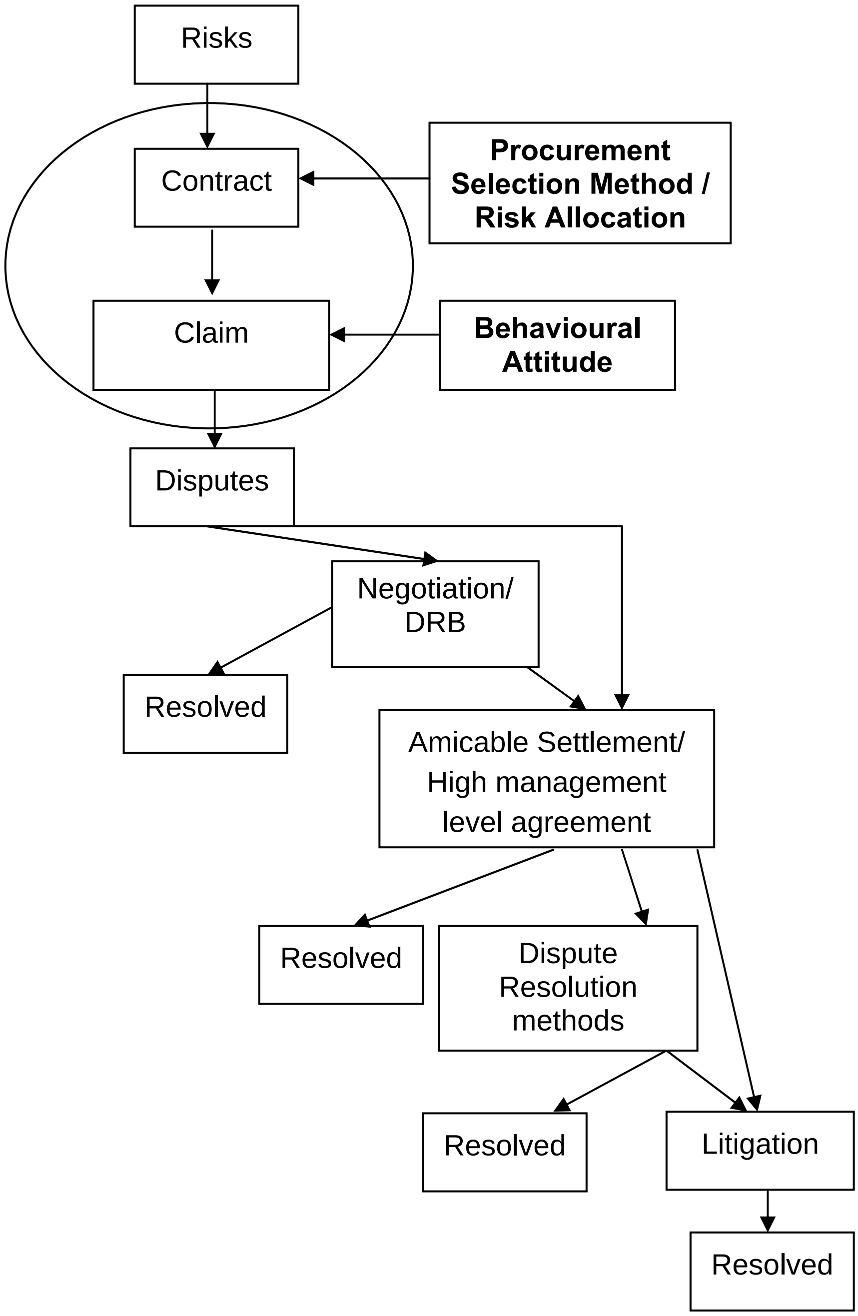

Figure 3 - Conceptual Flowchart of Dispute Evolution and Resolution

The literature clearly reflects the interrelationship between different factors. A study of disputes has led to the study of risks, conflicts, claims, procurement methods, and dispute resolution methods. Figure 3 shows a conceptual flowchart that describes the trajectory of disputes from inception to resolution based on the detailed literature review.

In addition, the literature reveals abundant research studying different aspects of the problem and proposing preventive and remedial measures at the different stages of the construction project. However, the construction industry continues to suffer from cost overruns due to disputes and there remains a need, recognized by many authors, to identify the generic causes of disputes. By reference to the conceptual flowchart in Figure 3 the proposed research questions can be stated as:

1. What is the impact of risk allocation in contributing to the incidence of disputes on construction projects?

2. Can effective project management / contract administration help mitigate claims and minimize construction disputes?

3. How does the behavioural attitude of the parties involved in projects affect dispute avoidance, management and/or escalation?

The long term aims of this research are therefore to examine the frequency and causes of common disputes in the Lebanese construction industry and to identify possible relationships within and between the risk allocation strategies adopted during the procurement of the construction works and the behavioural attitude of the parties. Once the relationships are understood, a theoretical framework will be developed to help prepare advisory risk and behaviour recommendations for construction projects.

The unit of analysis studied in the cases studies are the claims themselves. The research design consists of multiple case studies where the case studies are the contracts in construction projects that have embedded units of analysis i.e. the claims. At the first stage, documentation related to 25 different projects is studied to identify the scale of claim, the causes / reasons and the dispute resolution methods employed. The events and observations from these case studies will be further supported by 25 interviews conducted with practitioners involved in the above mentioned projects at the second research stage. The findings from stages one and two will be analysed and processed to formulate a framework of factors which contribute to the incidence of construction disputes. The third research stage will then test this framework through the development of a questionnaire to be distributed to practitioners throughout the Lebanese construction industry. The framework will then be modified accordingly and a set of conclusions and recommendations drawn.

The first two stages comprise two sources of evidence used in the data collection procedure: documentation and interviews. The 25 cases to be examined have been chosen based on the combination purposeful sampling method described by Patton [59] where two different sampling methods are applied by way of triangulation. These two methods are the:

- Maximum variation sampling where the cases are heterogeneous representing different parties to the contract and different procurement practices.

- Criterion sampling where all the cases examined are construction projects in Lebanon.

Accessibility to these projects is provided by a leading practice in the region. However, it is conditional on a confidentiality agreement regarding the names of the projects and the parties involved. The practice is a chartered quantity surveying and project management firm. Accordingly, their role in these projects varies between project manager, quantity surveyor, contract administrator, claim expert, and mediator. The parties involved in these contracts represent a significant portion of contractors and consultants taking a lead in the Lebanese construction market along with different owners, both public and private.

Abstract

With incontrovertible evidence that anthropogenic climate change is occurring worldwide, the need to safeguard critical community infrastructure in the face of increasing incidences of extreme weather events must be addressed. This paper reports the results of a risk management workshop conducted early in 2007 for the NSW Health Environmental Health Branch that considered possible risks to human health and impacts on healthcare infrastructure likely to be associated with these types of events in NSW, Australia. The findings from this study are generalisable to other communities and indicate a range of available controls to address and manage the identified risks and opportunities generated by climate change for critical healthcare infrastructure.

Keywords: Climate change, healthcare infrastructure, risk management, asset management

1. Background

This study was undertaken at the request of the NSW Health Environmental Health Branch as part of the *Human Health Impacts of Climate Change Adaptation Project* funded by the NSW Greenhouse Office, NSW, Australia. The NSW Greenhouse Office project was designed to provide research evidence and develop policies and programs that will enable NSW government service providers to adapt to the potential impacts of climate change.

The intent of the study was to undertake a preliminary investigation of the adaptive capacity of NSW Health infrastructure to increasing incidences of extreme weather events likely to be generated by climate change. For the purposes of the study, the IPCC definition was adopted, whereby ‘adaptive capacity’ is ‘the ability of a system to adjust to climate change, including climate variability and extremes, to moderate potential damages, to take advantage of opportunities, or to cope with the consequences’ [1].

Climate change research indicates that both mitigation and adaptation strategies are required to cope with the effects of climate change which now appear inevitable no matter the degree to which mitigation either becomes a higher priority or is in fact pursued. For example, the 2006 UNFCCC Adaptation Framework notes that ‘Until recently, policy makers concentrated on mitigation, partly because of worries that highlighting adaptation options might reduce the urgency for mitigation…mitigation and adaptation are not alternatives; both need to be pursued actively and in parallel. Mitigation is essential and adaptation is inevitable.’ [2]. This study has necessarily considered both of these approaches in the background research and in conduct of the risk management workshop. However the primary focus is on adaptation strategies required to safeguard essential healthcare infrastructure so as to protect the current and future health status of the NSW population.

The risk management approach towards adaptation strategies adopted by this study was developed in accordance with recommendations made by the UNFCCC [2], the Australian Greenhouse Office [3], CSIRO [4], UK CIP [5] and other authorities. For example a Norwegian study noted that: ‘Reducing the potential for defects or damage through the development of technical and organizational preventive measures (a risk management strategy) while at the same time applying the precautionary principle and discursive strategies in the design, construction and geographical localization of buildings, is likely to increase the robustness of the built environment in the light of the unknown risks of future climate change’ [6].

2. Introduction

As a developed country, Australia is well placed to protect its healthcare and other community infrastructure from the anticipated additional demands likely to be placed on it by increasing incidences of extreme weather events likely to be associated with climate change. However, although these demands may place only incremental additional loads on systems already designed to cope with disasters and other emergency situations, they require recognition, anticipation and responses to be identified within existing health asset management frameworks. This will ensure that should the predicted demands arise, appropriate responses will have been determined well in advance and incorporated into health asset management practices so that healthcare infrastructure will be able to cope with the increased load and stresses likely to be imposed. If not considered in advance, such responses will become reactionary without guarantee of success or adequacy, and possibly of much greater cost to the community in terms of damage to infrastructure and potential reduction in health status of the population.

It must also be recognized that climate change will affect the built environment in many and diverse ways. However, it is a problem that can be addressed with proper identification and planning, as supported by the comment made by the IPCC Report that: ‘Climate change will affect human settlements against a very dynamic background of other environmental and socioeconomic factors. Human settlements are expected to be among the sectors that could be most easily adapted to climate change, given appropriate planning and foresight and appropriate technical, institutional, and political capacity.’ [7].

3. Methodology

3.1 Aims and Objectives

The *parameters* of the study were deliberately restricted to focus on the facility-related impacts of climate-related extreme weather events such as heat waves (and bushfires), floods, storm surges, and tsunamis. It is anticipated that appropriate planning for health facility infrastructure will help reduce the potential adverse impacts of extreme weather events on the health of the community. The overall *objective* of the study was to identify a range of potential adaptation strategies for NSW healthcare facilities in coping with extreme weather events. More specifically it aimed to:

1. Explore the impacts that extreme weather events may have on healthcare buildings specifically in the context of the NSW climate (but with reference to the wider Australian context), focusing on the differing requirements by location.
2. Investigate the suitability and applicability of the suggested responses (gleaned from the existing literature) from a healthcare infrastructure perspective
3. Assess the "adaptive capacity" of health infrastructure in the light of healthcare, social, financial, technological, and political impacts in Australia resulting from climate change
4. Where possible, align potential strategies with existing disaster planning strategies

Finally it aimed at developing an Action Plan that summarises identified key risks and opportunities, and a strategy in dealing with each of these. In doing so, it also determined where further research and investigation are required in order to develop a cohesive NSW strategy for dealing with the impact of extreme weather events on healthcare infrastructure. [8]

3.2 Method

The study commenced with the identification of key stakeholders who were subsequently invited to a Risk and Opportunity Management (ROMS)[1] Workshop held over two days that was facilitated by Professor Martin Loosemore of UNSW. Key stakeholders were determined through a process undertaken by the authors of the study in conjunction with representatives of the NSW Health Environmental Health Branch. A total of ten people were selected initially on the basis of their professional backgrounds and current occupations in roles of influence in the healthcare and community sectors (Figure 1). Other criteria for selection then became their likely concern with the effects of climate change related extreme weather events on healthcare infrastructure (their objectives affected by project outcomes) coupled with their perceived abilities in determining effective adaptive responses and possible subsequent involvement in the implementation of these (their ability to implement the project objectives).

[1] The ROMS Methodology was originally developed for Multiplex Facilities Management and subsequently developed and used by many major public and private sector organisations throughout Australia and Asia. ROMS complies with AS/NZS 4360:2004 and other international risk management standards; The principles underlying ROMS have been published in [34] and can be explored further at http://cell-media.com/ROMS/

Ability to implement project objectives

Minor Stakeholders Clinicians Green Building Council of Australia	*Important Stakeholders* Experts/scientists Aust Building Codes Board Peak Industry Bodies (FMA, IHEA, etc) Private Hospital Associations
Major Stakeholders Rural services sector Aged care sector Community services sector Nursing care Mental health sector Local Government Planning Authorities EMA	**KEY STAKEHOLDERS** NSW Health Asset and Contract Services Ambulance/emergency Services Private - designers and/or contractors/ Government – NSW Dept of Commerce (Govt architect) NSW Health Statewide Services Branch NSW Health Environmental Health Branch NSW Area Health Services (clinicians/public health officers)– NSCCAHS NSW Greenhouse Office Aged Care Services Assoc (ACSA)

Objectives affected by project outcomes

Figure 1: Selection matrix for workshop participants

The identified key stakeholders were invited to participate in the ROMS workshop which following a background briefing for participants, was conducted in accordance with the structured process set out as follows.

Workshop 1
Step 1 : Stakeholder analysis and common objectives
Step 2 : Identify risks and opportunities to those objectives
Step 3 : Assess their magnitude and prioritise them
Workshop 2
Step 4 : Develop an action plan to minimise risks and maximise opportunities

Workshop proceedings and outcomes were documented in the ROMS format, and an accompanying report written to highlight the analysis of the findings and the key themes that emerged. In the first step of the first workshop, participants identified the following common objectives for the study:

1. *Quantifying impacts***:** To develop a research program to identify, analyse and assess impacts of extreme weather events on health infrastructure.
2. *Evidence-based practice:* To identify a range of potential facility-related responses to the health-care challenges posed by climate change, that may assist in influencing potential funders of climate change research. To ensure practitioner/researcher engagement to facilitate evidence-based practice by operationalising research, ensuring research is relevant, practical and disseminated in a usable format.
3. *Asset management planning:* To ensure procurement, design, FM, urban planning and asset management planning strategies enable effective health-care responses to climate change and do not exacerbate problems in event of a crisis.
4. *Ensuring behavioural change*: To raise awareness of climate change including changing public expectations and behaviours, securing buy-in from industry stakeholders by means of communication and education.
5. *Integrated planning:* To ensure a coordinated cross jurisdictional response to climate change at internal, local and society level involving: disaster planning; emergency services, private health care sector, and other non-health care community services.

These common objectives were then aligned with the initial project objectives identified by the NSW Health Environmental Health Branch for the study, and are discussed further in the results below.

4. Results

The outcomes of both workshops are summarised in the final report for the project. In the report itself, they are summarised in terms of their relationship to the objectives of the project sponsor, NSW Health and a draft Action Plan is then proposed for review and discussion by project stakeholders.

4.1 Risks to the Healthcare System due to Climate Change Extreme Weather events – Impacts on Human Health and Health Facilities

It was beyond the scope of the study (and not included in the objectives of the risk management workshops) to undertake specific or detailed investigations into the predicted effects of climate change generated extreme weather events on human health or the associated changing demands for healthcare services. This work is either being undertaken by others or more properly demands the skills of public health specialists and epidemiologists [eg 9-12]. However, the background briefing for the workshop and introductory remarks by NSW Health noted outline findings documented by other parties from journals and government reports.

The change in weather patterns, including increased variability and extremes, suggest that patterns of disease will alter both within NSW and Australia generally [1, 4, 13, 14]. Healthcare infrastructure may come under pressure as a result of those seeking refuge from extreme events (heat, storms, etc) and it may also be subject to increased demands by those suffering injury or ill health as a result of such events (e.g. elderly or vulnerable populations suffering from heat stress related to extended periods of higher than normal temperatures). While much of NSW will be drier, heavy rainstorms may be more frequent in central and south-east NSW, and in the far north-east, particularly in summer. In autumn and winter, heavy rainstorms are likely to increase in the centre and north-west of the State, and decrease on the coast. Increased average wind speed and extreme winds are expected in spring (greatest across central NSW). Along with these climate projections, it is also noted that the "loss of life, and the impact on hospital and emergency services, through extreme weather events is likely although not predictable" [3]. Consequently, "a major challenge in Australia is how to protect and improve public health systems…" [15]. The following table lists a range of extreme weather events that may be experienced more frequently or more severely as a result of climate change and, based on actual examples, indicates possible health impacts and associated facility impacts that have resulted and that may potentially occur again in the future.

Table 1- Health and Facility Impacts associated with Extreme Weather Events [Adapted from 30]

Events	**Health impacts**	**Facility impacts**
Heatwaves (and Bushfires)	In Australia and other countries, heatwaves are responsible for more deaths than any other natural hazard but are mostly underrated because they are viewed as a 'passive' hazard in contrast to the more catastrophic hazards such as tropical cyclones or bushfires [16, 17]. Heatwaves are likely to affect the elderly and other vulnerable populations (very young, dependent on alcohol or other drugs, chronically ill, etc) causing them to	Sydney heatwaves in 2005 "one hospital has been swamped by people not needing medical treatment - simply looking to take advantage of its spacious air conditioned reception area" [18]. The 7-day heatwave in Adelaide in February 1997 caused hospital computers to overheat and fail [16]. Water shortages and water supply failures may also become a problem as demand for water may increase dramatically. Transport systems suffer from problems and interruption due to possible

	seek admission to health facilities due to increased incidence of CVD and other ailments.	heat-related expansion of railway lines and steel bridges, and other associated damage to roadways [16].
Floods	The flooding of the river Elbe in 2002 in Saxony/ Germany required immediate public health action in order to ensure a proper public hygiene response [19]. Floods are significantly likely to result in degradation of human health and loss of life, high financial cost, trauma and associated human misery [19-21]	Where healthcare facilities are flooded, electrical power outages may be unavoidable. In the UK in June 2005, Warwick Hospital evacuated emergency patients by ambulance and helicopters [22]. Flooding creates access problems for physicians and other staff travelling to and from the hospital [23].
Storm surges	93 hospitals were adversely impacted Hurricane Katrina in the Southern USA in 2005, with 19 hospitals evacuated and 18 closed [24]. Numerous deaths were attributed to transportation shortages, although evacuation measures were aided by helicopters, buses, and ambulances. In March 2006, Tropical Cyclone Larry crossed the tropical north Queensland coast near Innisfail, giving pressure to medical services [16, 25], although at a much smaller scale than Katrina.	Water pushing several kilometres inland where land is low lying may potentially knock down healthcare facilities and wash away roads [19, 26, 27]. In March 2006, Cyclone Larry in north Queensland, the Innisfail Hospital was forced to close, thus requiring medical support from Townsville and Cairns Base Hospitals. Herberton hospital was without power until a generator was provided and leaking roofs resulted in emergency evacuation [16, 25].
Tsunamis	The South Asian tsunami in 2004 was one of the largest flooding disasters in recent history, causing about 280,000 fatalities in eight countries from Asia to Africa [28]. Post-traumatic stress disorders and problems of hygiene and infectious diseases were also noted, which caused many fatalities including a large number of suicides [28].	During the 2004 tsunami in Indonesia, 1 main referral hospital, 4 district hospitals, and 41 out of 240 clinics were destroyed [29]. In the Maldives, where most healthcare facilities escaped major structural damage, some facilities such as Mulee hospital lost all their medical records and equipment. Access difficulties further hindered the provision of health services following the disaster.

4.2 Possible Infrastructure Responses

While calls for responses to extreme weather events are evident within the literature, the workshop identified that a key barrier to moving forward with adapting to extreme weather events was the lack of understanding of the likely quantum and nature of the impacts of such events on health infrastructure. In particular, prior to any attempts at adaptation, the quantification of the impacts of climate change and the resulting extreme weather events was considered key to reinforcing understanding of the immediacy and severity of problem. Table 2 lists some potential adaptation responses by health and other authorities that may assist health services and infrastructure to cope with extreme weather events - these have been identified from existing research. They include immediate responses such as evacuations, as well as long-term facility responses to help mitigate the risk of facility failures. However the ability to translate these responses into facility planning policies and design are yet to be assessed in terms of the current adaptive capacity of existing health services and infrastructure.

Table 2- Summary of possible infrastructure responses for managing the risks associated with extreme weather events impacting on healthcare facilities [30]

POSSIBLE INFRASTRUCTURAL RESPONSES TO EXTREME WEATHER EVENTS	
Immediate	• Increased public awareness • Warning procedures for the community especially those at highest risk • Thermal control – airconditioning, close blinds, windows, etc (heatwaves) • Environmental control (to filter out smoke and dust, etc) • Emergency fire fighting response • Evacuation of those in immediate danger to safer facilities, surge hospitals, etc.
Long-term	<u>Urban planning</u> • Regulations – such as the Australian Standards, Building Codes, Health Facility Guidelines, Engineering Services guidelines – to ensure appropriate ventilation, air quality, thermal condition • Urban Design (e.g. land use, green spaces, water bodies) • Environmental management of high risk areas adjacent to urban areas or health facilities • Improved communication networks among urban planners • Redundancy built into road and transport networks to avoid isolation of facilities and emergency services • Availability of safe and environmentally controlled gathering spaces for the community to seek relief e.g. shopping centres, public libraries, etc, and to avoid unnecessary burdens being placed on health care facilities by those not in need of healthcare interventions. <u>Health System Responses</u> • Coordinated disaster responses – emergency services – ambulance, fire, police, etc that work with facilities to ensure healthcare delivery is uninterrupted • Relief plan: surge hospitals, counselling, etc <u>Facility Management</u> • Site selection and utilisation • Facility design, detailing, and construction • Maintenance of equipment, e.g. airconditioning and facility fabric such as roofs and downpipes, so that structural failure is avoided in a disaster situation • Backup and spare capacity for building services e.g. electricity, water, ensuring uninterrupted supply

The ROMS workshops indicated that an evidence-based approach must underpin adaptation strategies that are intended to respond to the threats posed by climate-related extreme weather events. However, the need to include adaptive strategies in the current health infrastructural processes has not yet been considered (i.e. design documentation and tender processes do not yet incorporate this requirement). Other difficulties in adopting this approach included the lack of evidence regarding the translation of adaptation strategies into facility requirements and designs, and the likely costs associated with these.

It should also be recognised that the current health infrastructural processes are predicated on the commercial realities associated with competitive tendering processes, and exist in a political climate faced with increasing expenditure needs for healthcare service delivery and infrastructure. Thus the need for greater apparent ‘efficiency’ in the expending of public monies often becomes the highest priority, and this usually involves reductions in capital costs. Should the need to incorporate adaptation strategies into healthcare design and facility maintenance become required, this may increase initial capital costs for health projects. This may conflict with current project delivery and funding processes which do not always recognise the link between capital and operational costs, and result in a backlash of resistance in those funding health capital projects to the incorporation of specific adaptation requirements.

4.3 Adaptive Capacity – existing and required

Research efforts to understand the impacts of extreme weather events on health services and health infrastructure are few and to date have not provided a comprehensive understanding of effective response strategies. Table 1 showed potential facility impacts already demonstrated to be associated with the health impacts generated by the identified list of extreme weather events. The workshop identified the lack of certainty around how climate change will impact the Australian community, and that a sense of urgency was beginning to become apparent but was yet to be translated into policy and adaptation strategies. Changing attitudes towards adaptation and then “ensuring behavioural change” is an important factor in enhancing the “adaptive capacity” of health infrastructure to cope with extreme weather events. Comprehensive identifications of the impacts on the social, financial, technology and the political climate are still at a relatively early stage.

Furthermore, the attitude of those managing and funding health infrastructure projects was identified as one impediment to the implementation of adaptation responses for health services and infrastructure. It was suggested that this might be partly be a result of the lack of understanding and certainty surrounding the likely additional impacts of extreme weather events on health services and infrastructure. It was suggested that research is needed to provide more evidence (including practical examples and case studies) to improve community and health system understanding regarding the likely effect of increasing incidences of extreme weather events on health services and infrastructure, and the adaptation of these to cope with the predicted impacts. A “bottom-up” approach is an alternative strategy and could be pursued simultaneously. Those working in and using facilities could promote an adaptation strategy at facility level and seek endorsement from those at higher levels of the organisation. Such efforts ultimately require great levels of stakeholder perseverance and commitment to participation in the process, as this may involve an incremental additional work load to those assessing facilities would result in ongoing assessment of the adaptive capacity of all health infrastructure. For example, specific building related data is gathered from such an assessment in addition to site-related data, plus the condition of building services such as electrical and mechanical systems, integrity of the building fabric, etc, could be assessed as required at an appropriate level of detail.

4.4 Integration with current disaster management strategies and other community responses

Currently, adaptation strategies to cope with extreme weather events are considered under the banner of disaster management and emergency planning in countries such as the US, UK, and Australia, in regard to the need to cope with terrorist attacks or outbreaks of infectious diseases within the Australasian community. However, it does not yet consider additional burdens likely to be placed on health services by increased incidence of extreme weather events. Consequenty, such efforts do not embrace clear adaptation strategies nor do they often address practical implications for infrastructure in order to safeguard critical service functions such as healthcare delivery. It is necessary to identify the need for “spare” or “surge” capacity [31] in new and existing healthcare infrastructure in order to cope with the increasing demands associated with extreme weather events.

The quantum of additional facility requirements or indeed the location of these facility resources is not yet identified, partly because the science surrounding the additional burdens on human health that may be associated with climate change has not yet been robustly investigated for the Australian situation, as noted previously. Moreover, one of the key impediments to understanding this issue that emerged from the ROMS workshop was the current lack of focus on the issue of climate change adaptation strategies within NSW Health itself. These require a heightened sense of urgency from those in NSW Health responsible for planning and funding the development of health facilities.

Another barrier to the development of suitable responses, as previously noted, is the lack of integration (or recognition of the essential interrelationship) of Capital Expenditure and Operational Expenditure budgets. This interrelationship is not always apparent during the planning phases of healthcare projects, with short term decisions sometimes made that cut capital costs in the shorter term, but often significantly increase operational costs over the longer term. Difficulties resolving planning issues are not uncommon due to the myriad different government authorities currently involved in planning the NSW urban environment. This problem also tends to be exacerbated by the inconsistencies in process and efforts between the different responsible authorities, plus the lack of continuity in the government bodies representing the different sectors due to their frequent changes in personnel, shifting areas of responsibility and thus their effective realms of influence.

4.5 Research Required

Impacts of Climate Change extreme weather events on Health and Facilities: Although awareness of climate change has permeated through the Australian government system and other funding bodies, many were still uncertain about its impact on Australia and the health of its community, its health services and infrastructure. It was also noted that there was uncertainty (and confusion) surrounding the government's commitment to pursuing the adaptation route for health infrastructure as opposed to mitigation strategies. Current research is now focusing on climate change related impacts on human health on a regional basis, for example, Campbell-Lendrum and Woodruff [32]. However, this study also notes that 'The attempt to carry out a full accounting of the health impacts of climate change rapidly clarifies significant knowledge gaps', which require further research to obtain more useful predictions of these impacts. [33]. The use of GIS[2] mapping, LIDAR[3] and other technologies to examine the impact on real locations of the predicted increasing incidence and variability of extreme weather events are feasible techniques already being used. These could be used to assist in modelling the impact of the impacts of climate change on existing health care infrastructure and to assess the suitability of proposed locations (or necessary re-locations) of future facilities.

Infrastructure Responses and Adaptive Capacity: Several strategies were identified by the workshop to encourage a better understanding of the suitability and applicability of adaptive responses through evidence-based practice. These included the development of innovative strategies through multi disciplinary research that should include accurate forecasting of implementation costs. To maximise the likelihood of implementation of these strategies, they should where possible align with current government policies and practices. Where possible, they should become an extension of existing processes and procedures and require minimal additional staff or equipment for implementation.

Integration with Current Disaster Management Strategies and other Community Responses: Suggestions made at the workshop to address this requirement included the need for applied research to be more prescriptive in its outcomes specifications and to include the prioritisation of efforts to respond to disaster planning strategies within agreed adaptation frameworks. As part of an expanded disaster response strategy, healthcare infrastructure becomes even more critically important to the community, and this fact should assist those asserting the importance of adapting health infrastructure to cope more effectively with extreme weather events. In practical terms, this provides an extremely robust argument for influencing the Asset Management Planning policies and processes of NSW Health. The role of health care infrastructure should be to support health system responses in disaster situations at least by not failing when placed under such additional pressure.

[2] ***G**eographic **I**nformation **S**ystems*, tools used to gather, transform, manipulate, analyze, and produce information related to the surface of the Earth. This data may exist as maps, 3D virtual models, tables, and/or lists (webopedia.com, accessed 05 June 2007)

[3] 'Lidar' or laser radar is a method for detecting distant objects and determining their position, velocity, or other characteristics by analysis of pulsed laser light reflected from their surfaces. (Answers.com, accessed 05 June 2007)

To assist in the implementation of adaptation measures, it is suggested that costs and operational benefits must be identified by those advocating climate change adaptation strategies. These benefits should be identified and tested against performance measures specifically developed for health services and health infrastructure, requiring engagement with building industry experts (contractors and facility managers) in the arena. These may include business continuity issues in disaster situations, with health services required to maintain current and increased levels of health service delivery in disaster situations.

4.6 Communication of Research Findings

Developing a greater understanding of the impact of extreme weather events on health infrastructure requires a range of strategies, particularly those emphasising clear and effective communication with stakeholders.

- Providing scientific information and evidence on the immediacy and severity of the likely impacts of extreme weather events on human health and health infrastructure in NSW
- Releasing research publications reporting findings from influential forums and respected research bodies
- Maintaining the relationship of project objectives to a wider national research agenda
- Continuing to engage with leading and/or credible researchers in the area (particularly in terms of applied research)
- Clarifying the extent of problems and costs that may be associated with neglecting the necessary adaptation efforts
- Identifying a range of possible adaptation strategies for health facilities in terms of suggested future projects, costs, programmes, actions and demonstrable outcomes.

Influencing clinical and asset management practices could be achieved by means of demonstration projects showing the implementation of health infrastructural adaptation strategies and ongoing evaluation of these. In addition, practices could also be influenced directly through development and implementation of government policy. This may be aided by keeping the dialogue simple, establishing mechanisms to facilitate cross sectional communications, and encouraging health services to be proactive in accelerating change and being brokers in determination of action agendas.

5. Discussion and Recommendations

This study has found that the current lack of understanding of the problems (nature, frequency, severity, and relevance) associated with extreme weather events in Australia (including NSW) has led to perceived uncertainty surrounding the need for adaptive strategies for health services and infrastructure in response to the increasing incidence of extreme weather events likely to be associated with climate change. Consequently, further research is needed to increase the understanding of the impacts of extreme weather events on both healthcare service needs and health infrastructure to ensure uninterrupted delivery of these services. This involves the quantification of such impacts, including the risks associated with ignoring them and not acting, as well as the benefits associated with a prompt response. The information should be made available and communicated in a form that may be clearly understood by the community.

Results from this undertaking should then be distributed in seminars and forums and through other influential bodies that endorse climate change adaptation agendas. Finally, as further research is undertaken and adaptation strategies implemented, an education and communication strategy should be developed to inform key stakeholders regarding:

- The likely impacts of climate change on the demands for health services in NSW health facilities
- The adequacy of current NSW health infrastructure capacity to cope with the additional demands likely to be imposed
- Implementation strategies for reconfiguring or augmenting capacity to cope with the identified demands
- The costs associated with this reconfiguration or augmentation, and assurances given that these will be met in order to ensure business continuity within the health sector in the event of natural disasters now and into the future
- Confidence that an integrated disaster planning and management strategy is in place that will ensure the continuity of operation of health facilities in the event of natural disasters associated with the increasing incidence of extreme weather events likely to be generated by climate change.

6. Conclusion

Although this study focused on a specific geographic region and health system (NSW Health) many of the findings are clearly generalisable to other settings and locations. The study demonstrates the need for a systems approach to developing adaptive capacity in healthcare infrastructure to cope with climate change. This includes the requirement to determine not only the impact of increasing incidences of extreme weather events on the health of the community that may increase the demands of the customers for healthcare services, but also to consider how to prevent health facilities failing under the demands placed on the building fabric due to these same events. Working with existing systems appears to offer the greatest chance of success in achieving both these aims. For example, where possible, tapping into existing disaster management frameworks will ensure more effective community responses and greater pressure for the development of adaptive capacity for healthcare infrastructure. This approach will thus also be more responsive to the existing political, social, technological and institutional capacity, wherever the healthcare system may be located.

Authors Note: This paper draws substantially on (and reproduces some parts of) the Report into the Potential Impacts of Climate Change Related Extreme Weather Events on NSW Healthcare Infrastructure, unpublished draft dated 31 May 2007, (Carthey et al., 2007). Therefore, acknowledgments must be made to Glenis Lloyd of the NSW Health Environmental Health Branch, the project sponsor.

Abstract

Construction is the largest user of materials of any industry. Hence selecting environmentally preferable building materials is one way to reduce the negative environmental impacts. The insufficiency of scientific data available in Sri Lanka for roof covering material selection is seen as a problem. The purpose of this study is to derive sustainability index for alternative roof covering materials which will assist the design team members to take informed decision. It was intended to take into consideration the environmental, economic and technical performance of the roof covering materials. Life Cycle Assessment (LCA) is adopted to assess the alternatives including the economic and technical performance. The attributes, Embodied energy, Reusability and Hazardous emissions to air measured in terms of Global warming potential (GWP), Acidification Potential (AP) and Criteria air pollutant (CP) are representing the Biophysical aspect of sustainability. The attribute, Life Cycle Cost represents the Economic aspect of sustainability and Functionality measured in terms of thermal performance represents the Technical aspect. According to the overall sustainability index derived, Asbestos takes the highest index while Zn/Al takes the second highest and Calicut tiles take the least index.

Keywords: Embodied energy, Roof covering materials, Life cycle assessment

1. Background

1.1 Sustainable construction

All economic sectors, including the construction industry, now face an inescapable challenge posed by the term “sustainability”. The construction industry is commonly considered as one of the largest industries in both developed and developing countries in terms f investment, employment and contribution to GDP. Consequently, the impact of the construction industry on the environment is also significant [7].

In 1987, the World Commission on Environment and Development (WCED) produced a publication entitled Our Common Future (WCED, 1987), which is referred to as the `Brundtland Report'. The publication described the concept of sustainable development as meeting the basic needs of all people and extending to all the opportunity to satisfy their aspirations for a better life without compromising the ability of future generations to meet their own needs [4].

The term `sustainable construction', was originally proposed to describe the responsibility of the construction industry in attaining 'sustainability'. First International Conference on Sustainable Construction was held in November 1994 in Tampa, Florida, United States of America. A major objective of the conference was `to assess progress in the new discipline that might be called "sustainable construction" or "green construction" [4].

Green design leads to sustainable development. Green design principles are adopted at design phases of construction. These principals are meant to affect the design so that the construction becomes sustainable." Green design" is intended to develop more environmentally benign products and processes [3].

Hill and Bowen ended up in figuring out a framework for the attainment of sustainable construction. They outlined two multi-stage frameworks which would lead to sustainable construction. They are as follows,

- Application of Environmental Assessment (EA)
- Implementation of Environmental Management system (EMS),

In the planning and design stages of projects, sustainable construction can be achieved by applying the principles, procedures and methods of Environmental Assessment (or Environmental Impact Assessment). A comprehensive traditional EA would evaluate alternatives for the sourcing of certain materials, such as the siting of quarries for stone aggregate, but would be unlikely to consider the life cycle environmental costs of most materials and products used in the construction process [4].

The traditional EA should be expanded to consider life cycle assessment of alternative materials and products which could be used in the construction process. In addition, the EA should ensure that efficiency is a key criterion in the use of water, energy and land. The results of such a life cycle assessment should influence the purchasing specifications for materials and products to be used. These examples illustrate how application of the principles of sustainable construction would expand the practice of EA towards the goal of attaining sustainability [4].

As Environmental assessment methods deal with assessing the whole building in terms of sustainability, they are inherent of the drawbacks that they do not consider the relative importance of criteria and they lack in considering whole life cycle of the product which is necessary as far as sustainable construction is concerned. Current methods for environmental assessment of buildings such as BREAM and BEPAC only focus directly two principles-

‘environment’ and ‘futurity’. They do not include criteria which explicitly assess buildings against either ‘equity’ or public participation [2].

1.2 Construction materials

‘If the construction industry is considered globally, it is by far the largest consumer of materials on planet Earth. The fact that construction materials are low-value should not surprise us; neither should it blind us to the importance of these materials. The sheer scale of consumption means that their use has a major impact on the environment, and economists, engineers and environmentalists have all devoted much thought to ways of measuring this impact. A number of criteria or indices of impact have been devised, with the objective of furnishing numerical data, which can help decision making. Qualitative assessments are useful up to a point, but if real progress is to be made it are necessary to quantify the impacts of materials consumption [6].

The concept of sustainable building incorporates and integrates a variety of strategies during the design, construction and operation of building projects. The use of green building materials and products represents one important strategy in the design of a building [5].

1.3 Building materials and sustainability

The overall performance of the building is the most important consideration in achieving more sustainable construction. Building materials play an essential role in increasing the energy efficiency of buildings and contributing to economic prosperity. Traditionally, materials selection for the design and construction of facilities has been based on economic and technological considerations, given the desired life span of a facility and the program of requirements and codes it must meet. In design environments where ecological, health, and ethical impacts are increasingly important, often the only way to choose from many different material alternatives is by relying upon on quantified professional judgment or past experience. The method should allow comparison of not only the technical performance and costs of materials, but also the immediate and long-term impacts their use has on the finite supply of natural resources and the ongoing needs for those resources by society. Together, these impacts comprise a measure of the sustainability of materials and should be given consideration during materials specification [1].

1.4 Aim of the study

Based on the background study, the necessity for scientific data which could assist the process of material selection was identified. And also it was found that such data do not exist in Sri Lanka for roof covering material which has a significant contribution to the sustainability of the whole building. Hence this study aims at developing a sustainability index for roof covering materials which could be used to assist selection.

The objectives for this study were as follows,

- To calculate the embodied energy of the roof covering material
- To establish the level of reusability of the roof covering material
- To calculate the emissions to air during the life of the roof covering material
- To determine the life cycle cost of the roof covering material
- To determine the functionality of the roof covering materials in terms of thermal comfort

2. Research Methodology

Life Cycle Assessment was adopted as the methodology for this study. Life Cycle Assessment is a “cradle-to-grave,” systems approach for measuring environmental performance. The approach is based on the belief that all stages in the life of a product generate environmental impacts and must therefore be analyzed, including raw materials acquisition, product manufacture, transportation, installation, operation and maintenance, and ultimately recycling and waste management.

This study was limited to the following roof covering materials,

Asbestos corrugated sheets.

Zn/ Al sheets

Calicut tiles

According to the release ‘Census of Population and housing, 2001’by Census and Statistics department of SriLanka, the above mentioned roof covering materials has the highest usage in housing units in SriLanka. (Simple pitched roof with 30x100 ft plan area was considered for this study).

Selection of the manufacturing organizations

Manufacturing organizations were selected based on their level of maintenance of documentations. Organizations which had obtained SLS standards or the ones which were owned by government were assumed to have proper documentations maintained. Where the organization did not meet the above mentioned requirements, more than one organization was investigated to cross check the figures and the average figures are taken as final figures.

Data Collection Procedure

Semi structured interviews with the professionals or technicians who are familiar with the production processes were done and observations of the processes involved were also adopted as other means of data collection. In addition, documents were referred where ever necessary.

3. Methodology and limitation for each objectives

To calculate the embodied energy of the roof covering material

Process analysis has been adopted in calculating the embodied energy for this study because the simple reason that it produces accurate results. Process analysis was carried out only at the final factories at least one for each alternative. Embodied energy figures already available for intermediate products were directly used.

To establish the level of reusability of the roof covering material

Reusability was measured in terms of the importance to be reused. It was calculated by the fraction of prices of old roof covering material and the new roof covering material.

To calculate the emissions to air during the life of the roof covering material

Major portion of the emissions during the life time of the roof covering materials is by transportation and during manufacturing, since the roof covering materials alone do not emit any gasses through its life time. Transportation at the final manufacturing factory was the only transportation considered for this study. Transportations at intermediate productions are not considered due to time constraint. The emissions were related to environmental impacts which could be grouped under LOCAL EFFECTS and GLOBAL EFFECTS. For the transportation by sea, the same emission factors of vehicles were considered because of the non availability of emission factors and of the fact that the emissions by sea transportation are obviously more than that of the land transport.

LOCAL EFFECTS

Acidification Potential; Acidifying compounds may be in a gaseous state either dissolved in water or fix in solid particles.

Criteria air pollutants; are solid and liquid particles commonly found in the air.

GLOBAL EFFECTS

Global warming potential; was considered as Global effect. Global warming potential is represented in grams of CO2 emitted.

In order to express these three impacts in CO2 equivalent values, following normalisation values were used (Table 1). However each impact was given equal importance.

Table 1Normalization values for environmental impacts

Impact	Normalization Values
Global warming	25 582 640.09 CO2 equivalents/year/capita
Acidification	7 800 200 000.00 millimoles H+ equivalents/ year/capita
Criteria air pollutants	19 200.00 microDALYs / year/capita

To determine the life cycle cost of the roof covering material

Life cycle cost was considered. Initial cost involved the cost of roof covering materials with the costs of roof frame and roof plumbing. Discount rate is arrived at considering the commercial bank lending rates. The interest rate was taken to be 15 percent for this study which is the average of the period, 1977 – 2001.

To determine the functionality of the roof covering materials in terms of thermal comfort

Because a research had already been done comparing the values for thermal comfort of roof covering materials, it was decided to use those as secondary data for this study in order to meet this objective.

4. Data analysis

4.1 Embodied energy

Embodied energy of calicut tiles

Four cases were examined in order to determine the Embodied Energy (EE) of calicut tiles. Table 2 contains the energy consumption at different stages of life cycle based on the findings of case 1. This table displays the energy consumption for 11, 200 numbers of tiles considered. Findings on other three cases had slight differences because of the difference in technology and transportation distances. Average Embodied energy of the four cases investigated amounted to 26,170.29 MJ.

Table 2Energy at different stages of life cycle of calicut tiles

Stages of Life cycle	Energy in (GJ)
Extraction	0.396
Transportation	3.079
Drying	123.696
Firing	125.047
Pugging and extruding	6.104
Embodied energy	258.322

Embodied energy of asbestos sheets

Table 3 displays the energy consumption at different stages of life cycle and the total embodied energy of asbestos sheets based on the findings at the factory investigated for 800 Asbestos sheets of the size 10’x3’. Only one factory was investigated for asbestos sheets.

Table 3Energy at different stages of life cycle of Asbestos sheet

Stages of Life cycle	Energy in GJ
Production of asbestos ore	64.602
Production of cement	129.616
Transportation	7.279
Manufacturing	3.330
Embodied energy	204.827

Embodied energy of Zn/Al sheets

Table 4 contains the energy consumption at different stages of life cycle and the total embodied energy of Zn/Al sheets based on the findings at the factory investigated for 12 Tons of Zn/Al sheets of 0.35 mm thickness. Only one factory was investigated for Zn/Al sheets.

Table 4Energy at different stages of life cycle of Zn/Al

Stages of Life cycle	Energy in GJ
Production of high tensile steel	417.600
Transportation	7.256
Manufacturing	0.046
Embodied energy	424.902

4.2 Environmental impacts

Environmental impacts of calicut tiles

The following table displays the average impacts of the four cases investigated for calicut tiles.

Table 5Environmental impacts of calicut tiles

Effects	g CO2 Equivalents
Global warming	2,894,797.89
Acidification	17.28
Criteria air pollutants	1,176.89

Environmental impacts of asbestos sheets

Table 6 Environmental impacts of asbestos sheets

Effects	g CO2 Equivalents
Global warming	484,183.00
Acidification	6.51
Criteria air pollutants	443.47

Environmental impacts of zn/al sheets

Table 7 Magnitudes of the Environmental impacts of Zn/Al sheets

Effects	g CO2 Equivalents
Global warming	482,710.20
Acidification	7.79
Criteria air pollutants	529.73

4.3 Reusability

Table 8 Reusability of the alternatives

Roof Covering materials	Average market price of old material (Rs)	Market price of new material	Reusability
Asbestos sheets	56.25	110.00	0.51
Zinc alum sheets	398.50	907.00	0.44
Calicut Tiles	6.50	24.00	0.27

Value indexes for each variables considered

Table 9 Value index for Embodied energy

Roof covering material	EE per 1 square meter of roof plan area	Value index
Asbestos sheets	134.90	100.00
Zinc alum sheets	1,448.43	9.31
Calicut Tiles	549.57	24.38

$$\text{Value index} = \frac{\text{Minimum value of EE}}{\text{Embodied energy value}} \times 100$$

Table 10Value index for Global Environmental impacts

Roof covering material	Global environmental impact in terms of CO2	Value index
Asbestos sheets	318.88	44.78
Zinc alum sheets	142.81	100.00
Calicut Tiles	49,211.56	0.29

$$\text{Value index} = \frac{\text{Minimum value of Global impact}}{\text{Global impact}} \times 100$$

Table 11Value index for Local Environmental impacts

Roof covering material	Local environmental impact	Value index
Asbestos sheets	0.30	50.00
Zinc alum sheets	0.15	100.00
Calicut Tiles	25.08	0.59

$$\text{Value index} = \frac{\text{Minimum value of Local impact}}{\text{Local impact}} \times 100$$

Table 12Value index for Life cycle cost

Roof covering material	Life cycle cost	Value index
Asbestos sheets	654,440.00	100.00
Zinc alum sheets	2,803,186.00	23.34
Calicut Tiles	1,040,520.00	62.89

$$\text{Value index} = \frac{\text{Minimum value of Life Cycle Costing}}{\text{Life Cycle Cost}} \times 100$$

Table 13Value index for Reusability

Roof covering material	Reusability	Value index
Asbestos sheets	0.51	100.00
Zinc alum sheets	0.44	86.27
Calicut Tiles	0.27	52.94

$$\text{Value index} = \frac{\text{Reusability}}{\text{Amount of best case}} \times 100$$

Table 14Value index for Functionality

Roof covering material	Functionality ranking	Index
Asbestos sheets	2	50.00
Zinc alum sheets	3	33.33
Calicut Tiles	1	100.00

$$\text{Value index} = \frac{\text{Minimum rank value}}{\text{Functionality rank}} \times 100$$

The following table contains the sustainability indexes for each alternatives considered. This sustainability index was arrived at by summing the value indexes derived for each variable for each roof covering alternative considered.

Table 15 Sustainability index

Roof covering material	Sustainability index
Asbestos sheets	444.78
Zinc alum sheets	352.25
Calicut Tiles	241.09

The following radar chart, graphically illustrates the level of sustainability of the each roof covering material considered. More the area a material is dispersed from the centre of the graph, the more its sustainability.

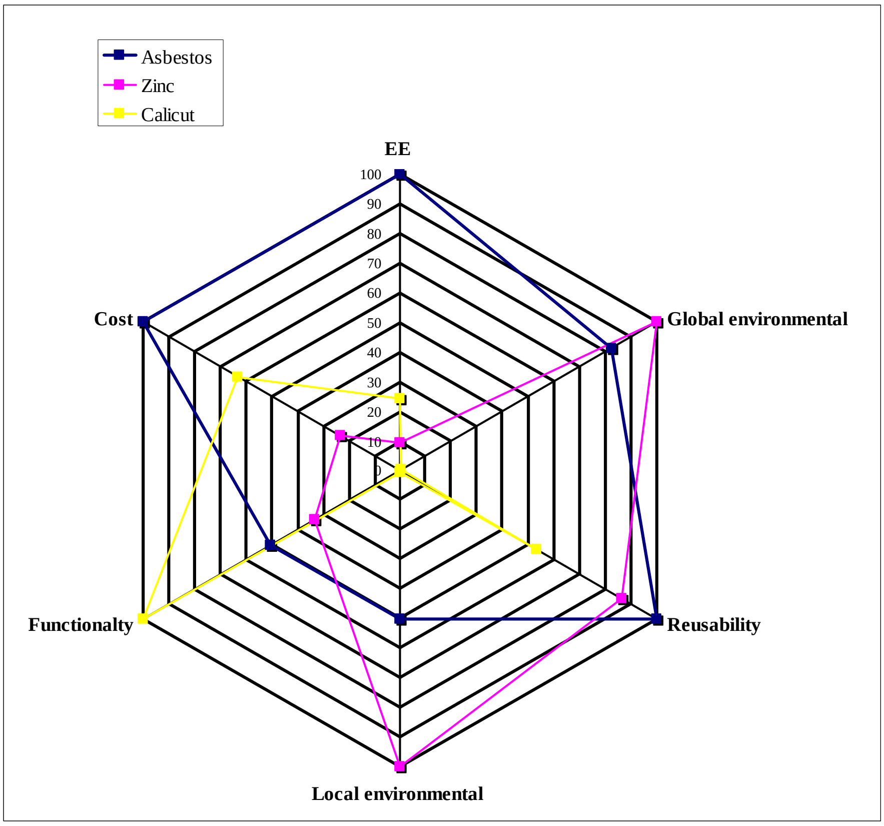

Figure 1 Graphical representation of sustainability of roof covering materials

5. Conclusion

Based on the findings of this research, Asbestos sheets have the lowest embodied energy coefficient where as calicut tiles have the highest. It is because of the reason calicut tiles uses fire wood extensively for production. Asbestos sheets are less energy consuming. However this increased energy consumption could be off set against the calicut tiles' longest life time.

As far as Global impacts are concerned, Zn/Al sheets have the lowest Global impact where as Asbestos and calicut tiles have higher Global impacts. The reason for the calicut tiles to have higher values for Global impacts (E.g. Global warming) is that it uses fire wood extensively which results in increased emission of CO2. Calicut tiles have the highest effect on the local environment too, due to its long transportation with large quantities and the immense use of fire wood. Asbestos sheets have high reusability index whereas the Zn/Al sheets have the second highest and calicut tiles takes the least. When comparing asbestos sheets and calicut tiles based on life cycle costing, asbestos sheets takes the lower NPV value, because of the reason that its frame cost is significantly less than that of calicut tiles', even though it has one replacement during the life of the building. For Zn/Al sheets the cost of roof frame and roof plumbing are comparatively high and it has three replacements during the life time of the building. Hence Zn/Al takes the highest NPV among other two roof covering materials. calicut tiles have the highest thermal performance reducing the cost of roof insulation and Asbestos and Zn/Al sheets have their thermal performance ranked second and third respectively.

The findings of this research are based on two limitations. Each attributes of sustainability was given equal importance; embodied energy and life cycle cost may not be of equal importance. No normalisation values were used in order to add the value indexes together to arrive at the sustainability index; reusability and environmental impacts are in two different units.

Abstract

In the UK the focus on design and planning processes has been strongly influenced by the need for decision-makers to respond to government policy regarding community involvement, the development of sustainable communities and transparency. The Consideration of sustainability alongside the financial impacts of the construction projects calls for the focus during the pre-construction stage of a life cycle of the project to shift towards the life cycle of the project. The major benefit of sustainable building projects is their low environmental impact within and after the construction stage and even after their deconstruction. Using good quality materials from sustainable sources will increase the lifecycles of sustainable construction projects and reduce their negative impact on the climate.

This research aims at developing an initial framework of the processes involved with sustainable socially owned housing projects which when further refined could help deliver better social housing projects. Interviews were conducted with construction professionals in the operating within the development processes of sustainable social housing projects. The emergent framework highlights the actual processes used on the ground to consider sustainable factors as well as the pre-construction cost evaluation of social housing projects. It examines the actual consideration of the project whole life cycle during the feasibility stage for this type of projects. This early consideration of sustainable issues in general and sustainable materials in particular helps to reduce the negative effects of the construction projects on the environment and prepare by the using of recyclable materials to avoid the awful impacts of unexpected disasters on the environment.

Keywords: Process mapping, Climate, Social housing projects, Sustainability, Cost

1. Background

Building materials are commonly selected through functional, technical and financial requirements. However, with sustainability as a key issue in the last decades, especially in western countries, the environmental load of building materials has also become a more important criterion. Causing the minimum possible harm to the environment and users through the design, construction, use upkeep and eventual end of life recycle, avoiding the need to destroy, and replace or abandon as unsuitable without proper consideration, should all be amongst the aims of the sustainable materials [1].

The building industry, directly or indirectly causing a considerable part of the annual environmental damage, can take up the responsibility to contribute to sustainable development by finding more environmentally benign ways of construction and building. The polluted air, land and water, climate change, loos of biodiversity are some of the negative consequences of unsustainable construction upon the environment [2]. Overall energy use, carbon dioxide emissions, number of threatened species, and water pollution levels all continue to increase; extreme weather events and other environmental disasters clearly indicate our increasing pressure on the planet [3]. The rising consumption of resources is more than the planet can bear [4]. The sustainability of a certain material based product is mainly dependent on the materials used for the product itself or during its lifetime. The selection of sustainable materials for a construction projects, recycling and reuse these materials and using renewable resources are of vital importance to respond to the environmental problem and prepare to avoid the awful impacts of the unexpected disasters. These sustainable materials determine the use of our natural resources as well as the amount of energy used for the production and the use of the product [5], [6] and [7]. However, it is also very important to select materials and equipment from sustainable sources, with the lowest in-use environmental impacts, with the lowest embodied environmental impacts, and with high-recycled content.

This paper reviews key elements of choosing sustainable materials approach as a background for understanding the environmental impacts of construction materials upon the environment. After this introduction, a discussion about sustainable material and recycling is developed for consideration of how to minimise the negative environmental impacts of the construction materials. Thus, the initial steps involved in the development of a process mapping of sustainable social housing projects examined as an example of the real considerations of sustainable issues in the construction projects. Finally, the paper concludes with some general recommendations regarding the importance of choosing sustainable construction materials.

1.1 Measuring environmental impacts of materials

The environmental impact of construction, sustainable buildings, designing for recycling and eco-labelling of building materials have captured the attention of building professionals across the world [8] and [9]. The greenhouse gas emissions, toxic emissions, habitat destruction and resource depletion caused during the extracting, processing and transporting of construction materials and then dealing with their waste have major environmental impacts. Corgolewski [10] explained that taking into account the environmental impacts of selecting durable and well performing materials chosen for sustainable construction projects should be done over their full life cycle including manufacturing, construction, operation, maintenance, demolition and disposal. In each phase, consideration of the energy used, resources consumed, waste generated, potential for recycling and emission generation should be given. Looking more specifically at the housing industry, the environmental impacts of the long-life materials in a house are significant in ways that create quality, long lasting environments with minimum damage to the planet [1]. It then goes further by minimising the embodied impacts of the construction materials used to achieve the design of the sustainable housing projects. Barton [11] explained that the UK government has become interested in sustainable housing during the 1990s, along with other mainstream actors, such as private sector house builders. Low carbon sustainable housing projects are one of the attempts to solve the climate change problem. Climate change has been judged by the UK government to be an important domestic and international environmental issue [12]. The UK government wishes to see all housing associations integrate sustainability into their procurement and development approaches in terms of a triple bottom line approach to project evaluation to create more sustainable housing projects. This will have important implications for all those organisations involved in social housing, it will place sustainability, and its assessments at the heart of housing procurement practice [13].

BREEAM incorporates a profiling system to assess the environmental impacts of commonly used building materials and components called *The Green Guide to Specification*, first developed in 1996. The *Green Guide* enables practitioners to tell if the materials and components they specify have a low environmental impact. Rather than using full life cycle assessments which are complex, time consuming and expensive processes, the environmental ratings summarised in the *Green Guide* provide a quick and easy way for designers and specifiers to assess their options [14]. The UK government has pledged to reduce energy consumption and CO_2 emissions to a level of 20% less than the 1990 figures by 2010. The manufacturing of building materials and components still accounts for over 10% of national UK energy use representing some 29% of national industrial energy use [15]; the environmental harm arising from the production of some materials also continues to be of concern. CIBSE [16] guide L explained that materials production and construction accounts for 30% of the total waste in the UK. Some production processes can result in volatile organic compounds VOC emissions, which can be irritants or toxins. Nitrous oxide NO_x, released in energy production and manufacturing combustion processes, is both a contributor to acid rain and reacts with VOCs in sunlight to produce photochemical smog that in turn is implicated in increased incidence of asthma and respiratory illness. SO_2, also released from the combustion of oil and coal products primarily, is the main contributor to acid rain [14].

It is evident that construction materials have a major impact on the environment. It is therefore very important to specify recyclable sustainable materials as one of the main processes during the pre construction stage to minimise the damage caused by the construction projects on the environment.

1.2 Recycling

Thormark [17] explained that recycling and reused building materials are very important issues in order to reduce the environmental impacts within the building sector. The main benefits of recycling are saving of natural materials, saving of energy, decrease of harmful emissions and reduction in space needed for landfill. In the early stages of product development, recycling or deposition must be taken into account to achieve sustainable products with a minimum of environmental impact. Appropriate design and construction practices can help components be easily extracted at the end of their useful life in such a way that they can be reused or recycled [10]. The selection of sustainable materials must strongly be directed to the future recycle-ability of a product in order to meet the demands of the future. Choosing sustainable materials for construction means that recycling these materials after deconstruction or during the reconstruction activities following disasters can be done in a number of ways:

• *Energy recycling*. The material is burnt and the energy is used for heating.

• *Material recycling*. The material is typically re-processed in order to make new products.

• *Re-use (or recycling)*. The product or parts of it can be used again, sometimes after reconditioning. Reconditioned products or spare parts are sold at a lower price than a new part which is typical for second hand markets (used car parts, etc.).

• *Breakdown*. Natural organic materials, many synthetic polymers and some metals can be broken down naturally in the nature or by chemical methods to environmentally friendly products or chemicals.

All processes mentioned above are generally restricted by environmental legislation, which is a way to minimise toxic products and/or emissions to be formed, which can lead to air or water impacts as well as affect human beings, animals and plants. Recycling can have different meanings as can be understood from the examples above. A clear definition of the word is recommended to avoid misunderstanding in specific cases [18]. However, typical recycling processes could be chosen after disasters depending on the type of the project and the materials used for the construction. It is very important to know the key sustainable factors which are taken into account during the whole life of the project and insure that choosing sustainable materials is one of the main processes to develop sustainable projects during the pre-construction stage of these projects.

2. Materials and process mapping in construction projects

Although the government is still striving towards the improvement in the construction industry since 1994, the success to achieve that is still apparently little. The recent highly instructive reports of Harty *et al*. [19] provided a comprehensive range of factors, some of which will affect the future of the construction sector. It was unsurprising, that sustainability, as one of the current trends which is considered of primary importance in the construction industry, is still short of getting to grips with the complexities and uncertainties of both the present and the future of the construction industry. These reports confirmed that there are still significant weaknesses in the construction project delivery processes. Project delivery processes are the processes used to get owners needs converted into a constructed facility, and include programming, procurement, design, construction, and operation. Lapinski *et al.* [20] supposed that part of the reason for high process waste is that owners and project teams have a limited understanding of which processes are the most important ones for sustainable project delivery. Further, the intermediate deliverables, activities, and outcomes of current delivery processes are best suited for conventional building types and are often unresponsive to the needs of sustainable building projects [21]. In addition, it is posited that process mapping can be used to improve the customer focus of the process by assisting in the elimination of the non-value added activities and reduce therefore the process complexity [22].

Having recognised that social housing is a major point for the development of a sustainable community, the UK government seeks to develop more sustainable policies in this type of publicly financed building project. As sustainable housing projects offer numerous benefits including energy efficiency, improved indoor environment quality, increased health and occupant productivity, and the minimization of resource usage during the construction and operation of the building. However, to achieve their performance benefits, additional requirements are often needed in the delivery processes for sustainable housing projects. The focus on design and planning processes has been strongly influenced by the need for decision-makers to respond to government policy regarding community involvement, alongside the development of sustainable communities and transparency. Riley *et al.* [23] explained that sustainable building projects require intense interdisciplinary collaboration, highly complex design analysis, and careful material and system selection, particularly in the early stages of the project delivery process. Lapinski *et al.* [20] claimed that a first cost premium is commonly associated with sustainable buildings because of their additional requirements to purchase better quality building components and super insulated building envelopes. However, the current project processes which are used to deliver sustainable buildings are often laden with wasteful rework, delays, changes, and overproduction [24]. Social housing projects are a good example of the building projects in UK, but it is asserted that they suffer the same critical weaknesses in their delivery. There is a great need to investigate the current processes of developing sustainable social housing projects, identify the various phases of social housing projects with particular emphases on sustainable issues to capture the actual stages during setting their budgets.

2.1 Generic process protocol

Research conducted by Shashar *et al.* [25] developed a generic process protocol for use in the construction industry. The process protocol is a mechanism that facilitates the arrangement and classification of all the processes that are involved in the design and construction of a project. It can be thought of as an information route-map of how the processes related to construction projects ought to work so as to produce a more efficient, effective and economical way of undertaking the design and construction of projects. It has been claimed that tangible benefits can be realised in this process through waste reduction, shortening the duration of projects and improving communication methods and channels [26]. The process protocol identified the main phases of activity that need to be addressed in the delivery of a client's project but as yet its many sub-phases remain to be fully detailed. The generic process protocol considers the whole lifecycle of the construction project whilst integrating its participants under a common framework. The process protocol is divided into a series of sub phases defined as: pre project, preconstruction, construction and post construction. Within each of these major phases there are sub phases that can be operated at the same time to make the process more efficient in smaller scale projects. One such sub-phase of the pre-project phase of the project is the pre-design phase. At this initial stage of the project the process is unpredictable because it has not yet been specified in detail and adopted in practice; such processes can change as the brief or clients needs progress. It has been claimed that performance at this sub-phase level depends on the capabilities of the individuals, rather than that of the organisation [25].

2.2 OGC procurement guide:

OGC guides [27] and [28] were provided in 2007 by the UK Government who underlined its commitment to sustainable development to achieve a better quality of life through the efficient use of resources. The first guide took the project procurement life cycle as its base and focused to deliver a sustainable solution which satisfies the social, economic and environmental aspects of sustainable development that should be addressed during the lifecycle. The project procurement lifecycle considers the whole life of a project from inception through to design and construction, operation and finally re-use or disposal. It is a process which identifies where and when key decisions are to be made and determines the critical outputs that should be delivered at each stage of the project.

The project procurement lifecycle according to this guide encompasses the following critical phases:

- Business justification
- Project brief and procurement Process
- Design brief
- Construction process
- Operation and management
- Disposal and re- use.

This guide was taken as a base which illustrates the processes by which the public sector client can procure and deliver construction projects that best promote sustainable development while still achieving optimum whole life value for money. Examining sustainability in the second guide helps the project team to identify the range of options and deliver the best value whole life solution. However, this guide highlighted the key areas of sustainability together with a series of questions and steps for action to help to choose the best solution for the project.

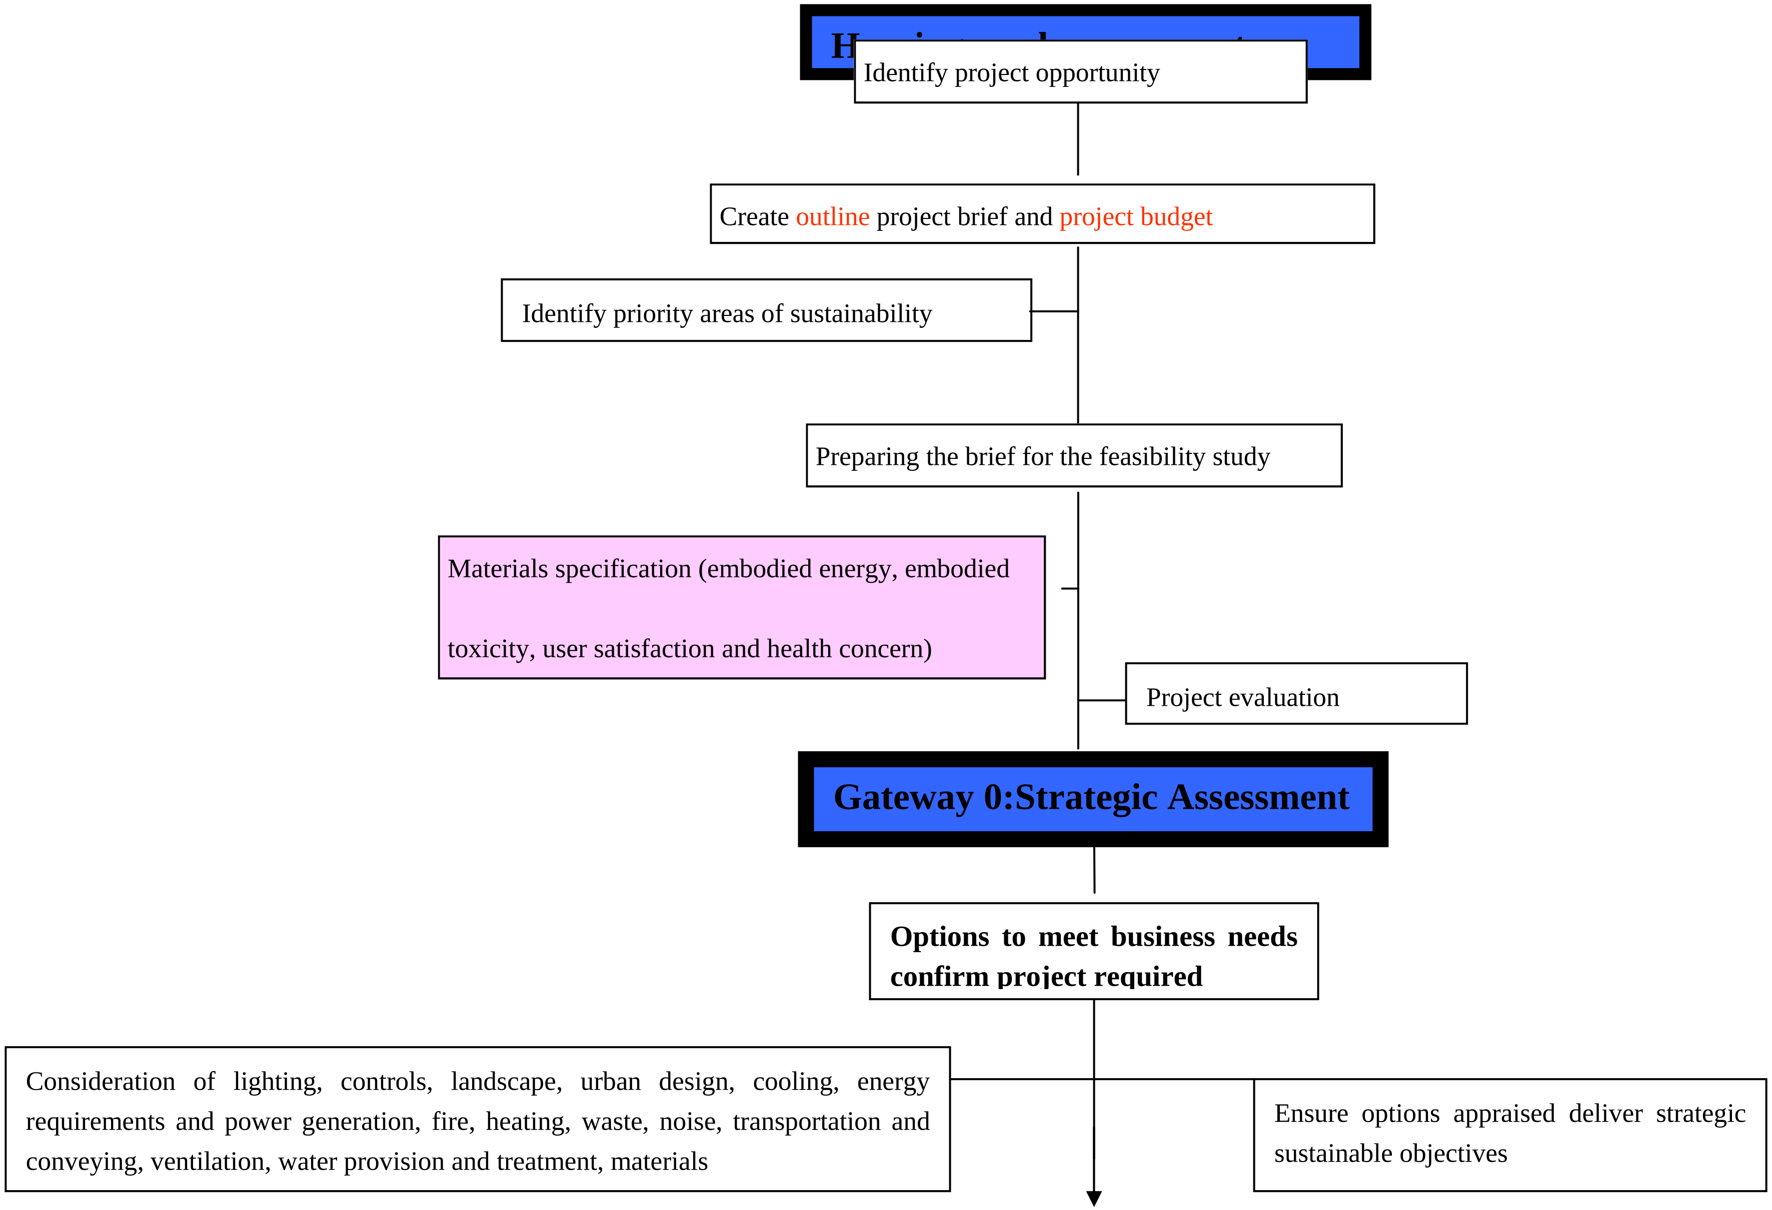
The consideration of sustainability is placed alongside the consideration of all the procurement processes in this guide. It starts with clearly highlighting of the importance of sustainability considerations with all the risks associated in the brief stage to the client to ensure that all parties involved in the project are considered in the project are conscious of the client’s needs and requirements. The tender appraisal process should be made clear so tenderers should be asked to provide full details of how the required sustainability objectives will be achieved. So in the pre construction stage the client must be satisfied that the proposals meet or exceed the original project and design brief. While the client and the integrated supply team should make provisions to minimize pollution and disruption during the construction period and ensure the health and safety of local residents as well as construction site staff. At the end the construction period and as a part of the commissioning and handover of the project, the client should be provided with training, facility operations and maintenance information, health and safety files and procedures for reporting defects.

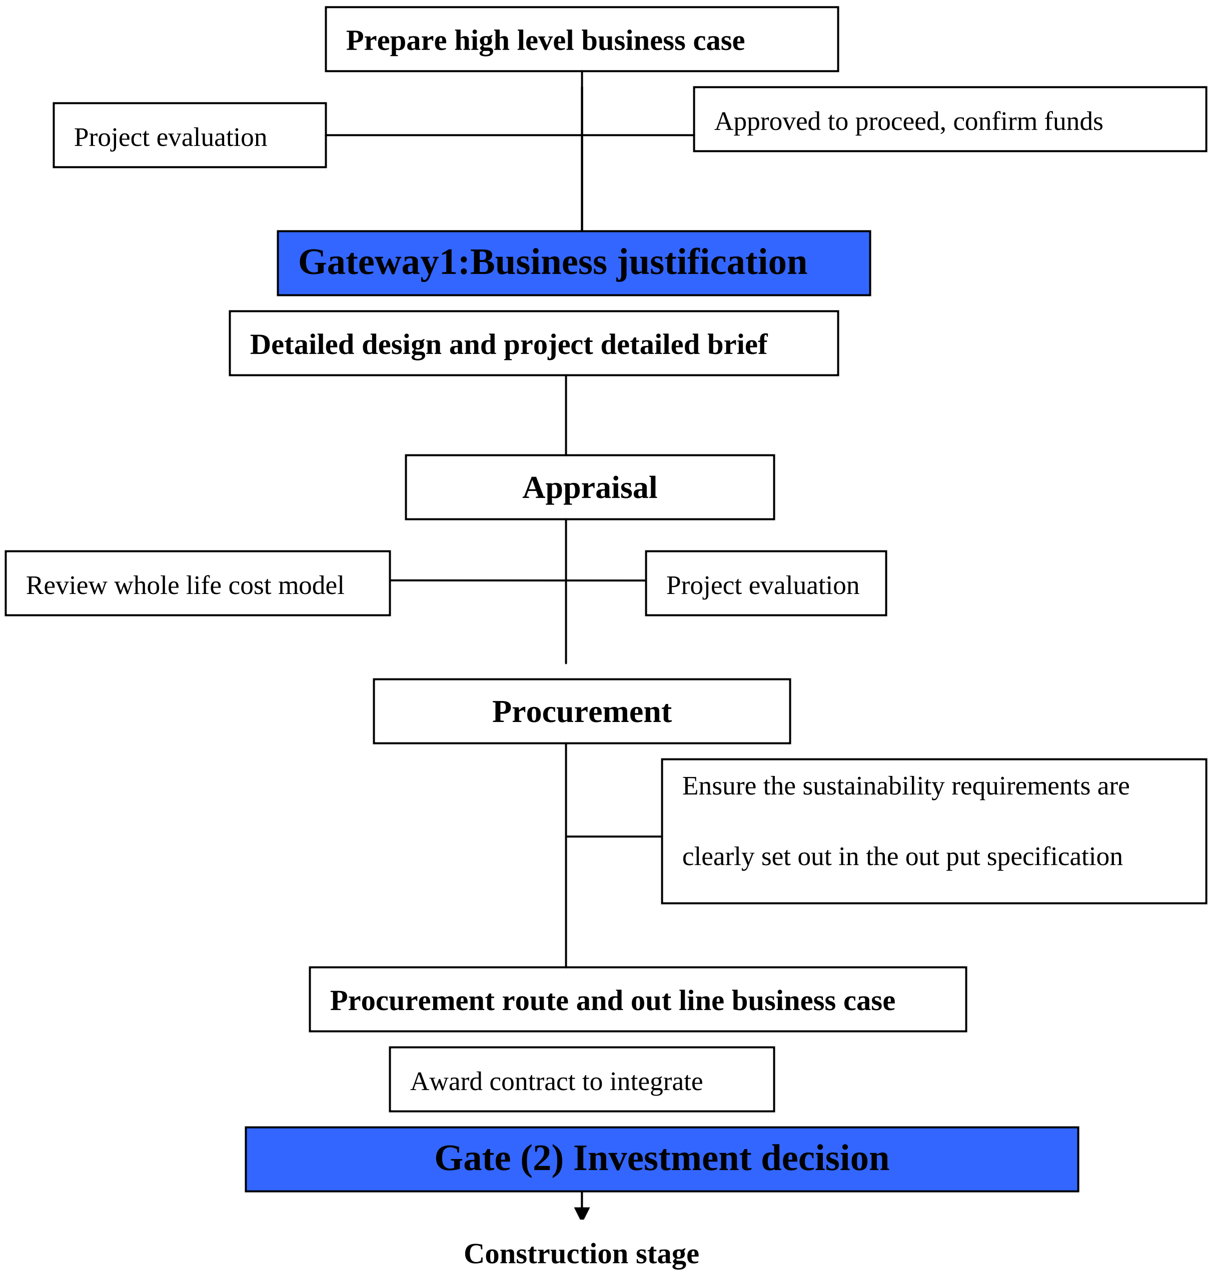
2.3 The research contribution:

The aim of this part of the research is to develop a process map as an essential tool for construction processes of sustainable social housing projects. Its aim is to check the reality of considering sustainable issues in general and sustainable materials in particular during the initial steps of developing the project budget. It aims also to evaluate the existing process maps and to identify when and how sustainable factors are taken into account in this type of projects. To achieve that, the research developed an integrated framework between the generic process protocol as an academic point of view of the process of developing the project and both of the OGC 2007 procurement and sustainable frameworks from the public funding projects point of view. Then this integrated framework was tested in the social housing projects of housing associations to check its validity.

Comparing of the Generic Process Model and the OGC model and pointed out some of their inconsistencies. It was not possible to find enough integrating points between these two frameworks as they have different critical phases and different hard gates. In addition; there is no clear mention for sustainability in the generic process protocol. For that and as publicly funded social housing projects in the UK are supported by the government, in addition to the great emphasis on sustainable issues within the whole life cycle of the building from design to construction and operation in this guide, this research aimed to check the validation of the integration of both the OGC 2007 procurement and sustainable guides for social housing projects of Housing Associations in the UK. Interviews were made with develop mangers in a number of the key Housing Associations concerned with developing sustainable housing projects in the UK. The aim of the interviews was to adjust the integrated OGC framework to suit the actual planning and construction steps experienced by practitioners on the ground who were involved in sustainable housing projects in the UK. It aimed also to show where, when and how sustainable materials are chosen. As a result of this analysis the work is able to highlight the exact stages and their timing involved in the consideration of sustainable materials in addition to other aspects of sustainability associated with the development of sustainable socially owned housing projects. The result of this research was a new grounded framework which can be used to set out a map of the processes involved in the development of sustainable housing projects in the UK. Table 1 showed the high level features of the framework and highlighted the stages of choosing sustainable materials for housing projects.

Table 1: Main features of the framework of the pre-construction processes of the actual sustainable housing projects in the UK





Prepare high level business case
Project evaluation
Approved to proceed, confirm funds
Gateway1:Business justification
Detailed design and project detailed brief
Appraisal
Review whole life cost model
Project evaluation
Procurement
Ensure the sustainability requirements are clearly set out in the out put specification
Procurement route and out line business case
Award contract to integrate
Gate (2) Investment decision
Construction stage

3. Conclusions

Sustainable materials and equipment have the lowest in-use environmental impacts, low embodied environmental impacts, and high recycled content. Producing sustainable building projects requires intense interdisciplinary collaboration, highly complex design analysis, and careful material and system selection, particularly early in the project delivery process. In addition, the process of developing the project cost is an integral part of the construction project management. Reusing materials or selecting those with high recycled content will reduce the depletion of natural resources and protect the environment. This research tried to make sure that sustainable housing projects consider choosing sustainable materials by highlighting the developing processes of this type of projects to encourage all new built housing projects to consider sustainable issues and use sustainable materials in their projects. The process map which was developed from the interviews which were conducted with housing associations in the UK showed that choosing sustainable materials is one of the main development processes. These sustainable construction materials are good to protect the environment during the lifecycle of the project and even for the recycling issues after its deconstruction.

Abstract

The building industry is constantly expanding with consequences on energy expenditure. As similar to the most countries, in Sri Lanka too building industry is the most Energy consuming Industry. In recent years there were much discussions regarding Energy conservation techniques to mitigate the demand side of the energy sector. Building design directly affects the energy performance of the building. The emphasis on energy Conservation has therefore, to begin at the design stage & control throughout the life cycle (Design, Construction, Operate and Maintenance) of the building project.

Buildings, energy and the environment are the issues that the building professionals have to address in current day projects. This is partly due to the increasement of public awareness on environmental issues related to building developments. Therefore, to achieve the energy efficiency goal, architects and building designers need to perform energy conscious designs in their relevant discipline. The expanded design team collaborates in early design stages to generate many alternative concepts for building forms, envelope and landscaping, focusing on minimizing peak energy loads, demand and consumption.

Purpose of this study is to find to what extent energy conscious design has been considered by designers in the Sri Lankan context, and to recognize the areas to be developed to achieve energy efficient building in the industry. The research methodology adopted was quantitative, within that questionnaires were used for detailed survey. A pilot study was conducted by through telephone interview prior to the detailed survey.

Through this research it is found that there should be mandatory energy guidelines enforced for the designers. In addition, designers' lack of knowledge on life cycle benefit; available technology; available energy efficient techniques; and non- usage of energy analysis tools are major hindrance to proceed to the energy efficient design.

Keywords: Energy Analysis Tools, Building Energy Code, Design Team, Energy Efficient design.

1. Background

In most of the countries, the building industry is the most energy consuming industry and it is constantly expanding with consequences on energy expenditure. Past twenty years of research effort had produced a consensus understanding of the impacts of energy consumption and the approaches to reduce this impact by using energy efficiency and the deployment of renewable energy technologies. Especially the Building Energy Efficiency codes have been developed in many countries, and almost all developed countries have enforced them [1]. Further the building energy simulation tools are in rapid development and now been increasingly used in building designs [2]. Therefore, to achieve the energy efficiency goal, architects and building designers need to design energy conscious designs in their relevant discipline. Hence this research is aimed to find what extent energy conscious design has been applied by the designers in the today's buildings in Sri Lanka.

In Sri Lanka, the demand for electricity is rapidly increasing. In the year 2004, electricity demand growth rate varies between 7% - 8%. Average Electricity consumption per capita is 348Kwh/person at the same period and it has grown by 8% from previous year [3]. It was forecasted that electricity demand will quadruple in the next 15 years. However the last few years have seen the power generation of the country gradually shifting more towards thermal power generation. In 2004, Gross power Generation increased by 5.68% but gross generation of hydropower plants were reduced by 13.63% at the same period [4]. It is estimated that by 2014, 82% of the total electricity demand will be met by thermal power generation [5]. At the same time, Authorities are finding very difficult to construct thermal power plants in the face of rising opposition from the local people on economic and ecological grounds.

In Sri Lanka main sectors of energy consumption are Industrial, Transport, household and Commercial and others (religious organizations, etc.). According to the Energy Conservation Fund (ECF) [6] for year 2003, percentage of consumption of Household and Commercial sector was 51.10 % when compare with the other two sectors at Industry and Transport which are respectively 24.41% and 24.80%. Among these, the rate of increase in energy demand in the commercial sector is the highest due to the rapid development of the sector, changes in life styles, contemporary architectural practices and lack of suitable energy saving technologies and building management/automation systems. Due to these reasons, the present annual electricity consumption in commercial buildings, which is approximately 1000GWh, is expected to increase by 28% of the total electricity demand [5].

According to the demand side Management, the energy demand in this sector can be reduced by applying various energy conservation techniques throughout the life cycle of the building. Passive cooling, shading and sun control, efficient daylighting and Heating, Ventilation and Air Conditioning (HVAC) systems, active solar and photovoltaic system are some of the main energy conservation technique. As per the ECF, domestic and commercial sector have 12% of conservation potential from the total annual consumption that potentially saves Rs 2.4 billion annually [6]. According to the UK Department of Energy Estimates that, the better design of new buildings could produce energy consumption reductions of 50% and that appropriate design intervention in the existing stock of buildings could result in a 25% reduction in energy consumption ([7]). The electricity cost in most of the high rise buildings in Sri Lanka are generally are 50% of the monthly operating budget [8]. Any reduction in energy cost will have greater impact on per square feet cost of the building. This will enable the building owners to reduce their office rentals. That will provide them a competitive advantage, especially when competing with smaller office buildings this overhead are comparatively low.

Therefore, to achieve resource conservation and efficient energy management in this area requires effective retrofit and innovatory design measures. By effective implementation of such measures, the commonly agreed and achievable target reduction is around 30%, with more optimistic expectations - up to 70% - for buildings incorporating advanced technology features [9]. However, such strategies and technologies have not yet been widely adopted by the construction industry. The majority of buildings are still been designed without energy-related considerations beyond those enforced by energy codes. One reason for this is that practitioners do not have the means to assess the impact of new strategies and technologies during the design stage.

The sustainable development has become a Global focus in present day industry. Buildings, energy and the environment are issues that the building professionals have to address in current day projects. This is partly due to the increased public awareness of environmental issues related to building developments. Therefore, to achieve the energy efficiency goal, architects and building designers need to design energy conscious designs in their relevant discipline.

2. Sustainable Design

Sustainable design is the thoughtful integration of architecture with electrical, mechanical, and structural engineering. In addition to concern of the traditional aesthetics of massing, proportion, scale, texture, shadow, and light, the facility design team needs to be concerned with long term costs: environmental, economic, and human.

The Rocky Mountain Institute [10] outlines five elements for sustainable design:
