As discussed, central to any successful partnering arrangement is the change in attitudinal and behavioural characteristics towards mutual trust and understanding. Green and McDermott [1996 cited 25] argue the attitudes and behaviour evident in the construction industry are deeply ingrained and that it is difficult to engineer any rapid movement away from such an embedded culture. According to Li et al. [33] partnering requires a long-term strategic plan with cultural change intervention in order to move beyond a traditional discrete project nature. In effect, the development of trust between organisations is seen as a function of the length of the relationship between them, and the mechanisms that led to this alignment are viewed largely as informal. On the other hand, researchers believe that it is possible to bring about change over the timescale of a single project suggesting the view that partnering can be engineered and does not have to evolve naturally [2, 23]. Despite the separation between informal developmental and formal instrumental views to alter the behaviour, behaviour is considered the result of conscious choices and actions and a complex interplay between structural imperatives and their subjective interpretation and enactment [2].

Since partnering is seen as changing behaviours and attitudes, cultural transformation cannot be forgotten in the process. Much of the literature tends to presume that cultural alignment is a prerequisite for partnering. However, it is certainly not easy to bring about cultural change to adopt a new set of behaviours as a consistent way of working among the people. Atkinson [45] identified fear, perceived loss of control, difficulty in learning to do the things differently, uncertainty, addition in work and an unwillingness to commit as the reasons for people to resist change. Hill and McNulty [46] portray fear and uncertainty as the main barriers to change. Conceptualisation of the relationship between partnering and culture [2]; resistance to change from traditional, adversarial and exploitative ways [32]; lack of cooperation based upon fundamental differences in interests between the parties to contract; profitability and uncertainty issues; unwillingness to commit fully to close, long term relationships, together with the construction industry perception of mistrust [26] can be considered as some of the reasons to resist cultural change towards collaborative relationships.

4. Research methodology

This study was launched as part of a Doctorial study on 'Rethinking leadership to address cultural and behavioural challenges in construction partnering'. Phase one of this research focuses on finding out the 'root causes of cultural and behavioural challenges in construction partnering' with empirical evidence. A questionnaire comprising of 10 questions was constructed from the synthesis of partnering literature. Thirty-nine potential problems were elicited from various partnering research, most of which were both economically and culturally driven issues. However, issues that were not culturally driven were excluded from the study with cultural and behavioural issues amounting to 34. These issues were then integrated, based on causality, to form the basis for 10 major questions to examine the magnitude and the root causes of the identified cultural and behavioural challenges in construction partnering in the UK.

Data was collected by means of self-administered expert interviews with each question containing both a quantitative and an open ended qualitative question. A total of 10 experts were randomly selected from academics and industry practitioners. Experience on partnering work of industry experts ranged from 2 years to 10 years while academic experts were selected with a minimum of 3 years of partnering related research experience. Experts were first requested to assess the extent of the identified challenges according to a Likert scale from 1 to 5, where 1='very low' to 5='very high'. They were then presented with an open question to express their perception on the root causes of the identified cultural and behavioural challenges. Most of the respondents were academics with industrial partnering experience and relevant partnering research.

4.1 Data analysis and results

A combination of quantitative and qualitative data analysis was carried-out in this phase to rank the collected data that gave rich details of the challenges and their root causes. Perceived root causes were rearranged with weightings taken from Likert scale to rank the root causes of identified cultural and behavioural challenges. Once again these root causes were integrated/grouped to form specific areas which leadership has to tackle to address cultural and behavioural challenges in partnering projects.

Table 1. A summary of major cultural and behavioural root causes

	Major cultural and behavioural root causes	Causations
1	*Organisational soft issues*	*Mistrust, attitude, culture, fear, resistance to change*
2	*Wrong partnering practices*	*Lack of mutual respect, risk avoidance and transfer, imbalance negotiations, faults with partnering arrangement, misrepresentations*
3	*Lack of understanding and resistance to understanding of partnering concepts*	*Lack of awareness and commitment, not realising the potential benefits, sceptical*
4	*Issues related to individual partners*	*Misalignment of objectives, negative thinking and mind set, inability to learn and unlearn, heuristics*
5	*Direct management issues*	*Lack of negotiation skills, lack of support from top management, imbalance of power*
6	*Lack of continuity of projects*	*Short term projects, lack of potential long term benefits*
7	*Bad experience*	*Past bitter experience with similar participants*
8	*Competitiveness*	*Perceived loss in competitive advantage, self cantered natural cautions*
9	*Financial pressure*	*Commercial imperatives and accounting issues*
10	*Traditional ways*	*Fragmented industry nature and common adversarial cultural problems*
11	*Issues related to project*	*Complexity, resource constraints, procurement routes*
12	*External environment*	*Social, economical, technological and political issues, public sector regulations*
13	*Immaturity of partnering concepts*	*Lack of dispute resolution techniques and related mechanism, lack of confidence*

5. Discussion: cultural and behavioural challenges of construction partnering projects in the UK

As shown in Table 1, 13 major cultural and behavioural challenges were identified, which were categorised in order to assist the next phase to determine suitable leadership practices to tackle these challenges. ‘Organisational soft issues’ were identified as the major area of root causes that focus on the non-suitability of cultural environment such as blame culture and adversarial attitudes. Fear, suspicion and mistrust were other causes of organisational soft issues. This area of challenge becomes more difficult as it associates with resistance and inability to change. Since this deals with changing ‘shared assumptions’, informal developmental and working solutions of leadership may only be the solution.

The study identified ‘wrong partnering practices’ as the second major area of challenge, which includes the absence of proper systems of communication, premature formation of partnering contract, corruption, lack of mutual trust, misrepresentation of ethos and ethics, imbalance of negotiation, absence of partners from the beginning other risk related issues. It is also perceived that clients normally use partnering as a cover for risk avoidance and risk aversion. However, few partnering projects were mentioned where the success of the project was achieved with the in take of major risks was taken by clients. The client’s muscle towards risk aversion can become a major hindrance to construction industry of the UK especially in this period of economic down-turn. Another area closely related to ‘wrong partnering practices’ is the ‘lack of understanding and the resistance to understand the partnering concept’. Lack of awareness of commitment, potential benefits, rewards and scientism are still in existence even after a decade of partnering in the UK construction industry. ‘Issues related to individual partners’ is the next major root cause with challenges such as individual reluctance to commit, negative mind set and different perceptions on win-win attitude.

The final major root cause worth mentioning is ‘direct management issues’ such as lack of negotiation skills, lack of support and undue pressure from top management, imbalanced power structures and lack of induction and training. Even though some of these are easy to overcome, it is important to be proactive. These management issues can also contribute and aggravate other areas such as ‘competitiveness’ and ‘financial pressure’. In short, most of these cultural and behavioural root causes will require cultural change to adopt a new set of behaviours as a consistent way of working among people. As stated above, leadership is originally the source of the beliefs and values that get a group moving with its internal and external problems [9]. Once a leader’s proposals continue to work, they gradually come to be shared assumptions of organisational culture. As such, leadership plays a very significant role in shaping the culture and it is very important to the change agents to lead the whole process, all the time.

6. Conclusion

The literature review shows the growing significance and evolution of partnering which is said to reduce adversarialism in the industry. Also the synthesis on partnering challenges shows the significance of cultural challenges to be tackled to improve the industry. Hence this research has been carried-out to identify the major root causes of cultural and behavioural challenges in construction partnering in the UK. Research found that organisational soft issues, wrong partnering practices, lack of understanding of partnering concept, individual partner’s issues and direct top management issues are the major areas of root causes and it is essential for leadership to play a very significant role in shaping the culture which in turn can bring further benefits by tackling cultural root causes in construction partnering projects.

Abstract

Currently the PFI infrastructure projects through out the world include toll roads, power stations, bridges, ports, water treatment plants etc and has accepted it as best suited for developing countries since infrastructure development is essential for the development of the developing countries, where the governments can not afford finance for such huge infrastructure projects. Even though there were eleven small scale power projects and one port development on Private Finance Initiative (PFI) basis, toll road projects with PFI procurement methods was a new concept to Sri Lanka. In 1995 government had proposed constructing the Colombo Katunayake Expressway (CKE) as the first PFI road project in Sri Lanka to reduce the traffic volume in existing Colombo Negombo A3 road. Fifteen well established foreign concession contractors bid for the project but PFI arrangement was terminated after several negotiation sessions. The study revealed that inflationary economic environment in the country, uncertainty on the coming government’s political support, uncertainty on government’s policy changes, public perception towards tolling, competition from existing A3 road, inaccuracy on traffic forecasting, inability of handling toll revenue by the politicians during the concession period, terrorist problem, inability of realizing concessionaires’ long term plan to enter in to PFI agreements for irrigation and hydropower projects and inability of having duty waivers from the government for imports of concessionaire as main reasons for the failure of PFI in CKE. Two root causes were identified by analyzing the failure factors as unfavourable political situation in the country and the conservative society. Elimination of the identified Root Causes and failure factors will lead to have successful PFI agreements for the future road projects in PFI procurement system.

Keywords: Facilitators, Impediments, PFI, Road Projects, Root Causes, Sri Lanka

1. Private Finance Initiatives

Private Finance Initiatives (PFI) is an alternative method of procuring services for the public sector. The private sector will design, build and provide funding for the capital projects and operate facilities for the public benefit [3]. Private consortia will receive revenue from operating this service, hence make a profit. The PFI procurement methods could be identified through the literature as Build Own Operate Transfer (BOOT), Build Own Operate (BOO), Build Operate Transfer (BOT), Build Operate and Renewal of Concession (BOR), Design Build Finance Operate (DBFO), Design Construct Manage and Finance (DCMF), Build Lease (or Rent) Transfer (BLT or BRT), Lease Renovate Operate Transfer (LROT), Build Transfer Operate (BTO), Rehabilitate Own and Operate (ROO), Rehabilitate Own and Transfer (ROT), Modernize Own/Operate and Transfer (MOT) and Build and Transfer (BT).

As mentioned by the Akintoye et al [1] there are many advantages of implementing PFI projects as they grant “value for money”, transfer of risk away from the public sector to the private sector and facilitate creative and innovative approaches, cap final service costs at pre-determined levels, reduce administration costs, reduce the amount of public money tied up in capital investment, reduce total project cost and improve the buildability and maintainability of projects, accelerate project development and avoid delays in project, give benefits to local economic development and transfer technological knowledge to local enterprises, solve the problem of public sector budget restraint and enhance government integrated solution capacity.

Success Factors for implement PFI projects from investor’s perspective can be identified according to the phases of a PFI project as follows:

Decision Making Phase: Appropriate project identification, available financial market, thorough and realistic cost benefit assessment, favourable legal framework, political support, sound economic policy, stable macro-economic environment and government involvement through providing guarantees

Preliminary Qualification Evaluation Phase: The capability of project promoter and experience with PFI project by promoter

Tendering Phase: Shared authority and responsibility, multi benefit objectives, competitive tendering system, transparency in the procurement process, technology solution advance, acceptable toll/tariff level and attractive financial package

Concession Award Phase: Multilateral investment guarantee agency insurance, special guarantees by the government, reasonable risk allocation, concrete and precise concession agreement

Construction Phase: Selection of suitable subcontractors, quality control and supervision, standardization of engineering contract, a multidisciplinary and multinational team and good relationship with government

Operation Phase: Management control, training local staff and sound environmental impact

Transfer Phase: Technology transfer and operation in good condition

In considering the opportunities presented by the PFI market, the contractors have identified a number of barriers to entry in to PFI market which were hindering their involvement as Lack of appropriate skills, high participation costs, high project values, lack of credibility and contacts, demands on management time and high risk. PFI risk can be identified as traffic revenue risk, land acquisition delay, demand risk, delay in financial closure, completion risk, cost overruns, debt servicing risk, political risks, financial risks, State-rooted risks such as prolonged negotiation period prior to project initiation, unfavourable economy in the host country, import or export restrictions, rate of return restrictions. Concessionaire-rooted risks can be identified as lack of creditworthiness, inability of debt service, bankruptcy, unfavourable economy of the country of the main stakeholders, high bidding costs, high design costs, high construction costs, errors in forecasting the demand, wrong estimate of cost trade-offs between different phases in the project's life cycle, risks regarding pricing the product, complex financial structure of the PFI projects, lack of co-operation in case of new initiatives, insufficient performance during operation, lack of guarantees, financing risk. There are Market-rooted risks as loan risks, fall of demand, taxation risks, fluctuation of the inflation rate and currency risks.

The scale and structure of huge infrastructure requirement, shortage of public sector financing, growing debt crisis and reduction of their external borrowing capacity have compelled many developing countries to shift their focus towards PFI in infrastructure projects [2]. Sri Lankan government is actively encouraging private sector investment in infrastructure on the PFI basis mainly for telecommunication sector as well as power generation sector due to their less risky nature. Five telecommunication projects, eleven power projects and one port development were implemented under PFI in Sri Lanka.

2. Background of the CKE Project

Even though in other countries PFI is successfully used in massive road development projects giving much more benefits to the government, it was not realized in Sri Lanka. The Government of Sri Lanka (GOSL) had initially considered PFI procurement methods for procuring the Colombo Katunayake Expressway (CKE) to minimize the government funding but received no proposal bids. Consequently the project was awarded in Design Build and Turnkey (DBT) procurement method. However, the DBT Contract was mutually terminated when overall construction work progress was 35%. This led to a further engagement to undertake study and prepare documentation with several negotiation sessions with foreign concession contractors for completion of the project under PFI arrangement, but ultimately it was also failed. Therefore, the government is now conducting negotiations to implement this project with Engineering Procurement and Construction (EPC) Turnkey basis. As a result of all these, there is a question "Why the application of PFI was failed in CKE project?" which is also the question of this research.

3. Methodology

Single Case Study Design was selected with In-Depth Study with Multiple Source Evidence to represent this critical case in application of a well established PFI theory.

Since, case study research generates a huge amount of data the multiple sources of evidence were collected and stored methodically and systematically in formats that can be referenced and sorted. The most important source of information was semi structured interviews which revealed the failure of applying PFI in CKE. Interviewees at different levels of the organization were targeted. Initially this was to ensure that any findings were not based on data coming from "one side" only. As it turned out, the different views that appeared through this multi-level focus became a major point in the findings from the study. To gain further information regarding the case and background details, documentation and the web data facilitated a great deal and it was capable of offering to double-check other information. The data collection also included a wide range of written material: annual reports, web sites and negotiation reports so on.

Snowball technique was used to recognize and select the interviewees. Snow ball technique involves concentrating groups of ideas pertaining to the same problem. In its simplest formulation snowball sampling consists of identifying respondents who are then used to refer researchers on to other respondents. But in most cases one person in a particular organization recommend people with same opinions. Therefore, for collecting multiple source information, different group of people were interviewed in the same organization with different opinions.

The questions for a semi-structured interview were ideally constructed some time before the interview and were sent to the expert so he/she can start to prepare responses. Printed or electronic list of questions were distributed to predetermined selection of interviewees prior to interview including questions such as; what are the PFI facilitators which were presented and not presented in the CKE project, what are the reasons for the absence of those facilitators, what are reasons for inability to make available those facilitators for the project, what are the PFI impediments which were presented in the CKE project, what are the reasons for existence of identified impediments in CKE project and what are the reasons for inability to eliminate identified impediments.

There were eleven interviews with the professionals such as Project Engineers and Project Directors from the PFI bidders and related government authorities for the project who were acted as the government's representatives. For an interview lasting 2 -3 hour, around 10-15 questions were asked. This allowed time in between the prepared questions to ask supplementary questions to clarified points and asked for more detail where necessary. Direct questions were also asked for respondents to answer "yes" or "no." when the answer is "yes" it became an open ended discussion. As well as, respondents had to give reasons when the answer was "no." The answers of one respondent showed to the other to get his opinion on other's answers. An important aspect of the technique is that the interview was recorded and later transcribed providing a protocol for detailed analysis.

Manual code based content analysis was selected as the methodology for analysing the collected data to identify PFI facilitators which were not presented, PFI impediments which were presented and their Root Causes.

4. Research findings

When analyzing the case of CKE it was obvious that both GOSL and concessionaires have agreed to enter in to a build agreement and the main disagreements within the government and also the within the concessionaires were rooted on the operation of the toll road by the selected concessionaire, because of the operation responsibility is with the concessionaire, it has to recover the total project cost plus profit from the toll revenue.

4.1 Impediments Present

Identified impediments of the CKE on PFI basis can be recognized as political risk, traffic revenue risk, financial risk, disagreement among upper level politicians and other unfavourable conditions in the country.

4.1.1 Political risk

The risk on the continuous political support and policy changes were identified by the respondents as the most important political risk factors which impeded concessionaires from taking the operation responsibility of the CKE. There was an uncertainty among the foreign contractors on the actions of the coming governments, such as terminating the concession or imposing taxes or regulations on the project that severely damage its value to investors; not allowing the private partner to charge and collect tolls as specified under the concession agreement; preventing investors from transferring earnings out of the country; or not allowing for contract disputes to be settled fairly under neutral jurisdiction.

It was obvious the importance of having a firm legal framework for the PFI projects in Sri Lanka to avoid such uncertainties that can arise from the government changes and policy changes. From the foreign contractors' point of view, it is essential to get the support from multilateral or bilateral financial institutions by the GOSL to mitigate political risks.

4.1.2 Traffic revenue risk

CKE is being the first Sri Lankan toll road project, foreign concessionaires had uncertainty on the user's willingness to pay tolls which is mainly affected by user's wealth, their attitude and value they assign for time saving. According to the government authorities' point of view, to change the people's attitude, people should be educated on the real meaning and the benefits of the PFI arrangements, difference between the privatization and PFI and on the importance of having a foreign concessionaires' involvement for the infrastructure development of the country.

Concessionaire also had a doubt on their ability to draw traffic from existing Colombo Negombo A3 road to generate new traffic. Further, foreign concessionaires have requested a minimum traffic revenue guarantee an extension of the concession term or cash compensation when the traffic volume falls below the minimum expected traffic levels from the GOSL in negotiation sessions as a treatment for the traffic revenue risk.

Concessionaires also had distrust on the accuracy of the traffic forecasting by the GOSL. Arguments were carried out on the factors such as land use and population growth along the route, public acceptance and use of the expressway, and various economic indicators used in traffic models with inherent uncertainties, which affect the traffic forecast. Some respondents suggested using refining methodologies and empirical equations for improving the long term accuracy of traffic volume estimates. But they have mentioned the importance of cross-checking of forecasted traffic volume by at least one independent consultant.

Possible toll rate issues were also discussed such as limitations of increasing toll rates with the inflationary economic environment in Sri Lanka, which is quite a sensitive issue, both politically and socially. Another issue was whether toll rate adjustments should be left to discretion of GOSL or be based on a formula that is usually linked to changes in some price index. Therefore, the respondents suggested establishing a straightforward, transparent, fair, and binding Toll Adjustment Mechanism by the GOSL and private concessionaire.

4.1.3 Financial risk

As mentioned by the relevant government authorities, for the CKE project GOSL highly expected the contribution of foreign financial institutions and sponsors for the project financing and conversely foreign concessionaires also expected a high financial security from the GOSL. The main impediments which discouraged foreign concessionaire for financing of CKE project was their uncertainty in the import export policies of the GOSL. They were in doubt whether the GOSL restrict their repatriation of profit by imposing taxes. Another main negative feeling was the unexpected increases in the construction cost due to the inflationary economic environment which will seriously affect the economic plan of the concessionaire.

Introducing a firm legal framework for the PFI arrangement of CKE project to avoid influences for the project from the government policy changes was the main solution which was proposed to encourage foreign investors to finance for the CKE project. Respondents also suggested expanding the concession operation period or compensating the concessionaire by GOSL to cover the increases in the construction cost due to inflation.

Another major impediment pointed out by the respondents was the currency risk, because if Rupees are not convertible at the expected exchange rate, it will not be able to pay the return on investor’s foreign currency for his capital. Therefore, the foreign concessionaires always assumed the exchange rate risk and inconvertibility risk, in the negotiation sessions even though the political risk insurance covers the inconvertibility. The main cause for the exchange rate risk is the inflationary economic environment in Sri Lanka and interviewers’ proposal was to mitigate exchange rate risk by indexing the toll rates to local inflation rate or to the exchange rate of the investor’s foreign currency. They recommended to use consumer price index as the inflation index and adjustments to be made according to a fixed schedule. Disagreements among upper level politicians

When considering the responses of the interviewers it was obvious that there were disagreements among the upper level politicians regarding the foreign concessionaire's operation of the CKE for the concession period. There had been several reasons behind the upper level objection. Under the PFI arrangement, toll revenue handling is completely with the foreign concessionaire for the agreed period usually more than ten years and during concession period politicians have no control over the toll revenue. The politicians had also thought that foreign operation of CKE would make a bad public impression of the government similar to privatization, and it would have adverse affect during elections. Respondents also believed when the top level decision makers' impression is bad towards the foreign contractor's operation, the lower level educated people also have to agree on their decisions even their own opinion is not the same. Therefore, it is essential to educate politicians on the benefits of having a PFI arrangement for realizing the CKE project.

4.1.4 Other unfavourable conditions

According to respondents, CKE bidders expected to involve in irrigation and hydropower sectors for concession contracts while staying in Sri Lanka by operating the toll road. But in negotiation sessions they understood that they will not be able to realize their long term plans due to public resistance to pay tariff for infrastructure facilities. On the other hand foreign concessionaires did not prefer to stay for a long operation period in Sri Lanka due to the terrorist problem. Respondents also pointed out that the foreign concessionaires do not like to live in such an uncertain environment for a long period even though it is possible to have an insurance cover.

4.2 Facilitators Not Present

The PFI facilitators, which were not presented in CKE project and the way of implementing those facilitators for a successful PFI agreement, are discussed next.

4.2.1 Unavailability of local financial market

As mentioned by the respondents, local financial market is not strong to finance for the whole project, due to high project cost and long payback period, although they will receive annual interest payments. Therefore, the project has to be financed by the foreign investors. So as mentioned under the financial risk, if there are local financial sources to invest for CKE project it will facilitate to reduce the effect of the currency risk.

4.2.2 Less supportive legal and policy frameworks

The respondents pointed out the main difficulty of developing a proper PFI agreement for the CKE project as inadequate assurance from the country's legal system to investors, which avoid obtaining an objective settlement of contract disputes. According to the respondents, political support for the CKE project negotiations was not much flexible. Concessionaires requested Minimum Traffic Revenue Guarantees, exchange rate guarantees, Toll Adjustment Mechanism and a firm taxation procedure from the government to draw the political support for a successful PFI arrangement. It is essential to have a comprehensive legal frame work for PFI projects including the operation of the project which is not available in Sri Lanka.

4.2.3 Unavailability of Sound macroeconomic environment

According to the respondents, a favourable country and concession environment is crucial for attracting finance and limiting the need for government undertaking of risk for the project. But in Sri Lanka there is a high inflationary economic environment which discourages financing sources to invest in CKE project as well as caused for the impediments such as revenue risk, currency risk and financial risk due to construction cost increases.

4.2.4 Lack of Government involvement: providing guarantees

Concessionaires supposed a variety of mechanisms to support their financings. They were discussed on the Equity Guarantees, Debt Guarantees, Exchange rate Guarantees, Grants, Subordinated Loans, Minimum Traffic Revenue Guarantees, Shadow Tolls, Revenue Enhancements and Concession Extensions. If the government provided guarantees for the PFI concessionaries, most of the impediments such as political risk, traffic revenue risk and financial risks could be minimized.

Impediments, which were not presented in the CKE, project to implement PFI procurement system could be identified as Lack of Appropriate skills, high project costs and lack of credibility, prolong negotiation period and completion risk.

PFI facilitators presented in the CKE project were the proper project identification, thorough and realistic cost benefit assessment, capacity of the project promoter, attractive financial package, acceptable toll or tariff levels, technology solution advantage and transparency in procurement process and reasonable risk allocation.

4.3 Root Causes

When the existing impediments and missing facilitators are scrutinized, it becomes obvious that some impediments have occurred due to lack of several facilitators and some missing facilitators have caused for presenting several impediments. Further, making available of some missing facilitators is the identified methods of eliminating certain impediments.

According to the analysis of the previous section it can be recognized key failure factors of PFI in CKE project as Inflationary economic environment in the country, Uncertainty on the coming government’s political support, Uncertainty on government’s policy changes, Public perception towards tolling, Competition from existing A3 road, Inaccuracy on traffic forecasting, Inability of handling toll revenue by the politicians within the concession period, Terrorist problem, Inability of realizing concessionaires' long term plan to enter in to PFI agreements for irrigation and hydropower projects and Inability of having duty free waves from the GOSL for imports of concessionaire

Further analysing of failure factors illustrates two Root Causes for the existence of all failure factors as Unfavourable Political Situation in the country and Conservative Society which are explained below.

4.3.1 Unfavourable Political Situation in the country

Failure factors which have occurred owing to the Unfavourable Political Situation in the Country can be recognized as Uncertainty on Political Support and Policy Changes, Inflationary economic environment, Inability to handling toll by politicians, Terrorist Problem and Inability of having duty waivers.

1. **Uncertainty on Political Support and Policy Changes**

Construction in Sri Lanka, as in many other developing countries, affects mainly by the national plan of each political group who is in power. When a new government comes in to power, previous government's working procedures and policies are changed, which has become a common scenario today. Governments can change government expenditure and taxation by imposing fiscal policies and money supply to the economy and interest rates can change by applying monetary policies. Further governments can change grants and subsidies, productive enhance measures, tax concessions and financial incentives by imposing supply policies. It can be expected several government changes within the concession period of the CKE project which can be defectively affected to the concessionaire by means of less supportive political plans and policy changes.

2. **Inflationary economic environment**

Normally inflation of an economy is occurred due to demand pull and cost push situations. In demand pull situation the demand for the goods and services is increased but the supply is not increased to fulfil the increased demand. In the cost push situation input prices of the producers are increased. In both situations, the prices of the goods and services are increased. Political decisions are also caused for the inflation as getting huge loans from developed countries as well as starting massive development projects with government funds. Therefore, to regulate the inflation of the economy the government of the country should be able to apply demand side policies as well as supply side policies at the correct time. But in Sri Lanka government seems not to be applied correct policies and if not change the country's unfavourable political situation, current inflationary economic conditions will prevail for the concession period of the CKE project.

3. Inability to handling toll by politicians

As mentioned by the respondents of government authorities, in Sri Lanka there is no standard procedure to handle public money by the politicians and therefore, more corruptions are occurred. Thus, most of the beneficiaries in superior levels have disagreed to allow concessionaires to handle toll revenue for the concession period, which takes generally more than ten years.

4. Terrorist Problem

Terrorist problem in the country also caused to keep away concessionaires from staying in the country for longer period for the operation of the toll road. As mentioned by the respondents, two main political parties in the country have two different responses towards the terrorist as peace talks and war. Therefore, it is very difficult to have a firm solution for the terrorist movement in the country.

5. Inability of having duty waivers for the concessionaire

Further the foreign concessionaires supposed to have duty free waves for their imports during the concession period. But the government refused to provide such facilities and did not respond favourably to accomplish a successful PFI agreement. Therefore, it is needed to educate politicians on the importance of having flexible procedures as well as collaboration between both government and concessionaire to form a proper PFI agreement.

4.3.2 Conservative society

Public perception towards tolling, Competition from existing A3 road , Inability to realizing long term plans by the concessionaire and Inaccuracy on traffic forecasting can be discussed as results from Conservative Society.

1. Public perception towards tolling and Competition from existing A3 road

Sri Lankan people used to get the infrastructure services free of charge from the government. Therefore, it will be really difficult to change their attitudes towards paying money for the free services that they have received earlier. Further, due to financial problems, there is an uncertainty whether the people will get use to pay money for tolls or will use the existing A3 road.

2. Inability to realizing long term plans by the concessionaire

CKE bidders expected to involve in irrigation and hydropower sectors for concession contracts while staying in Sri Lanka by operating the toll road. But, Sri Lankan people have used infrastructure as a free facility, specially in irrigation sector. Therefore it will not easy to get agree farmers to pay money for water.

3. **Inaccuracy on traffic forecasting**

Main component of the traffic forecasting is the public acceptance. Therefore due to the conventional society it is a risk to forecast public acceptance of paying tolls or tariffs for infrastructure facilities.

Further educational programmes are needed to educate both public and politicians on the benefits of having PFI arrangement for the infrastructure development of the country.

5. Conclusions

When studying the procurement history of the long waited Colombo Katunayake Expressway (CKE) project, it was apparent that there have been four attempts of project, but initial three attempts had been failures. The specialty was with the second bidding effort, which was the first Sri Lankan PFI procurement process in road sector.

This study revealed five main impediments to implement the project on PFI basis as political risk, traffic revenue risk, financial risk, disagreements among upper level politicians and other unfavourable conditions.

Uncertainty on the coming government's political support and government policy changes were the main causes for political risk and it was proposed to mitigate those unfavourable factors by forming a comprehensive legal framework and getting support of multilateral or bilateral financial institutions. Another significant obstruction for PFI was the traffic revenue risk, which had formed because of public perception, competition on existing A3 road, increase of tolls and accuracy level of the traffic forecasting. It was suggested to educate people on the benefits of PFI to make a better public impression. Inflationary economic environment was the reason for the increase of tolls and proposed to implement straight forward, transparent, fair and binding toll adjustment mechanism to reduce the affect on concessionaires from inflation. It was also advised to use refining methodologies, empirical studies and cross checking by independent consultants to improve the accuracy of the traffic forecasting. Grounds for the financial risk were the currency risk, uncertainty in policy changes and increase in construction cost. Currency risk was occurred due to inflationary economic environment. Index toll rates to local inflation rates, index toll rates to exchange rate of the foreign currency and involve local funding sources were the major currency risk reducing proposals. It was suggested to form a comprehensive legal framework to reduce the uncertainty on government policy changes. Inflationary economic environment caused for the construction cost increases and as mitigation, it was proposed to compensate the concessionaire or expansion of concession period. Fear of negative public impression, which can influence for elections and inability of handling toll revenue until the end of the concession period were the main sources for the disagreement among the upper level politicians on concessionaire's operation of CKE. As a remedying measure, it was proposed to educate politicians on the benefits of PFI. Other unfavourable conditions were the concessionaires' objection on staying longer period by operating the toll road due to terrorist problem and inability of realizing long term plans such as concession contracts for irrigation and power sector projects. Inability of having duty free waves from the GOSL for the imports of the concessionaire also was a negative factor.

Some of the main facilitators, which were discussed in the literature for a successful PFI road projects, were not present in the CKE project. Key facilitators found to be absent were; unavailability of local financial market due to high project cost and long payback period; less supportive legal and policy frameworks which can be eliminated by providing flexible government actions as minimum traffic revenue guarantee, exchange rate guarantee, toll adjustment mechanisms and firm taxation policies; unavailability of Sound macroeconomic environment due to inflationary economic conditions which can be reduced by providing sound economic policy to compensate concessionaire in highly inflationary situations; and lack of government involvement through providing guarantees.

The bidders for the CKE project were well established foreign concession contractors. Therefore, they were well equipped with appropriate skills and consisted with in house capacity. Hence, the impediments mentioned in the literature as lack of appropriate skills and high project costs, lack of credibility and contacts were not presented in the CKE project. Conducted negotiations were not too lengthy and completion risk was not with the contractor because the government had already settled all public interferences against the project, environmental clearances, government approvals and land acquisition at the first attempt of the CKE project.

When comparing with the facilitators identified in the literature, proper project identification, thorough and realistic cost benefit assessment, high capacity of the concession contractor, attractive financial package, acceptable toll level, technology solution advantage, transparency in procurement process and reasonable risk allocation were present in the CKE project.

Through the analysis, Two Root Causes were able to identify for the existence of the PFI failure factors as Unfavourable Political Situation in the country and Conservative Society. Therefore it is needed to educate both public and politicians on the benefits of having PFI arrangement for the infrastructure development of the country to eliminate the effect from the Root Causes for the CKE project.

E-LEARNING

Improving co-learner interactions through Web-based online assessments within distance learning settings

Abstract

Distance Learning (DL) is an educational model that is fast growing both in the UK as well as in the international education context. It has come into prominence with the advent of the internet technology particularly during the last two decades of the 20^{th} century. Due to the nature of delivery of DL programmes, the methodology in which students are assessed varies from one programme to another. One of the major influencing factors for achieving intended learning outcomes in a programmeme is the assessment strategy adopted. Tutors in DL programmemes have adopted various methods of assessments that could broadly be described as formative and summative assessments. A well documented formative and summative feedback for learners, especially early on in a course, will facilitate in their learning and provides opportunities for students to gain insight into their understanding of the course content. Learners often express their need for more empowerment within their modules to enhance their active involvement and interactions within the programmes. This is the main focus of this ongoing research under the Teaching Learning Quality Improvement Scheme (TLQIS) of the University Of Salford, UK.

This paper disseminates the first stage of the research project. The paper first examines literature within the area and explores the various online assessment tools available that can be incorporated to DL. It then sets out the overall methodology and conducts two case studies of DL courses within the School of Built Environment (SOBE), University of Salford. The next stages of this research project will evolve into DL courses conducted in other schools and faculties at University of Salford and other Higher Educational Institutes (HEIs) both in the UK and overseas. It is expected that the final results of this study will lead to recommending of guidelines on improving co-learner interactions within DL settings.

Keywords: Distance Learning (DL), co-learner interactions, web-based online assessments

1. Introduction

Advances in information technology (IT) is continually evolving; opening up additional channels for today's higher education (Chen *et al*, 2001). Distance education technologies have become more prominent during the last decade of the 20th century (Ingirige *et al*, 2005). Moreover, Chen *et al* (2001) noted that the application of IT have allowed universities to deliver multimedia course contents and enable students to communicate with their instructors and fellow students in both synchronous and asynchronous formats; hence making distance learning (DL) possible. DL, an educational model in which the student and the instructor are separated by time and space, is considered the current fastest growing model of domestic and international education (Poley, 2000).

Distance education had been around for more than a century, which according to Belanger and Jordon (2000), the history of technology-based DL was correspondence education, which started in Europe and the United States in the mid 19th century. Web-based technologies (WBT) in particular have expanded the interactive capabilities of distance education from solely asynchronous communications with long delays in response to highly interactive class meetings via text, e-mail, video and many more (Murphrey, 2001).

In the domain of higher education (HE) in the construction industry, DL has become a major source by which many HE institutes conduct their courses, particularly at postgraduate level. At the University of Salford, the School of Built Environment (SOBE) itself utilises the distance education technology tools in delivering Masters and PhD programme over the Internet (Ingirige *et al*, 2005). The new developments in technology have impacted the overall delivery process of the DL construction programme. It has been considered that one of the major influencing factors for achieving the intended learning outcomes of these programmes within an overall information and communication technology (ICT) enabled delivery process is the assessment strategy adopted.

Assessments can be considered as a significant way of interaction and providing feedback from the instructor to the learner and a medium for the co-learners to interact with each other. And, due to the significance of this area, SOBE received funding to conduct a one year study to improve the interactions of co-learners through web-based online assessments tools within DL settings through the Teaching and Learning Quality Improvement Scheme (TLQIS) within the University of Salford. This paper reviews literature within the field and examine the shortcomings and the overall utility within the available tools in improving co-learner interactions.

The paper has been designed and structured as follows; first, it will describe the methodology adopted. Then, it will look into research problems and subsequently the literature within the area;

e.g. definitions and characteristics of DL and enlisting available web-based assessment tools within the DL settings. Then, through two case studies of DL courses within the School of Built Environment, University of Salford, it is intended to identify currently used web-based online assessments tools within the DL settings and other issues within the area in improving the co-learner interactions within the DL. Finally, this paper concludes by suggesting the way forward.

2. Methodology

The research methodology approach adopted for this paper embraces the distillation of core research material gathered from a detailed literature review. The literature review encompassed concepts and issues surrounding DL. Two DL Master programmes (MSc 1 and MSc 2) within the School of Built Environment, University of Salford were looked into and used as case studies to achieve the following objectives:

i) To identify the delivery methods currently implemented within the DL settings;
ii) To identify the methods of assessment currently implemented within DL;
iii) To identify the available web-based online assessment tools used within DL;
iv) Identify gaps within the available tools and their capabilities in improving co-learner interactions;
v) Identify barriers in improving co-learner interactions within DL;

Interviews were conducted with the DL tutors in achieving the above mentioned objectives. The result and conclusion from this paper will recommend the way forward and inform the next stages of this research project.

3. Research Problem

Learners often express their need for more empowerment within some of their modules to enhance their active engagement. With all types of learning, including web-based learning, it is useful for students to receive constructive, timely and relevant feedback on their progress even within DL settings. Therefore, a mix of computer marked and tutor marked essays could be adopted for summative assessments. Online marked assessment is sometimes constrained by the medium in which it is operating. Computer marked assessments alone are not appropriate for marking or giving feedback on assignments such as essays or projects that require more than the mere production of knowledge. With the increase of DL programmes being offered there has been a corresponding increase in both synchronous and asynchronous mechanisms being developed to facilitate these assessments (Dede, 1996; Wilson and Whitelock, 1997).

Despite addressing the needs of the programme in developing a regime of assessment strategies, most learning communities express a feel of isolation. However, barriers in the form of resource constraints, sometimes affect the provision of pedagogic requirements such as maintaining appropriate co-learner interactions within the masters DL programmemes. This paper aims to address issues within the area in improving the co-learner interactions within the DL (e.g. factors and barriers in improving co-learner interactions, gaps and flaws within the available tools, etc) and proposing a way forward.

4. Distance Learning

4.1 Definitions and Characteristics

Several definitions have been cited for the term DL; among others; Majdalany and Guiney (1999) define DL as “instruction and learning practice utilising technology and involving students and teachers who are separated by time and space”. Jonassen (1992) defines DL as the volitional control of learning by the student rather than the distant instructor, while Perraton (1988) and Verduin and Clark (1991) define it as the separation of the teacher and the learner in space and / or time during at least a majority of the instructional process.

Hall and Snider (2000) characterised DL with three criteria; (i) a geographical distance that separates the communication between the trainer and the participant, (ii) the communication is two-way and interactive and (iii) some form of technology is used to facilitate the learning process. Keramiyige *et al* (2006) supported this view by considering the two significant characteristics of DL; which is (i) the distance between the tutor and the learner (either geographically or timely) and (ii) the learner centred learning mechanisms as opposed to the teacher centred learning in a traditional classroom based learning environment.

The additional characteristics of DL that has been discussed by Keegan (1986) include:

- The influence of an educational organisation both in planning and preparation of learning materials and in the provision of student support services; which distinguishes DL from the private study and teach-you programme;
- The use of technical media, print, audio, video or computer to unite teaching and learner and carry the content of the course;
- The provision of a two-way communication so that the learner may benefit or even initiate dialogue; a characteristic which distinguishes DL from the other uses of technology in education; and
- The quasi-permanent separation of the learning group throughout the length of the learning so that people are usually taught as individuals and not as groups, with the possibility of occasional meeting for both didactic and socialisation purposes.

There are many terms in relation to distance education and training, defined as follows in Table 1 (Du Mont, 2002):

Table 1: Definitions of Terms(Du Mont, 2002)

Term	**Definition**	**Source**
Asynchronous learning (sometimes referred to as Networked learning)	"A type of learning in which learners and instructors use computers to exchange messages, engage in dialogue and access resources" at any time and any place.	Commonwealth of Learning (2000) and Schocken (2001).
Distance education	"Planned learning that normally occurs in a different place from teaching and as a result requires special techniques of course design, special instructional techniques and special instructional techniques, and special method of communication by electronic and other technology, as well as special organisational and administrative arrangements."	Moore and Kearsley (1996)
Distance learning	"Instructional and learning practice utilising technology and involving students and teachers who are separated by time and space."	Majdalany and Guiney (1999)
Distributed learning	"Learning environment [which] exists among a dispersed student population, is structured according to learner needs, and tends to integrate traditional institutional functions (e.g. classroom and library)….through both synchronous and asynchronous communication."	Oblinger and Maruyama (1996)
e-Learning	"Can be a subset of distributed learning. Relies on digital content, experiences through a technology interface, and is network-enabled. Collaboration is a desirable feature of e-Learning…"	Lundy, Harris, Igou and Zastrocky (2002)
Open learning	"An arrangement in which learners work primarily from self-instruction, completing courses structured around specially prepared, printed teaching materials, supplemented with face-to-face tutorials and examinations."	William, Paprock and Covington (1999)

According to Du Mont (2002), definitions of DL exist which emphasise the *process* of educational and structure. Sherry (1996) noted that the terms "distance education" or "distance learning" have been applied interchangeably by many different researchers to a great variety of programmes, providers, audiences and media. Berge (1998) however note that there is a difference between the term 'distance education' and 'distance learning'. According to Berge (1998), distance education is seen as the formal process of DL, with information being broad in scope; e.g. college courses. DL however is seen as the acquisition of knowledge and skills through mediated information and instruction, encompassing all technologies and other forms of learning at a distance. In addition, Gotschall (2000) described DL as a broadcast of lectures to distant locations, usually through video presentations.

5. Distance Learning, Interactivity and Feedback

Butler and Winne (1995) define feedback as information that a learner receives about his or her learning processes and learning outcomes. Moreover, Gagne (1985) mentioned that learners may find frequent feedbacks useful and feedback to learners may be essential to effective learning (Reiser and Dick, 1996). DL conditions usually constrain when, where and how DL feedback occurs, because feedback is a function of interactivity, and interactivity changes from traditional to DL environments (Wolcott, 1996). According to Ley (1999), an instructor in a traditional classroom can more easily interact with students by easily giving simple knowledge of result feedback with more complex feedback as students require or demand. In DL environments, most distance instructors lack the logistical support or the technology to return papers and answer questions during the same session.

Planning for adequate and useful feedback through web-based online assessments can lessen the DL instructor's feedback burden, hence, improving co-learner interactions within the DL settings. Moreover, according to Ley (1999), without a feedback system in place, distance students engage in learning under the handicap of inadequate or no feedback at all. In traditional distance education settings, learners are often left to go through the process of learning in isolation with very little contact with tutors and peers, thus are confined to basic, 'static' interaction with material delivered through one-way media in the form of printed text, audio cassettes and/or video (Karaliotas, 1998). In addition, according to Karaliotas (1998), with the advent of new media and technologies, the use of affordable and well integrated two-way communication is now possible in distance learning, which in turn enables dynamic interactions.

According to Moore (1989), interactions take place in the learning environment in three ways; e.g. (i) with contents, (ii) with other co-learners and (iii) with instructors. This particular research concentrates more on the interactivity between co-learners in a DL setting. Karaliotas (1998) mentioned that DL environments offer plenty of opportunities for interaction with other learners, far more likely to be productive and complete than in traditional HE learning environments as they are independent of time and place due to their asynchronous nature, and more in line with the learning to learn process as they can be highly motivated and goal oriented. Interaction with learners takes place within collaborative activities, in threads of sociable exchanges, or philosophical and self-searching discussions. They are generated as; (i) asynchronous, Bulletin Board System (BBS) and email interactions and (ii) real-time moo and chat interactions. Asynchronous, BBS and email interactions seem to offer a more in depth discourse as responses are spread over time, to the convenience of the participants, while real-time, moo and chat interactions offer a fuller experience and rich content for a later asynchronous follow-up.

Learners' abilities to interact with the instructor, the peers, and the content can affect their performance in DL. Acker and McCain (1993) mentioned that "interaction is central to the social expectations of education in the broadest sense and is in itself a primary goal of the larger educational process and that feedback between learner and teacher is necessary for education to develop and improve" (p. 11). Online interactions take into consideration the characteristics of the learners as well as the communication technology. The interactive features of the current computer-mediated communication (CMC) systems, such as two-way video and instant feedback, have provided more options for learner interactions. Moreover, Gunawardena *et al* (1998,pp. 141) have interpreted interaction as "the process through which negotiation of meaning and co-creation of knowledge occurs in a constructivist learning environment". Wagner (1998) however argues that interaction can serve as a means to an end of enhancing learning and performance. Learner interactions require planning and structure in order to achieve the goal of active learning. According to Rohfeld and Hiemstra (1995), tasks such as debates, guest lecturers/discussants, polling, brainstorming, or student moderated discussions via CMC networks can help to increase student interactions for learning. The principles of student-centered discussion accord the students the responsibilities of facilitating online conversations. When the activities and tasks become an integral part of the learning process, learner interactions can be conducive to learning (Chou, 2000). This is where this research emphasises that web-based online assessment would be able to help enhance co-learners interactions within a DL setting.

6. Assessment

In addition to interaction and feedback, assessment is also considered an indispensable part of teaching and learning (Govindasamy, 2002). It can be considered as a way of interaction and providing feedback from the instructor to the learner and a medium for the co-learners to interact with each other. Basically, assessment supports the learning approach a student adopts. According to Marcus (2006), a varied combination of assessment activities provides sufficient opportunity for the student to demonstrate learning, while several assessment options allow learners to respond to different evaluation strategies. The choice of assessment methods is an important decision in instructional design (Stephen *et al*, 2007). This is especially more important in a DL programme, in which students often focus heavily on formal assessment requirements. In addition, assessment choices should support intended learning outcomes and also consistent with the desired learning approaches (Stephen et al, 2007).

According to Govindasamy (2002), assessment is typically divided into two types, namely the summative assessment and formative assessment. While summative assessment is used to grade students to demonstrate students' achievement and involves in making a final judgment of the students' achievement relative to the predetermined objectives; formative assessment is used as a diagnostic tool for students and teachers to identify and improve areas of weakness (Williams, 2000). In short, the purpose of a summative assessment is to justify students' grades and a formative assessment help to gather information on what students know and what they can do.

Many researchers (Brown and Knight, 1994; Buchanan, 2000; Henly, 2003) have emphasised the importance of formative assessment in student learning achievement. A learning environment with formative assessment has numerous benefits for learners. Many studies indicate that integrating the DL environment with web-based assessment have positive results (Velan *et al*, 2002; Henly, 2003). Formative assessments refer to activities that are used to help students learn, e.g. short tests and quizzes, question and answer in a lesson, assignments, homework and so on. Buchanan (2000) showed that a web-based formative assessment strategy is able to improve student learning interest and scores. Formative assessment is often done at the beginning or during a programme, thus providing the opportunity for immediate evidence for student learning in a particular course or at a particular point in a programme.

Summative assessment is what students tend to focus on. It is the assessment, usually on completion of a course or module, which says whether or not you have "passed". It is usually undertaken with reference to all the objectives or outcomes of the course, and is usually fairly formal (http://www.dmu.ac.uk/~jamesa/teaching/assessment.htm) and comprehensive in nature which provides accountability and is used to check the level of learning at the end of the programmeme (http://www.provost.cmich.edu/assessment/toolkit/formativesummative.htm). For example, if upon completion of a programme, students will have the knowledge to pass an accreditation test, taking the test would be summative in nature since it is based on the cumulative learning experience. Programme goals and objectives often reflect the cumulative nature of the learning that takes place in a programme. Thus the programme would conduct summative assessment at the end of the programme to ensure students have met the programme goals and objectives and attention should be given to using various methods and measures in order to have a comprehensive plan. Summative assessments can be seen as necessary for accountability and guiding instructions, whereas formative assessments are necessary for learning.

Efforts to implement DL will eventually move towards total automation of administrating the teaching and learning processes by means of a software known as Learning Management Systems (LMS). According to Govindasamy (2002), generally LMS include test builder tools that automate the process of authoring questions. In addition, most of these tools offer easy-to-use templates for authoring automatically scored questions; e.g. multiple-choice questions (MCQ), true/false questions (TFQ), matching questions (MQ), or short answer questions (SAQ). However, essay questions, projects, assignments, and case studies have been totally omitted, yet this should not be taken to mean that these forms of assessment are not needed to perform valid and reliable assessment, as computer marked assessments alone are not appropriate for marking or giving feedback.

Having additional developers of current LMS were probably driven by technology in choosing the question builders to be included in the system (Govindasamy, 2002). Creating quiz questions, possible answer options, assigning weights to the answers, automatically scoring the answers, and programme appropriate feedback for different answers provided by learners require a working knowledge of HTML, Java Script, and other programming languages. This is definitely too much to expect of instructors, therefore, the developers of the LMS probably felt it was necessary to provide instructors with these tools. In order to assess students by means of projects, case studies, assignments, and other artefacts of learning, what the instructor would normally do is to post the message on the bulletin board. Students would then be able to complete their assignments and submit their work to the instructor via e-mail or upload it as a web page for the instructor to assess manually (Govindasamy, 2002).

Upon receiving 'non-standardised' comments from tutors, students would then be encouraged to discuss the comments made with other co-learners within the DL community through discussion board participations and other medium of interactions. This is considered as a way to encourage co-learner interactions within the DL settings. Even while in the process of completing the projects, case studies, assignments and other forms of assessments, students are encouraged to discuss and interact with other co-learners within the DL community.

7. Web-Based Assessment Tools Available For DL

Educators usually spend a lot of time in creating assessments to measure students' knowledge and comprehension. Among the advantages of educational technologies are the web-based assessment tools made available to provide feed-back and improve co-learner interactions listed as follows (Ley, 1999):

- *Discussion board participation*
  According to Savage (1999), students seem to perform better when the discussion boards (or asynchronous communication) are required, where participation is 'rewarded' by a grade. This incentive of a grade brings a higher level of participation to the discussion, where students engage in dialogue begun by the instructor but often taking off on its own soon after (Greenlaw and DeLoach, 2003). Moreover, students then become co-constructors of the materials, examine alternative viewpoints and reach a consensus on a topic together (Greenlaw and DeLoach, 2003). Hence, discussion board participations can be seen as a mechanism in improving the interactions between co-learners within the distance learning settings.

- *Online quizzes*
  Online quizzes enables the instructor to regularly assess student understanding of the materials presented (Martyn, 2003), thus keeping the instructor on track of the students' performance.

- *Electronic paper and project submissions*
  Paper and project submissions can be performed using the Digital Drop Box, or file sharing. By submitting the paper electronically, students do not have to make physical contact with a

particular location in order to submit, and, there is less chance of the instructor losing the paper (Ley, 1999). In addition, an electronic receipt is automatically generated when the instructor receives the submission, enabling accurate records to be kept of who submitted the assignment and when (Thomas *et al*, 2002).

- *Reading outside of the assigned textbook (including hyperlinks and electronic formatted documents)*
  By posting hyperlinks to sources of information, and labelling them as required or recommended, the instructor can share these sources of information with students very quickly and easily at any point during the course (Horton, 2000; Palloff and Pratt, 2001). This therefore also encourages discussions and interactions between co-learners on the topics and information shared by the instructor.

  The internet also offers helpful resources that can be used to reduce the time it takes to create rubrics for projects, experiments, portfolios, and other performance-based items. There are also online resources to generate traditional, formative and summative assessments such as True/False and multiple choice questions.

8. Web-Based Assessment Tools within the School of Built Environment, University of Salford.

Based on the case studies conducted on the two DL Master programmes within SOBE, the following results have been achieved:

8.1 MSc 1

This programme delivers lectures through “Horizonwimba” and corresponds with the distance learners through emails generally. “Horizonwimba” is being used to accommodate for the need of using audio and visual modes of communication between the tutor and the learner. The visual and audio communication is accomplished through a web conferencing based system capable of establishing video and audio based communications between the tutor and the learner. It uses the voice transfer, application transfer and chatting facilities to deliver synchronous lectures. One of the problems both tutors and learners encounter in utilising web conferencing is the time that it takes to learn the various functionalities of the tool (Keraminiyage *et al*, 2006).

As mentioned in the previous heading, electronic paper and project submissions are seen to be one of the web-based assessment tools made available to provide feed-back and improve co-learner interactions. This programme has adopted written coursework comprising legal scenarios as a method of assessment which students will then submit via Blackboard (Bb) once completed. Any questions or enquiries regarding the coursework can be discussed with the DL tutor through email. There was no emphasis on co-learners interactions when deciding on the method of assessment to be implemented for this programme. Although this type of assessment is considered to be one of the web-based assessment tool available; it does not really encourage co-learners interactions unless if the DL tutors promotes the students to discuss and interact with co-learners by starting up a discussion forum in conjunction with the coursework in a discussion board or any other means of communication medium.

According to the DL tutor, no other web-based assessment tools have been used within this programme. There have been reports from students regarding the late feedback that they get back from the DL tutors. From the interview conducted, the DL tutor suggested that co-learners interactions through web-based assessment tools could be improved by conducting more group work assignments, support more interactions and discussions through discussion boards, emails and chat rooms.

8.2 MSc 2

This programme is taught via the internet with support that takes the form of an induction and other events such as networks that are all optional, plus a summer school that has a compulsory attendance requirement. Lecture materials are presented in accessible format which comprise text, diagrams and drawings (for which descriptor alternatives are available) and video presentations (for which audio and text captioning are available). Tutor support is provided via online tutorials, group discussions and individual communication (i.e. through email). Learners not only can engage with other co-learners formally through tutorials and email based group discussions but also informally through the student common room. The discussions and tutorial support is given both synchronously (time tabled online discussion forum) and asynchronously.

The method of assessment for this programme is designed to evaluate the student's abilities in achieving the intended learning outcomes for the module. During the start of the module, students are provided with details of learning activities and assessment dates. Students then participate in learning activities and non-assessed formative feedback is provided to them during the module to assist with motivational reinforcement. For each module, students are required to complete a piece of end assessment and the nature of this varies according to the module. In one of the modules, students' work was authenticated by practical assessment through an access appraisal and audit. The end assessment is considered as an electronic paper and project submission.

Based on the information given by the DL tutor, although it is found that no specific web-based assessment tools have been used for this programme, interactions between co-learners is basically encouraged through tutorials and email based online discussion forum as mentioned before, as well as interacting through the student common room. This is in line with the web-based assessment tool made available to provide feed-back and improve co-learner interactions as mentioned by Ley (1999).

9. Conclusion and Way Forward

The literature review along with the findings from the initial interviews done on DL programmes within the School of Built Environment, University of Salford, UK have provided the methodological basis for this paper.

Most of the DL programmes within SOBE delivers lecture materials in accessible format which comprise text, diagrams and drawings (for which descriptor alternatives are available) and video presentations (for which audio and text captioning are available) through online environments such as the "Horizonwimba". The delivery methods currently used within the programmes are both synchronous and asynchronous. The result from this study identifies that there is a lack of implementation of specific web-based assessments tools within the DL settings as per the various online tools available for online learning. However, several structural considerations of using some of the DL tools such as the nature of the student community (students with various disabilities) imposes constraints on the use of some of the tools although they provide opportunities for improving interactions among the co-learners.

Based on the in depth literature, web-based assessments tools have been found to help improve co-learners interactions within DL settings. Most DL programmes have just gone for the traditional assessment method, which is the written coursework due to lack of emphasis on co-learners interactions when deciding on the method of assessment to be implemented. Co-learners interactions within this method of assessment could be improvised by encouraging learners' interactions and discussions through discussion boards, chat rooms, etc. Written coursework could also be done as a group work instead of individual.

Further interviews will be conducted within SOBE for all the other DL Master programmes, which will enhance the guidelines on improving co-learner interactions within DL settings. The next phase will concentrate on other schools, faculties at University of Salford and finally on other HEIs in the UK and overseas.

Exploring the Effectiveness of an Electronic Classroom Communication Response System

Ian Frame, Amanda Hayler and Jo Bowman
Anglia Ruskin University
Faculty of Science & Technology
Department of the Built Environment
Bishop Hall Lane
Chelmsford CM1 1SQ
(c.i.frame@anglia.ac.uk)

Abstract

The growth in career interests in the built environment and recent changes to the structure and curriculum at Anglia Ruskin University has resulted in increased numbers of students studying the core subjects of building technology and services. Large lecture sizes create difficulties in engaging all students in the learning process, with particular problems of maintaining student attention, promoting discussion and debate, and checking student understanding of the subject matter. Feedback opportunities are also very limited. This paper gives an overview of how electronic classroom communication personal response systems (PRS) can be used to overcome some of these difficulties. This includes a brief description of how the technology works, examples of potential uses and benefits, and an examination of some of the issues to be aware of when using PRS. It is clear that the technology itself does not guarantee success, but, if used appropriately, there is evidence that it can have a positive effect on student learning, particularly when used in large group settings.

Keywords: Lectures, handsets, interactive, discussion, student engagement.

1. Background

1.1 The Problems of Teaching Students in Large Class Settings

The impact of the new curriculum changes at Anglia Ruskin University, introduced in September 2006, has produced fewer and larger credit modules (an increase in size of modules from 10 and 20 credits to 15 and 30 credits). In the Department of the Built Environment, the importance of Construction Technology and Services on these programmes has been increased, with 30 credits in Stage 1 and 30 credits in Stage 2. A deep understanding of this core area is central to the development of built environment graduates. Both of these changes have resulted in many more students in much larger groups - classes comprise 150 or more students with contact time of three hours per week, consisting of a lecture, workshop and tutorial.

With the move towards mass higher education, there may be an increased risk of student failure in the early parts of course provision. Firstly, with an increased number of mixed ability first year candidates, it is dangerous to assume that all students can be treated as mature adults who are well motivated to undertake their own learning. Secondly, the increase in class sizes counteracts substantial educational research that stresses the necessity of engaging the student with the subject matter in order to foster deep and lasting learning (see, for example, Laurillard, 2002 and Mayes, 2001). Engagement in the learning process is the key to success, but how can lecturers engage with students in large lecture groups when the amount and quality of interaction is limited and many students seem determined not to learn?

In his research project on student failure, Frame (2003) observed that some of the less able students:

- don't turn up to lectures at all (popular technique amongst failing students)
- turn up late, bring nothing with them, and sit at the back
- don't listen to the lecturer, instead they just copy everything down from the data projector (very effective ignorance strategy)
- never read their notes or handouts later (this risks reinforcing any accidental learning that has taken place)
- talk to friends in class, send text messages to each other, or listen to their MP3 players
- simply look out of the window, doodle, scribble and generally daydream or even sleep (popular on Friday afternoons)
- never make eye contact with the lecturers, as this may accidentally convey interest in the subject (a very dangerous learning activity)
- never bring a calculator for the more mathematical sessions or possess one that is so complicated that no one knows how to use it
- never ask any questions or answer any questions.

And if all else fails…

- divert the lecturers onto their favourite subject, away from the topic in hand (in the male-dominated built environment, football or cricket is a useful subject, or gossip about another lecturer always works).

For these students, conventional means of teaching in the lecture theatre may make it difficult for learning taking place. New techniques may be needed to ensure that the less motivated students are encouraged to behave like their more able counterparts in ways that promote learning.

Many genuinely interested and able students may still however have difficulties making the best use of the large lecture situation. Some students:

- are intimidated by the size of the group
- misunderstand the nature of learning and think that It is about being a passive listener rather than an active learner
- do not want to draw attention to themselves by asking embarrassing questions
- have difficulty concentrating for long enough periods (the concentration span of students during lectures is often quoted as 20 minutes)
- have few ways of checking on learning during the lecture.

It can be very difficult to stimulate, encourage and manage useful dialogue or debate in a large class setting. Question and answer techniques can be effective, but sometimes are just limited to a sub-set of the group responding rather than all students. Additionally, students at the back of the lecture may have difficulty hearing student comments at the front. In some lectures the flow of information is largely one-way, so lecturers will have difficulty in assessing if students are experiencing problems (see Figure 1). There is often little opportunity to obtain quick feedback that would assist in changing teaching approaches to meet the needs of students, particularly in the identification of those students who may require extra help and attention. This can facilitate the desire of the less able student to feel securely hidden within the large cohort.

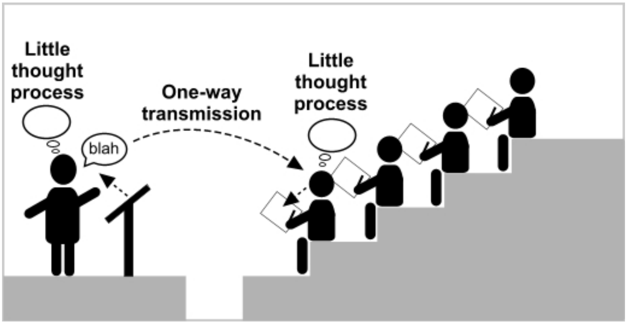

Figure 1 Transmission of information in the large lecture theatre

One definition of ‘a lecture’ useful to keep in mind is that, if you are not careful, a lecture is the means of transfer of information - from the lecturer’s notebook to the students’ notebook, without stopping to register in the brains of either. Thus, real meaningful learning in the lecture theatre may not occur.

A very simple model of learning modified from Race’s work (2001) is:

Doing + Feedback + Reflection + Modified Doing + Final Evaluation

= Proof of Successful Learning.

If all these components are present, candidates should have a strong chance of being successful in their studies. This can be very difficult to achieve in short modules delivered over one semester; during which perhaps only doing plus final evaluation takes place. There is little time for students to submit work within the module, receive meaningful feedback from the lecturer, reflect on it and then submit new work before undertaking the final examination not sure whether they are prepared or not. This lack of time for feedback may increase the likelihood of student failure in this final examination. One of the best ways of learning is to get on and do it, have a go and not be too worried about the risk of failure. Indeed, failure often has more of an impact and usually results in a change in behaviour reducing the risk of further failure. This failure however must take place before the final evaluation. Rust (2002) argues that we need to "build in regular tasks" to help students pace their learning. For this to be achieved however, students need regular feedback on what is going well and what is not. The challenge for lecturers is to devise methods of active learning with regular feedback to students on their performance, without producing a work overload for both student and staff, all within the very short time-span of a 12 week semester. Meaningful feedback can be achieved with small groups of students but becomes very difficult when lecturers are faces with very large (150+) cohorts of students.

2. Electronic Classroom Communication Personal Response Systems

In order to address some of these weaknesses, the Department of the Built Environment at Anglia Ruskin University is considering new ways of motivating and stimulating students in the subject matter in large lecture and tutorial settings. One possible solution is to implement an electronic classroom communication personal response system (PRS). Most people's experience of this type of technology is in popular television programmes, such as "Who wants to be a millionaire?" where the participant can ask the audience to assist in the response to difficult questions. This technology is increasingly being used within the higher education sector, as it enables the lecturer to interactively engage with a large number of students at the same time.

2.1 What is an electronic classroom communication personal response system?

The process of using a PRS, illustrated in Figure 2, involves the lecturer posing a question, which can either be carried out verbally or displayed using presentation software or from within the PRS software itself. Each student has a handset that allows them to choose the preferred option for the answer. The handset is then used to transmit this information to a receiver which is attached to the lecturer's computer. The software can be used to aggregate the responses and produce a graphical representation of the results, which can be displayed to the students via a data projector. These results can be discussed and the lecturer can then choose how to proceed with the next part of the lecture.

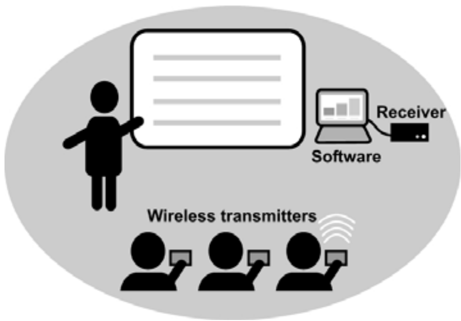

Figure 2 How an electronic classroom communication response system works

The Department of Built Environment is planning to pilot the use of a PRS with students during the academic year 2007/8. The system being used in the pilot study is the InterWrite PRS (Personal Response System) RF which consists of the following features:

2.1.1 (a) Handsets

These pocket-sized radio based handsets (Figure 3) comprise a variety of buttons for transmitting responses to different question types (such as multiple-choice, true/false and numeric questions). They include an LCD display that enables students to see their answers, as well as notification that their answer has been received. Each handset is encoded with a unique number that can be mapped to a student's name or identity number.

Figure 3 Radio frequency handset

2.1.2 (b) Software

The software gives the lecturer the flexibility to create questions within the PRS and/or utilise PowerPoint presentation slides. The lecturer can set up parameters such as time limits, number of choices, number of chances, and other options, as well as import questions from external sources. The lecturer can also select whether answers are anonymous (so no records are kept on individual responses) or known (where each response is recorded in a data file). With the latter option, individual responses can be graded and the results can be recorded and exported to a common Excel format.

2.1.3 (c) Receiver

The handsets transmit to the receiver which uses radio technology. This technology is faster in operation and more accurate in receiving signals than infrared. One receiver can support lecture halls of up to 2000 students.

3. The potential benefits of using an electronic classroom communication response system

As with any technology, a PRS is a tool rather than a teaching approach. Its educational impact, therefore, depends on how effectively it is used. Without careful consideration of how the technology can enhance the learning experience, there is a danger that its implementation could have a negative impact on both the student and the lecturer. Additionally, it is worth noting that a PRS is not necessarily introducing anything new to the lecture theatre - many interactive techniques have been implemented through non-technological means (see, for example, Bligh, 2000). However, teaching large group sizes presents particular issues that make it difficult to encourage interaction between students and between lecturer and student. In the literature reviewed, PRS has been used in a variety of ways, with students at all levels of education and in a range of subject areas. This next section summarises some of the uses and potential educational benefits of using this technology.

3.1 Encouraging participation

The main advantage of this technology is that it enables the active involvement of large numbers of students, not just one or two individuals - a major weakness of conventional lecture teaching. As Draper et al (2002a) states, the equipment requires “each learner independently to generate an answer whereas otherwise only the handful who put hands up really do this”. As such the lecturer receives responses from all students, rather a small section of the group. A common approach, based on Mazur’s (1997) “peer instruction” method, is to pose a question that students have to answer without thinking about it for too long. Without revealing the answer, the lecturer asks them to discuss it with their neighbour, which involves having to provide explanations and reasons for their choice. They are then asked to attempt the question again (Draper et al, 2002b). In Stuart et al’s study (2004), they found a greater number of students giving the right answer on the second attempt and concluded that it was likely “that the students who had a better grasp of the subject were able to convince their neighbour to change their mind and vote differently the second time.”

3.2 Providing timely feedback

A common problem in conventional class settings is the provision of suitable feedback to students about their performance. Often students have to wait until assignments are marked and returned before they receive any indication of how they are doing. With a PRS, answers are marked electronically and automatically, so feedback on performance can be given almost immediately. For students, the system allows them to see how their performance compares to the rest of the group and enables them to measure their own understanding. For lecturers, the system not only provides them with “a very useful means of checking students’ understanding of material covered”, but they can “more accurately determine what material should be revisited in tutorials, as well as in the lectures” (Elliott, 2003). In Draper at al’s (2004) study, one lecturer commented that “I could see exactly which points I had not conveyed clearly and could rectify it straight away”. The system can be also used for evaluation purposes in the same way questionnaires are used for soliciting student feedback about the overall course. The advantage of using a PRS for conducting course evaluation is that it can actually benefit the student group that provides the feedback - it can be done at regular intervals (rather than at the end of a course), it takes minutes to implement (rather than days) and enables modifications to be made during the current academic session (rather than a year later) (Draper et al, 2002a).

3.3 Increasing confidence levels

As Draper et al (2004) points out, it is not hard “to imagine that a first year student in a group of 300 people they don’t know, faced by a lecturer they have no personal relationship with, is reluctant to answer in public”. One way to foster student confidence at the beginning of a class with new students is to use the system for icebreaker activities. Through informal questions that elicit some background information about the group (such as age, gender, interests, etc.) and displaying the responses, mutual awareness is raised which may contribute to the feeling of belonging to a group (Draper et al, 2002a). The use of a PRS to display collective responses to the whole class can also be a reassuring experience for many students because they can see that other class members are thinking along similar lines. The anonymity of the system also provides better privacy than conventional ways of soliciting student response (such as 'show of hands' type activities) which is more likely to encourage participation from less confident students (Sharma et al, 2005). Additionally, the more accurate counting of the responses (compared to, for example, guessing the number of a show of hands) can make all students feel that their views are important, “and are not just lost in crudely approximate estimates” (Draper et al, 2002b).

3.4 Issues to consider when using an electronic classroom communication response system

While it is evident that the PRS-facilitated activities described above can contribute to creating a lecture environment that is active and engaging, the benefits of using the technology very much depend on how effectively it is integrated into the learning and teaching experience. In Draper et al’s study (2002a), student feedback was poor when it was felt that insufficient preparation had gone into implementing the technology and it was just being used ‘for the sake of it’. Effective use of PRS, as an integral part of the lecture, not only requires clear pedagogic goals, but, moreover, a willingness of the lecturer to move away from the Figure 1 model of lectures, which views them simply as a means of transmitting content (Van Dijk et al, 2001).

4 Research Pilot Study

The main objectives of this current project are (1) to review the added value of electronic classroom communication systems in large class settings, and (2) to ascertain whether the technology can help to address the issues of student engagement and motivation in the teaching of Built Environment students. The results of this work carried out in Semester 1 September 2007 to December 2008 will be presented at the conference as well as a demonstration of its use with delegate participation using the handsets.

A range of evaluation methods are being used, including:

- Observation of lectures (with and without the technology)
- Short informal interviews/ focus group discussions with sample groups of students
- Short informal interviews/ focus group discussions with lecturers
- Mid and end-of-semester surveys for students and lecturers (web-based via a VLE)
- Qualitative and quantitative analysis of the response data that is automatically collected by the electronic classroom communication systems.

One of the values of this PRS system is that at a conference presentation, delegates can be given the opportunity to experience for themselves the value of a PRS system by answering multi-choice questions using the handsets provided. They can express their views by voting on whether or not they feel that the system could be of value to them and in doing so, become part of future research finds.

5 Conclusions

This paper has outlined some of the problems and issues that can be encountered when teaching large lecture classes. It has explained the nature of one possible solution to overcoming some of these difficulties, in the form of PRS. Through a review of the literature about PRS, this paper has discussed some of the potential merits of using the technology, as well as some of the possible pitfalls.

The pilot study being conducted during the academic year 2007/08 will assess the added value of PRS (what can this technology provide that conventional class settings cannot?) and appraise how appropriate use of the technology can assist in increasing student participation and engagement with the subject matter in large class settings. Markers that will be important in assessing the success of the study will include such factors as: improvements in summative assessment results (exam marks), improvements in retention rates, improved student attendance at lectures, and favourable data from the evaluation surveys.

Alongside the potential benefits outlined earlier, it is hoped that the technology will assist in the sharing of knowledge about current practice across professions that is not easily obtained via the conventional class setting. Given that students are drawn from varied discipline backgrounds in the modules covered in this pilot study, this would not only benefit the students from different disciplines, but also inform the lecturer about up-to-date developments within that professional practice. Teaching staff will need time to become accustomed to the technology and develop its usefulness for their own teaching purposes. It is envisaged, though, that the sharing of experiences can be used to develop good teaching practice with using PRS, as well as build on work being carried out within Anglia Ruskin University and elsewhere.

Abstract

Quantity surveying measurement adopts prescriptive processes which are underpinned by an understanding of construction technology. The rules for measuring are complex, and are designed for experienced practitioners. Some students struggle to acquire the mix of skills and knowledge within the timeframe allowed. At Newcastle University (Australia) we are preparing high quality teaching and learning materials for both on-campus and on-line distance learning students. We are collaborating with the Department of Civil and Building Engineering at Loughborough University (UK) to develop e-learning measurement packages utilising 3D images. This paper describes and discusses some of the merits and challenges of the approaches we have adopted. The findings of an evaluation survey are also briefly described as well as plans we have for future developments.

Keywords: e-learning, measurement, quantity surveying.

1. The Context

According to the Australian Institute of Quantity Surveying [1] quantity surveyors get their name from the Bill of Quantities, a document which itemises the quantities of materials in a construction project. The quantities contained in bills of quantities are measured from design drawings, to be used by the contractors for tendering and for progress payments, for variations and changes and ultimately for statistics, taxation and valuation. Various dictionaries provide similar definitions including: *cost assessor for building work: somebody who assesses the cost of a construction job based on the amount of labour and materials required to complete it* [2], and *a person whose job is to calculate the cost of the materials and work needed for future building work* [3]. It is clear that quantity surveyors need to measure what goes into a building before they are able to assess costs. Indeed the Australian Institute of Quantity Surveying [4] considers measurement / quantification as a basic quantity surveying ability.

This need for would-be quantity surveyors to develop measurement skills is set in a changing job environment. In Australia, a buoyant construction industry is currently fuelling high student expectations. Job opportunities for graduates as well as for students as part-time employees are attractive. Students embarking on their studies come from a wide variety of backgrounds. Many are of mature age and already have a construction background. Few are female. Many are highly computer literate and expect to engage with their studies using computer systems. An increasing number bring with them financial imperatives of having to work to support their tuition. This latter point is emphasized by Mills and Ashford [5] in their investigation into part-time employment of construction management students. They identify a trend of increasing levels of student engagement in the workplace. More recently an Australian Vice Chancellors' Committee report [6] entitled 'A summary of findings from a national survey of students in public universities' confirmed that increasing financial stress was undermining students' abilities to study effectively.

These financial pressures cannot be ignored. A response that the National Tertiary Education Union Newcastle branch president Bert Groen [7] recently suggested might be occurring is where academics ask students to choose between their work and their studies. This is clearly unsatisfactory, and is obviously not to be advocated. Students require flexible alternatives that respond not only to their pecuniary requirements, but to different ways of learning that many of them engage in.

Barnes, Marateo and Ferris [8] cite Bonamici, Hutto, Smith, and Ward (2005) who claim that the current (Net or 'Internet') generation is unique in that it is the first to grow up with digital and cyber technologies. They observe that not only are NetGeners acculturated to the use of technology, they are saturated with it. By the time s/he has reached 21 years of age, the average NetGener will have:

- (spent) 10,000 hours playing video games,
- (written / responded to) 200,000 e-mails,
- (spent) 20,000 hours watching TV,
- (spent) 10,000 hours on cell phones, and
- (spent) under 5,000 hours reading.

The last point warrants further consideration. Anecdotal evidence suggests that many lecturers teaching quantity surveying courses may have unrealistic expectations of their students' reading skills. If Barnes et al's [8] data are indicative of Australian university students, lecturers need to recognise that the skills students enter University with are evolving and that many prefer to use digital materials rather than paper. Indeed, some staff may be structuring their teaching based on traditional learning preferences rather than those of NetGeners.

To further complicate the issue, quantity surveying students need to be able to ‘read’ construction drawings. To do this students need an amalgam of skills, knowledge and understanding: they need knowledge and understanding of construction materials and construction technology; they need to be able to visualise how various components fit together; and they need to have an understanding of construction plant and equipment, occupational health and safety issues, relevant legislation and so on. Clearly, measurement might be seen as a ‘basic’ quantity surveying skill, but it needs to be underpinned in a multitude of different ways.

The approaches to teaching quantity surveying measurement described in this paper are those adopted in the Bachelor of Construction Management (BCM) program in the University of Newcastle, Australia. We have responded to some of the abovementioned challenges in several ways.

- We offer our BCM program in face-to-face as well as on-line modes. This allows our students to study on-campus or as distance-learners, and provides them with the flexibility to decide at what pace to progress their studies.

- We deliver our courses using problem-based learning approaches.

- We have collaborated with the Department of Civil and Building Engineering at Loughborough University (UK) to develop several on-line measurement tutorials. These respond to students’ NetGen skills by harnessing the appeal of information technology, and exploits students’ preferences for engaging with e-materials. The tutorials have been developed by industry practitioners and are presented in a professional and engaging manner. They are short and ‘punchy’ (none are longer than 12 minutes), and can be viewed through Blackboard (the learning management system [LMS] our University uses) and / or downloaded to an iPod or to a Windows based Personal digital assistant (PDA).

This paper briefly describes the skills involved in quantity surveying measurement, illustrates the materials we have developed and then describes how they have been used. Indicative student evaluation data are also presented as well as brief plans we have for future developments.

2. The skills involved in measurement

In their paper on quantification skills in the construction industry, Fortune and Skitmore [9] comprehensively summarise traditional measurement skills and competencies. They cite Fletcher and Bannister (1931) who identified the "essential" attributes of a person quantifying construction work. These include: a thorough knowledge of building construction; acquaintance with the ordinary rules of mensuration; knowledge of the customs of each trade; tact; patience; accuracy; energy; common sense; initiative; and imagination to visualise building design details. Fortune and Skitmore [9] also refer to Willis and Newman (1988) and add to the aforementioned list the ability to write clearly, take care, think logically and possess a sound knowledge of building materials. Furthermore, Fortune and Skitmore [9] note that many of the qualities Mudd (1984) considered to be associated with contractors' estimators were very similar to Fletcher and Bannister and Willis and Newman but add: a good basic numerate education; experience on site; ability to read and interpret drawings; a neat, methodical and tidy habit; ability to cope with vast amounts of paper work; curiosity; confidence; and the flexibility to pick up useful information. Finally, in this respect, Fortune and Skitmore [9] mention Skitmore's (1985) work with practising quantity surveyors in early design-stage estimating and identify four further perceived characteristics as: good organisational ability; intuition; application; and aptitude.

We acknowledge the traditional skills identified above, but question the relevance of traditional modes of delivery for NetGen students. Many researchers question the efficacy of traditional lectures [10, 11 and 12]. Barnes et al [8] observe that the Net Generation represents nearly 7% of the population today (Bartlett 2005) and with nearly 49.5 million students enrolled in schools in 2003 (Enrollment Management Report 2005), responding to the specific needs of this generation of learners is becoming increasingly important. They go on to observe that the challenge of evolving pedagogy to meet the needs of Net-savvy students is daunting, but say that educators should note that this generation values education. Furthermore they emphasize that these students learn in a different way than their predecessors did, but they do want to learn.

A significant challenge for those teaching measurement is (and always has been) to ensure students have sufficient knowledge and understanding of construction technology to enable them to measure. Measurement (or 'taking off') is a process which requires a technical knowledge and understanding of building or civil engineering technology. However, at the time students are required to learn how to measure, many of them do not yet have this underpinning knowledge and understanding.

Taking-off may be considered analogous to the accounting profession's system of double entry book keeping and requires students to follow a prescriptive set of rules provided by published standard methods of measurement (SMMs). These publications do not explain the taking-off process. They are designed to provide experienced quantity surveyors with rules for taking-off in a standardised manner and rely heavily on readers understanding the 'technology'.

From a teacher's perspective the challenge lies in teaching SMM based taking-off processes to students who have just enough knowledge of construction technology to comprehend the measurement rules. This needs to be done without losing focus on demonstrating taking-off. Traditional lecture based approaches deal with taking-off and technology as two separate topics. Students learning taking-off have to continually refer to technology texts which are generally not compiled in the same order as SMMs (There are very few published construction technology texts that complement SMMs). This is clearly frustrating for students and must hinder their learning. We have adopted a different approach. By judicious use of image capture software and 3D modelling we have blended the necessary construction technology with the teaching of the measurement process as will be seen in the following sections.

3. Description of the QS materials

We have developed digital learning materials in a manner that enables them be used in a variety of ways including lectures, tutorials, or as reference materials. The range is due, in part, to the concise and focussed presentation we have adopted, and represents a continuation of our earlier work into Integrated Learning Objects [13 and 14].

The materials comprise:

- Video presentations which describe relevant measurement procedures and incorporate relevant documents such as selections from the Australian SMM [15], dimension paper, construction drawings, site layout plans and site photographs

- Supporting documentation including drawings and specifications (in hard as well as softcopy)

Materials for the following topics have been developed:

- Taking off and the Australian SMM

- Siteworks

- Excavations

- Concrete, formwork and reinforcement

Further materials for the structural steelwork, masonry and roofing are to be developed for delivery in Semester One, 2008.

4. Development of the QS materials

The QS materials were developed using two software packages, Camtasia Studio [16] and Google SketchUp [17]. Camtasia is a fourth generation screen capture program that provides a timeline which accepts video, images and audio. Video and images are arranged on a timeline and finally a voice-over is added. Figure 1 shows a developer's view of how these media are combined on screen. In addition, Camtasia provides a number of tools that enhance useability from an end-user's perspective. It is possible to 'zoom' and 'pan' to explore aspects of interest, and to access additional information / explanation by clicking on symbols which are available at various locations.

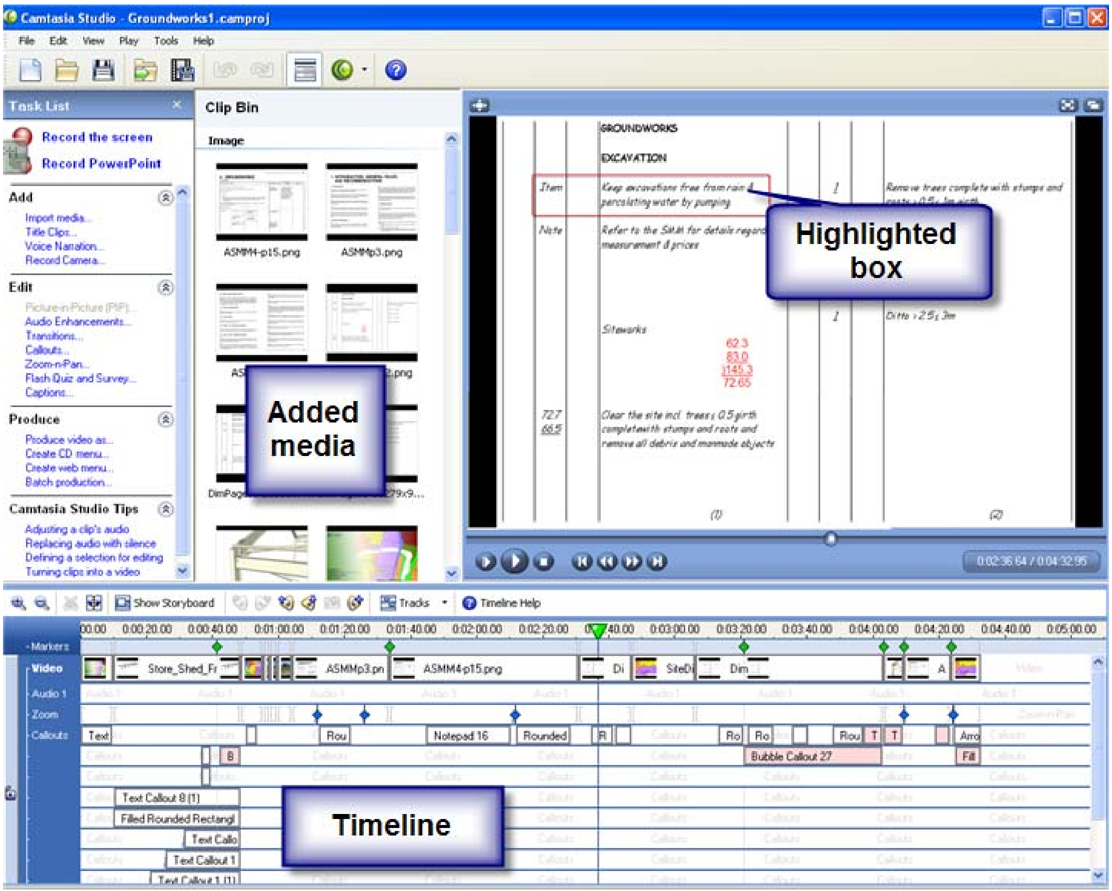

Figure 1: Camtasia workflow with media, images/video inserted on a timeline

Camtasia provides output in several formats including AVI, Flash, WMV, QuickTime, RealMedia, iPod video and mp3 audio. The Flash format has significant advantages; it streams particularly well without dedicated streaming software and allows interactivity via hot spots (which, when invoked, take users to another image, video or URL).

5. How we have used the QS materials

The digital measurement materials may used in a number of different ways.

- When used in lectures the materials may be presented as a discrete element around which discussions ensue.

- To service our distance learning students we use Lectopia, a system which gives distance learners access to lectures delivered on-campus. Lectopia allows lecturers to record their lectures from suitably enabled venues. Staff present their lectures as normal, and what they say and display (from their computer or visualiser) is recorded in a digital format. Once a lecture is over it is automatically processed and is ready for students to access through Blackboard within a short space of time. Distance learners are thus able to engage with the measurement materials in a similar manner to on-campus students.

- Our student population is dispersed over a wide geographic area. Some students work on remote construction sites without Internet access, and in these cases we make CD versions of the measurement materials available to them.

- Self paced learning is also possible. Students can work through the materials at a time and pace that suits them. When used in this way the materials are delivered through BlackBoard. iPod and Windows PDA versions are also available.

- We have also used the measurement tools during tutorials. Students are shown the materials and discuss various aspects face-to-face with tutors (for on-campus students) or via electronic discussion boards on our BlackBoard LMS (for distance learners).

We have explored a range of delivery routes. The measurement materials have proved to be versatile, and provide benefit to students as well as to staff.

6. Student evaluation

A representative sample of students (28 out of 76 students, 37%) responded to an on-line survey. They were split almost evenly between on-campus and distance learners ensuring that the views of both cohorts were represented. The majority (76%) used the measurement materials on-line from home (two students used iPods and two used PDAs), while 12% accessed the Internet from work and a similar percentage gained access from University. Three students experienced technical difficulties using the materials. The problems they encountered included the font size displayed on the iPod version, sound quality and old hardware. Our intention was to keep the materials short and 80% of students said that the length of the tutorials was about the right length of time. The remaining 20% felt that the materials were too short. We also anticipated that students would access the materials several times. This was indeed the case, with 64% of respondents saying that they had accessed each tutorial 2 to 4 times. Virtually all students found the materials easy to use. When asked whether they thought the materials would help them with their assignments, 88% of students said yes, and a similar percentage said that they would like to see more tutorials prepared in this way. Some free format questions were also asked. Students were asked how the materials had helped them. They said:

- It was explained in a straight forward manner and if I wasn’t quite sure about something I could listen to it again and understand how the example works. Sometimes when you read something its not always as straightforward as hearing it explained.

- It has provided a basic starting point and simplified each step involved in the assignments. It was easy to refer back to when I got stuck.

- It was helpful in that it put into practice what we had learnt in class. It also made some of the more difficult concepts clearer.

- You can go back to sections you don't understand, and listen again. Easy to follow and outlines the areas the tutorials is talking about. The ability to click for more information in some sections is very good.

We wondered whether students would prefer on-line tutorials to face to face ones. Their response was ambiguous: 56% wanted on-line as well as face to face tutorials, 40% wanted only on-line tutorials and 4% wanted only face-to-face tutorials. When asked whether they would like to be quizzed about what they had learned from each tutorial, 82% of students said that this would be useful, but did not want these quizzes to count for marks. All students saw 24/7 access as being useful or very useful.

Whilst the above views are acknowledged to be those of a small sample of students, they support our hopes and expectations, and encourage us to continue our developments.

7. What improvements / changes will we implement?

As previously mentioned, many novice quantity surveying students are not familiar with how to read and interpret construction drawings. A discussion of whether or not these students need to be able to prepare technical drawings before they can fully understand them is outside the scope of this paper. However, many software packages are currently available to help students overcome the limitations of 2D drawings. We have trialled 3D models developed using Google SketchUp and have been encouraged by the ease with which these have been created, and by the verbal feedback students have provided. Google SketchUp [17] is a powerful yet easy-to-learn 3D software tool that combines a simple, yet robust tool-set with an intelligent drawing system that streamlines and simplifies 3D design. From simple to complex, conceptual to realistic, Google SketchUp enables you to build and modify 3D models quickly and easily.

An example of a 3D model for a reinforced concrete pumping station is shown in Figure 2. Students are able to rotate, pan and zoom in on the model to gain an overall appreciation of the manner in which components fit together.

We intend to develop quizzes for students to use in conjunction with the measurement materials. These will be aimed at facilitating reflection and are likely to be non (or minimally) weighted assessment tasks. The questions we ask will provide a focus for students and will provide feedback that they have understood key aspects presented in the materials. Formative assessment, such as the quizzes, are important for giving regular feedback, providing opportunities for revision and for improving reflection and understanding [18].

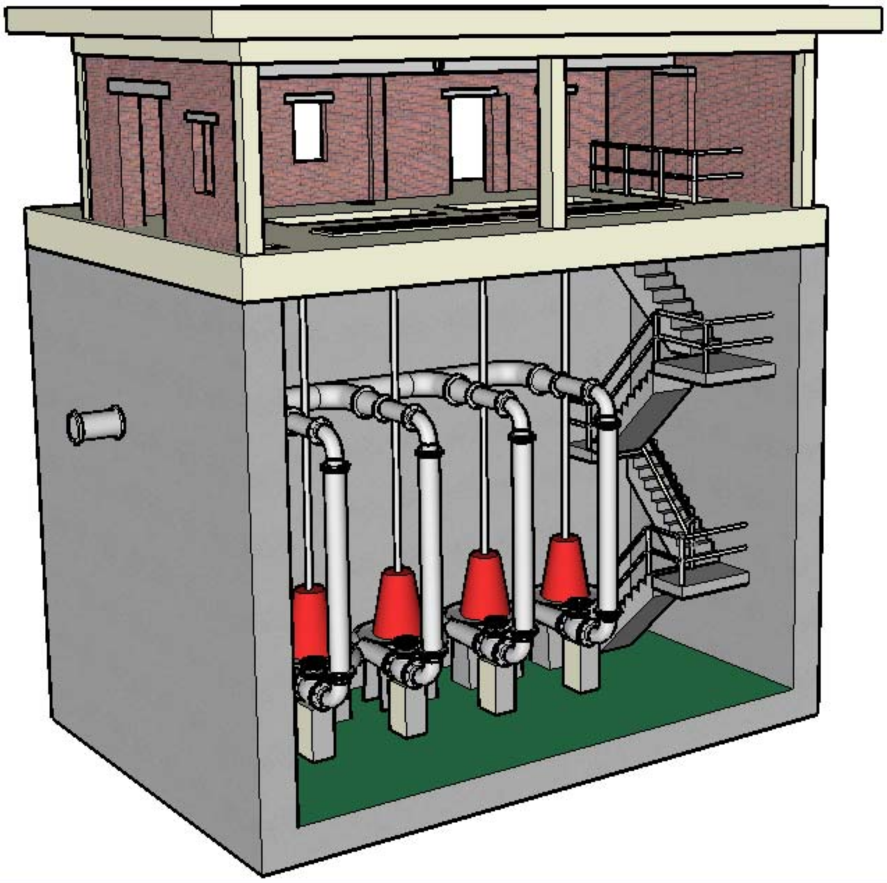

Figure 2: Various views of a pumping station, prepared using Google Sketchup

8. Concluding comments

This paper describes a modest step in harnessing the power of high performance processors now standard in all personal computers. 3D imaging and graphics have come of age and are no longer solely in the domain of design studios and TV stations. We have demonstrated what can be done on a relatively small budget with mature software and imagination. The scope for future development is constrained only by the foresight and imagination of developers. These tools are not intended as a replacement for traditional course delivery. They complement conventional approaches by providing students with convenient access to repositories of knowledge and procedures.

Abstract

Lately, distance studies, which are attempting at the best possible education for students and satisfaction of as many of their study needs as possible, are gaining wider popularity. Online questionnaires are increasingly used to get detailed opinions of distance learning students on various issues of studies. During the project EurAsia, it was identified that VEBER online questionnaire can be a useful tool for VGTU beyond the scope of the project EurAsia. An online questionnaire has been developed to facilitate the process of surveying related to implementation of the project EurAsia. The assessments helped to recognise that this tool helps VGTU to enhance its institutional system related to e-learning. Having identified the potential of this tool outside the scope of the EurAsia project, further experiments have been carried out to assess how this tool can be further developed to accommodate the requirements of the project EurAsia other institutional systems. The research showed that distance learning students not only want to express their opinion about the study process but to be active participants in shaping of strategic alternatives of the study process by electronic means, as well. In order to implement this idea, the authors proposed the Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students and used as a basis to develop the Ethical Web-Based Decision Support System (E-DS). Using the features of the VEBER online questionnaire, the developed Model and the E-DS System the process of distance learning can be additionally humanized and adjusted to ethical norms, which would have a positive effect on the whole distance learning process. Thus the institutions participating in the project EurAsia or offering distance learning studies could use the features of VEBER online questionnaire, the developed Model and the E-DS System in their activities. It would stimulate more efficient application of moral norms in the distance learning process.

Keywords: Distance Learning, EurAsia project, Ethical Decision-Making Models, VEBER Online Questionnaire, Decision Support System.

1. Introduction

The e-learning Master degree studies "Real Estate Management" was introduced at Vilnius Gediminas Technical University (VGTU) in 1999, Master degree studies "Construction Economics" from 2000, and Master degree studies "Internet Technologies and Real Estate Business" from 2003 (see **http://odl.vgtu.lt/**). There are currently 226 master students from all over Lithuania studying in these three e-learning master programs. In order to get the opinion of learners, traditional student surveys were frequent. The participation in the project EurAsia allowed to organise e-surveys. A survey of distance learning students on ethical issues of studies is reviewed in the article as an example.

The VEBER online questionnaire has been used within VGTU distance learning environment to administer student feedback questionnaires and surveys (see [16]). With the success of the VEBER online questionnaire being used in VGTU, the intention of join institutional systems development process within the EUARSIA project is to share the experience and the technology across all the partners and beyond. The practical application of VEBER Online Questionnaire (ethical behaviour of distance learning students at VGTU) within VGTU e-learning environment and proposals for join institutional systems development process within the EUARSIA project are briefly analyzed in the paper on the basis of ethical questions. The authors have developed the Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students and the Ethical Web-Based Decision Support (E-DS) System, which are briefly analysed further in the article.

2. Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students

Corey et al. [18] noted that because ethical codes cannot be applied in a rote manner and they are incomplete guidelines that reflect the values of the majority, practitioners are more likely to respond to a dilemma based on fundamental principles. The proposed Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students is based on ethical principles of autonomy, beneficence, nonmaleficence, justice, and fidelity that are viewed as fundamentals of the stages that make up ethical decision-making. Also, the proposed Model is based on decision-making principles (i.e. principle of a life cycle's analysis, principle of the interrelation of various sciences, principle of multi-variant design and multiple criteria analysis of ethical alternatives and principle of close interrelation between the alternative's priority and the interested parties and their aims). The decision-maker' freedom of choice is stressed in the principle of autonomy. The stakeholder is encouraged to take responsibility for his/her actions and assess the effects of these actions on others. According to the principle of beneficence it is important to meet the integrated university stakeholders (students, student community, lecturers, professors, deans, the Rector's Office, etc.) needs, e.g. physical, economical, social, political, emotional, spiritual, etc. The principle of nonmaleficence is strongly linked to the principle of beneficence and means doing no harm to others.

The principle of justice means the support of equal allocation of burdens and benefits among all university stakeholders. For example, universities must be the places where all of the campus, including the student community, lecturers and the Rector's Office, are actively cooperating to achieve their goals. Almost two decades ago, this fact was noted by Ernest Boyer [8], who claimed: "honesty cannot be divided. If high ethical norms are applicable to students, university staff must also have a perfect record."

Efforts are made to achieve a truthful, ethical and efficient solution, i.e. to optimize the life cycle of the ethical alternative (principle of life cycle's analysis). The problems of truthfulness, ethics and efficiency of the solution may be successfully solved only when the achievements of various sciences, such as philosophy, ethics, Law, psychology, management, administration, economics, etc. are used. The use of a principle of multi-variant design and multiple criteria analysis makes it possible to develop many ethical alternative versions and carry out their ethical and other kinds of optimizations throughout life cycle of the alternative.

Determination of ethical alternatives that are under consideration and their description in a quantitative and qualitative form (VEBER online questionnaire, data bases of best practice, etc.)

Stage 1. Obtaining objective and subjective information about ethical behaviour of stakeholders

Stage 2. Analysis of stakeholders (students, student community, lecturers, professors, deans, the Rector's Office, etc.)

Stage 3. Definition of the problem and determination of the nature of the dilemma of ethical behaviour of students

Stage 4. Search for the description of analogous typical situations in the available literature and a development of the best practice database. Determination of the ethical ideal is made in concrete circumstances.

Stage 5. Determination of the philosophy theories according to which the alternatives will be evaluated and the decision made

Stage 6. Development of comparative tables of ethical behaviour of students

Stage 7. Evaluation of ethical alternatives of ethical behaviour of students

Stage 8. Implementation of a course of action

Stage 9. Monitoring of the action and its outcome

Stage 10. Rehabilitation of the external and ethically advantageous environment in order to avoid potentially conflicting situations or to diminish their negative impact

Figure 1. Main stages of the developed Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students and their relation with EDSS

The above principles are landmarks of the proposed Model and as support to solving the dilema of ethical behaviour of students. In different situations a few ethical principles sometimes oppose each other, and grading them are difficult. According to Garfat and Ricks [17], ethics is no longer about determining "right answers", but whether and how the decision maker decides what action to take. Ethical decision-making is a process governed by ethical principles. Also, when confronted with a complicated ethical dilemma that is not evidently analyzed in codes of ethics, the decision-maker should check with an ethical decision-making model.

Based on the analysis of the above ethical decision making models (Cottone et al. [4], Robson et al. [11], Doolittle et al. [5], Greene et al. [6], Tymchuk [13], Walden [14], Bombara [3], etc) a Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students was developed by the authors of this paper. Some stages of the Model described in the paper (see Stages 1-3, 8, 9) are partly similar to the stages of the models proposed by some other authors. All other stages differ in principle, since the methods of multiple criteria analysis created by authors are applied and also, this Model is meant for the buildup of the Web-based decision support system. The proposed Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students provides a logical system and gradually guides and helps the stakeholder in the creation of acting in a way that includes moral behavior. These stages are the main steps of action and can be shaped into the framework of particular circumstances.

The ten stages of Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students are as follows:

Stage 1. Obtaining as much objective and subjective information about ethical behaviour of students (historical information, institutional, administration, legal, societal expectations and limitations, ethical principles involved, identified conflicts, etc.) as possible. Further, if possible, the decision-makers have to develop suitable arguments on diverse aspects of the dilemma so as to have a high-quality perception of the range of concerns and advantages for each position.

Stage 2. Analysis of university stakeholders (students, student community, lecturers, professors, deans, the Rector's Office, etc.). The university stakeholders are identified as the interested parties who are directly or indirectly influenced by the decision that is to be made. For a better understanding of the current situation, discussions among the various interested parties are often necessary. Also, some ethical dilemmas can be prevented through dialogue between university stakeholders. The discussion should engage all those who are the key university stakeholders, some of who may be the decision-maker and some of whom may be influenced by the decision. The reaction that results from such discussions clears personal values while determining value conflicts. University stakeholders have to act as a team in an effort to come to some commonly suitable decisions. All university stakeholders should accept some responsibility for the existing ethical behaviour of students and have to be a part of any proposed decision. The personal values, theoretical orientation, experience and other stakeholder features play a part in achieving ethical decisions. University stakeholders have to analyze their own value judgments, moral codes, experience with similar ethical behaviour of students, and decide how to avoid injecting personal biases into decisions. Also, the decision maker must examine the values of others university stakeholders. Compromises that may diminish harmful consequences should be analyzed. On the ground of the Model offered, decisions may be made from the viewpoint of one, several or all the interested groups.

Stage 3. Definition of the problem (conflicting ethical principles, value conflicts) and determination of the nature of the dilemma of ethical behaviour of students. According to Joseph (1982), an ethical dilemma is a conflict in which a person must make a choice between several correct and conflicting decisions, generally with some negative consequences. Traditionally, dilemma (ethical, legal/moral, etc.) involves a choice between competing goods with possible harmful consequences. Assessment of a dilemma involves the detection of different conflicting ethical principles. Typically, the ethical dilemmas are inherently problem ethical behaviour of students that do not lead to easy decisions and there is no right or wrong one that can be easily recognized. Therefore, conflict between values of the different university stakeholders leads to an ethical dilemma where there is no easy solution and no right or wrong answer to ethical behaviour of students.

Stage 4. Determination of the philosophy theories (e.g., utilitarianism, deontology, justice, etc.) according to which the ethical alternatives will be evaluated and the decision made. Determination of the ethical ideal is made in concrete circumstances.

Stage 5. Search for the description of analogous typical situations of ethical behaviour of students in the available literature and a development of the best practice database.

Stage 6. Development of comparative tables of ethical behaviour of students. The aim at this stage is to build options for the decision, in preparation for making the ethical decision and arguing for the choice. Results of the generation of all possible courses of action have been submitted in the table. By submission, such a display, of the multiple criteria comparisons can become more effectively supported. As in any problematic circumstances, the university stakeholders search for potential compromises by trying to find one that is most ethical and with the least negative consequences.

Stage 7. Evaluation of ethical alternatives of ethical behaviour of students. A decision maker must examine a large number of ethical alternatives, each of which is surrounded by a considerable amount of information. Ethical alternatives are analyzed along with the involved ethical principles and philosophical theories. The expectations and obligations of different university stakeholders are then considered. Ethical alternative solutions are compared in terms of the possible outcomes and according to the selected philosophical theories. Following on from gathering this information, the priority and utility degree of the ethical alternatives is then calculated. The utility degree is directly proportional to the relative effect of the values and weights of the criteria and is considered on the efficiency of the alternative. This helps a decision-maker to decide what ethical alternative best fit the ethical behaviour of students that is under evaluation (i.e. the best solution achievable given the available resources and the circumstances of the dilemma). Several decisions will have priority and the choice is according to the preferences of different university stakeholders and philosophy theories (e.g., utilitarianism, deontology, justice, etc.)

Priority of decisions depends a lot on whether one group or several interested groups make the decision, because different university stakeholders bring diverse experiences, beliefs, and moral codes into the decision-making process. The Ethical Web-Based Decision Support System (EDSS) developed on the basis of this model enables the analysis of ethical alternatives from the viewpoint of different interested groups. However, there is seldom an ideal decision to an ethical dilemma.

Stage 8. Implementation of a course of action. Implementing the decision may be the most difficult stage of the decision-making process. Ethical decisions are individual choices that may not be shared with other university stakeholders. The decision-maker may be in a solitary situation in implementing some decisions and willing to admit the consequences of a decision that is not supported by others.

Stage 9. Monitoring of the action and its outcome.

Stage 10. Rehabilitation of the external and ethically advantageous environment in order to avoid potentially conflicting ethical behaviour of students or to diminish their negative impact. Truthfulness, ethics and efficiency of the solution depend on the micro- and macro-levels of the external environment. Macro-level factors of the external environment such as religion, the existing cultural, social, ethical dimensions of the country, the executed university policy and the society influence the arising ethical problems and the ethical solution making. The micro-level factors (the university stakeholders, the applied formal code of ethics, rules, criteria of ethical behavior, ethical standards, codes of conduct) stipulate the ethical solution making to a significant degree as well. Therefore, on the grounds of cumulative experiences it is suggested that there be changes under these possibilities of the surrounding environment in order to decrease the possibility of a conflict situation arising in ethical behaviour of students or to diminish their negative impact. Developing an ethical environment also provides a background for ethical questioning, significant exchange, informed decision-making, and human consensus, in which all university stakeholders are satisfied. A few trends of rehabilitation of the external and ethically advantageous environment in order to avoid potentially conflicting ethical behaviour of students are following.

McCabe [9] propose to involve the whole campus community (students, faculty, and administrators) to effectively educate a student. If university only goal is to reduce cheating, there are far simpler strategies university can employ. But if university have the courage to set our sights higher, and strive to achieve the goals of a liberal education, the challenge is much greater. Among other things, it is a challenge to develop students who accept responsibility for the ethical consequences of their ideas and actions. University goal should not simply be to reduce cheating; rather, university goal should be to find innovative and creative ways to use academic integrity as a building block in university efforts to develop more responsible students and, ultimately, more responsible citizens. University campuses must become places where the entire "village" - the community of students, faculty, and administrators - actively works together to achieve this goal. As Ernest Boyer observed almost two decades ago – [1, 2], "integrity cannot be divided. If high standards of conduct are expected of students, colleges must have impeccable integrity themselves. Otherwise the lessons of the ‘hidden curriculum' will shape the undergraduate experience. Colleges teach values to students by the standards they set for themselves."

Students claimed that while they see numerous cases of cheating in higher education institutions and in the society, the role of disciplinary actions is important striving to reduce the amount of cheating in university.

The above-described Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students can provide decision-makers with quite a secure means of making difficult ethical decisions. This model can also help university stakeholders to make the best feasible decision in certain given circumstances. The proposed Model does not make ethical decisions, but explains the process for investigating a ethical behaviour of students. Based on the proposed Model of Multiple Criteria Ethical Decision-making an Ethical Multiple Criteria Decision Support Web-Based System (http://dss.vgtu.lt/ethic/index_eng.htm) was developed by the authors. In order to demonstrate practical application of the Model, a survey was carried out in Vilnius Gediminas Technical University (VGTU). The survey gives a more detailed explanation of Stages 1 and 2 of the Model.

3. Ethical Behaviour of Distance Learning Students at VGTU

The form of a survey was selected for the research of ethical issues related to behaviour of distance learning students in the Faculty of Civil Engineering at Vilnius Gediminas Technical University. The VEBER online questionnaire of 24 questions has been used within VGTU distance learning environment to administer student feedback questionnaires and surveys (see [16]). The experience of many analogical surveys [1, 2, 9] carried out in the world shows that when students think that organisers of surveys will find out the authorship of a questionnaire, then such surveys give the results which distort the real situation greatly. None of students wants to reveal his/her confidential information to the staff of the university.

Therefore all distance learning students could answer all questions anonymously by using the VEBER online questionnaire. The survey consisted of two steps. One step when a student selects the most appropriate answer to the question. The other step when the student specifies the theory of ethics on which he/she based the answer. Theories of ethics were introduced to students before the survey, i.e. the students were briefed on the main points of different theories of ethics. The questionnaire included four main theories of ethics: deontology, utilitarianism, justice and teleology. For example, when carrying out an analysis of university stakeholders, it is expedient to apply the utilitarianism theory. In such an analysis the objectives and needs of university stakeholders can be analyzed, various decision ethical alternatives worked out and positive and negative consequences of these ethical alternatives on university stakeholders that are under consideration can be determined. According to the utilitarianism theory, whether a certain action is considered bad or good depends on its consequences and not on intentions. Utilitarianism says that what is morally right is whatever produces the greatest overall amount of pleasure, happiness, ideal values (freedom, knowledge, justice, and beauty) and preference satisfaction to as many university stakeholders as possible. The criterion of a moral action consists of those rules of conduct, which give most utility to all the university stakeholders. Actions that meet the needs of university stakeholders are considered to be good. However, when conducting such an analysis of the stakeholder's requirements various problems occur. For example, what is of the greatest good for the greatest number of university stakeholders without violating individual rights in different situations? Is it goodness, efficiency, profitability and/or pleasure? Which needs of which university stakeholders are to be given priority? How can one take into consideration the qualitative parameters (health, security, public benefit)? By using experts and multiple criteria analysis methods one can solve these problems, to some extent.

Thirty-nine distance learning students participated in the survey anonymously: 26 male (67%) and 13 female (33%) respondents of ages from 20 to 60. Most students were from 20 to 30 years old (27 people; 69%), a smaller number of respondents formed the group of ages between 30 and 40 (8 people; 21%), and the least number of people were of ages from 40 to 50 and from 50 to 60 (2 people in each group; 5% each).

Given the question whether they would cheat during an examination, 12 students (31%) answered that they would if they knew nothing. Slightly smaller amount of students answered that they would cheat if they were sure that they would not get caught (9 students; 23%). Two students (5%) would cheat during an examination. Seven students (18%) would not cheat during an examination. Six people (15%) would not cheat even if they knew nothing. Three students (8%) would not cheat even if they were sure that they would not get caught. Students based their answers to the question about cheating in an examination on the following theories of ethics: deontology (6 students; 15%), justice (23 students; 60%), teleology (4 students; 10%) and utilitarianism (6 students; 15%).

Similar results have been obtained in other countries too. For example, in 1993 McCabe [9] surveyed nine medium to large most USA competitive colleges and universities, thirty years earlier, had participated in the landmark study of college cheating conducted by William Bowers [2]. Bowers's [2] project surveyed over five thousand students on ninety-nine campuses across the USA and provided considerable insight on how often students were cheating and why. Two outcomes of McCabe [9] 1993 project are particularly noteworthy in comparison to Bowers's results. First, there were substantial increases in self-reported test and exam cheating at these nine schools. For example, 39 percent of students completing the 1963 survey acknowledged one or more incidents of serious test or exam cheating; by 1993, this had grown to 64 percent. In 1993, many students simply did not see cheating as a big deal, so it was easier to acknowledge - especially in an anonymous survey. Second, there was no change in the incidence of serious cheating on written work; 65 percent of students in 1963 acknowledged such behavior, and 66 percent did so in 1993. However, student comments in the 1993 survey suggested that this younger generation of students was more lenient in defining what constitutes plagiarism [9].

Lecturers have the most important role in exercise of ethical standards, because students consult both their contemporaries and their lecturers about their studies process. In order to foster a proper attitude of a student, lecturers must acknowledge and validate academic honesty as the most important value. Without such acknowledgement of values, many students may find cheating meaningful, because they can revert to the secondary school strategies, i.e. cheating to get a better mark and blaming excessive loads, lack of time and providing other similar reasons, i.e. students presume that if lecturers fail to act in cases of obvious cheating they sort of invite cheating. This stimulates dissatisfaction of students who learn honestly. They feel deceived because of lecturer inactivity.

Most students, 28 people (72%), do not consider a peek at notes as cheating, whereas other 11 (28%) claim that a peek at notes may be equal to cheating. Students based their answers to the question whether a peek at notes is equal to cheating on the following theories of ethics: deontology (7 students; 18%), justice (16 students; 41%), teleology (7 students; 18%) and utilitarianism (9 students; 23%).

Three students (8%) would copy a course project or homework of another person, 5 people (13%) possibly would copy, 9 people (23%) possibly would not copy and 22 people (56%) would not copy. Students based their answers to the question about copying a course project or homework of another person on the following theories of ethics: deontology (6 students; 15%), justice (19 students; 49%), teleology (6 students; 15%) and utilitarianism (8 students; 21%).

One (3%) probably would inform against a cheating student, two (5%) probably would not inform against a cheating student and 36 (92%) would not inform against a cheating student. Students based their answers to the question whether they would inform against a cheating student on the following theories of ethics: deontology (6 students; 15%), justice (13 students; 34%), teleology (9 students; 23%) and utilitarianism (11 students; 28%).

Most students (18 people; 46%) probably would allow another student to copy from them during an examination, 16 (41%) people would allow to copy, three people (8%) probably would not allow to copy and two people (5%) would not allow to copy. Students based their answers to the question whether they would allow another student to copy from them on the following theories of ethics: deontology (7 students; 18%), justice (13 students; 34%), teleology (6 students; 15%) and utilitarianism (13 students; 33%).

Eleven (28%) of the respondents would ask help from another student during an examination, 20 (51%) probably would ask for help, five (13%) probably would not ask for help and three (8%) would not ask for help. Students based their answers to the question whether they would ask help from another student during an examination on the following theories of ethics: deontology (10 students; 26%), justice (11 students; 28%), teleology (3 students; 8%) and utilitarianism (15 students; 38%).

Among the actions that are considered the least ethical for students, 24 students (62%) selected informing against another student for cheating or copying of course project/homework, 13 respondents (33%) selected copying of homework or a course project and only two people (5%) selected cheating during an examination.

Analysis of Codes of Ethics of students from other universities showed that such examples of inappropriate student's behaviour as denunciation of another student for cheating or copying of course projects or homework were absent. Thus, according to the Students' Code of Ethics, such behaviour would be ethical; however, the majority of students not only would never inform against another cheating student (97%) but also consider it to be the least ethical student's behaviour (62%).

Students based their answers to the question about the least ethical acts of students on the following theories of ethics: deontology (4 students; 10%), justice (18 students; 46%), teleology (8 students; 21%) and utilitarianism (9 students; 23%). Analysis of Codes of Ethics of students from other universities showed that such examples of inappropriate student's behaviour as denunciation of another student for cheating or copying of papers or homework were absent. Thus, according to the Students' Code of Ethics, such behaviour would be ethical according to all or the majority of theories of ethics.

Two (5%) students would bribe a lecturer to pass an examination, four (10%) probably would bribe, eight (21%) probably would not bribe and 25 (64%) would not bribe. To summarise, six students (15%) would bribe a lecturer in certain circumstances and 33 students (85%) would not bribe.

In December 2003, Group for Social Analysis surveyed students from Lithuanian higher education institutions on corruption. The sample of the survey included 14 universities and 25 colleges. 33% of students who participated in the survey admitted to giving a bribe to a lecturer and 6% bribed staff of higher education establishments. First and second year students are the most bound to bribe a lecturer [10]. Students based their answers to the question about bribing a lecturer on the following theories of ethics: deontology (8 students; 21%), justice (20 students; 51%), teleology (6 students; 15%) and utilitarianism (5 students; 13%).

Six distance learning students (15%) would agree to pay for preparation of homework, a course project or a graduation thesis, 10 (26%) probably would agree, eight (20%) probably would not agree and 15 (39%) would not agree. To summarise, 16 students (41%) would agree to pay for preparation of homework, a course project or a graduation thesis in certain circumstances and 23 students (59%) would not agree. Students based their answers to the question whether they would agree to pay for homework, a course project or a graduation thesis on the following theories of ethics: deontology (5 students; 13%), justice (19 students; 49%), teleology (6 students; 15%) and utilitarianism (9 students; 23%).

We see the following inviting offer in the website of the company "Auksinė Plunksna" which offers graduation theses for sale: "Our country's situation makes students work while studying in order to earn living and to pay for education, which becomes more and more expensive each year. Therefore, the studies suffer, and it becomes more difficult to find a balance in life. What are the choices? To postpone the graduation thesis to the next year or to complete the studies nevertheless?". Without a context, we could think that this company does not suggest ordering a graduation thesis but offers consulting services on specific studying issues instead. In fact, a student who uses services of this or other companies is not a passive observer. He/she must submit exact information about his/her faculty to the company and specify the requests and remarks of his lecturer, the academic adviser, in the course of preparation of the thesis: “The thesis will be written gradually, its parts will be corrected by your academic adviser, thus we grant quality and high evaluation. Practically, the academic adviser is the guarantee of quality: his/her pieces of advice will determine the contents of the thesis”.

These increasingly spreading phenomena cause obvious concerns. Not because of the cheating on lecturers and administrations of higher education institutions but mostly because such acquisition of diplomas is based on a peculiar “clear conscience”. Advertisements of such service companies do not hint on the fact that those who use their services would not be able to get such or even a better diploma with own efforts. The students who earn their grades through efforts of other people probably do not encounter any moral dilemma. Hardly ever they doubt their ability to complete higher education independently, “if they would study”, “if they had time to learn”, “if they were not forced to earn their living”. Thus the circumstances, the general situation of studies and other problems as if not subjected to the student’s conscience are the biggest culprit in this case. The process of studies becomes a most primitive relationship of product exchange based on laws of time saving. Graduation theses are written by those who have time and are acquired by those who can pay for them. Moral issues are usually disregarded in a market [12].

Among the top penalties for cheating students, one student (2.6%) selected a lower grade, three students (7.7%) selected increased tuition fees, seven students (17.9%) selected public announcement of names of cheaters, 14 students (35.9%) selected warning and 14 students (35.9%) selected elimination from the university. Students based their answers to the question about the top penalties for cheating students on the following theories of ethics: deontology (7 students; 18%), justice (19 students; 49%), teleology (7 students; 18%) and utilitarianism (6 students; 15%).

4. Conclusions

In order to humanize VGTU distance studies and to strengthen their ethical nature, the VEBER online questionnaire was implemented and the Web-based Model of Multiple Criteria Ethical Decision-Making for Ethical Behaviour of Students developed within the project EurAsia; the latter was used as a basis for the development of E-DS System. Besides, the performed research allows to make different conclusions. For example, today’s students are more concerned about the reaction of their contemporaries and the university administration to the norms of honest behaviour promoted by staff and administration than about the norms themselves. Indeed, students expect the university administration’s to declare how they should become honest, non-cheating and respectful towards teaching and learning. Even when students hear the statements but watch other students cheating and lecturers being tolerant by ignoring, students will take cheating as a means to pass an exam with a better possible mark. Many students ask: “If lecturers are not concerned about cheating, why should I be?”

Abstract

The aim of this paper is to study the contribution of the new technologies (Search Engine Rankings, Multi-variant Optional Module Design and Multiple Criteria Analysis; Voice Stress analysis, IRIS recognition) to Intelligent Library and Intelligent Tutoring Systems. The article briefly describes use of these newest technologies in e-learning. The authors of the article have developed a voice stress database, which contains students' answers given during an examination, and a specific algorithm, which is a core of the Voice Stress Analysis Subsystem and which can evaluate a student's knowledge by giving a rather precise mark after a psychological test performed prior to the examination. A similar research of IRIS recognition technologies is being performed successfully. Practical application of the Biometrics Technologies, Intelligent Library and Tutoring System within the EURASIA Project is briefly analysed in the paper.

Keywords: EURASIA Project, Intelligent Library and Tutoring System, Voice Stress analysis, IRIS recognition.

1. Background

The EURASIA (EURopean and ASIan Infrastructure Advantage) Project is being carried out with the financial assistance of the European Union under the Asia-Link Programme. EURASIA project aims to enhance the capacity of the partner institutions for training, teaching and research activities required for the creation and long-term management of public and commercial facilities and infrastructure. One of the main activities includes development of a professionally accredited postgraduate curriculum, and design and delivery of training courses. In order to increase the efficiency and quality of delivery of the above-mentioned training, teaching and research activities, an Intelligent Library and Tutoring System within the EURASIA Project (ILT-EAP system) was developed. The features of ILT-EAP system include the search for and finding of useful material, multi-variant optional module designs, multiple criteria analysis and selection of the most rational alternatives of teaching material according to students' requirements. The personalized scenario is dynamically generated with emphasis on the requirements of each student. Besides, the System combines concepts of voice stress analysis and IRIS recognition technologies.

2. Intelligent Library and Tutoring System for the EURASIA Project

Search engine rankings have been adopted in most advanced intelligent libraries (Alexandrov [1], Gutwin [5], Hsinchun [6], Kaklauskas [7], Ruch [10], Trnkoczy [11], Wang [12]) and tutoring systems (Armani [2], Brusilovsky [3], Day [4], Lucence [8], Pouliquen [9]). As part of the ongoing Illinois **Digital Library** Initiative project, research proposes an intelligent personal spider (agent) approach to Internet searching, which is grounded on automatic textual analysis, general-purpose search and genetic algorithms (Hsinchun [6]). Pouliquen [9] use parsing techniques to extract information from texts, and provide a proper semantic indexation which is used by a medical-specific **search engine.** Day [4] use the Jakarta Lucene full text indexer to index full texts of textbooks. Jakarta Lucene is a high-performance, fully-featured text search engine library written entirely in Java. Its technology is suitable for nearly all applications that require full-text searches. It is also readily available and has a good API for our needs. ITA [9] index chapters, sections, and subsections of textbooks. Highlighters are used to highlight the index context. Finally, the ITA provides reading recommendations for students via a chapter similarity function. However, intelligent libraries (Alexandrov [1], Gutwin [5], Hsinchun [6], Kaklauskas [7], Ruch [10], Trnkoczy [11], Wang [12]) and intelligent tutoring systems (Armani [2], Brusilovsky [3], Day [4], Lucence [8], Pouliquen [9]) with search engine rankings cannot select chapters (sections, paragraphs) of a specific text, which are the most relevant to a student, cannot integrate them into learner-specific alternatives of teaching material and cannot select the most rational alternative, i.e. cannot develop alternatives of training materials, perform multiple criteria analysis and automatically select the most effective variant. However, an Intelligent Library and Tutoring System within the EURASIA Project (ILT-EAP system) can perform the aforementioned functions. No-one thought of the above function before, so this attempt is the first. The approach helps students to obtain suitably tailored material for an e-learning course. The above and other improvements are possible by using the ILT-EAP system.

A lack of optional alternative modules provides lesser opportunities to satisfy students' needs. Students, who gain basic knowledge in their field, often lack knowledge necessary for specific work. Students usually waste too much time in finding useful study material. Discovering the most rational study material among all that is available in a vast number of modules can have more meaningful outcomes for students. The main objectives of our work is development of the methods, algorithms and ILT-EAP system for searching and finding useful material, carrying out multivariant optional module designs, multiple criteria analysis and selection of the most rational study material alternatives according to students' requirements. Also the ILT-EAP system combines concepts from voice stress analysis and IRIS recognition technologies.

The ILT-EAP system consists of nine subsystems: Domain Model, Student Model, Tutor and Testing Model, Voice Stress Analyser Subsystem, Iris Recognition Analysis Subsystem, Subsystem of Multivariant Optional Module Design and Multiple Criteria Analysis, Database of

Computer Learning Systems, Decision Support Subsystem and Graphic Interface. The Domain Model, Student Model, Tutor and Testing Model, Database of Computer Learning Systems and Graphic Interface are quite similar to existing Intelligent Tutoring Systems. The Voice Stress Analyser (VSA) Subsystem, Iris Recognition Analysis Subsystem and Multivariant Optional Module Design and Multiple Criteria Analysis Subsystem are innovative Intelligent Tutoring Systems solutions. VSA and Iris Recognition Analysis Subsystems are briefly analysed below.

3. Voice Stress Analyser Subsystem

The muscles of a human throat vibrate in a range of 8-12 Hz and this range is called a micro-tremor. When a person is emotional or stressed the vibration shifts from 8-9 Hz to 11-12 Hz, and the more intensive the stress the higher the frequency of such vibrations. The Voice Stress Analyser Subsystem (VSA) measures stress in a human voice. The research aim was to compare data received during an examination with ILT-EAP (information on correct and incorrect answers, time periods for each question, and the number of times a student changed an answer to each question of a test) with similar data received from the Voice Stress Analyser (VSA) Subsystem, to make practical conclusions and to plan future research. This research helped to determine changes of students' psychophysical conditions during examination. During an e-test, students were asked to select one correct answer from the provided alternatives and to say the answer aloud. The sound record of each answer was then saved into a PC memory with an identification code for listening and further analysis. Records were analysed by using the VSA Subsystem and the frequency range of micro-tremors for each specific answer to an e-test question was determined. Higher frequency of voice vibrations was determined when analysing voice answers to "unknown/difficult" questions. It was found out that the emotional stress of a student was higher when answering "unknown/difficult" questions.

The reliability of the results was assessed by making a correlation analysis of emotional stress and of evaluations of correct answers (in percent) to test questions. The analysis showed that a correlation exists between emotional stress and the correctness of an answer. During the experiment, a total of 4,000 voice records in four student groups were examined and analysed. The research helped to determine whether questions can be classified (in respect to students) as "known/simple", "unknown/difficult" and remaining questions in-between these two groups. Higher than average emotional stress was experienced when answering the "unknown/difficult" questions, and zero or minor emotional stress in case of "known/simple" questions. Having analysed the whole set of answers, a direct relationship was noticed between the emotional stress and the correct answers (in percent) to an e-test. During the research, the average micro-tremor was calculated for each question. Part of the results is shown in Figure 1.

Figure 1 shows the relation between a student's correct answers and the average micro-tremor frequency of the answers to test questions. The x-axis shows numbers of the test questions for students who were passing the examination. During examination, students had to mark and to say aloud the right answers to 20 questions within 10 minutes. The left side of the y-axis shows the correct answers (in percent). The right side of the y-axis shows the average micro-tremor frequency of each student during the examination. Besides, the Figure 1 shows two correlating curves obtained during the research; they show the direct relationship between the correct answers and the average micro-tremor frequency.

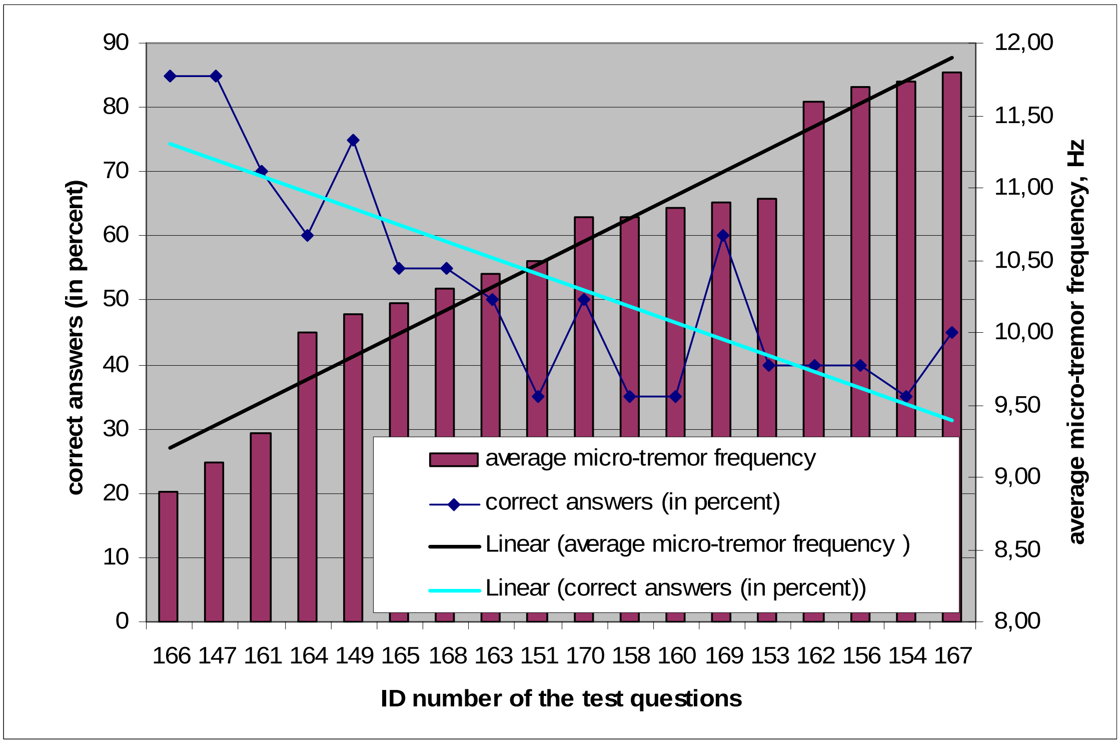

Figure 1: Correlation between the emotional stress and the correct answers (in percent) to the e-test: the x-axis indicates the numbers of the test questions, and the y-axis indicates the average micro-tremor frequency (Hz) in the student's voice (on the right) and the correct answers (in percent) (on the left)

Currently students' knowledge can be automatically assessed (instead examination) by using VSA Subsystem on the basis of student psychological tests, accumulated historic voice stress data, determined regression equation and special developed algorithm. The VSA Subsystem automatically assessing a student's knowledge before examination according to the student's spoken/oral answers. For example, when a teacher gives a student such 9 questions as "Are you well-prepared for the exam?," "What mark would you give to your knowledge?", "Have you learnt everything?", etc. before examination, and the student can be assessed quite precisely by giving a mark by using VSA Subsystem (special developed algorithm). Figure 2 illustrates the comparison of the marks given to students during the e-psychological test performed prior to the examination (using the Voice Stress Analysis System) and of the marks given during the examination itself (using the Intelligent Testing Subsystem). The regression-correlation curves seen in Figure 2 show interrelation between the marks given during the e-psychological test and the marks given during the e-examination itself.

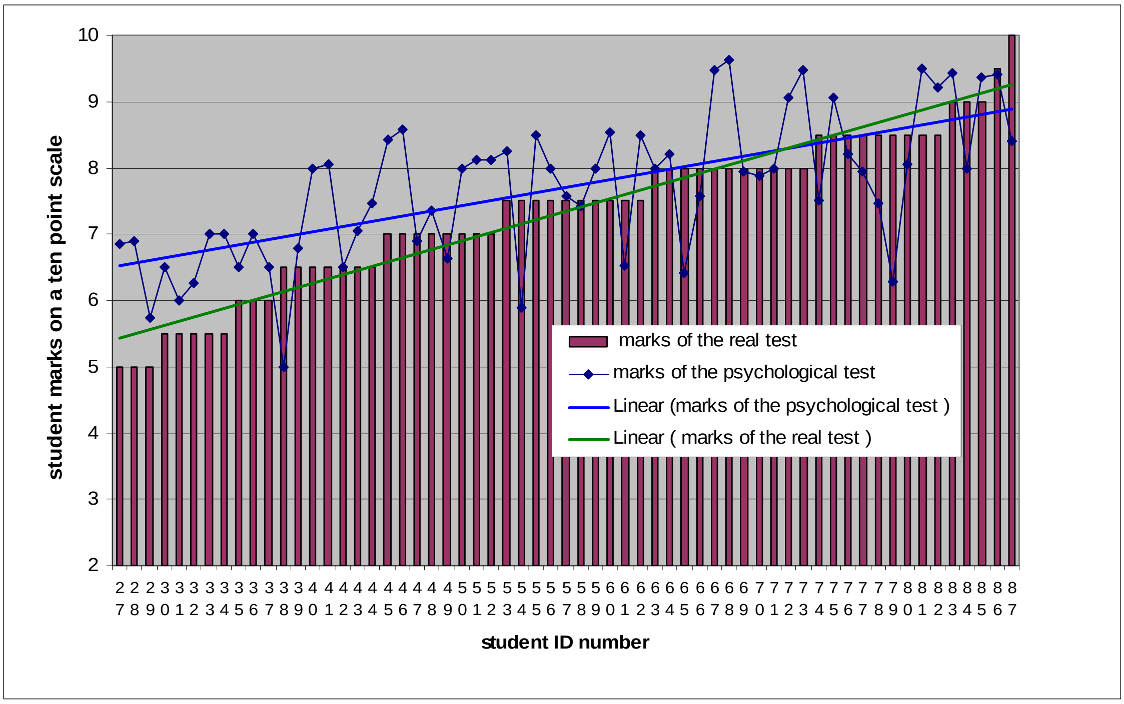

Figure 2. Comparison of the marks given to students during the e-psychological test prior to the e-examination and of the marks given during the e-examination itself

Legend:
y-axis: marks of students on a ten-point scale;
x-axis: students' IDs;
"marks of the e-psychological test": marks given to students during the e-psychological test prior to the e-examination using the Voice Stress Analysis System;
"marks of the real test": actual marks given to students during the e-examination using the Intelligent Testing System;
"linear (marks of the psychological test)": regression-correlation linear trend, which describes the marks given to students during the e-psychological test prior to the e-examination using the Voice Stress Analysis System.
"linear (marks of the real test)": regression-correlation linear trend, which describes the actual marks given to students during the real e-examination.

4. Iris Recognition Analysis Subsystem

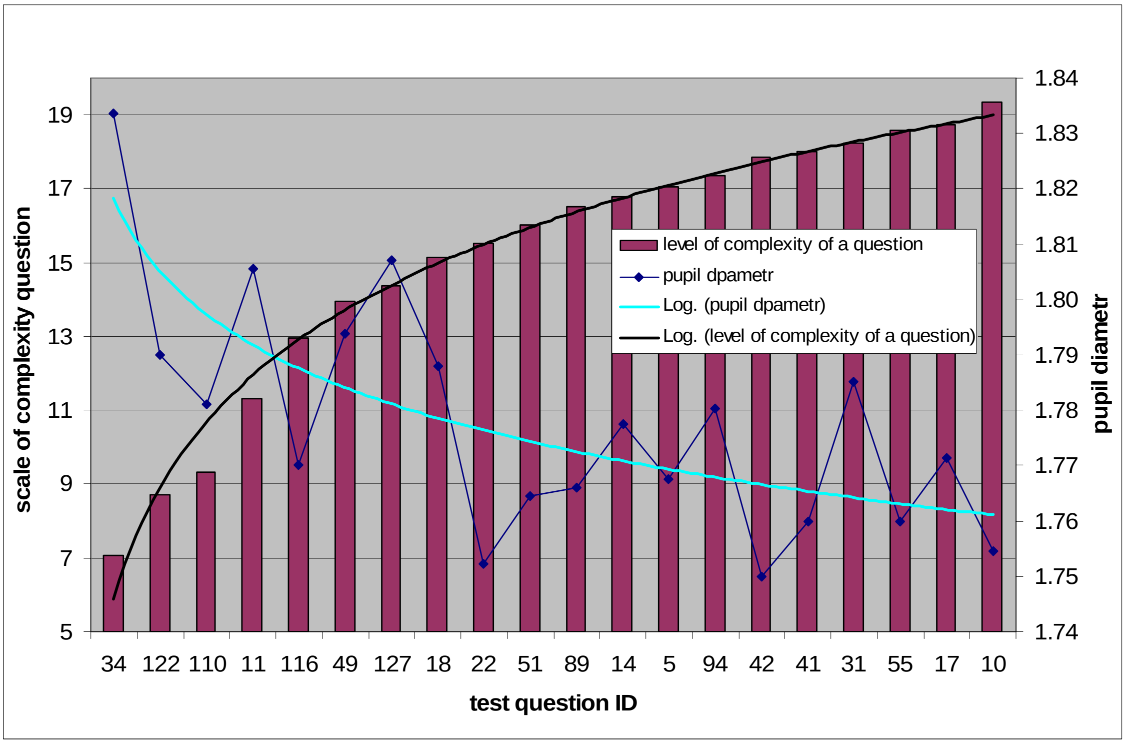
Students, sitting at a computer during the exam, were invited to answer 20 questions. It was a multiple-choice test. The questions were classified according to their complexity: from the easiest to the most difficult. The complexity of a question was determined according to the percentage of the students who answered it. Most of the students gave correct answers to the easier questions. Certainly, each person has a different opinion of what a difficult question is. However, previously, data has been collected and statistically processed, on the grounds of which such levels of complexity were determined, taking into consideration the exam results of the majority of students.

Currently, the research is in progress, and the interdependence between the changes in the eye iris diameter and the emotional state of a person is being investigated. During the research, a micro video camera, which records the changes in the diameter of a student's eye iris and transfers the data to the computer, is mounted in front of a student. Employing special software, an iris is photographed every three seconds and the results are saved in the PC hard disk drive, in separate files. Employing the *Matlab* software environment and adjusted scripts, the eye iris diameter is calculated from the video pictures, and the recorded changes are saved in the database. A database was obtained as the final result, where the students' answers to the e-questions and information about the changes in the iris diameter during the exam were stored.

All the students were provided with the same questions. Answers had to be given in 15 min. During the exam, the changes of the eye pupil were recorded by a video camera fixed on the head. Photos of a pupil were taken every three seconds in order to determine the moment of the change in the diameter as precisely as possible. Another step was to measure the diameters of all the pupils. Eye pupil is then digitised and stored in a PC database of enrolled students. The whole procedure takes less than a few seconds, and can be fully computerized with voice prompts. Moreover, while a student was answering, the time when the student progressed to another question and when he/she pushed the button to choose the answer was recorded automatically. The taken photos were matched to the provided questions with reference to the time, and the average pupil diameter was calculated. Thus, a pupil diameter is determined, which corresponds to a particular question, e.g. if a student was thinking for one minute before answering the question No. 1, then all 20 photos are taken (as the eye was photographed every three seconds), and the average of measurements is deduced. All the 20 pupil diameters corresponding to 20 questions were determined by such a sequence. According to them, it was possible to determine the student's reaction to each provided question. The changes in the eye pupil of some students were very clear and obvious (the pupil diameter might have changed by up to 5,5 mm); in others, the changes were insignificant (5,25 to 5,35 mm). We may draw a conclusion that those students, whose pupil diameter underwent minor changes, were better prepared for the exam, they worried less and questions did not seem so complicated to them.

The research helped to find out, whether an actual interdependence exists between the correct answers (in percent) and the changes in a pupil diameter. Figure 3 depicts the dependence of a pupil diameter on the correct answers (in percent). The *x*-axis indicates the ID numbers of the questions answered during the e-test and the *y*-axis indicates the average of a pupil diameter (*on the right*) and the correct answers (in percent) (*on the left*). In case a student answers all the questions correctly, he/she may collect a maximum of 20 points (100 percent). Figure 3 also shows two correlated curves obtained during the research that indicate direct dependence of correct answers (in percent) on the changes in a pupil diameter.

Figure 3 shows that the more complicated was the provided question the bigger the diameter of a pupil was. It widened most when answering the question No. 34. And actually, only 7 people out of 20 answered this question correctly. We may draw a conclusion that this question was most complicated. Moreover, a reciprocal process may be observed: the easier the question (more students answered it) the smaller the diameter of a pupil is. Figure 3 obviously shows that the assumption was proved. The higher the pressure a person experiences (uncertain of his/her knowledge or sees the question for the first time) the wider the pupil of his/her eye becomes and its diameter increases.



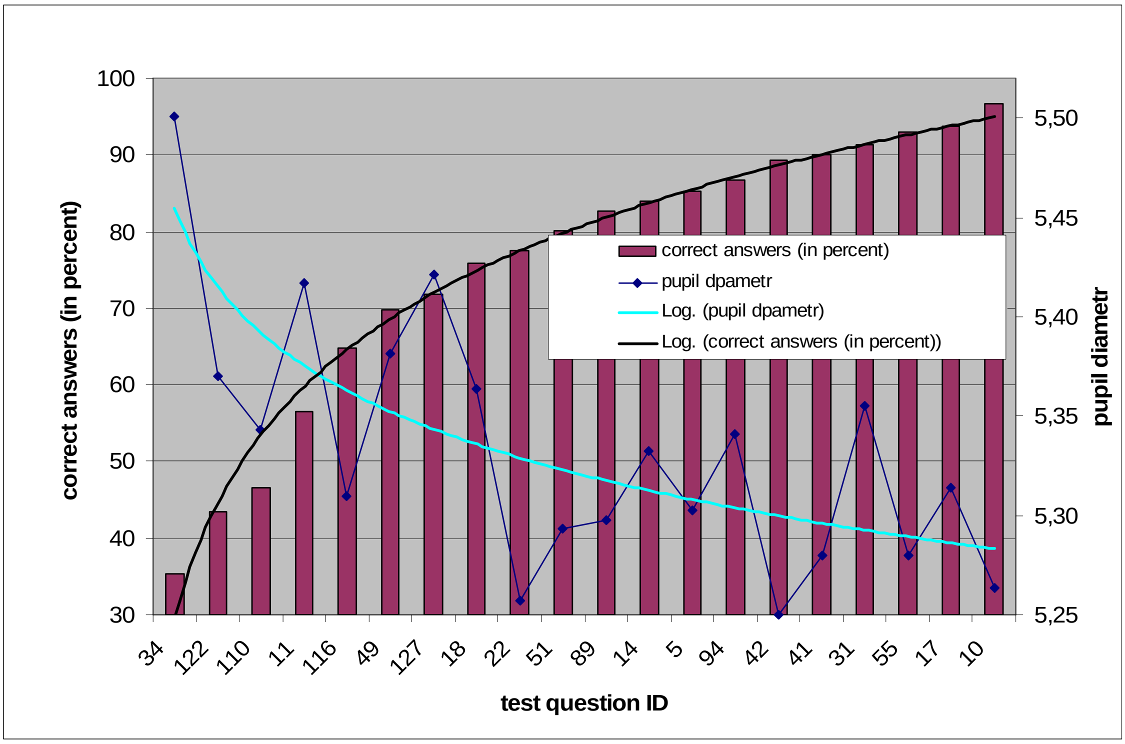


Figure 3: Dependence of a pupil diameter on the correct answers correct answers (in percent): the x-axis indicates the numbers of the test questions, and the y-axis indicates the average of a pupil diameter (on the right) and the correct answers (in percent) (on the left)

Supposedly, in the future, student's knowledge will be evaluated automatically taking into consideration the obtained data and determined interdependences. For example, a lecturer gives several questions to a student about the level of preparation to the exam, and the Iris Recognition Analysis Subsystem, with regard to the changes in the average of the student's eye iris, and taking into consideration the obtained data as well as determined interdependency, will be able to perform an automatic evaluation of his/her knowledge.

5. Conclusions

EURASIA project aims to enhance the capacity of the partner institutions for training, teaching and research activities required for the creation and long-term management of public and commercial facilities and infrastructure. One of the activities includes development of an Intelligent Library and Tutoring System within the EURASIA Project (ILT-EAP system). Authors of the paper applied the new technologies (Search Engine Rankings, Multi-variant Optional Module Design and Multiple Criteria Analysis; Voice Stress analysis, IRIS recognition) in the development of ILT-EAP system. The current features of the developed ILT-EAP system include the search for and finding of useful material, multi-variant optional module designs, multiple criteria analysis and selection of the most rational alternatives of teaching material according to students' requirements, application of biometrics technologies, etc. Future research intends active application of other biometric technologies (pulse measurement, blood pressure, biometric mouse, etc.) in e-learning. Also the future of this research is to study how to implement the new e-learning technologies (Search Engine Rankings, Multivariant Optional Module Design and Multiple Criteria Analysis, Voice Stress analysis, IRIS recognition) in e-teaching of MSc and PhD students of construction and real estate sector according to the objectives of the EurAsia Project.

Abstract

The profile of students reading for construction management degrees is changing. In Australia, a buoyant construction industry is currently fuelling high student expectations. Job opportunities for students (as part-time employees) and for graduates are attractive. Students embarking on their studies come from a wide variety of backgrounds with a profile that is significantly different from the early 1990's when the Bachelor of Construction Management (Building) program started at Newcastle University (Australia). This degree was conceived to meet the needs of the local building industry. It embraced problem-based learning as its main tenet and was developed to be delivered to on-campus as well as to distance learners. Reviews by the Australian Institute of Building and the Australian Institute of Quantity Surveying as well as the University have highlighted the need to respond to market requirements and student expectations. Over the past two and a half years the degree has been redeveloped to embrace mixed-mode delivery of courses to on-campus as well as to distance learning students. This paper describes how the degree has evolved and the manner in which e-learning has been harnessed to deliver an innovative problem-based learning curriculum in mixed-mode.

Keywords: e-learning, problem based learning, distance learning, mixed-mode learning, blended delivery.

1. Background

The opportunities for would-be construction managers are considerable. A recent KPMG survey (2007) notes that the demand for construction is expected to increase significantly over the next five years. The report observes that the "single overwhelming conclusion that can be drawn from our study is that the shortage of qualified contractors is without doubt the biggest challenge to new construction projects in the future. Furthermore, with market demand expected to increase significantly over the next five years, this issue looks set to intensify as the pool of qualified contractors able to bid for projects is reduced and the wider shortage of skilled labour contractors impacts the ability of teams to deliver on projects." The findings of this survey are significant as they address the global market for construction. Closer to home, a recent survey conducted by the Master Builders Australia (2007) acknowledges marked differences between states and sectors but goes on to note that in "the non-residential sector conditions are strong and are expected to continue to improve. In contrast, current conditions in the residential sector are reported as poor. However, in a significant finding after negative results in previous surveys, builders now expect residential activity to improve over the next six months."

There are clearly good job opportunities in the construction industry, and these are reflected by buoyant recruitment to tertiary level construction programs. Students embarking on their studies at the University of Newcastle come from a wide variety of backgrounds. Many are of mature age and already have a construction background. Few are female. Many are highly computer literate and expect to engage with their studies using computer systems. This profile is significantly different from the early 1990's when the Bachelor of Construction Management (Building) program started at Newcastle University (Australia). Then the degree was conceived to meet the needs of the local building industry, and focused largely on domestic and commercial opportunities in the region. It embraced problem-based learning as its main tenet and was developed to be delivered to on-campus as well as to distance learners.

In addition to the changed profile of our current intake of students, an increasing number of them bring with them financial necessities of having to work to support their tuition. This latter point is emphasized by Mills and Ashford's (2004) in their investigation into part-time employment of construction management students. They highlight a trend of increasing levels of student engagement in the workplace. More recently an Australian Vice Chancellors' Committee report (2007) entitled "A summary of findings from a national survey of students in public universities" confirmed that increasing financial stress was undermining students' abilities to study effectively.

These financial pressures cannot be ignored. A response that the National Tertiary Education Union Newcastle branch president Bert Groen recently suggested (McKenny, 2007) might be occurring is where academics ask students to choose between their work and their studies. This is clearly an unsatisfactory approach, and is obviously not to be advocated. Students require flexible alternatives that respond not only to their pecuniary realities, but to different ways of learning that many of them engage in.

Hodgson, Sher and Mak (2007) note that the profile and expectations of construction students is changing. Not only are many of these students acculturated to the use of information technology, they are saturated with it. Lecturers need to recognise that the skills students enter University with are evolving and that many prefer to use digital materials rather than paper.

2. Current developments in the BCM program

Our Bachelor of Construction Management program is delivered by staff in the School of Architecture and Built Environment. The School comprises three disciplines viz., construction management and quantity surveying, architecture and industrial design. Degree programs at our University are subject to scrutiny from accrediting bodies as well as from the University itself. In 2004, our construction management degree (Bachelor of Construction Management [BCM]) was reviewed as part of our own internal quality assurance procedures, and by the Australian Institute of Building and the Australian Institute of Quantity Surveying. Several recommendations were made and we have responded in various ways. In the context of these recommendations the BCM program was re-conceptualised to address the changing needs of our stakeholders. Figure 1 shows the context within which the program was re-conceptualised.

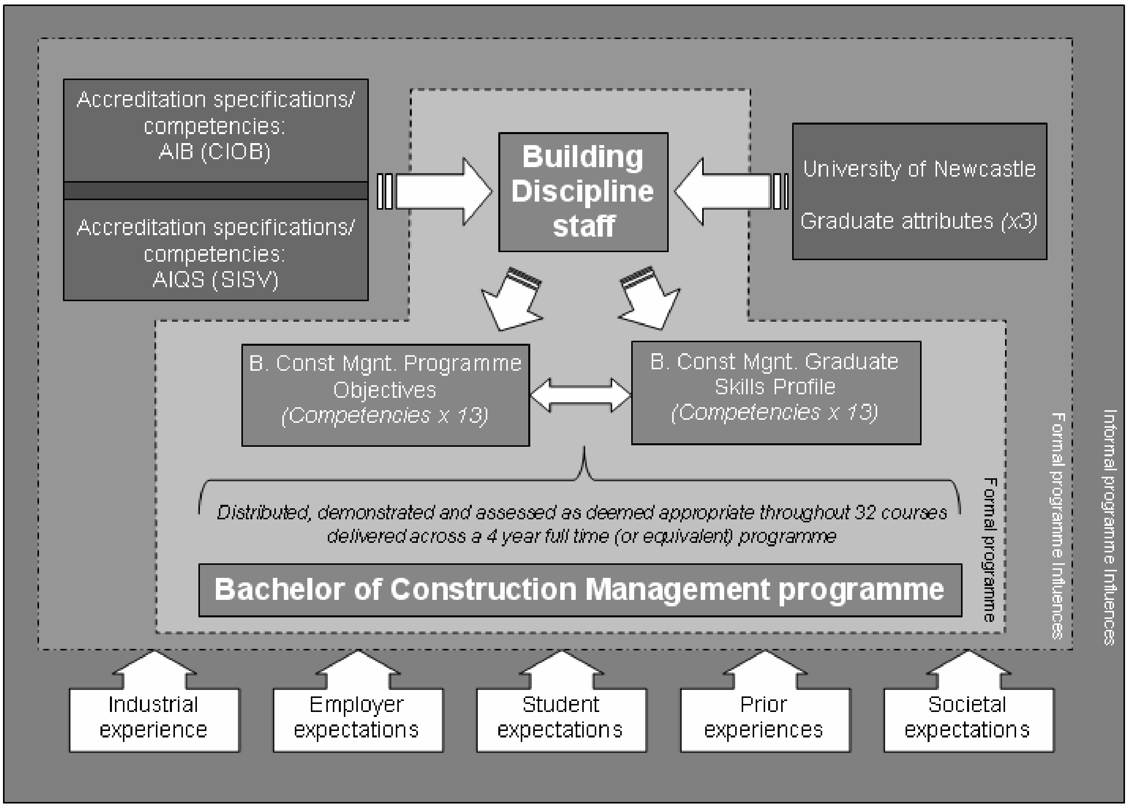

Figure 1: Context within which the BCM program is embedded

The re-conceptualised BCM program has responded to the review recommendations and the general trends in the Australian higher education sector (mentioned above). The re-conceptualisation was aimed to:

- Cater for the changing demands/needs of students

- Increase efficiency of the program delivery
- Re-conceptualise the teaching philosophy to enhance student learning and to conform to stakeholder requirements
- Enhance the quality assurance processes

This paper discusses how the new BCM program has addressed these issues through the following strategies:

- We use of Information Technology to facilitate flexible learning and improve efficiency. We now offer our BCM program in mixed-mode. This allows our students to study on-campus or as distance-learners, and provides them with the flexibility to decide at what pace to progress their studies.

- We have improved teaching efficiency and quality by combing the delivery of BCM and Architecture courses that were previously taught separately.

- We have approached PBL integration differently and introduced electives.

- We have developed a robust map of graduate skills and knowledge that links to all stakeholders' requirements.

3. Use of IT to facilitate flexible learning

Our program employs range of IT and online tools to create flexible and effective learning environments for students. We use the Blackboard learning management system, Lectopia on-line lecture system, Audio recording systems, online tutorials and tele-tutorials to facilitate student learning.

3.1 Blackboard

Staff have been using Blackboard for several years, and have developed expertise in most aspects of on-line pedagogy. Blackboard provides the equivalence of an on-campus classroom experience to on-line (distance learning) students. For example, all courses on our BCM program provide students with access to electronic course outlines, course materials (lecture notes, lecture recordings, reading materials), and relevant websites.

In addition, specific assistance is available from our Library to help students locate relevant materials. Our University's Teaching and Learning unit have developed targeted electronic materials to support our construction students in working in groups and in writing technical and other reports. Members of staff are skilled in engaging on and off-campus students in groupwork and in electronic discussions (Sher and Williams, 2007).

3.2 Lectopia

The University of Newcastle has invested significant funds in information technology infrastructure to service on-line delivery of teaching and learning materials. A major component is Lectopia, a system which gives students access to recorded lectures via the Internet. Lectopia allows lecturers to record their lectures from specific venues (there are currently 31 Lectopia-enabled lecture theatres in our institution). Staff simply present their lectures to on-campus students and what they say and display (from their computer or visualiser) is recorded in a digital format. Once a lecture has finished it is automatically processed and is ready for students to access via Blackboard within a short space of time (usually a couple of hours). Lectopia also provides podcasts of classroom lectures, which students subscribe to for automatic download of classroom lectures.

3.3 Audio recorded lectures

In addition to Lectopia, staff audio record their lectures (and some tutorials). These recordings are then made available to students via Blackboard in mp3 format. This approach is designed to service students without broadband access, as well as those who wish to use their iPod's to listen to lectures (whilst travelling to and from work, or at other convenient times).

3.4 Tele-tutorials

Notwithstanding the abovementioned array of (largely) asynchronous electronic teaching and learning aids, it is sometimes convenient for staff to communicate synchronously with students. In such instances, tele-tutorials are conducted.

3.5 On-line quantity surveying measurement tutorials.

A significant challenge for those teaching measurement is (and always has been) to ensure students have sufficient knowledge and understanding of construction technology to enable them to measure buildings. Measurement is a process which requires a technical knowledge and understanding of building or civil engineering technology. However, at the time students are required to learn how to measure, many of them do not yet have the requisite technical knowledge and understanding. Measurement requires students to follow a prescriptive set of rules provided by published standard methods of measurement (SMM). These publications do not explain the taking-off process and are designed to provide experienced surveyors with rules for measuring in a standardized manner. From a lecturer's perspective the challenge lies in teaching SMM based measurement processes to students who have just enough knowledge of construction technology to comprehend the measurement rules. We have collaborated with the Department of Civil and Building Engineering at Loughborough University (UK) to develop several on-line quantity surveying measurement tutorials that assist on and off-campus students to understand these processes (Hodgson, Sher and Mak, 2007).

3.6 3D models

As previously mentioned, many novice quantity surveying students are not familiar with how to read and interpret construction drawings. A discussion of whether or not these students need to be able to prepare technical drawings before they can fully understand them is outside the scope of this paper. However, many software packages are currently available to help students overcome the limitations of 2D drawings. We have trialled 3D models developed using Google SketchUp (2007) and have been encouraged by the ease with which these have been created, and by the verbal feedback students have provided. We are currently developing 3D construction drawings in addition to traditional 2D drawings to facilitate students' understanding of the manner in which buildings are constructed.

4. Program rationalisation and re-conceptualision of our the teaching philosophy

The changes to the BCM degree are significant, and extensive resources and effort have been directed to developing and delivering what is effectively a new curriculum. Delivery of the redeveloped courses to on-campus BCM students commenced at the start of 2006. The new program structure is illustrated in Figure 2. This approach allows efficient utilisation of cross disciple skills for student learning.

4.1 Problem-based learning

The BCM program is based on a Problem Based (PBL) curriculum. Traditionally, in universities, PBL is expressed in terms of the content that is taught and the sequencing of this content, embodied in courses. It is argued that a PBL curriculum consists of the:

- application of concepts and theories to practice/real world situations,
- concepts and theories that inform practice of the discipline
- processes of the discipline
- processes of learning

The problem-based learning (PBL) approach adopted in the BCM degree builds on an established body of knowledge, at the heart of which is the intention to improve the effectiveness and relevance of student learning (Brubacher, 1977, Boud and Feletti, 1991). Students should be 'empowered learners' who have the capacity for autonomous learning and an inner drive towards continuous and lifelong learning (Candy, Crebert and O'Leary, 1994). The motivation must be initiated by an assessment process that places the student's development at its heart (Newble and Entwistle, 1986). Since its inception, the BCM program has incorporated PBL as one of its central tenets. Continuing this approach, the redeveloped program retains PBL as an integral part of students' learning experiences. Integrated PBL courses are included in all years of study, and provide opportunities for students to assimilate and exercise newly acquired knowledge, understanding, and skills by engaging in a variety of different exercises.

SEMESTER 1 — 1ST YEAR [1000 LEVEL]	SEMESTER 2 — 1ST YEAR [1000 LEVEL]
Construction Integrated Project 1	Construction Law and Legislation
Communication in the Built Environment 1	Building Condition Reports and Surveying
Construction Technology 1	Communication in the Built Environment 2
Construction Ecology 1	History & Theory in the Built Environment 1

SEMESTER 1 — 2ND YEAR [2000 LEVEL]	SEMESTER 2 — 2ND YEAR [2000 LEVEL]
Open elective	Construction Technology 2
Construction Integrated Project 2	Health and Safety in the Built Environment
Measurement of Building Works	Estimating and Tendering
Economics in the Built Environment	Construction Procurement

SEMESTER 1 — 3RD YEAR [3000 LEVEL]	SEMESTER 2 — 3RD YEAR [3000 LEVEL]
Construction Ecology 2	Research In The Built Environment 1
Construction Technology 3	Open elective
Construction Business Management	Construction Integrated Project 3
Construction Project Planning	Construction Integrated Project 4

SEMESTER 1 — 4TH YEAR [4000 LEVEL]	SEMESTER 2 — 4TH YEAR [4000 LEVEL]
Construction Technology 4	Construction Integrated Project 5
Construction Ecology 3	
Research In The Built Environment 2	Construction Integrated Project 6

KEY		
	Courses taught to BCM & Architecture	Courses taught to BCM students
		Integrated Projects taught to BCM students

Figure 2: Structure of redeveloped BCM program

The question of choice for the implementation of a PBL curriculum is based on the characteristic of PBL to facilitate a fully integrated curriculum. This is defined in the goals of PBL programs, and includes an ability to *(a) develop high professional competency (b) reason critically and creatively (c) make reasoned decisions in unfamiliar situations (d) adapt to and participate in change (e) appreciate another person's point of view (f) make self evaluations,* *identify own strengths and weaknesses and undertake appropriate remediation (g) work productively as a team member*

The mixed mode delivery re conceptualised the PBL integration. The 30 units subjects (courses) that allowed cross subject integration in the old program were discontinued. Now subjects (courses) are delivered as specific knowledge delivery courses and integrated project courses. Knowledge and skill delivery courses employ PBL to allow inter-subject integration, i.e. integrating concepts with in a subject domain (Micro integration). Integrated Projects employ PBL to allow intra-subject integration of knowledge and skills of students (Macro Integration). Moreover, targeted reflection has been introduced to promote reflective practice.

4.2 Reflective practice

Central to PBL is the idea that students develop as reflective practitioners, requiring them to develop the ability to "think-in-action", to develop an awareness of "knowing how they think", which progressively translates into managing their own thinking, increasing their problem-solving skills, ultimately developing as a life-long learner (Fonteyn, 1998). This practice is mirrored by the staff in the BCM program who actively develop new and innovative ways to foster and gauge the students' developments as reflective practitioners (e.g. Brewer, Jefferies, Gajendran and Williams (2007); Brewer, Gajendran, MacKee and Williams (2004) and Brewer, Gajendran, MacKee and Williams (2003)). These have variously included reflective journals, the combination of reflection and self-assessment in reflective self-assessment tools, and most recently the inclusion of student reflection within assessable items as reflective footnotes. The efficacy of each of these innovations has been evaluated using multiple perspectives.

5. Quality Assurance: continuous improvements

5.1 Aligning and mapping student learning

The PBL curriculum is aligned with the development of students' graduate attributes. The proficiencies of graduates then become the basis for the development of course objectives. The University of Newcastle identifies three broad domains of graduate attributes as important outcomes of a university undergraduate degree: professionalism, community responsiveness and scholarship. The domains of attributes are generic to all undergraduate programs and reflect the University's scholarly values in relation to teaching and research, the employability of graduates and partnerships with the community. They define the abilities of each graduate that transcend disciplinary outcomes. The program specific attributes within the domains are developed in various disciplinary and interdisciplinary contexts. The BCM program has developed 12 program specific graduate skills. These skills and the corresponding university attributes are listed in Table 1. Each course identifies which specific attribute is targeted in that course, and all of these attributes are delivered across the program.

Table 1: Construction Management Program Skills Mapped against University Graduate Skills

	Professional Graduate Skill	**University Graduate Skill Profile**
1	Use knowledge of the construction industry, the environment and social processes that inform and contribute to construction practice, to optimise decision-making and evaluation of construction practices and processes.	Professionalism[1]
2	Be able to develop, implement and evaluate strategies that result in and/or contribute to successful construction and construction related projects.	Professionalism Scholarship[2]
3	Be able to communicate effectively with stakeholders and members of construction teams to facilitate project delivery	Professionalism
4	Demonstrate leadership as appropriate, to manage construction and construction related projects and/or processes	Professionalism Community responsiveness[3]
5	Be able to work effectively both independently and collaboratively in interdisciplinary and multi professional environments and teams to facilitate clients centred construction project outcomes	Professionalism
6	Function ethically, and within legal parameters, and conduct themselves in a professional manner.	Professionalism Community responsiveness
7	Perform the range of industry skills required by professional bodies, appropriate to their employer and context	Professionalism Community responsiveness
8	Be able to conduct and critically evaluate construction industry research and demonstrate an understanding of its contribution to the development of construction industry knowledge and practice.	Scholarship
9	Demonstrate professional and personal behaviour consistent with a commitment to lifelong learning, accountability in practice and the promotion and development of construction industry professions.	Community responsiveness Scholarship
10	Demonstrate creativity, lateral thinking and/or promotion of entrepreneurship and innovation within the context of work processes and procedures.	Professionalism Scholarship
11	Demonstrate understanding of social, cultural, global, environmental, ethical and business opportunities in the construction industry, and an understanding of the need for and principles of sustainable development	Community responsiveness
12	Demonstrate a capacity to inform themselves, their clients and the community of the social and environmental consequences of the actions and projects in which they are involved and the capacity to apply their skills and knowledge in the interest of their employers and clients without compromising the welfare, health and safety of their community	Scholarship Community responsiveness

5.2 Student evaluation

The Discipline of Building engages in a constant process of improvement in the BCM program. This is only possible because it undertakes frequent evaluation of courses, teaching, and the program itself, using techniques that provide multiple perspectives. These include student evaluations of each course, every time it is offered, using a standard University survey instrument, the results of which are recorded, reported and publicly published on our University website. Graduates of the program are also surveyed prior to exit, and again some time after they have graduated to elicit feedback on their overall experiences. The results are then fed back into the Discipline as an input into the continuous improvement process. Focus groups are also conducted with the students in each year of the program to augment the Student Evaluation of Course surveys, providing fine detail on the issues. Finally, many individual staff members conduct student evaluations of their own teaching, using centrally administered, anonymous survey questionnaires customised to investigate their particular style of teaching and assessment. The combination of all of these evaluative techniques invariably results in a program that continuously evolves and improves in order to meet the needs of the students.

6. Concluding comments

Like other disciplines, construction management and quantity surveying education needs to adapt to widespread changes. For example, measurement and other office and site practices have been revolutionised by computer technology, and industry practices have evolved in response to changed contractual conditions. These changes have necessitated revisions to traditional CM & quantity surveying curricula. The problem based learning CM degree program that has been successfully implemented at the University of Newcastle has been revised over the past three years. It is now delivered in mixed-mode, providing on and off-campus students with innovative and flexible education. This structure is continually evolving, and it is inevitable that the curriculum currently being delivered at our institution will be different to that of the future.

Endnotes

[1] **Professionalism:** An attitude or stance towards work and activity: Graduates of the university, through well-founded knowledge and skills within their fields of study will be enabled to act professionally with honesty and integrity. They will be enabled to act effectively and ethically in decision-making and problem-solving and work both autonomously and collaboratively. They will have the ability to respond effectively to change and to seek continuous improvement in practice.

[2]**Scholarship:** An attitude or stance towards knowledge and learning: Graduates of the university will have a scholarly attitude towards knowledge and learning, having a commitment to the expansion of knowledge and a respect for intellectual integrity and the ethics of scholarship. As scholars they will be enabled to apply logical, critical and creative thinking to the advancement of knowledge and understanding through a capacity for rational enquiry and self-directed learning. They will be able to communicate their knowledge effectively.

[3]**Community responsiveness:** An attitude or stance towards society: Graduates will be enabled to play effective and responsible roles as members of local, national and global communities. They will have a capacity for perspective forming and an appreciation of the philosophical and social contexts of their

disciplines. They will have the capacity to engage in constructive public discourse to sustain communities.

Technology Enabled Learning – Lessons Learned from Irish Initiatives

J. Wall
Dept. of Construction & Civil Engineering, Waterford Institute of Technology, Waterford, Ireland

D. T. Phillips
Dept. of Materials Science and Technology, College of Science & Engineering, University of Limerick, Ireland

Abstract

The presentation of lifelong learning opportunities for construction professionals in an effective yet flexible manner presents a number of challenges for educational institutions. The changing profile of full-time undergraduates highlights they encounter similar challenges. This paper outlines an EU project that addresses these challenges and describes the methodology adopted in developing a portal for continuing professional development (CPD). Features of the portal are outlined in addition to a methodology to evaluate its continued development and maintenance. The paper concludes with an analysis of a module delivered through Technology Enhanced Learning (TEL) and how the lessons learned from this exercise assist refining the CPD portal towards its full-scale implementation.

Keywords: blended learning, lifelong learning, portal, technology enhanced learning.

1. Introduction

Bridging the gap between lifelong learning needs of construction professionals and higher education using technology is a challenging undertaking if it to be executed effectively and successfully. One of the most significant changes in education has been the increased availability of information and communication technologies (ICT) at work, school and in the home (Condie and Livingston, 2006). Given the increasing evidence that ICT and the Internet are transforming the way in which society accesses information, there is growing support for Garrison and Kanuka's (2004) observations that these tools will be a significant transformative innovation for higher education in the 21st century.

A consortium of European third level institutions and a multimedia company collaboratively formulated a framework for deploying blended Continuing Professional Development (CPD) to the construction industry. The consortium secured funding from the European Union (EU) in the field of Information and Communication Technology (ICT) and Open and Distance Learning (ODL) in education. The rational behind this project was to create an innovative international learning resource that is widely accessible to construction management professionals. The resource serves to improved knowledge and skills within the industry. In the paper, the development of the CPD portal to date is outlined and the output compared with the findings of an independent undergraduate module running at the University of Limerick using the open source virtual learning system, Sakai. The findings of this study are used to fine-tune the professional CPD template towards full implementation.

2. Designing a CPD model for Construction Management Professionals

In the original proposal, an open source learning management system, e.g. Moodle or Sakai, was the agreed host to receive any of the resources that maybe deployed. This was a strategic decision made at the onset of the proposal. The choice of using an open source solution was made based on cost and the greater flexibility that it brings to the collaboration as the project evolves.

The design process applied in the development of this separate learning resource is presented in figure 1 while the key activities in each phase are outlined in table 1.

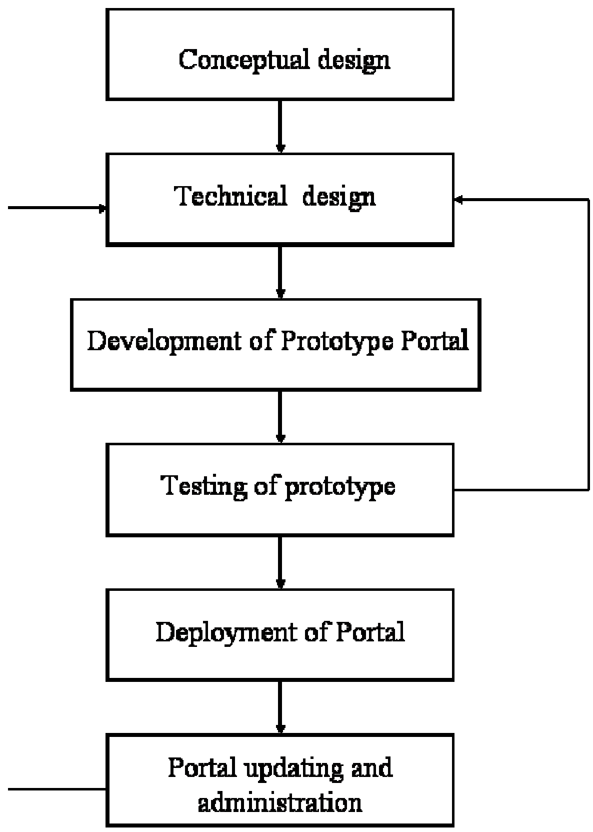

Figure 1: Separate Resource Development

Table 1 Key Activities for each Phase of Portal Development

Phase	**Features**
Conceptual design	The development of a brief to define the conceptual, functional and technical requirements of the CPD Construction Portal
Technical Design	The conceptual solutions and modifications identified in a series of partner meetings as part of brainstorming sessions to facilitate the technical design of the educational portal design
Development of Prototype Portal	The development of a small prototype of the portal to facilitate testing
Testing of prototype	Initial testing of the features and functionality of the prototype portal was undertaken in some of the partner institutions
Deployment of the portal	Based on the initial testing of the portal, the portal was deployed
Portal updating and administration	An ongoing requirement as part of the maintenance and sustainability of the initiative

Figure 2 illustrates the fundamental concept driving the development of this independent resource in a fashion that will strike a balance between traditional classroom instruction and technology-facilitated learning. This is a complex issue and achieving the correct blend is a challenging undertaking that requires innovation and ingenuity in the resource design.

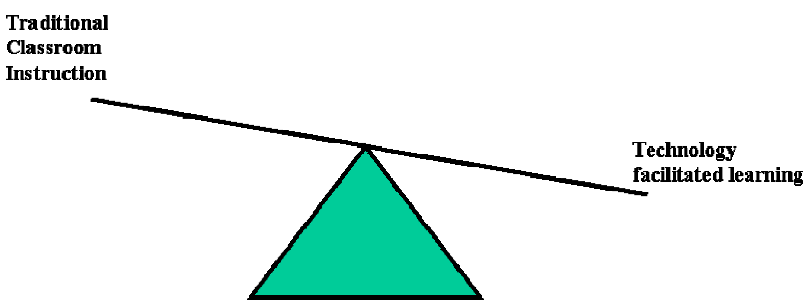

Figure 2 Striking a balance between traditional and technology facilitated learning

To date the major output of the project has been the development of a framework that hosts a series of on-line training modules, a reference bank of materials, web-based services such as discussion groups and bulletin boards to act as a forum for the exchange of information and ideas between educational institutions, industrial and professional bodies. As a part of the project, manuals and good practice guides, based on the interim and final evaluations have been formulated and are available for download by the subscriber. Figure 3 summarises the components that constitute the CPD Portal.

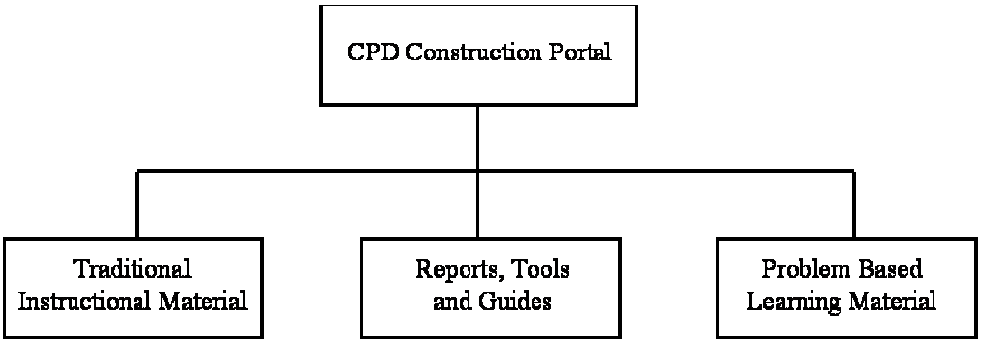

Figure 3 CPD Construction Portal

3. Portal Functionality

The Home page for the Portal for Continuing Professional Development (www.cpd-construction.com) is outlined in figure 4. Once an individual navigates to the homepage for the portal for CPD, there are a number of elements that the user can engage as part of the portal. There is an open access area contained under the Main Menu page. Included on the homepage is a description about the project, a description about the project partners, research papers presented as part of the project work, guides for both participants and teachers, a contact details page and a link to a framework for deploying CPD based on research carried out on the project. There is also a course categories section and a login section. These are controlled access areas within the portal.

Figure 4 Home Page Blended Learning Construction Portal

In this CPD Construction Portal, there are a number of key functional requirements and elements to be considered for the viability and sustainability of the initiative. There are a series of overlapping elements in developing a portal for CPD for construction management. Figure 5 outlines the various parameters to be considered for the Blended Learning Construction Portal.

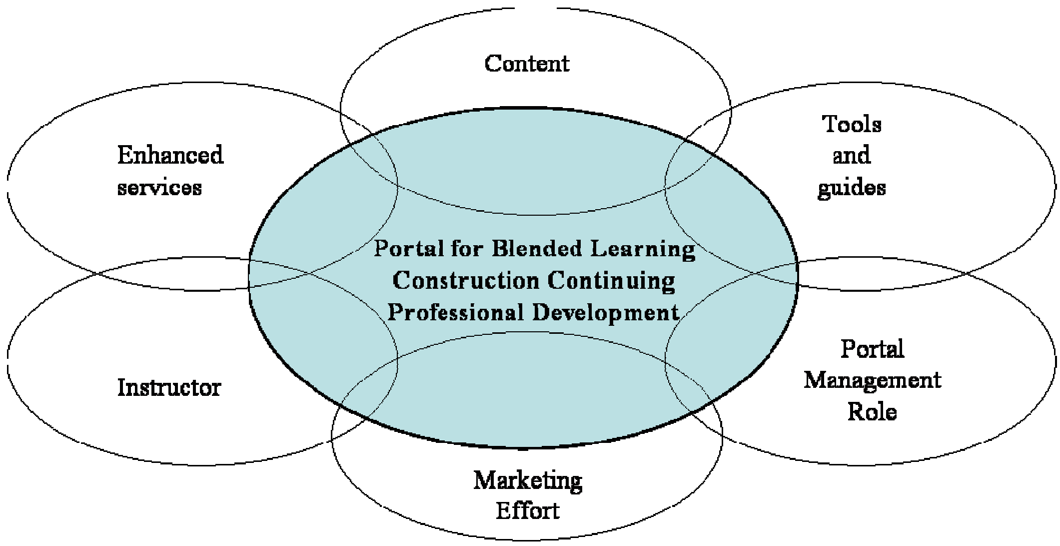

Figure 5: Responsibility for Blended Learning CPD

As content aggregators, web portals provide efficient access to information and services online (Neumann et al., 2005). The dissemination potential of the developed CPD Constriction Portal is endless and is only bounded by the thought and effort dedicated by the partners to this initiative to promoting the outputs. Internet marketing can play an important element in the dissemination of the information. With the well established networks of each of the partner institutes and the strong established linkages with professional bodies and construction representative adssociations in each of the countries cross links from each of these websites to other partners of the programme could be established. This could broaden considerably the dissemination potential of the project.

Table 2: Responsibilities and Key Activities for CPD Portal

Responsibility	Key Activities
Enhanced services	The enhanced services element includes the Moodle Learning Management System, which hosts the resources. Technical support for both participants and tutors on involved with the portal is part of the enhanced services role. Much of the technical troubleshooting and general administrative support and backup services should all be encompassed as part of the enhanced services element.
Content	Currently there is material developed for a number of areas in construction management. The challenge in developing any content for a blended initiative is striking a balance between what can be facilitated online and what may be delivered traditionally. To date content has been developed that covers subject matter in areas including: (i) Project Scope Management, (ii) Project Planning, (iii) Network Analysis, (iv) Risk Management and (v) Project Cost Estimating. Problem based learning where participants are allowed to share experiences can operate very effectively. Resources developed to support this include: ➢ Scottish Parliament ➢ Hoover Dam ➢ Sydney Opera House ➢ Bell Rock Light House Much of the content has been designed to facilitate independent and self-directed learning.
Instructor	The instructor has a key role to play in any blended learning initiative. Ensuring that instructors are aware of all the resources available, the functionality of the portal, and understand the role that they have to play in the ultimate deployment and facilitation of the resources is a key consideration. The instructor must change the way he or she performs their role from the more traditional role. Learning new skills, embracing a more flexible approach, an openness to using various technologies and assuming much more the role of facilitation are key skills that the instructor must embrace.
Marketing Effort	To ensure the longer-term sustainability of the portal for continuing professional development there is a requirement that a professional approach is undertaken. Involving new partners, countries and networks beyond the period of support for this project is key to the long term financial sustainability in growing the database of

	learning material, dissemination of the information and the possible establishment of a separate organisational structure charged with the delivery of CPD focused on the needs of the construction industry.
Tools and guides	The tools and guides element consists of suggestions on how to integrate resources and tools available developed into blended learning programmes along with some of the key issues to be considered. A series of support tools such as web-links for the problem based learning elements have been created and uploaded into the framework.
Portal Management Role	The certification of the accuracy and appropriateness of scholarly and teaching material placed on the resource is a fundamental issue. The portal management role is a key aspect of this initiative looking to the future. As well as supporting the instructor and participant with technological issues and challenges, the verification of content, quality assurance and monitoring of both the traditional and online elements of this initiative will be crucial in the longer term.

4. Case History: Pilot TEL Survey Using an Undergraduate Cohort

The time demands placed on full time undergraduate students is fast approaching that of the professional practitioners. In addition to attending college, many students hold a part-time job in addition to managing a birage of other personal and social interests all competing for an ever-reducing amount of personal time: there is little doubt that a major sea change has taken place in 21st Century education, at least in Ireland. The change has been coming for well over a decade and can be linked to Ireland's increased prosperity and thriving economy. The full-time student now seeks greater flexibility and autonomy in the way they receive and advance their education.

To this end, the second case study looks at the delivery of an introductory module on geology and soil mechanics using TEL. This virtual learning system supplements lectures and laboratory exercises by offering greater flexibility for the student to manage their education. Announcements on the course and other matters are automatically emailed to the student while the interactive calendar acts as a reminder of key project milestone dates well in advance of submission deadlines (Figure 6). Frequent assessments are undertaken throughout the module (Figure 7) within a timeframe agreed jointly by the learner and lecturer. This approach promotes learning throughout the module and facilitates active reflection on the course material; a more desirable outcome when compared to traditional rote learning for a heavily weighted end of semester examination.

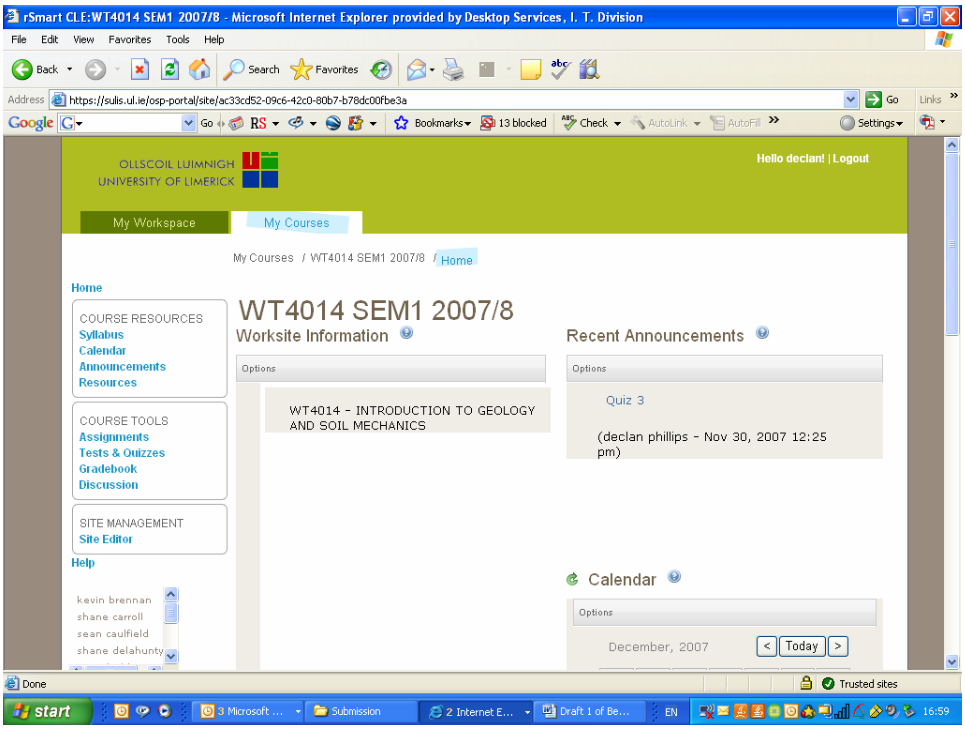

Figure 6: Module Site Displaying Communication Tools

The features utilised in Sakai are similar to those presented in Figure 3. Second year construction management & engineering students encounter TEL for the first time in this module and therefore receive a short briefing on the key features of Sakai. Funadmental issues such as logging-on and accessing the course material are outlined. Later in the module a short follow up session on the use of tools for 'assessment' and 'tests and quizzes' are presented. The continuous assessment element of the module accounts for 50% of the course marks and all submissions and course material are delivered digitally thereby creating a paperless 'green' module!

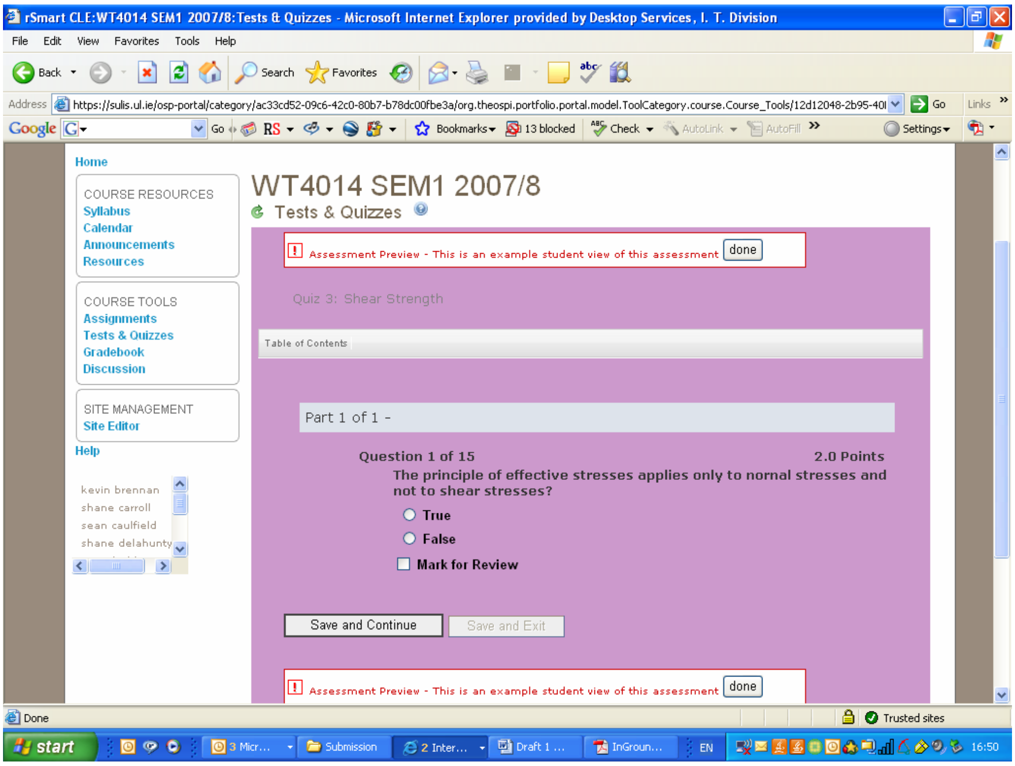

Figure 7: Typical Quiz

The opportunity to assess the experience garnered from this approach along with learner feedback provides an interesting pilot exercise that is used to troubleshoot the efficiency of the professional CPD portal. These tools contribute to learning throughout and module and provide prompt feedback on performance; a welcome addition to closing the 'learning circle' for the student. However, substantial difficulties remain with slow network speed when accessing Sakai either on or off campus. Moreover, after a preset period of inactivity, the system automatically logs-off students[1] and blocks assessment submissions with large file sizes (due mostly to digital images embedded in the documents). These difficulties are no more than teething problems that can be easily overcome with proper planning and technical support. They were nevertheless a source of immense frustration for the students who, perhaps due to a personal rapport developed with the lecturer, tend to be more accommodating when these difficulties arise. This tolerance is less likely with professionals' up-skilling via a web based blended learning programme.

[1] This was particularly a problem as students undertook research when answering quizzes on line

5. Longer Term Sustainability of CPD Construction Portal

The potential access to the outputs of this project is unlimited. The principal beneficiaries from this project's outputs are; construction management professionals across a wide range of disciplines that will profit from the collaborative development, lecturing staff from the institutions participating in the project, teaching staff at higher level institutes outside of participation institutions and researchers in the construction management field. Professional bodies charged as part of their charter to ensure that CPD opportunities are available, taken by members can also be encouraged to be involved, and can benefit from the project.

There is a requirement that the portal and the infrastructure to support the portal is an environment that facilitates and encourages access to lifelong learning opportunities. Active collaboration with both industry and the various professional bodies is key to the sustainability of this initiative. Collaboration of like-minded partners and peers will offer the opportunity to break out of the confines of traditional institutions and allow innovators to collaborate. If other private companies wish to use the learning objects as part of corporate development, programmes assistance and guidance can be offered as well as access to the learning material and framework on an agreed annual fee basis.

Encouraging collaboration is viewed as key to sustaining this project initiative as the EU funding ceases. This project network can act as a forum for dialogue and exchange. Research carried out by DG Education and Culture of EU Commission (2004) highlighted that there are different models that educational institutions are embracing with respect to incorporating e-learning into curriculum. The CPD in construction portal is a pioneering attempt to put forward a new model that may facilitate educational institutions integrating technology in the delivery of lifelong learning programmes.

Involving both professional institutions and construction representative bodies is seen as a key to the long term sustainability of the project. Any certification of the training and learning offered, possibly during and certainly after this project, will be based on it meeting the requirements for CPD of these professional bodies. The offering of these programmes could generate a revenue stream that can be re-invested into the network.

Other higher level institutes external to the partners will be invited to become involved in the network. In order to achieve the longer term goal of developing a database of learning material, a sharing of costs and benefits will be encouraged to sustain this initiative. Professional bodies in each of the partner countries will facilitate access to and ensure the availability of the material to construction management professionals throughout Europe.

6. Discussion

The facilities and capabilities offered by e-learning and technology in the delivery of training are considerable. Bruce (*2003; p 24)* notes "*today's students think of the Internet the way their parents and their grandparents…viewed electricity: ubiquitous and only noticeable when not available.*" For undergraduates' integrating technology into the process of learning is not a significant challenge. This may not be the case for more mature construction professionals accessing lifelong learning opportunities, where ICT presents a significant challenge.

Based on the research carried out as part of the EU programme, there is potential for such a portal and an opportunity for more collaboration to take place between the professional bodies, industry and higher education in the delivery of CPD using technology. If CPD becomes an obligatory requirement for continued professional recognition, this will have knock on effects for the professional bodies in terms of resource requirements to manage and police the content of the material delivered. Therefore, the professional bodies have to make a strategic decision that policy and policing of CPD is an essential component for the future success of the industry and profession. However, studies such as Hurst et al. (2007) in the UK indicate that industry does not place the same importance on CPD as the professional bodies.

As Thomas (1995) suggested for CPD to be well supported and regarded there has to be collaboration between employers, employees, the professional bodies and educational providers in developing an environment that encourages and facilitates access to CPD. To capitalise on this research and bridge the gap between, (i) higher education, (ii) the requirements of the various professional bodies and (iii) the needs of industry, there are a series of steps that should be undertaken:

1. Establish and test the infrastructure and framework which will act as the host platform for the technology facilitated CPD initiative
2. Establish the appropriate learning outcomes and competencies required by the professional bodies
3. Determine the breakdown of traditional and online delivery of the learning. As part of this ensure that as many methods of instruction and learning as possible, i.e. both formal and informal methods of learning are encouraged
4. The content delivered must be eligible for CPD credits by the relevant professional body. For educational institutions this means building links with the professional bodies and ensuring the quality of the delivered learning will meet both the competencies and learning outcomes required by such bodies
5. Where appropriate, register on the network of training providers compiled by the professional bodies. This will ensure, where applicable, that professional bodies' logos can be used. It will also assist in dissemination of the programme.

Through the execution of these various steps, an effective programme of CPD, meeting both the professional institutions and industry's learning needs can be deployed. Educational institutions are in a better position than most to capitilise on this though the formal QA systems that exist in the sector and in individual institutions, through undergraduate programmes developed which fulfil the criteria of the various professional bodies to meet industry needs.

7. Conclusion

The rational behind the first case study is to create an innovative international learning resource that is widely accessible to construction management professionals thereby facilitating improved knowledge and skills within the industry. It is well recognised that the integration of e-learning and blended learning into programmes is led by motivated and enthusiastic individuals with little extrinsic rewards structures to encourage these initiatives.

To date the major output of the project has been the development of a framework that will host a series of on-line training modules, a reference bank of materials, web-based services such as discussion groups and bulletin boards to act as a forum for the exchange of information and ideas between educational institutions, industrial and professional bodies. However, unless a strategic approach is adopted, resources deployed, and an appropriate support infrastructure is put in place, the longer-term sustainability of this initiative will be jeopardised.

The undergraduate case study presented highlights many of the benefits of delivering course material using TEL. In general, there was unanimous recognition that TEL improved the learners' experience, particularly the easy access to module documentation and the frequent assessment of course material using the 'tests and quizzes' option. These tools have contributed to learning throughout and module while prompt feedback on performance is a welcome addition towards closing the 'learning circle.' The instant emailing of module announcements and the highlighting of key milestone dates on the module calendar were also popular features. The system was not however without flaws, in particular, the following findings should be addressed if a professional CPD portal is to operate successfully:

1. Accessibility and slow of network speed were the greatest source of frustration for the users. A number of respondents noted being automatically logged-out by the system particularly when undertaking a module quiz. It is likely that these issues will also be concerns for the lifelong learner using technology as part of CPD.
2. Network restrictions on file size came to the fore when assignments with large file sizes (due to digital images) presented unforeseen difficulties for students submitting work close to the deadline.

While these difficulties can be overcome with appropriate advanced planning and the establishment of a proactive technical support team, the undergraduate pilot survey of TEL serves to stave off negative sentiment that would inevitably exist were these difficulties encountered by the construction professional. Moreover, the part time learner accessing material online from remote sites and poor ICT communications infrastructure may be de-motivated by slow or untimely access to resources. In conclusion, this work incrementally advances the CPD portal towards its full-scale implementation.

The use of online asynchronous discussion forums in the development of deep learning among postgraduate real estate students

Clive M J Warren
School of Geography, Planning and Architecture, University of Queensland
(email: c.warren@uq.edu.au)

Abstract

The role of learning management systems in real property education is examined in this paper with particular emphasis on the use of asynchronous discussion boards. The research shows that students readily respond to the use of online tools for communication and as an administrative tool discussion boards have a significant role in reducing the level of one to one communication required. They also enable student engagement with their peers in providing feedback. The use of discussion boards to achieve reflective writing and deep learning among students is demonstrated with a significant number of students participating at this deep learning level. The research clearly supports the use of these tools in enhancing learning in postgraduate courses and demonstrate that students are strategic in their approach to learning and will only fully engage with learning tasks where they are assessable and thus contribute to their objective of passing the course.

Keywords: real estate education, learning management systems, discussion forums, reflective writing, assessment.

1. Background

1.1 Developing technologies

Higher education is experiencing an explosion in online teaching tools. It is little more than ten years since anyone had heard of learning management systems but now everyone asks do you use WebCT or Blackboard. Hardly a semester goes by without a new building block being added to the range of online tools available to academics to 'enhance their teaching'. There is limited research however, as to the added value these systems bring to increased educational outcomes for students. Educational research has struggled to keep pace with the developing technologies. This has led to some criticism that it is the technology that is dictating the approach to teaching rather than sound pedagogy adopting the technology as an enhancement over traditional methods of course delivery.

This paper will explore the pedagogical rationale for the use of online tools in the delivery of postgraduate real estate courses and, in particular, explore the value of asynchronous discussion forums in engendering deep learning among students. The learning management systems commonly used in higher education, typically WebCT and Blackboard along with a range of other software packages and bespoke systems, offer the ability to communicate between members of a group in a threaded open communication visible to all members of the group.

1.2 Discussion forums in education

Discussion forums in which instructors and students post to a threaded asynchronous discussion provide a convenient mode of communication, but do they add to the education of students? Do they ‘change the way in which people understand the world around them, rather than as an accretion of facts and figures’ and thus lead to learning? (Ramsden 2003;79)

Discussion has long been a part of traditional class interaction. Online discussion forums, however, provide a very different format in that students are required to write their responses and post them for all to see. The process of writing in itself causes the student to engage in reflection: ‘Writing is the manifestation of thought. It is guided by and grounded in knowledge and experience. It is self-generated, constantly reviewed, questioned and revised’ (Redmon & Burger 2004;158). Thus the very act of writing is a learning activity that contributes to knowledge (Knowlton 2005;165; Pena-Shaff, Altman & Stephenson 2005). There are other benefits attributed to the written approach to discussion in that it is less prone to be dominated by a single participant and allows students not interacting in their first language to be able to spend time constructing their contribution (Havard, Du & Olinzock 2005). The asynchronous nature of the discussion is seen by Redmon & Burger (2004;158) to be a distinct advantage as it is ‘less bounded by convention’ and as such it can become a more effective medium for reflection. It would seem that there are strong positive outcomes for teaching and learning in adopting this written form of online interaction.

The literature shows that some negative aspects of online discussion are evident. Some students report a fear of presenting written thoughts for class comment (Havard, Du & Olinzock 2005). Other authors report an initial reluctance in students to participate largely linked to the unstructured nature of the process (Beyth-Marom, Saporta & Caspi 2005; Grandon 2006; Redmon & Burger 2004), indeed Pena-Shaff, Altman & Stephenson (2005;416) report that 51% of students do not view discussions as an efficient learning medium. The extent that these negative aspects are outweighed by positive aspects will be explored in this paper.

The literature on online discussion clearly shows that it is a challenge to motivate students to participate. Most research on the application of discussion forums indicate that active participation only occurs when the task is a formal class requirement with contribution towards grades (Grandon 2006;374). The compulsion to participate is argued by Knowlton (2005) to be an inhibition to active participation, as students seek to meet minimum standards rather than actively participate and reflect freely on others’ contributions. Pena-Shaff, Altman & Stephenson (2005;421) report a negative impact on participation where discussions are graded and found that some students ‘rebelled against the fact that discussions were graded.’ These students consider assessment counter to the aims of free and open participation in the discussion.

Thus the literature shows that asynchronous discussion forums, where reflective writing is required, can add to the learning experience of students and result in a deeper understanding of the subject under review. The literature shows that obstacles exist to successful use of discussion forums online; this is particularly so in engendering student participation and where assessment is not applied to the discussion, but on balance positive outcomes are reported across a number of disciplines.

1.3 Deep and surface learning in discussion forums

In the literature, it is recognised that student participation can vary widely from very shallow 'I agree' postings to deep reflection on the issue under discussion. Several authors have developed taxonomies to assist in classifying postings (Grandon 2006; Greenlaw & DeLoach 2003; Havard, Du & Olinzock 2005; Knowlton 2005; Pena-Shaff, Altman & Stephenson 2005). Each of the taxonomies of discussions have a common goal of differentiating between surface and deep reflective participation in the discussion. Greenlaw & DeLoach (2003;38), for example, provide a six level taxonomy of 'Critical Thinking', defining levels from 'unilateral descriptions' to 'merging values and analysis.' In this latter level students are 'able to move beyond objective analysis to incorporate subjective interests' (Greenlaw & DeLoach 2003;39). Similarly Knowlton (2005) provides a five point taxonomy ranging from passive to meta-cognative which closely resembles the stages from shallow to deep reflective learning to achieve 'internal mental representations of the learning process' and an 'environment well-suited for examining personal transformation' (Knowlton 2005;169). Other taxonomies are more about the level of discussion than the quality. Grandon (2006) provides a table of five discussion types, differentiating between support and administrative discussion through to participative discussion. The metric in this taxonomy is related to the level of use and satisfaction, and the former only where participation is voluntary. This taxonomy identifies that self-efficacy is important within participative discussion thus recognising the need for reflection and the need for more than surface learning. What is evident from all of the literature is that some measure of the student use of discussion forums is desirable and, that if real learning is to be achieved rather than just the transfer of administrative information, then students must be encouraged to be more than 'lurkers' within a forum, they need to actively participate and reflect on the postings of others (Knowlton 2005) . The measures applied to a forum must reflect this desired outcome.

1.4 The role of the instructor in online discussion

The level of instructor participation within an online discussion forum seems to fall into two distinct schools of thought; those that see the instructor as an active participant or leader (Dennen 2005; Pena-Shaff, Altman & Stephenson 2005; Redmon & Burger 2004) and those that strongly advocate that the instructor's role is one of moderation only (Dennen 2005; Heckman & Annabi 2006). The moderator role is only considered effective, however, when participants are encouraged to actively participate and reflect on the postings rather than instances where the instructor is imparting information in a more administrative discussion (Havard, Du & Olinzock 2005). Most authors conclude that the instructor must provide timely feedback to students in order for participants to value the discussion process (Pena-Shaff, Altman & Stephenson 2005;425).

The literature clearly supports the use of online discussion both at a surface administrative learning level and, more importantly, as a method of achieving deep learning and cognitive maturity in students (Pena-Shaff, Altman & Stephenson 2005;423). A clearly articulated taxonomy that recognises higher levels of deep and reflective learning will encourage active student participation at this level. The need for compulsory participation has its pros and cons but most authors recognise that assessment is part of the learning process and can encourage greater active and meaningful participation. The asynchronous nature of online discussion supports a written, more measured participation, which can negate some of the negative aspects of class discussion felt by those for whom the discussion is not in their first language or who are reluctant to speak freely in classroom situations.

1.5 Discussion forums in real estate education

There is considerable anecdotal evidence to suggest that the use of discussion forums in the education of built environment students is widespread. Certainly within the Australian context most courses delivered in the region are supported by learning management systems and a good number utilise discussion tools to some degree or another to enhance those courses. There is, however, little published research on the outcomes of utilising these tools and little research into student attitudes to online learning.

This paper reports research into the attitudes and practices of postgraduate students studying real property courses in a traditional on campus setting. It examines attitudes towards the use of online tools to support traditional classroom based learning with a particular emphasis on the use of asynchronous online discussion boards. The research compares the results from undergraduate students and postgraduate students studying real property courses within a traditional on campus setting. The paper examines the development of deep learning among students via the use of online discussion as a component of a wider course design.

2. A survey of student attitudes to asynchronous online discussion and an analysis of learning in online environments

This paper reports on a survey of both undergraduate and postgraduate students studying real estate courses. Students in these courses were encouraged to utilise the discussion forums within the learning management system, in this case Blackboard, to complete a range of tasks.

2.1 Methodology

In order to evaluate the use of asynchronous online discussion forums in real estate education, both quantitative and qualitative research methods have been employed. Two iterations of student perception questionnaires were used, each containing both open and closed questions.

In addition student discussion board postings were analysed. The use of a case study approach to draw on experiences of conducting online discussion in nine courses over a period of three years is also discussed.

The principal research method comprised a questionnaire which was developed to determine student's perceptions of the online teaching environment and the use of discussion boards as teaching enhancement tools. The questionnaire design for this initial survey was kept deliberately short in order to attract the greatest response rate from students. The questionnaire comprised ten separate questions. Nine of these were closed questions and required either a Yes / No or Don't Know response, or they sought an opinion based on a Likert scale of five possible responses plus a Don't Know option. The final question was open ended requiring an opinion from students of their experiences. The survey questions asked student attitudes to the broader use of online teaching tools and, more specifically, their practices using the discussion forum tools. The discussion tool used within the courses under study was at two distinct levels. All the courses had a very general level discussion designed to answer student concerns and queries relating to the course and to provide feedback. This discussion is superficial and fulfilled a more administrative role than seeking to attain any learning benefit. The second level of discussion, administered to a single cohort of postgraduate students, required active posting and critical thinking around a series of questions relating to content from the course and established by the discussion moderator.

This initial survey was administered online via Blackboard in the last week of semester. Participation in the survey was voluntary and responses were anonymous. The survey was administered to both undergraduate and postgraduate students undertaking courses across all years of the real property degree programs. It is acknowledged that by choosing to administer a survey using a web based learning content management systems that there is a bias toward students who are familiar with and comfortable using the technology. This constraint is considered, however, to be minor given that all students in the courses surveyed are required to use the technology for obtaining course materials and submitting assignments and, as such, must be familiar with its use.

A second questionnaire was developed for use with a group of postgraduate students who, as part of an assessment item, were required to actively participate in three separate online discussions each lasting over a four week period. Each discussion was initiated by the discussion monitor by posing a question relating to a provided reading. Students in this course were required to make a minimum of three postings to each discussion forum. This second questionnaire, in addition to the first survey described above, sought student feedback on the specific discussion forum assessment item. As with the initial survey this questionnaire was administered via Blackboard in the last week of semester following completion of the discussion forum assessment item.

In addition to the direct survey of students a review of participant's contributions to the three discussion forums described above provides insight into the students' abilities to undertake the assessment task. The instructions given to students clearly articulated a requirement that they be reflective in their postings, building on fellow students' postings and developing a depth of understanding of the discussion issue. Prior to commencement of the course students were provided with a guide to reflective writing and it was clearly articulated that the requirement is to not just report but to critically analyse and reflect on the postings of others. Textual analysis of the discussion against the assessment taxonomy provides insight into the extent of student participation and depth of learning achieved through this task.

3. Data analysis and results

The student survey of three separate cohorts at both undergraduate and postgraduate level provides a rich data source from which to derive an understanding of real property students' attitudes towards the use of online technology to augment traditional teaching practices.

3.1 Use of online learning management systems

Students were asked to rate their use of the Blackboard learning content system. Using a 6 point Likert scale, they were asked if the Blackboard system helped with their learning, in the course. The majority of students either agreed or strongly agreed that Blackboard helped their learning with 84% of undergraduates and 89% of postgraduate students responding positively. Those that strongly agreed were 44% and 67% respectively, which clearly shows that a majority of students are very positively oriented toward the use of Blackboard. Indeed, only one student, a first year undergraduate, responded negatively to this question.

The frequency of interaction with the Blackboard system could give an indication of the level of engagement with the course. Interaction may be through posting to the forum or simply by viewing the postings of staff and other students. When asked how frequently students viewed the discussion forum 45% checked the discussion more than twice a week and, of these, 30% check more than three times per week. The less frequent observers of the discussion were, 18% who viewed the discussion less than once per week and 6% less than fortnightly. Postgraduate students were less frequent viewers with just 33% checking more than twice per week. Weekly checkers were the largest group at 28%, with 22% in both the less than once per week and less than once per fortnight categories. The lower rate of views by postgraduate students is perhaps a reflection of their lower level of participation in the discussion which is discussed below.

3.2 Use of discussion board tool for course administration

There is a clear role for the use of discussion boards to help in administrative functions particularly in larger classes. Answering student queries can be addressed via a discussion board where students, themselves do not consider the communication of a personal and private nature. It has become increasingly evident over recent years that the ease of communication via email has resulted in increased communication from students to teaching staff. By addressing queries via a 'Frequently Asked Questions' discussion board and encouraging students to offer answers and opinions to their peers can significantly reduce the time spent by staff and students in dealing with these administrative procedures.

Students across all of the courses were asked a series of questions relating to their use of the administrative discussion board. There is a clear disparity between the results obtained for undergraduates than postgraduates to the question. Did they use the frequently asked questions (FAQ) discussion forum on Blackboard? Undergraduates reported a 73% usage of the discussion board, while only 28% of postgraduates used the site. This disparity of results between the two student groups is also reflected in the response to the usefulness of the discussion forum. Using a Likert scale question, 71% of undergraduates found the discussion forum useful while only 33% of postgraduates found the site of use. The level of negative response was only minor with 7% in both groups falling into this category. A neutral response was given by 56% of postgraduates.

There is no explicit reason indicated as to why there is a difference in response between postgraduates and undergraduates to the usefulness of a FAQ discussion forum. Students were asked if they had directly emailed the course leader during the semester with questions, a practice that had been discouraged in favour of the FAQ discussion forum. Undergraduates had a 45% positive response, while 61% of postgraduates responded positively. It is evident from these figures that a large number of students continue to use the more direct and individual email approach over the open discussion forum. This shows that there is still a strong preference to use email or other direct contact methods particularly by postgraduate students. There is however considerable scope to enhance the discussion approach and build further on its use, requiring students to use the FAQ and only responding to questions posted to the discussion forum are among the simpler ways of encouraging greater use. A more subtle approach might be to anonymously post simple questions and answers in order to encourage students to emulate what appears to be one of their peers using the forum.

The differing, lower level of use of the forum by postgraduate students is not explained within the survey. One possible explanation may be the difference in class sizes which facilitate a closer discursive approach to teaching within postgraduate lectures. This would not explain, however, the higher level of email correspondence directly with teaching staff. This aspect of the research requires some follow-up investigation in order to explain the difference before a greater reliance on discussion forums is pursued.

The promotion of peer interaction within the administrative discussion board was seen as a positive feature. The ability to answer fellow student's queries was reported as a positive feature by 87% of undergraduates and 83% of postgraduate students within the courses. When asked how many students answered their peer's queries, 26% of undergraduates said yes while only 17% of postgraduates responded positively. It is evident from this data that students value the ability to interact in this way although only a modest percentage had actually utilised the ability to respond. A review of the discussion board confirms these figures. It is interesting to note that in posting questions almost two thirds did so anonymously, and yet when answering other students a greater proportion were prepared to put their name to the response.

Students were asked if they thought that postings to discussion boards should be allowed to be anonymous. Only 13% of undergraduates thought that they should, the majority 67% neither agreed nor disagreed. This contrasts with the postgraduate findings where only 16% thought posting should be anonymous, 33% were neutral and 45% disagreed with anonymous posting. There is no explicit reason given for this difference, however, one might surmise that it reflects the closer relationship that postgraduates enjoy in smaller classes together with a more mature attitude to learning.

One important factor revealed in the literature on discussion forums is that students should not feel threatened by the experience of posting their thoughts in an open forum. To try to investigate students attitudes to this, students were asked if they felt supported by their peers in posting to the forum. Undergraduate students responded positively with 59% agreeing or strongly agreeing with the statement that they felt supported by other students in posting to the discussion. A neutral response was given by 23% while only 4% did not feel supported by their peers. A similar result in terms of a positive response, 56%, was reported by postgraduates, although 22% posted a negative response revealing that they did not feel supported by peers when undertaking online discussion. This result shows that the majority of students felt positively supported; however the larger negative response from postgraduates raises some questions as to why this might be the case. It must also be considered that it is unlikely that students would always feel completely supported by their peers as they are working in what many conceive as a competitive environment where grades have to be fought for against competing students.

3.3 Use of assessable discussion boards

The second part of this research relates to a single postgraduate course where, as part of the assessment, students were required to participate in an asynchronous online discussion covering three separate topics each over a 4 week period. In addition to the questions posed above this group of students were also asked to evaluate the course based discussion board.

The discussion was made an assessable item within the course. It was made assessable as in the previous year a similar discussion was promoted with students and participation proved minimal. Students responded very positively to the question should the discussion be an assessment item, with 71% saying they agreed or strongly agreed, while only 14% disagreed with it being assessable. In a related question they were asked if they would have made fewer postings if the discussion was not assessable; 29% responded with much less and 42% with less. Only 14% said they would have posted the same. This result clearly indicates that students are motivated by assessment and passing the course and will avoid items that do not directly contribute to that goal.

While students appear oriented to strategically participating in learning activities that contribute to the final grade, 72% found the discussion a worthwhile learning tool for the course. No students posted a negative response to this question although 15% were neutral. This is a good indication that students enjoyed the discussion task. Students also felt that the asynchronous nature of the discussion allowed them to give a more considered answer than they would in a classroom discussion, with 70% responding positively to the question.

An analysis of the discussion forum itself provides some insight into the usefulness of the tool. It should however be noted, however, that only 15% of students made more than the required three postings to the forum compared to 25% that did not even make this minimum. Looking at the text of the students that made below requirement contributions their postings can be categorised in the marking taxonomy given to students as superficial. They report on information researched but not necessarily fully in tune with the discussion or they provided unsupported opinion. These students demonstrated that they were going through the motions rather than engaging in deep learning. The students who fulfilled the discussion requirements provided a mixture of approaches. About half of the students took a minimalist approach, posting articles and other research items addressing the issue posed. The results from 36% of the participants achieved assessment scores equivalent to meeting the required level of critical analysis and reflection. These students clearly demonstrated an engagement with the issue under consideration but also built on the dialogue of others adding critique of items posted. Of those students achieving high marks, 12% performed at distinction level, demonstrating a high level of learning and critical analysis of the problem.

The results of analysis of the discussion board content show that a many students did not achieve a level of deep learning from the exercise, or at least did not demonstrate that learning in their postings. What is evident, however, is that at least 36% of students engaged in the discussion demonstrated a deep understanding of the issue under discussion and were able to enter into critical argument with peers as to the value of any particular item posted. This level of engagement in deep learning demonstrates that asynchronous discussion forums can achieve sound learning outcomes for at least a third of students within the cohort and, as such, justifies the use of this technology as a supplementary tool in teaching real property courses. Further work is required however to refine the discussion tool to achieve even greater levels of learning.

4. Conclusions

The literature shows that the use of technology in teaching is growing almost daily and that there is an ever increasing array of tools available to support higher education. The literature also shows that very limited research has been undertaken to demonstrate the pedagogical rationale for utilising many of the available technological solutions. This research paper has attempted to link the literature on the benefits of reflective writing in engendering deep learning among students with the use of asynchronous online discussions.

The research has clearly shown that at both undergraduate and postgraduate levels there is a widespread acceptance of the learning content management software, in this case Blackboard. Students readily interact with the online system and welcome its use in teaching and as a primary means of communication. It also demonstrates that most students are active users of the systems and if not active participants they are certainly monitoring postings. The results in terms of the use of discussion forums for administrative uses is certainly positive, showing that the majority of students are prepared to use open, asynchronous communication to ask and receive feedback on course related queries. This finding has significant implications for academic staff leading larger courses as it provides a tool for reducing the level of one on one interaction via email and telephone. It also provides a forum in which students are able to assist peers and to work as a group in providing assistance and feedback. This ability to ask and have answered questions in an anonymous form is seen as a valuable attribute, that removes the possible embarrassment that may be otherwise felt in asking a simple or naive question. There is also a positive aspect of students responding to their peers in that they themselves need to be fully engaged with the content and procedures within the course in order to post a meaningful response. It of course remains essential that lecturers monitor and moderate the postings so that students are aware that any statement made by a peer in error is quickly addressed. The level at which this peer assistance occurs could be increased but at any level must be a positive over the non-involvement that occurs when communication with staff is constrained one on one.

The other and more pedagogically important aspect of the use of online discussion is in its use as a teaching tool that seeks to achieve an increase in students learning and understanding of the subject. There has been some debate in the literature as to the merits of assessing online discussions. The results of this project clearly show that postgraduate real estate students strongly favour the assessment of discussions. This is reinforced by the clear indication that if it were not assessable then discussions would not receive the same level of attention. Indeed experience from previous years and using the same discussion format support this finding. It is a fact of life that postgraduate students with their heavy work, study and home commitments are strategic in their approaches to education and will ‘cherry-pick’ those elements within a course that contribute directly to passing the subject. That said a proportion of students are driven to achieve high grades and have a passion for understanding the issues, and, as such, will seek within a discussion to go beyond the base requirement with more detailed and a greater number of postings. The evidence from this study shows that while an assessed discussion many will still seek to undertake the minimum requirement in terms of postings and do not engage in any deep reflection of fellow student’s points. A significant number of students do however use the discussion as intended, and research and critically assess postings of others. Analysis of contributions has also shown that these students are engaged in deep reflective learning of the course materials and, as such the use of asynchronous discussion forums in real property courses has proved a pedagogically sound approach to enhancing learning in real estate students.

Abstract

This paper describes the development of a web-based support environment for students undertaking the first year Eco-House design project as part of the Environmental Building Degree Programme at the University of Plymouth in the UK. This e-Support environment provides students with a flexible and extendable search structure that allows them to obtain deeper information on specific systems they can apply in their designs, or on fundamental issues that the project raises. The resource links into websites of manufacturers and product data as well as giving access to serious academic papers. It will be developed further over future years to provide an expanding source of information and inspiration for subsequent generations of students. This paper describes how the e-Support environment was developed using an action research cycle, which included using critical reflection and feedback from different stakeholders. It presents the current form of the environment, an estimate of the impact on the Eco-House design projects, and areas identified for further development and improvements.

Keywords: web-based resources, studio teaching, support, Eco-House

1. Introduction

The Eco-House project is the main element of coursework on the Domestic Construction Technology module ENBS 111, taught to first-year students working towards accredited degrees in Building Surveying, Environmental Construction and Construction Management at the University of Plymouth, England. The project is embedded in the Environmental Building Programme which aims to support students through a variety of mechanisms, which include formal lecturing, close tutorship relations, and self-learning, see for instance Murray *et al*. [1]. The Eco House project is carried out as group work in a studio teaching setting culminating in a range of outputs including drawings, models and product information (Figure 1). More general information on the Eco-House project is provided in de Wilde and Pilkington [2].

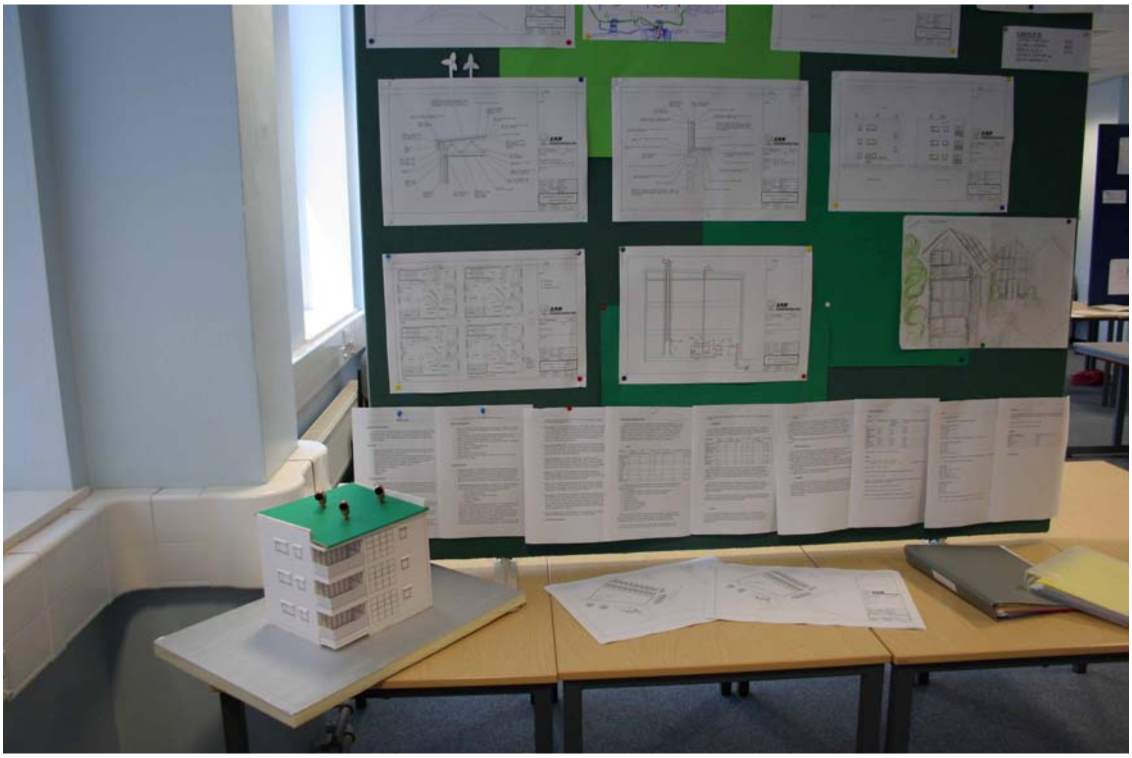

Figure 1: Eco-Project final results from the 2006-2007 academic year.

While the Eco-House project is viewed by students and staff as a valuable element of the course, previous experience indicates that there is insufficient time during design surgeries for the tutor to advise in depth on specific construction and services systems, materials and other issues that students may enquire about. This problem is inherent to the nature of studio design where students are asked to come up with different ideas and approaches, which cannot all be covered in contact time. The e-Support environment has been developed to address this issue by providing students with a search structure that allows them to obtain access to in-depth information on specific systems they may apply in their designs. To do this the e-Support environment links into websites of manufacturers, product data and serious academic papers and will be developed on an ongoing basis to provide an expanding source of information and inspiration for subsequent generations of students undertaking the Eco-House project.

2. Objective

The overarching aim of the e-Support environment is to provide flexible opportunities for students to deepen their knowledge of key aspects of domestic eco-construction. To achieve this aim a student portal or independent website has been developed to achieve the following objectives:

- Provide a (flexible and extendable) search structure that allows students to obtain deeper information on specific systems they apply in their designs, or on fundamental issues that get raised;

- Provide links to websites of manufacturers, product data as well as serious academic papers;

- To inspire the building designs of subsequent generations of students doing the Eco-House.

The main beneficaries/stakeholders for the development of an e-Support environment are the first year students that undertake the project. The environment allows students to work and learn flexibly (at their own pace, at the time of their choosing, and in the environment of their choice), by integrating the resource within the university's web-based intranet, which is available to all enrolled students. A second beneficary is the module leader because the support environment helps teach, guide, inform and support the students in their coursework in a way that would previously have had to be done on a one-to-one tutoring basis.

Other parties that might have some interest in the e-Support environment include:

- Students on other years / modules of the Environmental Building Programme, who might have an interest in some of the subjects covered or might be doing similar assignments.

- Other lecturers on the Programme, who might want to use it in their teaching.

- The ICT Support team of the University, including the library, who might want to ensure set-ups like these fit into the overall university-wide system, or might want to bolt-on to this structure.

3. Methodology

The underlying thrust of the work presented in this paper is the development of a a major learning resource through an incremental, informed, reflective and ongoing process. The overarching methodology used in projects that aim to improve (teaching) practices, and the environment in which this practice takes place, is known as action research. The main characteristics of action research have been defined by Martella *et al.*[3] as research: 1. where the researchers have a stake in the outcomes; 2. that addresses real-life situations; 3. where the ultimate goal is to make changes to some practice; 4. where the researchers participate in the process; and 5. that sees solutions disseminated in some manner.

The main aim of the action research presented in this paper is to improve the learners' experience. The research has the form of a cycle of diagnosis (identifying or diagnosing a problem), action planning (consideration of alternative courses of action for solving a problem), action taking (applying course of action), evaluating (studying the consequences of an action) and specifying learning (indentifying general findings), all of which revolve around developing a system/structure serving the main aim [4].

Within the cycle, one of the most important elements of data gathering is obtaining feedback on learners' experiences. Here, triangulation involving the use of different data sources in order to overcome the problems inherent in using a single one, [3] has been applied in gathering feedback. The following information gathering techniques have been used:

- Previous feedback on the 2005-2006 Eco-House project has been revisited in order to identify any trends or findings that might guide the provision of additional support for the future academic cohorts. This has been based on reviewing existing, collated data at the disposal of the lecturer.

- Informal, unstructured feedback from students who undertook the project in 2005-2006 has been solicited from the current 2nd years students by means of a brainstorm session at the end of a lecture, in order to solicit their views and experiences and to obtain an informed opinion on the proposal to produce this resource.

- First year students undertaking the Eco-House project were encouraged to explore and use a prototype e-Support environment as a pilot. They were asked for feedback both in a very informal way, inquiring about findings during design surgery sessions and formally by means of an anonymous, structured questionnaire upon completion of the project.

- Specific in-depth feedback was requested from colleagues on the Environmental Building Programme. This feedback was structured by asking colleagues for feedback along the same lines set out for the students, but with the request to view the whole effort from an educational view next to the practical 'face-value'. These colleagues are also all experts on the topic covered by the e-Support, and hence able to comment on contentual matters.

- Directed technological feedback has been obtained from the ICT support staff by means of directed email questions.

4. Background on Support Environments

In construction education, especially architectural, studio teaching has been a central concept to teaching design for most of the twentieth century [5]. This is because studio teaching sees students involves students in learning by doing, experiencing the design process in an active, hands-on manner, and integrating the different disciplines needed in design. Design projects and studio teaching are also successfully being used in other fields of engineering [6].

The e-Support environment, as envisioned for the Eco-House project, makes use of advanced ICT facilities that are seeing an ever-increasing uptake in academic programmes. A good overview on the role of such systems in teaching construction technology to undergraduate students in provided by Chung *et al.* [7]. As stated by Race [8], the use of internet as a tool in teaching has some risks, like getting side-tracked by fascinating things that are unrelated to the actual task. One solution is development of a set of interactive pages by the lecturer, which might help in directing the students to appropriate sources of information, rather than having the students search for themselves [9]. When using the internet in this manner within a course, the teacher/lecturer can be considered to be a 'coordinator of learning experiences' [10]. A more detailed breakdown is provided by Garrison and Anderson [11] who discern three main teaching roles within the area of e-learning:

- design and organisation;
- facilitating discourse;
- and direct instruction.

To guarantee the integrity of a website, one needs a team to maintain the site and a regime for updating and vetting the information it provides. In creating an interactive support instrument like a website, lecturers developing such resources need to be aware of five main issues [10]:

- the *time* needed to develop and maintain the material;
- the *role of technology*, which might both help or hinder the lecturer and students;
- changing *barriers arounds topics/issues* in the context of the web;
- the need for *training* of the learners in using the instruments available;

- and *infrastructure* requirements.

For the development of the e-Support environment, the context has been the status of the ICT-infrastructure at the University of Plymouth in the year 2006-2007. Basically this consists of a 'Student Portal' facility, which is a web-accessible folder structured within the constraints of Microsoft Outlook on the intranet of the university [12]. Whilst undertaking the development of the resource it has become clear that the ICT-infrastructure within the University of Plymouth would be significantly upgraded in the new year [13], which had to be taken into account when planning for the future use and enhancement of the resource .

5. E-Support for the Eco-House Project

5.1 Development Process

The development activities have been undertaken through the following cycles within the overall framework of action research:

1. Diagnosis – identification of guidance information and subsequently aims and objectives for the project.

2. Action planning – development of a plan of action for the creation of an e-Support prototype

3. Action taking – actual creation of the e-Support prototype (version 1).

4. Evaluation – analysis of preliminary learners' experiences with the initial prototype (mostly technical glitches)

5. Diagnosis – identification of technical problems with the prototype

6. Action planning – involvement of ICT Support to solve technical issues

7. Action taking – technical solutions by ICT Support implemented, resulting in migration to e-Support prototype (version 2).

8. Evaluation – gathering of data on learners experience with e-Support prototype (version 2).

9. Diagnosis – analysis of contentual feedback, problem areas as identified

10. Action planning – development of ideas for migrating the e-Support prototype version 2 to the new ICT infrastructure, and making it a core element of the upcoming Eco-House project (2007-2008).

The above activities are graphically represented in figure 2.

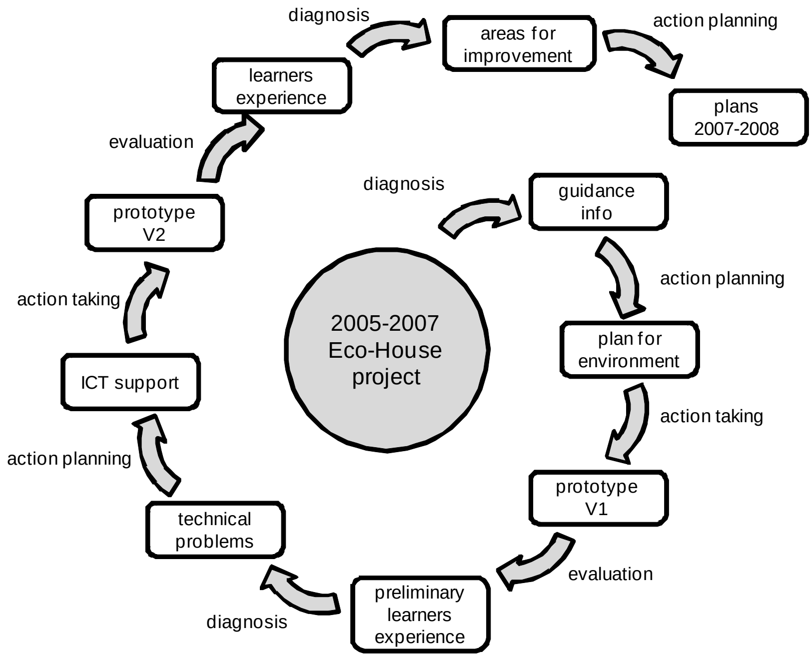

Figure 2: Activities and processes undertaken in the development project of the e-Support

5.2 E-Support Prototypes

Feedback collected over last year's (2005-2006) Eco-House project has been reviewed, in order to inform the development of an instrument to support the 2006-2007 cohort. While the feedback collected was general in nature and for instance included remarks over the split-up in teams, timing of end presentations in relation to the exams, it also suggested that the Eco-House project 'should provide learners with opportunities to do some of their own research', and that one way of improving the project would be to 'put more emphasis on background reading'. At the same time a recommendation was to 'make the project less formal', seeming to indicate that students like some amount of freedom in how they go about this particular piece of coursework.

A small group of four students from the same group from which the above data was collected (2005-2006) was informally asked about the idea of developing an e-Support environment before embarking on the project. It must be noted that these were mostly the high-performing students who enjoyed the project, and had a good working relationship with the lecturer. Overall these students supported the idea of developing a 'support website'. They suggested that the resource should include a number of local Eco-Houses in England, preferably even South-West England where the eco house project site is located (the examples provided in the course notes [14] are mostly international). Furthermore, they suggested that links could be provided to the local authoraties relevant to the project, and requested inspirational material for the selection of house building systems.

The initial development of the e-Support environment has been based on the notion that it is generally recognized that one of the prime ways of promoting access to the internet is to develop a clear and organized page (“hub”), with a clear and simple style [15]. It was decided to keep to this hub theory without adding additional features. One could easily make a more complex e-Support system that includes for instance technologies like a blackboard messaging system, virtual meeting facilities, project data repositories and RSS feeds; however, such aspects might distract from the basic information gateway that was envisioned. Furthermore, including these in the Student Portal facility might result in practical difficulties that are beyond the scope of the one term effort allowed for in the project.

The basic layout of the hub has been designed based on access from a starting page on the portal. This starting page has been used to set the context for a prototype support system, and to carry basic instruction for users. From the start page, a link is provided to the actual hub. This allows a quick overview and access to the main categories of information included in the prototype version. Categories of information provided are based on the suggestion of last years students to include links to UK-based case studies, and categories defined by the lecturer: case studies, design principles, design tools, planning & regulations, energy systems, water systems, and construction materials.

Each category has its own separate page, where a collection of links is provided, together with a short description of what information is accessed by following the link. This additional information is useful as it allows the lecturer to make students aware of commercial context, slightly opiniated subpages, etcetera. The content of the webpages has been based on an organically grown collection of weblinks collected on the topic of Eco-Houses by the lecturer over the 1996-2007 period, completed with an intensive websearch tool to add links where specific topics were felt to be missing. While the original idea was to have students undertaking the design project to find and suggest links, it was deemed better to set standards by grounding the e-Support system in academic experience.

The e-Support system has been created using Microsoft Frontpage 2000. Resulting HTML-files have been uploaded on the portal, and tested for accessibility through the student portal from the lecturers office computer. A typical screendump from one of the e-Support pages is shown in figure 3.

6. Evaluation

The key deliverables of the project were identified as:

1. To provide a flexible and extendable search structure to find information that can be used in the design project

2. To provide links to external websites of manufacturers, products, academic information

3. To inspire the actual design work of students undertaking the Eco-House project.

A prototype e-Support has been developed and improved, with the process described in the previous sections, delivering key outcomes one and two. Key outcome three, inspiration of student's design work, is hard to measure by its very nature. However, feedback obtained from students leads the author to believe that some success has been obtained in this area.

Going beyond the strict deliverables, the underlying critical factor for the e-Support system has been to develop an environment that serves the students undertaking the Eco-House project, enhancing the learning experience.

Evaluation of the learner experience has been taken to be a continuous process. Data collection for student feedback, supporting evaluation of this learners experience, has been ranging from very informal (literally a discussion with students while undertaking design surgeries) through to formal feedback questionnaires. Furthermore, academic colleagues have been asked to comment on the prototype system with the learning experience in mind.

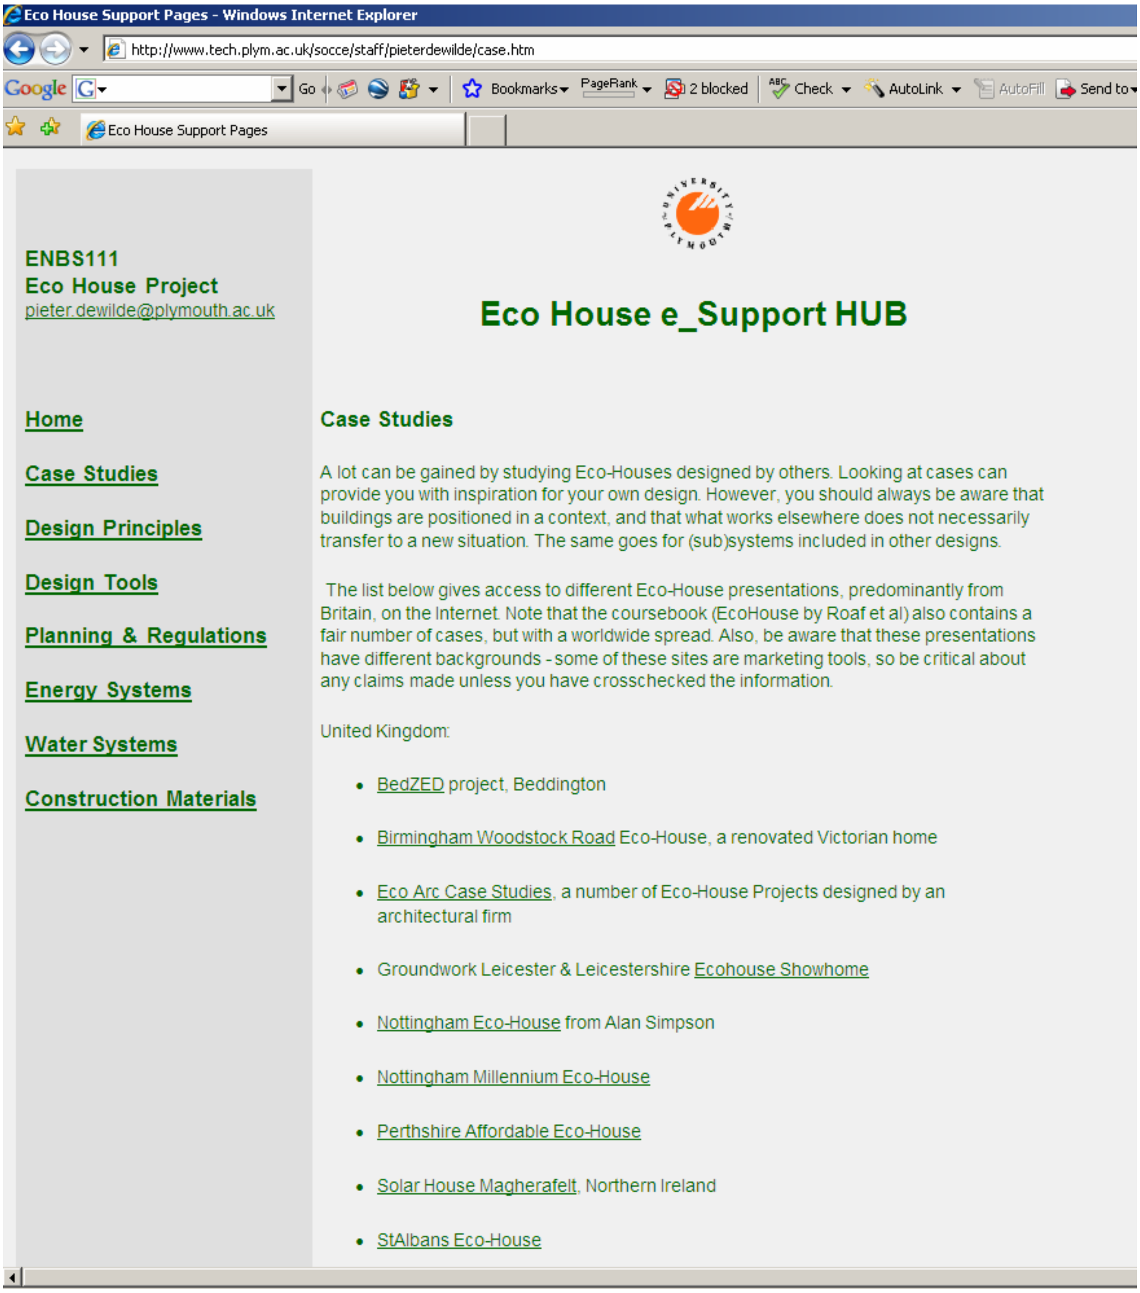

Figure 3: screendump from one of the e-Support pages

The scope of student feedback received to evaluate the e-Support is limited. Many of the informal discussions revolved about technical access to the system, which was mainly related to the University of Plymouth Student Portal currently in use, (due to be replaced in the next academic year). In general, the tutor's experience was that getting students to access and use the system proved hard. For instance, an end-of-project feedback questionnaire showed that out of 21 responses; 9 students said to have used the e-Support system (43%), while 12 did not (57%). The actual percentage of non-users is probably higher; as this might be amplified by non-respondents to any queries or email (overall response rate was 21 out of 47, i.e. 45%). This might be due to the fact that a cautious approach was taken, including the use of a full ethics protocol, which might have been taken by some students as 'voluntary material only, no need to bother'. In future, further monitoring of student's use of resources provided and reasons for not using material available will be a priority. Interestingly, this finding was mirrored by the feedback received from colleagues. One of these pointed out an observed parallel with a module where students were supplied with module books as a baseline reading resource, but failed to use this. From here it can be said that students should be actively encouraged to make use of such resources, for instance by requiring the underpinning of their designs by referencing to such information as provided in the e-Support system. This suggests the development of an active link between the project assignment and resources provided (text books and e-Support) for the next academic year.

Overall however, the general feedback on the structure of the e-Support was positive. There does not seem to be any need to change the basics, only further development with more links, and perhaps a few more commenting words on selected topics. The information linked to by the e-Support has been deemed very useful and interesting, and might be of use outside the scope of the ENBS 111 module. For instance, it has been suggested that the resource might be made available to students on a related Master Programme.

A minor aspect brought to the attention by deep feedback from colleagues is the need for a constant monitoring of whether links work, due to constant changes on the websites to which an e-Support systems links. In the current year this was all checked when the prototypes went online; even then a short time later already shows some links becoming erroneous. This seems another area where learners might take control of their own resource/support, and might be asked to feedback any problems encountered.

7. Conclusions and Discussion

In general, the reactions by those who used the e-Support offered were encouraging – students for instance found the system '*very good and easy to use. Really in depth and the stuff you need.*' and commented on it as having a '*good, nice and simple structure. Good information. Not any suggestion to improve right now.*' It seems therefore that the lay-out and content of the e-Support system is working well in supporting students, and can be kept as-is for future years.

The author of the system feels less successful in getting the students to engage with the support provided. The e-Support environment was intended to be offered as additional help, and therefore a lot of effort was put into making the system easily accessible. However, this was not sufficient to get all students to access or make good use of the resource. This finding reflects a general trend noticed in the cohort, where students seem to be making little use of the textbooks suggested, and seem overly reliant on lecture presentations and hand-outs in preparing for the exams. The suggestion to tie the e-Support into the assignment and require students to make use of it will be taken forward, as this can only help the students in becoming aware of the availability of the resource and encourage wider use and search later. Another option might be to work on making the environment more attractive and interactive, while maintaining the present focus on good contents.

In terms of providing support for the design project, it is believed that the e-Support has benefited students in carrying out their project, but linking the use of the system to specific characteristics of the final projects has been evasive. A more direct link between parts of the assignment and information contained in the e-Support system might benefit this link as well.

On the short term horizon, the e-Support environment will migrate to the new Student Intranet Module Website in September 2007. The basic structure will be kept in place, with links updated and expanded. The coming year will also see the modification of the Project Assignment, to encourage students to engage with the resource by means of specific tasks, making some basic use compulsory. Further options will also be investigated. Topics to be investigated include positioning the e-Support environment in such a way as to support continuing professional development (CPD), as suggested by for instance Wall *et al.* [16], including a part of the website to support online collaboration and lecturer input as described in Zimrig *et al.* [17]. Providing web-based project presentations and assessments will also be explored in the long run.

Abstract

The UK construction industry has a particularly low participation rate of women, both for those employed in the industry and for those engaged in training. The statistical analyses reveal that women are earning a greater number of professional degrees and entering the labour force; however, these women are not reaching the top corporate management tiers. It has been identified that lack of training has helped to prevent entry of women into the management ranks in many organisations and keeps women at lower levels within management. In this context, it is vital to consider the impact of proper training and development (T&D) towards the women's career advancement in the construction industry. Accordingly, this paper highlights those aspects which will be addressed when designing a feasible research methodology for the study under consideration. The paper illustrates how the philosophical issues directed the use of case studies as the suitable research strategy and selection of Individual as a case in this particular research. The paper will be concluded with a discussion on the importance of case study design in gaining the maximum outcome from the research.

Keywords: Case Study, Research Philosophy, Research Strategy, Training and Development, Women's Career

1. Background

The UK construction industry accounts for 10% of GDP and employs 2 million people [1], of which under 11% are women [2]. This makes the construction industry one of the most male dominated industries, which thus presents challenges relating to equal opportunities [3]. However, there is now a noticeable widening of the debate around the business benefit of diversity [4]. Recent research has highlighted one of the objectives in the diversity movement in construction is to increase numbers of women in the industry [4]. It is assumed that a greater number of women will be a clear sign of increased equal opportunities policies working, and reduce the skills gap and labour shortage in industry [4]. Thus, a logical solution to increase the number of women in the industrial professions is attracting more women to the industry initially and then subsequently increasing the retention of them [5]. Hence, both recruitment and retention is equally precious to raise the number of women. Numerous research studies have been conducted into how to attract women into construction [6] [7] [4]. However, the desired effect hasn't as yet been seen in the construction industry. The problem at the moment appears to be that women are leaving the industry before they have reached higher management positions, or that they are remaining in junior positions longer than their male peers. Several barriers have been identified which prevent them progressing within the industry. Furthermore, structural barriers exist to exclude women from the sector, such as facilities, training, career progression, education, lack of promotion prospects, industry culture, and flexible working hours [8] [9] [10] [11] [12] [7]. Additionally, [6] identified that lack of training has helped to prevent the entry of women into management ranks in many organisations and kept women at lower levels within the management hierarchy. The [13] study highlighted a lack of T&D as a particular barrier to the career progression of women in any sector. Through the literature, it was identified that the concept of women's career advancement and construction T&D is not adequately exploited. Therefore, this study intends to address the gap in construction T&D and women's career advancement in the construction industry. Accordingly, the aim of the study is to explore the impact of T&D towards women's career advancement in the construction industry. Accordingly the following research questions were formulated in order to fulfil the research aims;

1. Why is women's careers advancement important to the construction industry?
2. Why is T&D important to women's career advancement?
3. What is the current status of T&D, on women's careers advancement?
4. What are the barriers faced by women, receiving T&D in the construction industry?
5. How can T&D address the issue of women's careers advancement in the construction industry?

This paper discusses the research methodology adopted for this study with particular reference to the use of Individual as a case in the research strategy selection. The philosophical undertaking of the research pertaining to the study is presented firstly followed by a discussion on the selection of research approach and research strategies. The case study design is presented in the next section, highlighting the rationale behind the use of Individual as a case in the case study design. Next, the paper examines the research techniques, data analysis are used in the study and finally the conclusion.

2. Designing a research methodology

Research methodology refers to the overall approach of the design process from the theoretical underpinnings to the collection and analysis of the data [14]. There are many factors to be considered when choosing an appropriate research methodology; the topic to be researched and the specific research question are the primary drivers in the choice of methodology [15]. The study is focused on women, who are working within the professional capacity in UK construction organisations. The boundary of this study is considered as an environment, where women's career advancement is carried out. The conceptual model given in the below illustrates the concept of this research derived from the literature review. It shows how the research problem is embedded within the scope of this research. The core of the model represents the unit of analysis of the study; women's careers which are embedded in construction organisations within the construction industry. It indicates different career phases and the need of different T&D in each career phase in the organisations. Accordingly, investigation of different T&D requirements in different career phases such as; Idealism, Endurance and Reinvention phases will be the scope of the research. Further, it shows the need for identification of different T&D in the different career phases may help to advace women's careers in the construction industry. Therefore conceptual model (Figure 1) maintains the direction and cohesion of elements by representing a holistic research methodology.

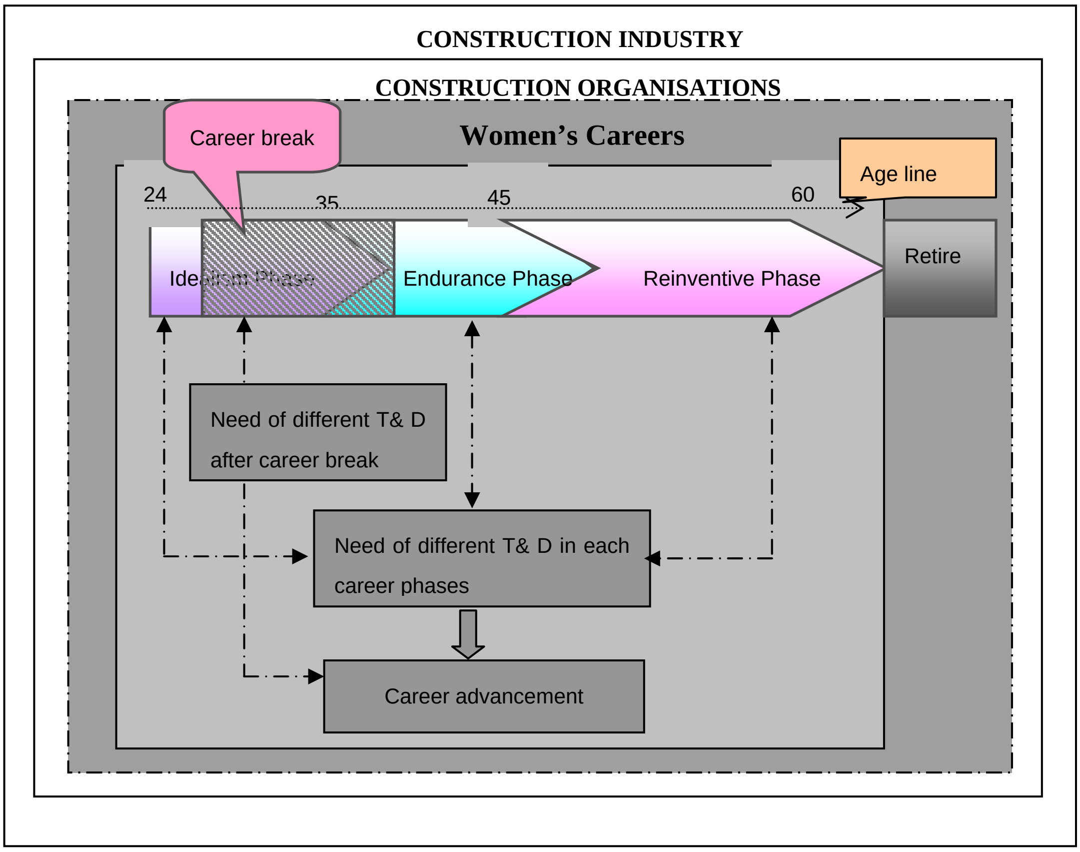

Figure 1: Research conceptual framework

For this purpose, the hierarchical model of research methodology by [16] is used. Within this research "onion" as shown in Figure 2, the research philosophy found at the outer ring, "guides and energises the inner research approaches and research strategies. Further, choices, time horizons and data collection and data analysis are constituted" [16] .The following sections further describe the research philosophy, research approaches, research strategies, techniques and procedures.

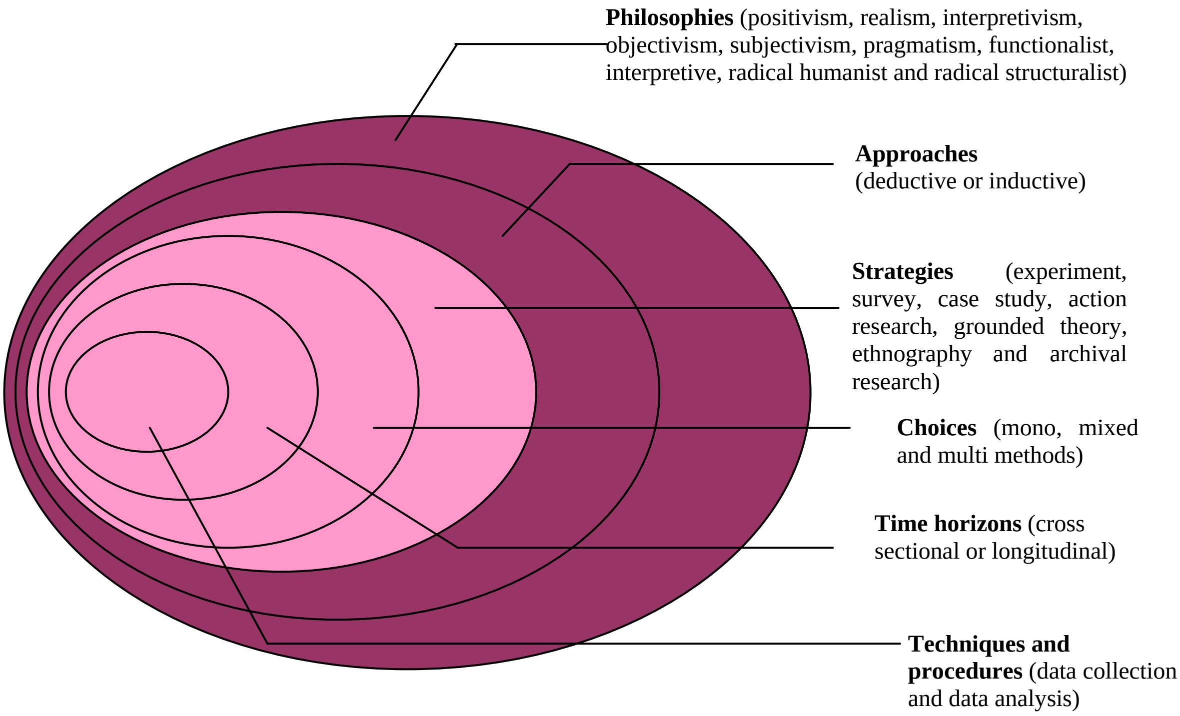

Figure 2: The research "onion" [16]

2.1 Research philosophy

The research philosophy contains important assumptions about the way in which we view the world [16]. In part, the philosophy the researcher adopts will be influenced by practical considerations. However, the main influence is likely to be the researcher's particular view of the relationship between knowledge and the process by which it is developed [16]. In this discussion, three major ways of thinking about research philosophy are identified: epistemology, ontology, and axiology [16]. Epistemology concerns what constitutes acceptable knowledge in the field of study [16]. [16] identifies three traditions of philosophies: "Positivism," "Realism" and "Interpretivism". Positivism argues that "working with an observable social reality and that the end product of such research can be law-like generalisations similar to those produced by the physical and natural scientists"[15]. Realism is another epistemological position that relates to scientific enquiry. The essence of realism is that what the senses shows us as reality is the truth: that objects have an existence independent of the human mind [16]. Interpretivism emphasises the different between conducting research among people rather than objects [16], where the social scientist should welcome and appreciate the different views and meanings that people place upon their experiences [17]. Ontological assumptions or the assumptions that are made about the reality of the nature is other important aspect within the research philosophy [16]. Moreover, this raises questions about the assumptions that researchers have about the way the world operates and the commitment held to particular views. Within the research philosophy, Axiology involves the values, ethics, and belief systems of a philosophy. It is a brand of philosophy that studies judgments about value [16]. Axiology concerns assumptions about the value the researcher attaches to the knowledge. Interpretivism (social constructionism) suggests that the research is value-laden [18] whereas positivism suggests the researcher should retain a value free view.

This discussion provides a basis to judge the philosophical base of the study in question. As set out by the aims and objectives, this research involves the study of complex interactions between people in real-life settings. Furthermore, this study requires the researcher to be a part of the environment and interaction is needed within the environment to identify the different views of people and to interpret them. For instance, the views about the importance of women’s role in the construction industry, factors which are needed for the successful attainment or enhancement of women’s career in construction, suitable T&D models and methods for their career enhancement. It requires appropriate understanding of the context and the process of women’s careers, and acquire knowledge by the use of reasoning, intuition, or perception. Accordingly, it can be argued that Interpretivism is preferred over positivism and Realism stance of epistemological undertaking for this research. This research involves women in different construction organisations, in different career phases. So, individual woman will perceive different explanations on the impact of T&D towards women’s careers in construction industry from their own experience in the industry. Further, the research environment is not expected to control and simplify with assumptions as in deductive research methodologies and the free flow of ideas, perceptions will be encouraged and studied. Hence, it can be seen that this research favours a subjectivism rather than an objectivism stance in the ontological assumptions. The research requires respondents to come up with their own views on T&D and women’s career enhancement issues in the industry. Whilst interviewees engage in different career phases of women in different organisation and will have different experiences, finally different answers may appear. Therefore, it may be difficult to arrive at sensible answers. Hence, research may add her own value to those answers since, the researcher is quite familiar with this area of research due to personal experience of the career enhancement process and T&D programme. In this sense, this research is based in the value laden position in axiological purposes. Subsequently, the selection of suitable research approach is discussed in the next section.

2.2 Research approach

The research will involve the use of theory which, may or may not be made explicit in the design of the research, although it will usually be made explicit in the presentation of the findings and conclusions [16]. This is dependent on whether the researcher should use the deductive approach and design the strategy to test the hypothesis, or the inductive approach, in which the researcher would collect data and develop a theory as a result of his/her data analysis [16]. By considering the above facts and aim & research questions of the research, the researcher will be able to interview women working in the industry to share their experiences on career enhancement and identify the impact of T&D has towards their career enhancement, and the barriers they faced during their career. The result of the analysis would be the formulation of the theory. Thus, this particular research adopts the inductive approach. By considering the research approaches, it leads towards the selection of suitable strategy for the data collection. Thus, the following section outlines the discussed research strategy.

2.3 Research strategy

Each research strategy can be used for exploratory, explanatory and descriptive research [19]. Some of these belong to the deductive approach; others to inductive approach [16]. They are guided by philosophical underpinning and focuses the appropriate methods of research strategy. There are a number of different research strategies ones research can be based upon [19] [10]. Figure 3 illustrates how the research strategies can be positioned within the epistemological and ontological continuums. It can be seen that experiments and surveys are governed by positivist and objectivism stances whereas case studies, action research and ethnographic approaches are towards interpretivism and subjectivism stances.

[19] identifies three conditions which have to be considered when selecting the appropriate research strategies;

- the type of research question posed
- the extent of control an investigator has over the actual behavioural events
- the degree of focus on contemporary events

According to Figure 3, experiments and surveys take the positivism and objectivism positions in terms of the epistemological and ontological undertakings respectively. Since this research takes the interpretivism and subjectivism with regard to the philosophical stances, use of experiments and surveys are unjustifiable. Experiments and surveys are conducted under controlled environments wherein the former situation the phenomenon and the context is separated and in the latter situation investigating the context is difficult due to the limited number of variables set out [19].

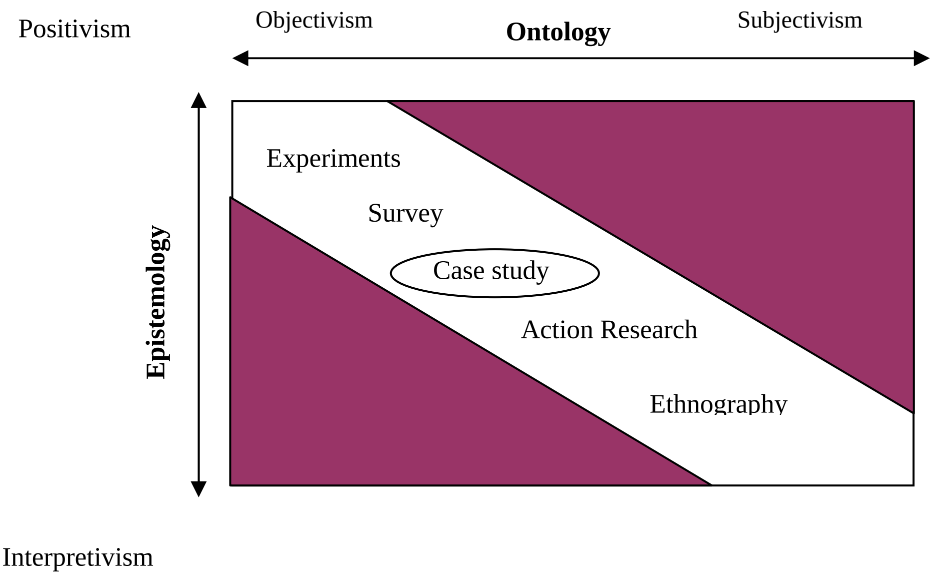

Figure 3: Research strategy (Adopted [29])

Since this research falls under the interpretivism and subjectivism stances, the researcher has to make a choice between ethnography, action research, or case studies. According to [20], the Ethnography approach provides the researchers insights into the beliefs and values of human, social, and organisational aspects of socio-cultural phenomenon. Further, Ethnography research takes a considerable time period [21]. In action research, the researcher will be a part of the environment under study, tries to solve practical problems [22], and attemptss to influence and change the attitudes and behaviours of the participants [22].

[23] defines case study as “a strategy for doing research which involves an empirical investigation of a particular contemporary phenomenon within its real life context using multiple sources of evidence”. Moreover [19] highlighted the importance of contexts, adding that, within a case study, the boundaries between the phenomenon being studied and the context within which it is being studied are not clearly evident. Case studies are carried out in a way that incorporates the views of the “actors” in the case under observation [24]. Due to the open ended inquiry used in case studies, it is suitable to build theory and generate hypotheses [25]. Further, case studies provide the opportunity of dealing with a full variety of evidence such as documents, interviews, and observations [19].

Research under consideration does not intend to influence or change the attitudes or procedures of the participants or the environment. Nor does it intend to study behavioural patterns or physiology of the participants as in the case of ethnographical studies. Hence, the use of case studies is preferred over action research and ethnography. Case study approach is therefore, suitable for this research to explore the women’s career within the context of construction industry and T&D aspects within the case study organisations. The case study approach too provides the opportunity of carrying out an in- depth study about the links between women’s career advancement and construction T&D. Additionally, this research has the characteristics of exploratory and explanatory case studies. According to [19], the nature of the research questions posed has an effect on the research approach. [19] argues that “how” “why” questions favour th*e use of case studies and the use of "what" question is suitable for the exploratory type of researches. Research under consideration has a combination of "how" "why" questions coupled with "what" questions. The following reasons could be listed as the key points for the selection of case study methodology for this research;*

1. Does not intend to control/ manipulate the environment under examination
2. Does not intend to interfere with the attitudes, perceptions or the procedures of the environment (as in the case of action research)
3. Analyse contemporary events
4. Requires an in-depth study on the selected environment. Thus, it will be advantageous to rely on multiple sources of evidence and the selection of a small sample to allow an in- depth study
5. Requires exploring and analysing the "real life" context of women's careers in construction industry and T&D.

Above section describes the selection of the most appropriate research strategy for this particular study. Case studies were identified as the suitable research strategy. The following section therefore describes the design of the case study.

2.4 Case study design

A research design has been identified as the "logic that links the data to be collected (and the conclusions to be drawn) to the initial questions of study" [19]. [26] argues that the research design guides the researcher to collect, analyse and interpret the observations made. Four major types of case study designs exist according to the 2 x 2 metrics suggested by [19]. They are single holistic, multiple holistic, single embedded and multiple embedded. In order to select choices between the holistic or embedded case study, the unit of analysis is a vital fact to be considered in the research. According to [27], they have identified the unit of analysis is a "phenomenon of some sort of occurring in a bounded context". According to [14] it is the focal point where the variables, phenomena and the research problem refer to and about which the data is collected and analysed. Therefore, the unit of analysis of the research under consideration is women's careers as highlighted in the section 2. Further, the research is consistant with a single unit of analysis, thus research is towards the holistic case study. The use of single case studies is preferred when the study represents a critical case, extreme or a unique case, representative or typical case, revelatory case or a longitudinal case [19]. The research in question does not fall under these categories, thus multiple case studies are preferred over a single case study. [28] argues that the evidence gathered form multiple cases studies is often considered as more compelling which resulted in a healthier and a stronger study. Sampling logic will not be used to select the case studies i.e. to select a sample from the pool of respondents/whole population (such as with surveys). Thus, analytical generalisation is preferred over the statistical generalisation where the findings will not reflect the whole population. However, it is intended to claim literal replication by comparing the findings from the multiple case studies. The research under consideration is more towards the multiple holistic case studies. Women's careers will be the focal point of the research. Therefore, Individual woman is a case when considering the unit of analysis in the research. Consequently, collection of data from more than one woman will be the multiple case studies in this research and replication logic is used in order to justify the reliability of the collected data. The approach to case studies in this research involves theory building and verification. That is to build up research questions via the literature review and verification of them through multiple data collection methods, analysing the data within and across case studies and finally reaching the conclusions.

The section above discussed how the case studies will be designed to facilitate the theory verification process. The following section discusses the research technique, which will be used in the data collection and analysis stages of the research.

2.5 Research techniques

As discussed in section 2.1 this research takes the interpretivism, subjectivism and value laden stances in terms of research philosophy. Having identified the research philosophy and research approach, the next step is to determine the appropriate research techniques for the study. Accordingly, the section below will look into research techniques which are suitable for the research.

Intended data collection techniques describe the ways and means to fulfil the "aims and objectives" of this study by carefully addressing the research questions. In this research, semi-structured interviews will be conducted among the top female mangers and middle level mangers in the organisations, to understand the context of women's careers in the construction industry and the applicability of T&D towards their career enhancement. When the same results are obtained through different mechanisms, the confidence of the results is high, as the weaknesses of one method will be compensated by the strengths of another. Thus, results obtained from this research will be more convincing and accurate, increasing the "construct validity" of the research.

In addition to the use of multiple sources, a case study data base will be created which consists of case study notes (resulting from the interviews), tabular material obtained from the case study or created from the researcher, narratives produced by the researcher. The database will be used to store and retrieve the sources of evidence in a presentable manner. During the data collection stage, it is also expected to use case study protocol which consists of interview procedures, general rules that will be followed during the case studies. In addition, consistent interview guidelines are expected to be used. The use of a case study database, case study protocol and consistent interview guidelines will increase the "reliability" of the research. Having discussed the data collection methods, the following section now describes the data analysis methods of this research.

2.6 Data analysis

Data analysis consists of examining, categorising, tabulating, testing or otherwise recombining both quantitative and qualitative evidence to address the initial propositions of a study [19]. It is important to have a data analysis strategy as it will guide the researcher to select the appropriate data analysis tools, to make sure that the evidence is treated well, and to generate sound and convincing analytical conclusions while discarding alternative interpretations [19]. This research will match the data gathered from semi-structured interviews through top managers and middle level managers. Content analysis will be used to code the textual data gathered from the semi-structured interviews.

Before starting the data analysis, all the interviews were converted into text. Thus, the transcripts of the interviews will be made ready for analysis. The data reduction is done by reading through the transcripts and extracting the most relevant data for all of the questions listed in the interview guidelines plus any additional questions that were raised during the interview. To display and identify the relationships of concepts derived from the interviews and observations, cognitive mapping techniques will be used. In order to facilitate the data analysis process, computer software packages are expected to be used namely NVivo and Decision Explorer, for content analysis and cognitive mapping respectively.

Arriving at conclusions for the study involves interpretation and drawing meanings from the displayed data [27]. The data from this research will be summarised and conclusions will be drawn.

3. Conclusions

This paper identified the need of developing a research methodology in fulfilling the aims and objectives of a study and thereby addressing the research problem. The investigation of women's career advancement in the construction industry concept within T&D process demanded the interpretivism, subjectivism and value laden stances in terms of the research philosophy. The aforementioned philosophical understandings and need for carrying out an in-depth analysis without interfering in the research environment led the way to selecting case study as the most appropriate research strategy and individual as a case in this research. Selection of individual as a case in this study is more suitable than the stakeholders in the case study. Selection of individual women in different career phases is more appropriate since the unit of analysis is women's careers. It can also be concluded that the proper understanding of the philosophical issues followed by a clear definition and design of research strategy are essential elements in developing successful research. The philosophical understanding of the research ensures the compatibility and consistency between research philosophy, approach and techniques while the clear definition and design of research strategy would generate unbiased and more convincing research outcomes.

Abstract

The issue regarding lack of women leaders in construction has been a prominent concern for many years because women in mainstream management reduces potential managerial skills shortage in the industry and increases women's interest for construction related occupations. This paper is based on a study, which was designed to identify the role of women in leadership positions in the UK construction industry and the barriers confronting their careers. A literature review has been carried out followed by four case studies that were developed around four female leaders in the industry in order to identify the role and the barriers confronting them. Results of this study revealed that role of women leaders in construction is yet to be improved both in terms of number of leaders and the significance of their role. However, the findings of the case studies show that the majority of women leaders do not find problems in their leadership ability and the recognition which is received, however working in a site environment brings additional inconveniences to women in performing their role as leaders. Further the study revealed that women leaders in construction face career barriers which prevent them from advancing towards leadership positions. The results from the case studies indicate that the task of balancing family and work commitments, childcare problems and old boys networks are the most common barriers encountered by women in leadership positions in construction.

Keywords: Barriers, Construction industry, Leadership, Women

1. Introduction

This paper is based on a study, which aimed to identify the role of women leaders in the UK construction industry and the barriers confronting their careers. In identifying the role of women leaders, the study attempted to examine the duties and the job satisfaction of female leaders, their leadership styles, characteristics and abilities and the significance of their leadership in terms of number of women leaders in the industry, the extent of contribution and their positions in the organisations. The study also explored the experiences of female leaders in order to identify the barriers confronting their career in leadership positions. Since the examination of barriers is an important step for developing women leaders in this industry the research study was structured to identify the areas of obstacles from organisational and personal dimensions by considering the perspectives from women leaders and their co-workers.

Accordingly, the following section of this paper provides a background to the study addressing the role of women leaders in the UK construction industry, their leadership styles, the determinents of leadership styles in construction and barriers confronted through a literature review. The subsequent section describes the methodology adopted to collect and analyse empirical data of this study followed by the findings and the discussion. Conclusions are given in the final section of the paper.

2. Background

2.1 Women leaders and the construction industry

According to Vinnicombe and Singh [1] senior women are rare in many male dominated companies, so that many women managers have few role models. According to Kanter and Burke and McKeen, more feminine ways of managing may be included in the acceptable behaviours for future senior roles by female role models in the organisations [1]. A survey carried out in the UK construction industry shows that the ratio between male and female management staff is 6%:94% [2]. In the "managerial and administrative category", in the construction industry, women are concentrated in specialist positions (including personnel and public relations) rather than mainstream management [3]. When women in managerial positions are dis-proportionate in organisations, they become more vulnerable as well being in a minority [4]. Increased access of minorities has been identified as an effective way of changing the existing culture of the industry, in order to overcome its various problems including lack of women, as acknowledged by many construction professionals [2]. Improving women's participation in leadership roles will enhance the rights, freedom and opportunities of women [5] in the industry.

Helgesin [6] argues that women's central involvement in managing households, raising children and juggling careers gives them a capacity for prioritisation in a leadership role that men typically do not possess. Women generally, possess feminine characteristics like emotional, sensitive, expressive, co-operative, intuitive warm and tactful nature while masculine characteristics such as being aggressive, independent, objective, logical, rational, analytical and decisive are commonly associated with men [7]. Although feminine characteristics are the most commonly associated qualities with women, Korabik [1] found that women in leadership positions were higher in masculinity than the general population. Grant [8] suggests that as women move up the corporate ladder, their identification with the male model of managerial success become evident and some of the women mangers consequently reject even the few managerial feminine traits they may have earlier endorsed.

However, It has been found that female leadership tends towards a style defined as ‘interactive leadership’ and women adopt more democratic and participative leadership styles, [9]; [10] that involve: encouraging participation; sharing power and information; enhancing self-worth; changing self interests for an overall good; relating power to interpersonal skills; and believing in better performance when feeling good.

However, the nature of an industry and its characteristics are extremely influential in determining the most effective leadership styles for it. According to [8] especially, issues about the gender of leaders cannot be fully understood without reference to organisational culture. Not only culture but socialization within the society and the workplace, nature and demographics of an organisation, gender and gender ratio of the industry also influence leadership styles [6]. In considering leadership styles, the unique characteristics of the construction industry such as project characteristics, contractual arrangements, project life cycle and environmental factors can have an impact on leadership styles in construction [11]. Since construction is a project-based industry it creates temporary multi organisations with extensive team work that has a significant impact on leadership behaviour of managers. Cleland [12] argues that project leadership should be appropriate to the project situation because leadership is a continuous and flexible process.

2.2 Career barriers to women leaders

The literature on women in construction identifies that women have progressed slowly and have confronted a greater number of barriers in their development than their male counterparts. Previous studies found that although there is no discrimination in formal announcements, some of the construction organisations have differentiated pay levels for men and women in leadership positions. According to the Employment Service [13] it was identified that full-time non-manual women workers earn less than 60% of that paid to their male counterparts in the industry. In addition the informal networks and cultures that are male-dominated often become barriers to women's progression. Most importantly the corporate inequities in advancement opportunities and rewards discourage women from seeking top management positions. It was also found that women are less frequently offered rotational job assignments to areas that are on the revenue producing side of the business, which ultimately decreases their chances for promotions to top management of the organisation [14].

After mining and quarrying, the construction industry is renowned for its male dominated culture. According to Powell et al. [15] engineering in the UK has a popular image of being tough, heavy and dirty and these powerful cultural images have helped to reproduce occupational segregation whereby engineering is perceived as unsuitable for women. In many instances male senior executives and professionals have old boys network which have shared experiences between themselves [16]. Therefore women find it difficult to fit into this atmosphere except in appendage roles. Furthermore the prevalence of gender stereotyping and the incidence of sexual harassment also remain major threats to women especially for their career development into senior managerial positions.

Women are given tasks which are intended to test their ability to work in a male environment [3]. This is a challenge especially to those who are interested in developing their career in construction. Some researches found that, refusal to carry out such tasks led women to be accused of incompetence and be seen as a legitimate target for further harassment. In certain instances this became a black mark for their future offers. However poor performance in these tasks led women to reinforce gender stereotypes and jeopardise their chances of acceptance for their promotions. Female managers emphasised their personal qualities as critical factors in their career such as, capacity to hard work; integrity; desire for responsibility and positive attitude [3]. Due to barriers created within them and from the external environment women lack confidence and assertiveness to go for positions of power [17]. Their reluctance to compete for senior jobs is a major barrier created by them. In addition, their lower aspirations and inappropriate expectations [18] hinder their careers in leadership positions in senior management.

Although most female students are continuing to perform well in studies, their choice of educational field segregates them from the field of construction. Their educational segregation limits their access to higher level construction related courses, which require formal qualifications. This seriously undermines their opportunities to enter the construction industry at a managerial or professional level. Their entrance into lower levels or into middle level at later stages of their career, affects their progress towards leadership positions.

Most importantly the construction industry fails to consider the issues associated with women's commitments towards job and family life [19]. The long hours of work required from senior managers to actively participate in the management is incompatible with women's domestic responsibilities. In addition to above, the time, duration and location of the meetings sometimes create role stress to women. Women have felt that they are the only or one of very few women attending the meetings [20]. In addition, women's commitments to child care and elder responsibilities prevent them from carrying out these tasks. This challenge of balancing the career and the family is a major barrier for their career advancement and women's career break due to maternity is a blow to their advancement. Some women even drop their job, do not take any interest in developing them or do not take an interest in promotions.

3. Methodology

Case studies were selected as the most appropriate research strategy for this study because it is considered that case studies provide the opportunity for studying real-life phenomenon in detail without any control over it. Four case studies, which were developed around four female leaders representing different disciplines within the construction industry (Table 1), were carried out in order to achieve the aims of this study. The unit of analysis of the case studies was decided as the individual leaders because on them only the conclusions were drawn at the end of the study.

Table 1: Case Studies

	Description
Case Study A	• She is the Assistant Director of Estates and Facilities Division of a public body, which is attached to a university hospital in England. Her division looks after the management of estates, property, facilities and construction projects of the hospital and these responsibilities direct her to deal extensively with different teams. • She is in her early fifties, married and mother of two children who depend on their parents.
Case Study B	• She is the Financial Director of the UK's northern wing of an internationally wide construction company. Her main responsibility is built around managing company accounts. All financial related issues of the company including accounts of their construction contracts are handled by her subordinate staff. • She is in her mid thirties, single and expecting her first child.
Case Study C	• She is an Associate Architect in a well established architectural design firm in the North of England. Her responsibilities range across a broad spectrum, i.e. design to contract administration. She has to interact with different categories of people including subordinates of project architects, designers and technical staff as a leader and also with clients and building contractors. • She is in her late thirties, married, mother of two young children and expecting her third child.
Case Study D	• She works as a Site Quantity Surveyor on a construction site, located in the North West of England. Her employer is an internationally reputed large construction company. In contrast to the other three cases, she does not have direct subordinates under her according to the organisational hierarchy but she has to get some work done through the assistant site quantity surveyor and influences sub contractors and site workers in certain circumstances. • She is in her late thirties, married and mother of four children where the eldest is employed and not a dependent on her and her husband.

A detailed study was carried out on each female leader's career, career progression, leadership style and ability, and the barriers faced during their career progression. Views regarding the selected female leaders' leadership and her career difficulties were obtained from their superiors, peers and subordinates to gain an overall perspective. Semi-structured interviews were conducted with the leaders, their superiors, peers and subordinates in order to collect data on the leaders' careers, career progression, their leadership styles and ability and, the barriers confronting their career towards leadership positions.

Further, the Personal Attribute Questionnaire [1]; [21]; [22] which was developed by J.T. Spence, R. Helmreich and J. Stapp in 1975 was used in order to assess the personal characteristics of leaders. There are twenty-four items in this questionnaire each measuring one personality characteristic. There are eight questions on socially desirable instrumental traits generally associated with males, eight questions on expressive traits which are known to be associated with females and the remaining on androgyny traits, the characteristics of combined male and female qualities. All these items are presented in a five-point bi-polar format with a masculine label at one end and a feminine at the other [1]. The questionnaire was given to all four female leaders and asked to indicate the extent to which they possess each of the eight masculine characteristics, each of the eight feminine characteristics and each of the eight androgyny characteristics on the 1 to 5 scale.

In addition to the interviews and the questionnaire, organisational documents such as organisational charts, employment records and other relevant documents of the respondents' organisations were studied in order to understand the positions of respondents in the organisational hierarchy, their duties, roles and number of female employees in the organisations.

The data collected through the semi-structured interviews was analysed using a three step process of data reduction, data display, and conclusion drawing. A data matrix was produced by tabulating the interview data; the respondents are listed as columns and the questions as rows for data display. This system makes it easy to identify patterns in the responses. Two data matrix were constructed in order to analyse the data gathered from the interview. Firstly single site matrix were constructed using information from each case. Secondly cross site matrix were constructed using information from different cases in order to compare and analyse the experiences of women leaders across different cases [23].

The questionnaires were analysed by adding the scores on each item of a particular set (masculine, feminine and androgyny) together and dividing by eight. According to the set of attributes, which scored the highest average among above three, the nature of personal attributes of a particular leader was decided.

4. Findings and discussion

4.1 Leadership of women managers

According to the interview data, women leaders of all four cases admitted that they perform all the duties which have been prescribed to their designations. They have never felt that their roles were under-estimated except in the experience of case D leader about misusing her skills for some clerical work in the absence of the site secretary. These leaders were satisfied with their roles and they are confident with their skills and competencies whilst they all agreed that they have to learn more through experience.

Further, all four leaders perceived leadership as an essential and critical skill for their career advancement. Leaders of case A, B and C, believed that their leadership style depends on the situation to be tackled and the people who are to be dealt with and perceived themselves as more democratic styled leaders. The leaders in the first three cases, who were in higher positions in the organisations and whose work was not based on construction sites, were confident about their leadership ability and believed that they receive the recognition and acceptance from their working environments. The superiors, peers and subordinates irrespective of their gender were extremely positive about these three leaders' leadership abilities and agreed that they do not have any problems in their leadership. Similarly, the leaders did not think that their leadership is undervalued compared to male managers' leadership. However, they all disclosed that they need to have a thorough knowledge on their subjects, they have to be familiar with the culture of the organisations and they have to possess internal organisational knowledge to be successfully accepted as leaders.

In contrast to the other three leaders, the case D leader possessed a negative attitude about her leadership ability and the acceptance and the recognition she receives from her site working environment. She was not confident about her leadership skills and believed that it is harder for women to gain the necessary respect as leaders in the construction industry.

According to the data collected through the Personal Attributes Questionnaire, leaders of case A, C and D possessed more feminine attributes and the other leader perceived herself as a more masculine personality. A close relationship between the self-perceived personal attributes and the nature of the leaders' careers could be seen through the questionnaire findings. Apropos, the case B leader, whose self-perceived personal attributes are more masculine, had a similar career to a male leader because she had lesser family commitments with no childcare responsibilities and she hadn't had any career breaks as yet.

4.2 Confronting barriers to women leaders

The difficulty in balancing the family and work commitments is a more frequently quoted barrier within the study. Although women and men want a successful career and a happy family, it has been a difficult task in finding the balance between work and family life for them. Since women generally perform a large share of household tasks, this has been found to be a major barrier for women in continuing their job career. Three case studies show that women in leadership positions who have families are confronted with difficulties in balancing their family and work commitments. However the case B female leader from a construction contracting company, who does not have family responsibilities or any dependents, didn't consider the task of balancing her commitments as a barrier to her career. She did acknowledge the difficulty of balancing work and family commitments for women leaders.

Child care is one of the important aspects in family commitments that needs time and priority. Three of the female leaders from this study stated that they have faced difficulties with regards to child care. It has been noticed that the importance which women give to their child care and the adequacy of child care facilities has had an effect on women's careers. Case C female leader who is from a consultancy firm, while explaining her career she said that she would have moved up in her career faster but it was hindered due to distractions by having children and maternity leave. However her commitment towards work through working from home and making few visits to the work place during the break helped her to progress to a higher level. She also mentioned that in addition to women's commitment to continue their career, the understanding between the employer and female employees has significant effect on their career continuity. Although generally women take larger share of child rearing activities, one of the subordinates of case B leader said that it is also`a problem to men, as nowadays men also take the responsibility of child caring. However he stressed the importance of improvements in child care facilities to facilitate both men and women to progress in their careers.

The old boy network is found to be another common barrier in the construction industry since it is a male dominated industry. Among four female leaders, two females from construction professions have faced problems with old boys network. According to female respondents, when women attend meetings or events where there are no other women or very few women they generally find it more uncomfortable and which sometimes leads to their lesser contribution towards decision making specially in executive meetings. This ultimately affects their promotion and advancement opportunities.

In addition the culture of organisation has a significant impact on those who work within it. An inhospitable culture within construction organisations is one of the most significant barriers to women's advancement and also a major factor in diminishing their satisfaction in work. It has been mentioned as a mitigating factor by the case D leader who works in a construction site. However case B female leader who comes from a different discipline has not felt any difference with regard to the culture in her work division though she is from a construction company. Further, one of her subordinates who is also from the same discipline, when explaining his view about the culture of his work environment said that they are sheltered by their professional background as they have an equal number of women and men. However he recognised that in construction there are probably more hurdles to cross for women due to the nature of the people who work in the industry.

Stereotyping can have an influence on the way in which men and women are perceived in the workplace. Among all four cases, the female leader who works in the construction site has experienced this difficulty. The use of stereotypes as the basis for assessment can result in dissatisfaction in work. When case D female leader from the construction site explained about her experience on site said that it is harder to get respect for women in construction. In addition it was found that women face problems when they give instructions to get the work done. However this is often noticed in construction sites.

The industry wide practice of working long hours is seen as a barrier to women. However three of the female leaders commented that the flexible working hours and home working are a great advantage to them. In addition they stressed the importance of better understanding between superiors and women in their view. According to the female leader from the construction site, when work is judged based on the number of hours worked then women face problems unless proper facilitates are provided to overcome them. Although she has recognised the need to work for long hours on a regular basis she found it difficult to challenge this.

In addition to the female leader from the construction site who realised the need for better working policies for women, case B leader recognised the difference between policies in construction and other sectors. She said that very minimal facilities are given in construction, such as minimum legal requirement for maternity leave. Furthermore a lack of female leaders in higher positions in the organisation leads to difficulties in obtaining the required facilities or allowances as certain facilities are not in place before a need was recognised. Gaining the knowledge regarding the policies which can facilitate them to continue their job career while giving importance to family life as well was also mentioned.

In order to obtain views of others about the barriers faced by women interviews were conducted among superiors, peers and subordinates of the female leaders. However most said that their female leaders do not face any difficulties. Interviews were conducted among male peers of female leaders who were considered for the study in order to understand their views on barriers faced by them during their career. However in contrast to female's perspectives about their own barriers, male employees stated that they didn't face any problems.

5. Conclusions

The findings of the literature revealed that there is significant under-representation of women in the managerial positions in the construction industry, especially in mainstream management. However, according to the case study findings, women's leadership was highly appreciated by their superiors, peers and subordinates in the organisations and they did not see any problems of women being leaders as far as they have the necessary skills and competencies. Apropos, the case study findings of this study illustrated that women leaders in construction make a significant contribution to the industry.

As the literature illustrates, it is believed that women possess more democratic styles of leadership. This was confirmed by the case study findings of this study because all the female leaders perceived themselves as more supportive and understanding in their leadership. Although the literature says that there is a tendency for women to adopt more masculine attributes when they move up their career ladder, the results of the case studies did not prove it. However, a close relationship between the self-perceived personal attributes and the nature of the leaders' careers could be seen because the leaders who had close career characteristics to male leaders perceived themselves as having more masculine characteristics.

The case studies revealed that the female leaders who were in the higher positions in the organisational hierarchies were extremely confident about their leadership skills. It can be stated therefore that the level of authority a leader possesses has a significant influence on the recognition and the respect received.

The results reflected that the difficulty in balancing family and work commitments, childcare problems and old boys networks are the mostly mentioned barriers encountered by women in leadership positions in the construction industry. In addition female leaders mentioned that the unfriendly environment when she is the only female in the meeting or event also leads to career problems. It was noted that women working on a construction site also encountered more problems. However the barriers encountered by women in leadership positions and its extent differ from one discipline to another although they all work in the construction industry. Further the study found that employees who work with the female leaders expressed that there are no problems to women leaders. However some recognised that there are problems which still prevail in a few segments of the construction industry. They expressed that this situation will change with time while recognising the need for more women to the industry.

The Construction Supply Chain and Supervisory Skills for Housing Market Regeneration

Chris Guthrie, CFM, School of the Built Environment, University of Salford, Greater Manchester M5 4WT, England, UK
(email: c.guthrie@salford.ac.uk)

(email: andrew@platten78.freeserve.co.uk)

Abstract

In the UK a key driver for the regeneration of failing neighbourhoods is the housing market renewal programme. As part of this process the specification and the management of the physical regeneration of the existing housing stock is a prime concern in order to achieve appropriate project outcomes. Achieving quality and customer satisfaction in existing homes and new build designs, using locally sourced contractors, workforce and supply chain, presents key challenges in meeting the decent homes agenda and in achieving best value through a framework procurement process.

The series of market intelligence reports produced by the UK Sector Skills Council, Construction Skills have identified critical skills gaps in the national and regional market place. This research paper explores the recommendations of this data, linking to demand led initiatives, which are now operating regionally. The issues arising from this work relating to supervisory and management shortfalls are explored. The research was initially conducted with regional and local construction contractors, to gauge the extent to which such higher level skills are developed. From this study, it was evident that deficiencies are apparent and that a proactive process of development of local and accessible educational and training provision is required. A focus group study was conducted to validate the survey outcomes and to develop a practical development plan to bridge the gap between skills and people.

The study progresses to make recommendations regarding professional skills needs, supply chain development and seeks to define options for the development of a sustainable local industry base.

Keywords: Construction management, skills gaps, regeneration

1. Background

Forecasted figures (Construction Skills, 2006) show that 285,300 people will be employed by the construction industry in the North West of England this year and that this figure will rise to 305,600 in the next 4 years. Of these, nearly 12,000 new entrants are to be expected by 2011 and the vast majority of these will be non-professionals. Despite the overall increase in numbers employed, slightly more (12,000) will be leaving the sector than will be joining (11,600) by this time. As the previously quoted report notes, "*these inflows, transferring from other industries…are likely to need some form of training*". It may be that the provision of a clearly defined career path would go some way to retaining these new entrants.

For those already employed in the sector over the period from 2006 – 2010 will also see a situation, whereby "*Three out of the four occupations with the highest Average Annual Requirement…are focused on management and organisation*". In order to attract these individuals the availability of educational opportunities (either further or continuing) will be instrumental.

Evidence from elsewhere in the North West of England (J21, Oldham / Rochdale Pathfinder Report, 2006), suggests that those skills developed for business activities are influenced by existing strategies and do not relate to innovation and new practices. It could be argued that this is a short term approach to capability and capacity, and as such provides evidence that limits many construction companies in the North West as a whole in their failure to fully benefit from the opportunities presented by the various regeneration projects now operation in the region.

Within the East Lancashire sub-region, the Elevate Housing Market Renewal pathfinder focuses upon wards within 5 local authorities (comprising Borough Councils include Blackburn with Darwen, Hyndburn, Pendle, Rossendale and Burnley and Lancashire County Council). These districts are subject to the extremes of housing market failure and societal collapse. As a means of addressing the issue of poor housing conditions, failing neighbourhoods and the decent homes agenda, Elevate are progressing a programme of new housing development and repair using a combination of best value procurement and local supply chain development. As part of its procurement process, Elevate has focused upon a key objective to trap as much of the regeneration spend (£100m 2006-2008) in the sub region as possible. This is through actions and key performance indicators to use of local labour, contractors and suppliers, where ever possible. Unfortunately, this aspiration is currently is not fully realised due to capability and capacity issues. In this respect, it is clear that issues such as skills, capability and vision are critical factors. The evidence for this is based upon Elevate's own review of company capability through an ongoing tendering and feedback process provided by the Centre for Construction Innovation (CCI NW Pre-Qualification Questionnaire Feedback Report, 2006). Therefore with the knowledge the Elevate programme has a further 10 years to run, it is of utmost importance that that these capacity issues are resolved for the long term economic benefit of the area as a whole. The availability of a relevant, accessible and flexible education and training provision will be a critical driver in achieving this goal.

2. Supervisory Skills in Context

The issue of supervisory skills within the construction sector in East Lancashire is not a purely a local one. Indeed the issue of skills within the sector as a whole is an area of some concern as the construction industry moves towards the target of a fully qualified workforce (Turner, 2004). Recent legislation with respect to taxation arrangements suggests that the industry as a whole is subject to an externally imposed modernisation agenda (Chan and Dainty 2007). For many smaller construction companies, who are predominant within the sector nationally (Chan and Dainty 2007), this poses significant problems and challenges.

The complete range of skills which are required to achieve successful project management are extensive and demanding, if effective lasting and sustainable regeneration is to be achieved. Both the English Partnerships Report (2004) and the Egan Review of Regneration Skills (2002), both identified the need for the creation of a skills structure to increase the performance and enhance the delivery by regeneration teams. The Academy for Sustainable Communities (ASC) explicitly links construction management skills with skills in regeneration (amongst others). If the aspirations of and for sustainable communities are to be realised then there are other concerns. In this respect, regeneration practioners, within the sub region, regard their competency levels as not sufficiently high. (Platten et al, 2006).

Of the skills most lacking in publicly funded, but privately delivered projects, partnership working, where a shared set of values is important, is the biggest cause for concern. This lack of familiarity with partnership working causes other problems, as Platten et al (2006) note, "*There is often a reluctance on the part of both local authorities and contractors to take the lead in joint projects and this reluctance is due to a lack of project leadership in terms of both capacity and capability, in both the public and private sectors*."

Elevate East Lancashire are of the opinion that any sucessful regeneration project in the sub-region will involve building capacity in terms of project management and partnership working skills in both the public and private sectors. Given that these skills generally need to exist at the supervisory or managerial levels, there are very obvious implications for the skill sets needed within the construction sector.

If one focuses specifically on the construction sector, then current training provision is stongest at the skills and crafts level, indeed the sub-region hosts Accrington and Rossendale College, a nationally recognised Centre for Vocational Excellence. However, managerial and supervisory skills provision is less well endowed, further what little provision that does exist does not offer a route for aspiring construction professionals with the appropriate professional body accreditation, which is critical to job proomotion. The lack of professional skills such as, Quantity Surveyors, Planners and Project Managers within the sub-region means that often these services have to be sourced outside the region, which often drives up the salary base (Turner & Townsend 2005). There is also a difficulty in retaining skilled individuals, who tend to migrate from the area to more well paid opportunities elsewhere. It is critical to note that there is significant evidence of employer lead demand for this type of educational provision in a format that is accessible through the medium of blended learning, including modes of learning such as part time provision, on line learning and workshop style presentations.

In summary, there is a wealth of information available in the form of studies, reports and academic papers that both highlight and illustrate the need for a more coherent and acessible educational infrastructure in East Lancashire.

3. Methodology

The aim of this paper is to assess how small to medium enterprises (SME's) in the East Lancashire construction sector currently manage their training needs in terms of professional skills. This assessment takes account of what training is currently available, how it is delivered and also investigates the issues of barriers and accessibility to prospective candidates. Regionally, this approach has implications for the development of a robust, qualified and professional construction industry that meets the increasingly demanding conditions for supply chain entry. If these attributes can be attained through the delivery of a high quality, industry specified and accessible skills training, then the long term sustainibility of the sector should be assured. To date, preferences would seem to be given by employers to more vocationally orientated qualifications rather than those which are purely academic in nature and delivery.

This paper builds on the work of and draws from, a number of previous studies notably the Construction Skills Network Employment Forcasting Model (Construction Skills, 2006), The Construction Skills Gap Analysis and places their findings and recommendations in the context of the East Lancashire construction industry.

The fragmented nature of the construction industry in the sub region makes quantative data collection difficult, companies are often too small to have the spare the time to complete surveys and as a secondary consideration, they are often suspicious of the stated objective. This finding in itself provides scope for further study in how SMEs and mirco organisations interact with the representative industry bodies. However, for these reasons a varied range of methods of methods were used to reach the reported conclusions in this study.

In order to scope the investigation, an initial telephone survey was carried out with a sample of 24 local companies (this listing was selected from a market of 1800 local companies using the Businesslink Northy West database, from the post code area of East Lancashire and who employed more than 5 persons). From figure 1, it can be seen that the majority of these companies (66%) have 20 or less employees.

The telephone survey involved a number of information gathering questions such as the company name, location, turnover, number of employees and main work areas. Questions relating to the employment of supervisors were also asked with regard to number of employees at this level and their qualifications. Further, interviewees were asked to provide a Likert scale reply to the relative importance of particular construction related supervisory skills areas. These areas were selected from a variey of sources including the National Occupational Skills

Standards and contract performance criteria. These skills included: the monitoring of quality, regulations and health, safety and welfare; obtaining and assessment of technical information; enhancing working relationships; providing guidance on problems within an ethical framework; monitoring contract progress, quantities and certification; confirming and monitoring the dimensional control of construction and installation projects; ensuring the handover of engineering products; recording the condition of projects, assets, facilities and installations and finally implementing the maintenance of projects, assets, facilities and installations.

Opinions were then gauged on how these skills could be met through bespoke training solutions or through public access courses such as a recognised NVQ award or an academic award such as a HNC/D, foundation degree or undergraduate honours degree. In addition the interviewees were also asked whether this training could be provided locally or with an established provider from outside the catchment area of the regeneration zone.

The results of this preliminary phase were then used to shape and inform the secondary phase.

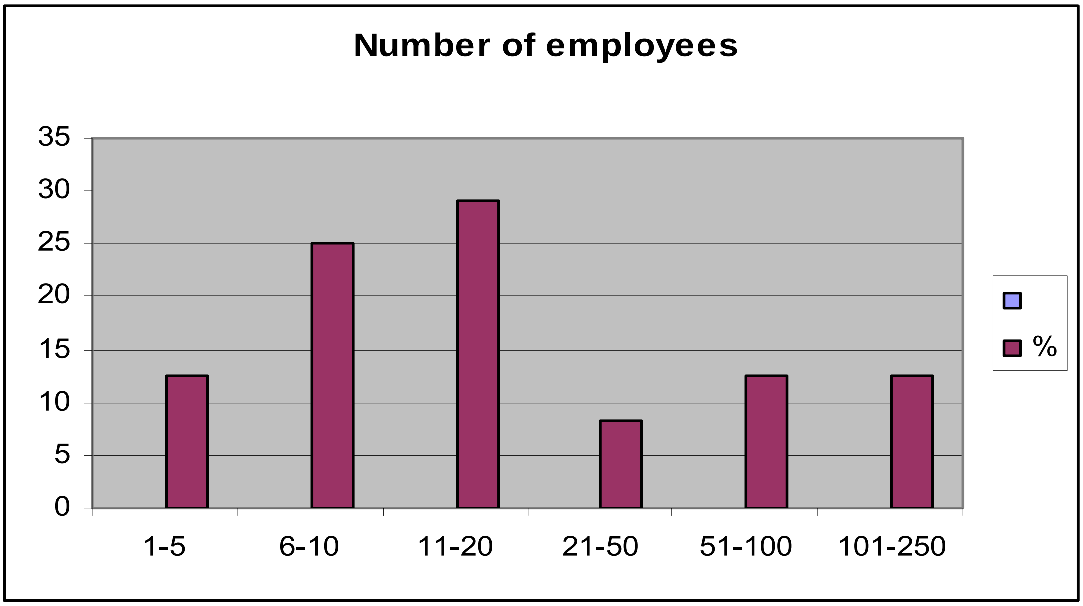

Figure 1: Range of company size in the East Lancashire sub-region.

The second phase of the study comprised a series of innovation circles conducted with attendees at a series of best practice events hosted by Elevate East Lancashire with the assistance of the Construction Knowledge Exchange NW (CKE), which is a practice development project, based at the University of Salford. In addition, the study used the round table discussions arising as part of the Elevate supported Independent Training Group (ITG). The ITG is a Construction Skills funded project, which seeks to provide support to SMEs in development training needs and promoting access to training solutions. Participants in these events were asked a series of questions by a group facilitator that were informed by the initial research.

These questions included a confirmation of how supervisory skills were obtained and for which skills areas, such as site supervision; health and safety management; Quantity Surveying or

Project Management. Participants were also asked to comment upon why this mode of training was undertaken, for example the facilitator prompts included function; person based; a business need or as a legal requirement. In addition, the regionality of that provision and preferred modes of study were also investigated. The meetings functioned by seeking an open discussion on the issues raised by the questions. The facilitator also worked with the group to find a collective solution to the issues raised and an action plan to take forward the items discussed. In this study, the innovation circle outcomes are not reported in full in order to control the focus and content of this paper. A third input to the research originated in work, which was completed in parallel to the above studies, which was geared to support a bid for development funding. In this study, Elevate through its partner Further Education Colleges accessed a range of local and regional companies to gauge the demand and support for a locally based training provision for supervisory skills.

4. Study Findings

From the first phase of the study, table 1 presents the findings of the survey responses concerning the relative importance of the nine skills areas, which contribute to the supervisory qualification. The companies rated the attainment of formal skills, as more, rather than less important, with the exception of "Ensuring the handover of engineering products". Many companies felt that this was not an area in which they had any or much experience. A clearer picture emerges, if the total weighted value attached to each area is measured and the Likert preferences are assessed by the use of a preference index (PI)[1]. In this case, the most siginificantt area is felt to be "Monitoring quality, regulations and health, safety and welfare". The explanation might be that this is criteria that is strictly monitored and can leave a non-compliant company exposed from a legal standpoint.

Table 1: Importance rating of Supervisory Skills

Importance of achieving formal supervisory qualifications in:	**1**	**2**	**3**	**4**	**5**	N/A	**Total weighted value**	**PI**
Monitoring quality, regulations and health, safety and welfare	1	0	5	3	15	0	103	0.85
Obtaining and accessing technical information	1	1	11	6	5	0	85	0.70

[1] PI = ∑w / W x N (w = score assigned by each respondent over the range 1 to 5 where 1 represents the lowest weighting and 5 the highest. W = the highest weighting factor (5) and N = the number of respondents (24).

Enhancing working relationships	1	0	7	7	9	0	95	0.79
Providing guidance on problems within an ethical framework	1	1	4	7	11	0	98	0.81
Monitoring contract progress, quantities and certification	1	1	3	6	13	0	101	0.84
Confirming and monitoring the dimensional control of construction and installation projects	1	0	4	5	14	0	103	0.85
Ensuring the handover of engineering products	0	3	3	4	5	9	56	0.46
Recording the condition of projects, assets, facilities and installations	2	3	1	9	9	0	92	0.76
Implementing the maintenance of projects, assets, facilities and installations	1	4	3	9	7	0	89	0.74

zzThe next two most important areas are “Confirming and monitoring the dimensional control of construction and installation projects” (103) and “Monitoring contract progress, quantities and certification” (101). These are clearly supervisory type duties and recognised as such as is the importance of being qualified in them.

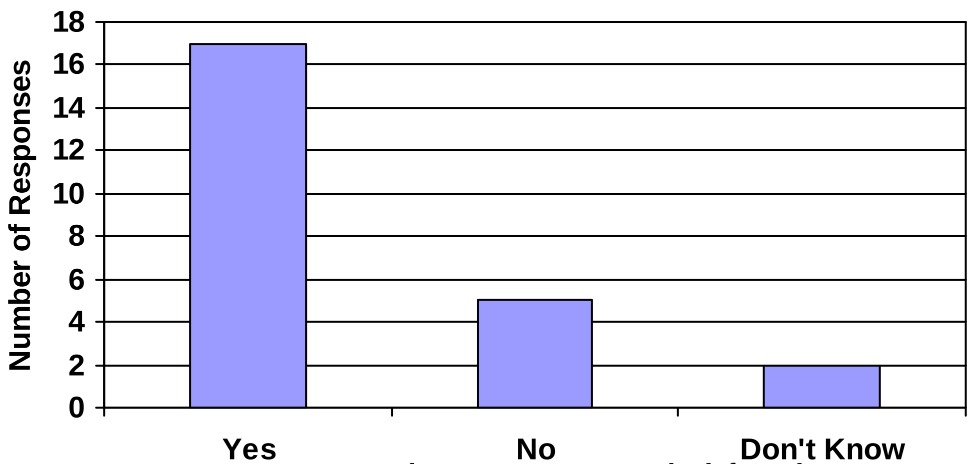

Figure 2: Questionnaire responses to the question “Do you think formal supervisory qualifications are likely to become more important in the future?”

With regard to the growing importance of supervisory skills, figure 2 indicates that over 70% of companies commented in the telephone interviews that these skills will become more important in the future, but as the next question will illustrate, they have no firm plans as to how they will manage this issue. From the telephone survey, 5 companies (21% of the sample), who said that they did not think this to be the case cited their belief that “experience is more relevant than qualifications”.

When asked if such skills should be provided locally to meet the needs of the local working population, an overwhelming majority of 96% (23) of the companies asked cited that they would like to access local provision. Whilst, one company that answered this question negatively, noting that they already complete all their own training in house.

In the second phase of the study, two focus groups events were conducted, the first of these was with 20 construction companies from within the region. Working in four sub-groups, each group was asked to reflect on how the companies currently met their training needs and what factors they anticipated might change how they meet these needs in the future.

It was apparent from the focus group outcomes, that all claimed to have training plans in place and while tending to be the smaller SMEs, they were all making strenuous efforts to makes themselves fit-for-purpose in terms of entering the HMR supply chain. For many, however, they found problems in terms of finding time to complete Pre-Qualifying Questionnaires and gathering the requisite information. The survey also asked companies to demonstrate how they approached responsibilities ranging from health and safety to waste management. The respondents claimed to be coping adequately in terms of acquiring the necessary supervisory skills, mostly via the Construction Skills 5 day Site Managers’ Safety Training Scheme (SMSTS), but were aware that acquiring more senior managerial qualifications, when the time was right, would pose its own problems. The focus was to prefer tailor made training and personnel develop solutions, which met with their commercial needs.

This preference for a vocationally based training solution over a more academic programme, begs a wider question as to whether the academic provision available meets the needs of employers. By further prompting, comments relating to the flexibility of provision, start and finish times of courses and duration were all common responses.

It was reported that development needs were met in a variety of ways, mostly using external training providers from the private sector, on an ad-hoc basis and as per specific project requirements. Many seemed aware that this was a time consuming exercise in terms of sourcing training, when needed and felt that both the local colleges and professional associations needed to develop “courses which are more applicable to requirements of developing supervisors to managers” (sic). This specific need to progress supervisors to managers and the wherewithal to do so was a recurring theme in the focus group.

The second focus group was conducted with members of the Independent Training Group (ITG). This group is composed of six contracted construction companies, who have satisfied the requirements for entry into the Elevate supply chain. These companies are currently working on a £30 million building refurbishment programme across the sub-region. Both the survey results and the initial focus group reflections were used to inform the structure and content of the second ITG focus group.

In their focus group, they stated that they had training plans in place for trades and crafts, but felt that the 5 day SMSTS course was sufficient for the supervisors and managers. The group expressed the view that only the training and development of Quantity Surveyors warranted a formal academic qualification. This gives rise again as to whether the academic courses currently on offer truly reflect the needs of the industry and whether current perceived shortfalls have reduced the view point that higher education can provide a workable solution for employers. This same point was made in a research conducted by the University of Northumbria on behalf of the Chartered Institute of Building concerning higher education (CIOB, 2003), which specifically stated that "University providers must meet the changing needs of the Industry, for example preparing students for CSCS registration."

In terms of capacity, when a purely East Lancashire perspective is adopted, the sub region tends to reflect, if not accentuate the regional trends and attitiudes. Research completed by the Centre for Construction Innovation North West (University of Salford. 2004) identified a series of shortcomings in local construction companies that actively mitigated against their benefiting from programmes such as housing market renewal. The shortcomings are predominently centered around the following areas; wherein (i) The vast majority of companies employ less than 5 people, this placed limits on capacity to support training and places challenges in developing this approach, which in turn limits capacity to grow and develop, which in turn limits capacity to bid into HMR projects, that (ii) Qualifications are not widespread with 69% hold NVQ 2 or none at all. However, there is an apparent paradox at play here because; 55.% feel their current skill level does not match requirements and that 48% had difficulty recruiting managers/supervisors.

Companies are aware of their deficiencies, because they also cited in the inovation circle sessions, that management planning as a area of concern as part of the national drive toward a fully qualified workforce. ie. they have positively identified managerial skills as a barrier to expansion. When the barriers to accquiring these skills are addressed, time (81%), resources (42%) Commitment of staff (30%) and availability of training (27%) were cited as the major barriers. A more flexible delivery method offering a variety of accessibility and delivery opportunities might be the solution sought by many smaller companies expressing a wish to expand, but felt unable to take advantage of the current avenues to expansion due to percieved risk. As the research concludes, the task facing construction companies in East Lancashire, is to change their collective culture from the short term to the medium and long term. Changing this culture is about gaining the confidence to develop capacity.

5. CONCLUSIONS

The development of construction skills and the supply of professional trained candidates is a prime focus for development in the North West region as defined the sector skills council strategy documents. Management skills needs for the construction sector a concern both nationally and in the regions, wherein there has been an increasing emphasis on the need for higher level skills as a key driver for productivity. There are however, unique aspects of the construction industry that make the acquisition and retention of skills problematic. This issue was also identified as a key issue in a regional housing market renewal study (Dewhurst 2007).

Once a construction company has attained significant size and capacity, then the flow of work becomes continuous particularly through long term partnership programmes. For companies to attain this status will require a set of pre-conditions which relate to human resources, investment in knowledge capital and project experience. Currently and despite the gradual economic slow down the private housing market, the regeneration areas are experiencing an unprecedented amount of public sector investment. In the period 2006 – 2010, the projected regeneration spend in the East Lancashire sub-region is £623m (Elevate 2005) which arises from Housing Market Renewal (HMR), Building Schools for the Future (BSF) and the various NHS primary care initiatives. It would appear therefore, that the pre-conditions for growth are in place and the challenge is to ensure that local companies can leverage maximum benefit from these opportunities.

The access to available and appropriately formatted training and education programmes is extremely limited however, with no accredited course provision that will lead to a recognised award for construction managers. This poses significant access problems for new and existing managers in the industry and for aspiring companies to develop their skills base. In an effort to resolve the educational provision, Elevate, in conjunction with three Further Education Institutions in East Lancashire, have attempted to achieve a common approach to this issue.

Further, Dewhurst (2007) concludes his report by noting that the continued trend of the local and regional industry to focus upon short term solutions will be ill prepared for future challenges and to develop a lasting sustainable solution to the current skills issues. Given the size and scale of construction projects (both current and proposed) in the sub-region over the next 5 – 10 years, it would appear from this study that the local construction industry must receive continued and significant support if it is to take advantage of the opportunities for growth, which are now in place in the sub-regions.

Developing Cost Effective Mid-Career Learning Support for Construction

Eur Ing Professor James A Powell OBE DSc
Salford University, Greater Manchester, UK M5 4WT
(email: j.a.powell@salford.ac.uk)
based on Case Materials of Construction Action Learning facilitated by Dr Caroline Davey and Jennifer Powell, also of Salford University &Drs Elvira Lantelme and Ercilia Hirota of Universidade Federal do Rio Grande do Sul

Abstract

Over the past decade with significant support from the North West Development Agency, under a project which became known as NetworkingNorthWest (the "educational micronetworking of Small Medium Enterprises (SMEs)" project), the author conducted international benchmarking of best learning practices for skills development in construction across the world. This paper will compare and contrast the experience of developing a balanced learning approach for SME's from within the construction industry in Brazil, South Africa and the UK. The balanced learning used is a combination of facilitated Action Learning, traditional and e-Coaching and eLearning materials developed specifically for small contractors. A critical aim of the work, which it is believed has general applicability, has been to understand the contribution more relevant skills development can have to construction modernisation and improvements of the construction industry in terms of process productivity, product quality and human work conditions in particular. In striving to achieve these objectives the studies revealed the main barriers for effective innovation and how these might be overcome (by processes such as action learning and eCoaching) to support innovation implementation in construction businesses. It also showed that Action Learning (AL) component of the learning, with SETS of 'construction partners in adversity' finding "common ground" for useful discussions led to innovation for wealth creation. In particular once common ground was established SET members often continued to network and form alliances outside of the Action Learning environment. SME construction owner-managers felt able to discuss both personal and business issues that have such an influence on each other. Finally, AL offered the opportunity to take time out of the business and "disengage" with the operational allowing them to become more strategic.

1. Context

1.1 Construction Research at Salford and Universidade Federal do Rio Grande do Sul

For many years research in construction at Salford University and at the Universidade Federal do Rio Grande do Sul has been particularly directed to contributing to the development of construction solutions and service support based on a systemic approach. As such, its research considers all aspects that influence the construction of building environments, as well as the performance of the construction industry as a whole. In a systemic approach the construction process is considered in very broad terms from conception, through design, materials production and execution, to use and maintenance. The approach is an integrative one, taking account of all interactions between these diverse construction phases.

The two universities' main objective has been to develop highly capable teachers, researchers and technicians, as well as producing scientific research of the highest international standing with respect to Lean, Agile and Advanced Construction. All our researchers have a strong focus on application. This can be attested by the numerous collaborative projects the group has developed with the industry over the year and with a myriad of international partners. Its main areas of research to date have been on topics such as: Sustainability; Construction Management and Economy; Materials Technology, Components and Construction Systems; and Information Systems.

Much of the research in both these university construction departments has been to contribute to construction modernization and the improvement of the industry performance in terms of process productivity, product quality, and human work conditions. There has been a particular concern to build a strong theoretical basis to our research and development. Such theory – concentrated learning according to Lauri Koskela - was needed to ensure that our growing systemic understanding of how best to improve the construction management process actually finds its way into successful built solutions. From this firm theoretical base we have then moved on to develop better learning approaches, to turn theory into practice, which is the subject of the present paper. Our hope in doing this is that improved learning approaches will enhance the fast and effective transfer of new and useful managerial concepts into the practical context and encourage their full uptake to enable better working on building sites and for the industry as a whole.

1.2 Mid Career Learning for Construction SMEs– a European Perspective

Governments and their training organisation across Europe are extremely pessimistic about engaging small to medium sized enterprises (SMEs), especially from construction, to become more innovative and for wealth creation as a result of higher learning. In the UK funding has been consistently available to help such SMEs take advantage of this enterprise learning [1], but the Council for Excellence in Management Leadership (CEML) [2] report that is much more currently available is disconnected to the real needs of SMEs and as a result poorly used [3]. In such a context, the present author was keen to develop a demand driven approach for mid-career construction learning which would recognise the real needs/demands of SMEs, help them learn how to learn from themselves how to cope, indeed flourish, by developing new ways of working suitable for themselves, thus enabling them to respond quickly and effectively to new opportunities. Construction SME owner-managers are action oriented and much of their learning therefore is context-dependent and experientially based. Rae and Carswell [4] have shown clearly that SME learning which occurs primarily through activities such as; trial and error [5], problem solving [6], discovery [7], experimentation and copying [8], facing success and setbacks [9], making mistakes [10] often occurs opportunistically and incidentally [11].

1.3 'NetworkNorthWest' – The Change Agent

The NetworkNorthWest project ran from 2003 to 2005 funded by approximately 1.3m Euros of grant from the North West Development` Agency (NWDA). It was scoped at a time when there was a growing concern about the failure of agencies and universities across Europe to engage successfully with Small to Medium Sized Enterprises(SMEs) to encourage development and creative thinking to stimulate innovation, which would result in improved performance, growth and wealth creation. *There are 360,000 such SMEs in the NW City:Region, who require for survival to be at the leading edge in the global knowledge economy, but who have rarely been considered as a key audience by Higher Education.*

There had been concern for some time within the UK's Northwest Development Agency that while innovation in big business was being supported, little was being done to develop innovation in SMEs in the region. Meanwhile, traditional business support was being seen to be intimidating or inappropriate and failing to meet the needs of the majority of the regions SMEs with engagement with businesses with less than 50 employees around 14%, while for those with less than 10 employees it was likely to be below 5%. The figures for engagement with universities were equally low with only 20% of businesses following that route. Besides the time commitment required, the main issues here appeared to be the perception that offerings were too theoretical, academics were out of touch with the reality of running a business, language used in resources made them less accessible or that previous poor learning experiences indicated that "university is not for me".

The challenge therefore was how the University of Salford (and its partner Universities such as the Universidade Federal do Rio Grande do Sul) could be creative about engaging with SMEs who failed to seek business support, in a way that they might learn how to be more innovative for wealth creation. Previous studies by Salford had shown it was possible *to engage and empower small businesses in a cost effective way by developing an approach which: answered the SME's, 'what's in it for me' question; fitted their normal ways of working, but also set them realistic and fund earning challenges; and finally used a real world language and 'just-in time' learning approach. It was also felt that such an approach would only work by sharing the responsibility for the development of educational materials and the delivery in a broad university partnership*

1.4 Being Creative about engaging and empowering (construction & other) SMEs

The intention of the project was to provide a new and creative *way of offering business support* for SMEs which would allowed the SME rather than the provider to set the learning agenda so that learning was relevant to their own situation.

We already knew that the action learning process, which originated from the work of the late Prof Reg Revans here at Salford, had a strong following in the global corporate business community where it was regularly used for leadership and organisational development. However, evidence from research here at Salford had also suggested that the process would be equally valid for groups of managers from similar positions in different SMEs. Furthermore, our international benchmarking work also suggested that there was little use of action learning as a process for supporting SMEs, but where it was used, it created a real difference.

Salford's unique approach was to work with its higher education partners, both across the Manchester city-region and internationally (especially for construction in Brazil and South Africa) who had already *formed a powerful partnership with its own formal quality assurance framework*, bringing SME managers together in action learning groups (SETs). In such learning contexts, participants were encouraged to learn with, and from, one another and draw down additional academic or business support as required. Key to this process was the *development of the participant's ability and confidence to challenge one another's preconceived ideas, enabling them to be creative about how they approached business challenges so that they became innovative about how they did business and their offerings to market*. They formed strong 'learning partnerships-in-adversity, their SET against the world, working for each other; a social context where profound questioning of each other led to deep and useful learning. The construction SMEs were also supported by learning facilitators, who acted as coaches to deal with individualised problems and issues of each SME.

The project was also keen to ensure that the SME participants had fun as part of their learning experience and hence the Let's Bounce brand was developed which distanced the project material from more serious academic and business support offerings. This material was in hard copy and e-Learning forms available through the www.networknorthwest.co.uk web site and could be accessed by all SMEs in the City:Region; *all these materials were developed by SMEs , with the help of others, in a form that could be immediately used in their businesses with effect a toolkit for successful innovation and enterprise action.*

2. Action Learning – A fuller perspective of the adopted process

2.1 The Basic Principles behind Action Learning, especially in the Brazilian Context

Quite early in its development, the universities already mentioned in this paper[1] began to develop research concerning organizational learning and managerial competence development. This research developed as our staff recognised the need, not only to understand the main technical problems facing the construction industry, but also how the industry could properly and easily learn for themselves how to implement, with greater effectiveness and efficiency; the new solutions, concepts, principles, and innovative technologies developed by the two universities. Important principles concerning organisational learning and competence developments also soon revealed themselves in two areas and were thought to be worthy of further consideration. In particular two questions appeared key to our researchers:

- What are the main barriers for innovation implementation in construction?
- How can they best be overcome?

In trying to answer these questions, both Elvira Lantelme and Ercilia Hirota, key researchers in organisational learning at the Universidade Federal do Rio Grande do Sul working under the supervision of the present author, undertook a detailed literature review. From this they proposed that one of the major barriers standing in the way of managers seeing, thinking and acting more appropriately in their normal practices related to the existing learning (or rather training) processes adopted by most in construction as they tried to understand the new. The team believed a better educational approach was needed to help mid career professionals learn new competencies quickly and with effect.

For her PhD research, Lantelme investigated several approaches that could be used for managerial competence development which were to be led by herself and her colleague, Hirota. With respect to one of these, action learning, she and Hirota visited the Revan's Centre of Action Learning and Research at the University of Salford. Action Learning is a process where groups of 5 to 7 professionals (a SET) come together to tackle real problems and issues from their working lives, develop solutions and reflect upon the success and failure of their resulting actions – thus learning from self and other reflective processes. SET meetings, facilitated by an Advisor, are characterised by certain accepted 'soft' rules and benign structures designed to encourage being 'authentically present' in someone else's issues – a truly empathetic response where a 'reciprocity of perspectives' enables both the questioner and the questioned to learn new ways of learning in context.

---

[1] Six other British Universities were also involved in the overarching project which provided the resources to undertake the case studies upon which the following findings were drawn. These were the universities of Bolton, Liverpool John Moores, Manchester Metropolitan, Lancaster and Central Lancashire.

Through joint working between the Universidade Federal do Rio Grande do Sul and University of Salford, supported by the British Council, a firm partnership was developed between both Institutes who were considered to be developing best national practices for their own country for construction. The Brazilian researchers had a period of apprenticeship at University of Salford to learn to become SET Advisors in the context of Action Learning. Although the literature they had explored emphasised the effective use of Action Learning in managerial development [12], they had found few studies giving a sound contribution to understanding the learning processes within Action Learning programmes [13]. Therefore, while in Salford they took the opportunity of talking to SET Advisors from the Revans Centre, as well as participating in SET meetings as observers, to see how the process worked and gain their own understanding of how to implement a learning process that initially seemed quite unusual compared to traditional training.

After this visit, these researchers, became very enthusiastic about Action Learning and especially its potential for the development of managers' competence with respect to innovation for wealth creation in construction. Action Learning seemed to fit well with the concept of competence *development,* which had been adopted by the Universidade Federal do Rio Grande do Sul as a guiding principle to all their work. In particular they saw the potential of Action Learning in the way it enabled:

- a proper focus of learning towards better working practices; this was through explorations of real and actual problems faced by managers in their daily activities;

- penetrating questioning of issues, challenges and problems at a sufficiently deep level to enable those practices with better practice to develop quite naturally; this included enhancing construction managers ways of exploring, reflecting and listening about those human and informational resources (knowledge, skills, attitudes – formal and informal) and enabling managers to mobilise better on site leadership through their actions thus improving a site's effectiveness and efficiency. This learning process was also felt to be useful in helping managers to recognise their managerial and leadership deficiencies, giving them deeper understanding of personal issues and emotional intelligence requiring improvement. Through exploration of the meanings people give to certain ideas and concepts in the context of their action, they believed the managers could self-learn new process of real value to themselves;

- better action in context as an exercise of knowledge mobilisation; early research had shown this to be a vital to competence development for construction.

In an attempt to understand the Action Learning approach better, its general processes and especially how best to be a Set Advisor for themselves, during 2000 they formed two experimental SETs in Brazil; one with five post graduate students and another with a group of three directors of small and medium construction companies. Hirota acted as the SET advisor for this exploration and Lantelme participated mainly as an observer.

It is important to stress that all the Action Learning SETs developed at the Universidade Federal do Rio Grande do Sul had the clear objective of understanding construction managers´ learning processes during the Action Learning, as well as the Action Learning process itself. The focus of this Brazilian project was with individual learning, not with the results or impact of that learning process on any construction enterprise performance. Furthermore, most of the companies they worked for were not even aware that participants of the experiment were actually participating in an Action Learning programme. They decided to not to tell the companies about the detail of Action Learning, but worked with committed volunteers, because they did not feel themselves at this stage to be sufficiently experienced in Action Learning SET advice. Before developing regular educational programmes in an area new to themselves, they wanted to undertake these early explorations to become more professional as SET Advisors, to build up their confidence in the Action Learning process and their control of it, and to understand its real value before going further.

After supporting the first two short experimental SETs, to sensitise herself to the process, Hirota started a third Action Learning SET with construction managers responsible for general site management to put her newly acquired SET Advisory experience into action. This SET lasted for 4 months, had fortnightly meetings and was formally studied as part of Hirota's own doctoral programme. One of the members of this SET was actually interviewed as part of the first benchmarking exercise, because with only a short period of induction in Action Learning, he had learned sufficient about the process to adopt its major principles in the normal working processes of his company with great effect. For her own doctoral research Lantelme thought she still needed to understand better how Action Learning could be used to develop managers' competencies and also to investigate deeper the relationship between the learning and action. By this stage she had convinced herself of the validity of this learning process, but was determined to undertake a rigorous experiment to prove the concept to others. More details of the style of Action Learning adopted, the nature of the learning development she led and the findings from her doctoral studies form the remainder of this benchmark report.

Hirota and Lantelme were both highly influenced in their choice of a better educational approach to support practical learning about change, by the research of Schon [14] and also by other literature on the topic of organisational psychology. This is stressed, in some detail beyond the scope of this case study, in Hirota's successful doctoral thesis (in Portuguese, 2000) where she investigates in detail the relevant relationships between cognition and action. This led her and Lantelme, who was to be the SET Advisor to the major case reported here and in the appendices, to adopt strategies as SET Advisors which were much influenced by the ideas of 'inducing managers to expose and reflect on their own mental models for action, to reveal the beliefs, feelings and emotions that guided their actions to others who could help them understand their strategies against the best of currently espoused theories expressed in a practical way'. Hirota and Lantelme initiated their SETs in a traditional Revan's type way, but gave greater early emphasis on helping managers understand their personal psychological values and behaviour. NORIE researchers also believed in providing as full a feedback service as possible to the learner managers in the progress of their Action Learning. They did this, using 'learning trend' charts, which showed plots of the progress of the learner against key concepts with respect to these.

2.2 Action Learning in the British and South African Context

The previously mentioned NetworkingNorthWest project undertook examination of Action Learning in the British and South African context. In Britain 133 SME businesses were supported through 19 SETs established across the North West region, in processes essential similar to that used in South Africa; 28 businesses of those study related to the construction industry or its partner organisation. Since the scale of this British development was extremely large, each partner of the programme agreed to deliver a number of action learning SETs but the precise methodology to be used was not prescribed. This project was prepared to be flexible about many aspects of delivery, as long as core principles were adhered to, it was felt that flexibility not only allowed the team to capture best practice but also allowed participants to customise their own experience to meet their needs. Data from these SETs was collected for external project evaluation and forms the basis of the more general findings mentioned later in the paper.

Unlike other forms of facilitated meetings, the Action Learning process used in both the British and Brazilian cases, dictated that the SET members own the process of the SET meetings. They set the ground rules and, within reason, dictate the time, precise frequency and location of the meetings Good action learning facilitators become part of the team and often take a relatively minor role in the proceedings, their key skills are to use good listening skills and ask excellent questions that challenge the status quo, drill down into issues and keep the process of the meeting on track. At the end of the session *they ensure that participants take away actions to be completed, and that the subsequent outcomes are reflected on and reported to the next meeting to share the learning from the action taken.*

Also as part of the NetworkingNorthWest project, international benchmarking was undertaken to enable the production of a set of resources and guidelines on true global best practice in this type of intervention with SMEs as part of the development of resources to support this type of learning. The Brazilian example was described in full in section 2.1, but I also undertook a case study of a learning development used in South Africa, based on a Liverpool development, known as Business Bridge. Business Bridge is a peer-to-peer network, used in and around Johannesburg which seemed to have been used with much effect to encourage innovation and wealth creation in South African SMEs.

Just as in the British and Brazilian Action Learning, there are facilitators who keep the learning process developing, however in the Business Bridge Meetings they take on an extremely proactive role, especially between meetings, in providing coherent support for any SME's actual enterprise development and in setting up themes for future meetings. Action Learning advisors in the NetworkingNorthWest Action Learning SETs could learn from this that the power of the telephone in supporting early constructive actions for change stimulated by SET members is also valuable. Similarly, in Business Bridge, the use of Action Learning style minutes to give immediate feedback of the learning from the meeting is seen by it's facilitators, to be helpful and constructive in support of SME change. As in the NetworkingNorthWest SETs experience, BBM found the neutrality and responsiveness of the facilitator to be key.

2.3 The Research Project and Integrating the Findings of the projects

The project, formally known as "Networking North West" and informally as "Bouncing Higher", was funded by the NWUA so that the authors Mid Career Construction Professorial Learning Research Team could undertake a comprehensive R&D study into the learner needs of small to medium sized enterprises. Using a full action learning approach, the learner needs and learning processes of about 40 owner managers of SME construction companies, working in 7 AL SETs, were elicited using a portfolio of methodologies including: thematic interviews, empirical observations, case study explorations, ethno-methodology and full learner reports of all action learning meetings. All the material were content analysed and, using a grounded theory approach, a new model of mid career professorial learning was developed known as "Consilient Leadership". The funding from this research led to further formative evaluation and to the development of a "balanced and open learning portfolio "of materials suitable for SMEs. Finally a summative evaluation was also undertaken. 'Research' in this project relates to the original investigations of the learning needs of SMEs.

The project was managed by a researcher with an academic background, she had worked for worked for many years in industry and was skilled at communicating at many different levels to overcome the difference in "languages" between SME participants, academics and business support agencies. She also acted as a SME in her own right and *therefore acted both as a participant observer on the development and an observing participant in the personal testing and evaluation of materials and support.* Her role was to undertake relevant content analyses of all materials and thought successive summarising to elicit the major findings and other interesting conclusions. Shown in the next section are some summary findings from all the projects taken together as they concern those SME’s relating to the construction sector.

3. Major Impacts and Overall Findings

In general the only limitation to the action learning process relates to the time limits of the meetings themselves. This was on the basis that the ‘learning space’ provided for the managers had the right balance between deep reflection to give confidence and deeper understanding on the one hand and learning from creative and innovative actions at work – the required implementations from each meeting. Hirota (15) had also noticed some reluctance on the part of the managers to implement actions which emanated from the meetings. SET Advisors always tried to provide compelling advice to encourage action for change with respect to the most difficult skill to learn from the beginning of the SET. If not handled sensitively and correctly, through good SET support, the real benefits of Action Learning - to improve work and actual processes at work - may well not be followed through with action and hence the real benefit maybe reduced.

Table 1- Examples of some of the learning outcomes reported by the evaluation team and Facilitators

Management Development	**Realisations**	**Technology**	**Information Transfer**	**Tangible Outcomes**
Development of production management skills through ensuring enough materials are on site for continuous work The use of Microsoft project to help the practical management of their businesses Adoption of longer-term strategic focus and longer-term goals Development of time management skills Manager moving away from operational aspects of the business Review business plans Learning to share worries/issues with SET A more strategic approach towards the business. Movement from "employee" to "entrepreneur" mindset – e.g. knowing the market, staying ahead of the market, and paying attention to small but important things. Listening to the variety of perspectives within the group has allowed members to build confidence and move on to growing their businesses	Development of understanding of customer needs through questioning and reflection from other SET members An understanding that computers are not to be feared rather they can be used to help and improve businesses Development of understanding that a business can grow through effective marketing strategy Understanding of how new technologies can be applied in a way which will help to grow the businesses. Realisation of underlying problems with businesses e.g. realisation by owner – manager that their business had no clear direction or strategy Learning can be fun Realisation that original aims and plans for the business were out of touch with the current direction of the business. Realisation that growth must be in accordance with the owner-managers own ambitions and hopes for the business. In one case this meant continuing the businesses ethical stance. Realisation that "experts" don't always hold the answers – more useful to start asking yourself the right questions(as you are the expert on your own situation) and then take action as this is the best way to learn. You can learn from any action you take whether the outcome is positive or negative There has been a realisation that a balance has to be sought between running these companies as a "creatives" and as profitable businesses.	Computerisation of files Development of websites after formal input on web design Use of Microsoft Project and other business packages Discussions and action in the area of internet marketing Development of understanding of the use of SAGE programme for accountancy related purposes. Use of new software tools	Community awareness Where to gain help and advice in order to make decisions about expansion Development of Knowledge around the use of Microsoft programmes Gained knowledge of funding opportunities for SMEs How the action learning process can stimulate innovation Alliances formed with university departments with a view to a future joint venture. Employment of a marketing expert to help with strategy Use of techniques to achieve longer-term focus such as "futurising" Opportunity Cost Understanding of how to examine profit and loss accounts Information has been transferred regarding: Limited Companies VAT Outsourcing Business Link services Further courses Information about potential investors Sharing expertise in certain areas.	Development of new construction products and services e.g. new light lunch menu and eye tests after 5pm. Networking and building alliances with former competitors to bid for larger contracts and manage peaks in workload. Increased turnover Seeking further development through courses Development of more sophisticated marketing strategies helped by website design Employment of new staff to meet increased workload Networking and alliances e.g. several members from different backgrounds are currently working together who would not have previously considered this as an option. In line with more strategic approach, new staff employed to deal with technical work to free up owner-managers' time The purchase of new premises Employment within in the SET

All SET members who sustained their involvement in the SET to its completion, clearly enjoyed the process and gained a great deal concerning their own self-awareness especially with respect to valuable personal (‘therapeutic help as they called it) lessons. Nevertheless, *most of the volunteer action learners were prepared to spend more than*

30 hours contact time working in their action learning SETs, while the remainder (less than 10%) had at least spent between 3 and 30 hours in the process; this is a considerable commitment from busy construction professionals who often loathe giving up even the most minimal time for training and education. All participants grew in confidence and every participant had a different learning outcome; see table below for just some of the many examples of successful delivery, outputs and outcomes.

4. Specific Findings

The research also revealed some more specific findings with respect to the learning of mid-career professionals. These findings are now reports item by item.

4.1 Key Learning Point 1

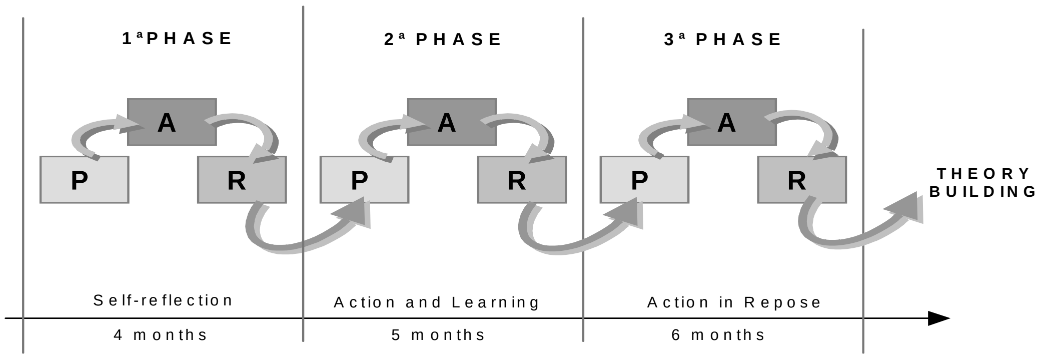
It is important to have facilitators for all forms of educational micro networking for SMEs to have: an empathy with, and personal professional expertise to share with their SMEs; be capable of coaching, rather than advising their SMEs; and willing to be supportive in difficult areas of their enterprise development

4.2 Learning Point 2

Even fairly inexperienced SET Advice can lead to best practice in SME learner development by sticking to the basic principles of Action Learning as espoused by Professor Reg Revans. This finding complements previous ones by Powell et al [17] and the Networking North West Evaluations [18]. Explaining this in more detail, using the Brazilian Action Learning SET as an example which operated for fifteen months, from December 2000 until January 2002. It consisted initially of five construction managers, all civil engineers, and finished with four. Two managers left the SET as they felt unable to give the time to it and one new one was invited by the SET members to join them after the fourth month. The professional profiles of the SET members completing the exercise are shown below. The managers who were involved were well known to the Universidade Federal do Rio Grande do Sul and seemed open to action and change.

Bernardo	Production Manager of medium sized construction company responsible for the development and construction of major residential and commercial buildings. He was also the manager in charge of the company’s maintenance department.
Alexandre	Production manager of a small construction company that works as a contractor for private residential, health and commercial clients. During his participation in the SET he had co-ordinated the process for implementation of the ISO 9000 certification in his company.
Roberto	After a long period of working as an assessor for the state government in the ‘Secretario de Habitaçao’ this manager returned to private construction work as a self employed engineer. During his participation in the SET he was working as a site manager in a medium sized project developed for a private client. He was hired by the design office that developed the project.
Klaus	Director of a small construction company in the interior of the state of Rio Grande do Sul. His company developed and constructed many different projects; commercial and industrial buildings; industrial ‘pisos’, steel structures. He mainly works for private clients.

All of the managers were invited individually and volunteered to take part without their companies being aware of their detailed involvement excepting in the case of the company director. However, the companies had all been working with the University for sometime and welcomed their approach. Most of the managers were interested in the possibilities offered by the SET to exchange understanding of practice and learn more from each other. To the managers it was an opportunity to develop new competencies in order to deal better with their practice in their own work context. The four managers had never worked together before, although they were acquainted with each other. There was another member of the SET who acted as a participant observer - Claudio Antonello, an organisational psychologist was undertaking her own doctoral studies and helped Lantelme record the activities and behaviour of the SET during its operation. The resulting SET ‘Action Minutes’ provided useful feedback to the SET members on their individual learning processes. Elvira Lantelme – the doctoral researcher undertaking the Brazilian case - provides her own short narrative to give the reader a feel of the progress of the SET during its fifteen months of operation in her doctoral thesis (18) for those who read Brazilian Portuguese. In summary here, starting with the overview, during the development of this AL Set there were three planning-action-reflection cycles.



The actions determined different SET members reactions which established three different Set phases. The analysis and reflection done in each cycle allowed for better understanding of AL process and redirections in Set Adviser strategies and actions for facilitating the Set. Set advisers Changes in managers’ behaviour can be observed in the graphics below, mainly by comparing the curves on the different phases of the set.

As Bernardo moved into the second phase of his Action Learning experiences he was much more conscious about his controlling and centralising management style as well as about his resistant (reactive) behaviour in the set. On the second phase he developed some changes in the way he was managing his team at the maintenance dept., giving them more autonomy to take decisions. His behaviour in the set also changed, as it can be observed in the graphic (resistance – b) below. He was more open to the set questioning and more committed to contributing to the learning of others (a)

In his second phase, Alexandre managed to improve his own engineers’ participation and commitment in the improvements his companies were making as a consequence of quality certification. In different moments in the SET he asserted that his participation in AL resulted in many changes in his behaviour in the work and in his personal and family life. He said he developed his capacity to listen to others, paying attention to their opinions and being less resistant to them.   These changes reflected also in his behaviour as a set member, more committed with his SET partners’ learning and less resistant to questioning as the *graphic below shows. He was very satisfied with the results achieved in his work and also about the changes he observed in himself.*

Roberto radically modified his behaviour in the SET. As a good listener and observer he had always had a good perception of the others problems and as such could contribute with challenging and penetrating questions. The graphic below, shows the frequency of his interventions, and also reveals his commitment increased in the second phase. As a consequence he acquired the respect of the other SET members. He did not actually say much in the SET, but when he said something the others stopped to listen. But, in the second phase, the graphic reveals that his own behaviour was still very resistant to questioning.

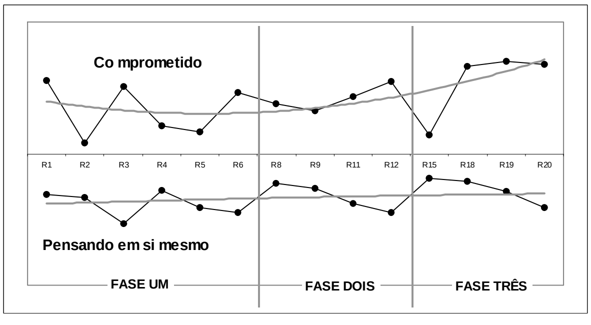
Klaus also modified his behaviour as a SET member during the second phase of the Action Learning. When he first participated (in the 4th SET meeting), it had already started. He said he felt like a substitute member, not part of the group. In the 2nd phase he started talking more, asking more questions and also demonstrating more commitment with the other learning (graphic a). Klaus was more conscious about his insecurity and difficulties in taking decisions in order to put his ideas in to practice. In different moments he discussed this issue with the SET. His difficulty in acting became a true barrier to his learning.

If we analyse the graphic below for the SET as a whole, we can observe a tendency for them to become less resistant to questioning and have a greater commitment to the process itself. Except for Klaus, who was very much confronted by SET members in the second phase of the Action Learning, the Managers perceived themselves to have developed more trust and commitment

"I think the group became more friendly. It was very sincere when someone commented, when you said you would leave: that does not matter, the set will continue. This is something that characterises the set. This process has been important to everybody" (Roberto, final interview)………..".I would say, it was a good reflection moment. We have a lot of trust between ourselves. There is a true preoccupation about the others. Commitment developed" (Alexandre, final interview). "I think trust in the group evolved, confidence evolved. For me, this programme is very good, that is because I don't mind travelling" (Klaus, final interview)

At the end of their formal Action Learning support, only Bernado expressed his doubt about whether the SET should continue. However, in his interview in this benchmark, he made it clear that his view had now changed and was supportive of the SET continuing in some form.

a) as a SET member



b)) as a problem owner

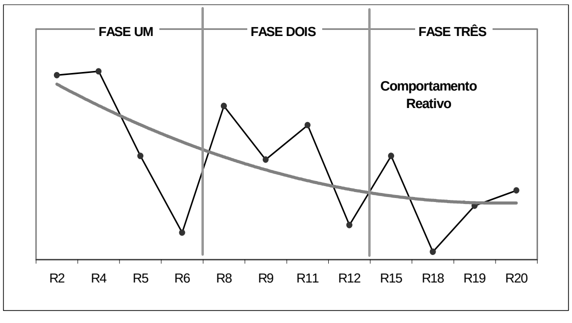


Figure 1 Bernado's behaviour as a SET Member

In his opinion at the end of phase three of support, the SET lacked a clearer systematic way of working. He was also fairly conservative about the level of trust and confidence that had been developed in the SET.

"I felt the SET oscillated, there were meetings that did not add value. He seemed to be walking in circles…

I think it oscillated a lot, it could have added more value". …..“I think Action Learning should have a more systematic way of working, sometimes we were lost (…) but in terms of learning it was good. I think it could be better. We are more mature, but not that much".

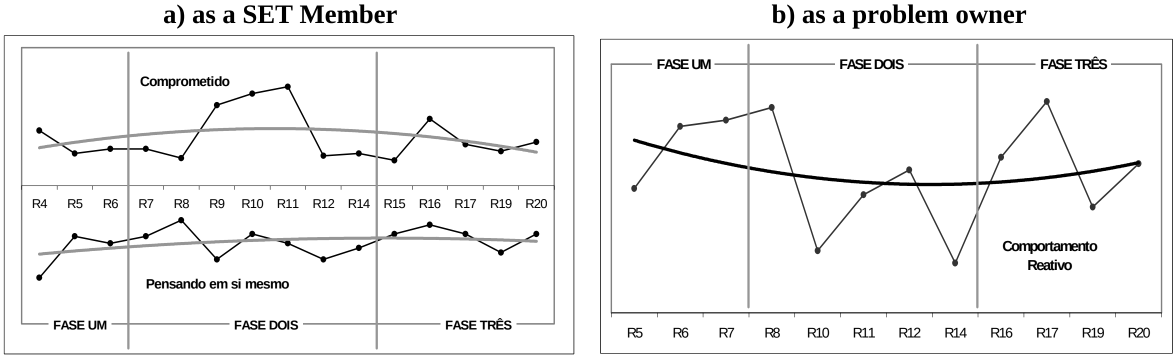

Figure 4 Klaus's behaviour as a SET Member.

4.3 Learning Point 3

It is clearly important for SET members to want to participate in an Action Learning SET voluntarily. Those who left the SET did so of their own accord. Since the results of any SET meeting involve putting change processes into action, there will be a clear impact upon any participants own company. Without the support of the company to enable the testing of new actions at work it is not possible to follow through educational purposes with effect. This is unlike traditional workforce training which requires no implementation, so any learner needs the full support of his/her company, supervisors and the bosses to take full part in the process. This was possible, in the main, for the four managers with respect to their own actions.[2]

The AL SETs in this paper focus towards the psychological, self-awareness and emotional intelligence aspects of Action Learning which have particular effects that are mentioned later in this paper. Initially, for the first six months, the meetings were held fortnightly and then on a monthly basis to the end of the period in which formal learning support was provided. Network North West Educational Micro Networking meetings were held mainly at monthly intervals.

4.4 Learning Point 4

Our Experience of the right frequency of the learning process shows that fortnightly Action Learning meetings were essential to keep up the momentum of understanding about Action Learning and indeed for one SET participant in Brazil he had understood sufficient about the general principles of Action Learning during such a short period to introduce it into the mainstream working of his company to good effect.

All SETs went through different phases. In phase one, which was called ‘the therapeutic phase’, SET members mainly discussed their personal problems relating to their work such as, job satisfaction, difficulty in controlling their different workforces and general emotions and feelings relating to their jobs and their colleagues. In short, it was found that ‘it is impossible for the small business to separate the personal issues from the technical when dealing with SMEs and indeed it may be extremely counter productive so to do’.

4.5 Learning Point 5

Those who had experienced the Action Learning in this experiment indeed enjoyed this unusual and counter-intuitive process; counter-intuitive in the sense that they were learning from each other, rather than a teacher. They also found it valuable to their own self-development and put themselves in charge of their own learning – an experience unlike any other they had found in conventional training. Two of them were sufficiently enthusiastic about the process to introduce it into their own companies with positive effects. Spreading these positive experiences of Action Learning in this way by ‘enthusiastic word of mouth’ firstly indicates their own positive evaluation of the process and secondly shows their willingness to share this experience with others. NORIE, as in the Networking North West, has shown this form of marketing for SMEs is the best way of attracting new participants into this novel educational process.

[2] One of the SET members – Alexandre - was so enamoured of the Action Learning process that he tried to develop an in house initiative with his own production managers based on the benefits from his own experiences in Action Learning. Lack of support by his own directors for this, curtailed progress on the initiative. Action Learning meetings were regularly interrupted by other work requirements and some managers left the SET because they did not have time for full participation. Other managers wanted to take part, but again time was not made available to ensure adequate SET participation. However, Rio Grand du Sol and Alexandre are now working with other directors with a view to further implementing Action Learning within the company.

All SET members, when asked, felt this was the best way to enrol new SET members and were even prepared to be captured on short marketing 'video clips' themselves giving reasons and recommendations to others. They suggested they could be of two types:

- For those initially intrigued by the idea of the AL process, the best way would be to indicate simply how, and in what way, the process had particularly changed their working lives; how it had enabled them to penetrate more deeply with effect into socio-technical issues that had previously been impenetrable - 'let me tell you how it was for me!'

- For the more cynical, who might feel the process odd and, even counter-inductive and long winded, a more subtle approach might be to stress the eventual long term impacts and benefits of this learning process and to ask the cynical just to "suspend their disbelief" and give the process a chance. Through continuous, slow, subtle but gently persuasive support, the aim would then be to win colleagues over. Roberto had most interesting thoughts in this respect. He had learned so well how to win people over in this that he had developed a new consultancy practice to offer this as a service to colleague engineers.

4.6 Learning Point 6

Providing learners with concrete information on their learning progress, through learning trend charts, proved to be an extremely positive way of marketing and overcoming barriers to change and those "bad but common" practices normally highly resistant to change. Good feedback at the right time can provide realistic ways of sustainable and competent new "good" practices, when the learner is ripe to learn.

4.7 Learning Point 7

It is important for work focused learning of real benefit to the industrial participant learners, that Action Learning SET Advisors ensure the right balance of learning support between enhanced manager's self-awareness, empathising with the workforce and understanding the social aspects of the working context on the one hand, with building new professional capabilities, adopting relevant new technical approaches and gaining a good systemic understanding of new competencies in practice on the other. All our researchers confirm that, properly delivered, Action Learning does allow deeper useful learning that is sustained beyond the support of SET advice. However, to ensure quality impact on site management does require careful intervention of the Advisor to guide SET members towards the sort of simple questioning approach proposed by Revans. With such a focus major work-based improvements in managerial action are engendered, tested, and honed to become useful new "tools" in support of change.

4.8 Learning Point 8

While significant therapeutic and personal development seems to occur, no matter what kind of SET advice is given, experienced SET Advisors know how to carefully refocus individuals to be able to face up to real work issues, problems and challenges. The learning charts developed in this study have helped give the necessary feedback to facilitate better development in this respect. Such focusing is essential in ensuring the earliest "return-on-their investment" for the participants in Action Learning, and especially for their companies.

4.9 Learning Point 9

All SET members welcomed the role of the SET Advisor in focusing them towards deeper and more useful questioning of work activities. They all reported her improvement of this focusing as her experience increased and the way she gently opened up their emotional intelligence aspects of their working lives, thus helping them put all things – technical, managerial, process, methodology – into a more complete perspective enabling them to act in a more integrated way.

4.10 Learning Point 10

Even for SETs lasting for some time, the role of the Advisor still continues to be useful in "shaking members out of their complacency" and focusing them onto work relevant issues with the right kind of questioning at he right time.

4.11 Key Learning Point 11

Coach facilitators can act as intelligent brokers to enable corporates and SMEs to learn from each other in a virtually beneficial way.

4.12 Key Learning Point12

The Action Learning process does seem to be a good way of getting those who are traditionally weak learners, such as in construction, who often those who fail in the traditional educational system, to fully engage and grow in capability and competence.

4.13 Learning Point 13

The South African benchmarking exercise particularly showed that it can be extremely useful to have between meeting contact with SET members in order to:

1. *prompt them to do the actions they agreed;*
2. *find difficulties they were experiencing in i);*
3. *learn what sort of problems, issues and challenges were likely to be discussed at the next meeting so the Advisor could prepare better.*

4.14 Key Learning Point 14

The facilitator in the Business Bridge Meetings took an extremely proactive role, especially between meetings, in providing coherent support for any SME's actual enterprise development and in setting up themes for future meetings. This is much like John Whatmore's between meeting support in his Creativity Clubs [20]. Action Learning advisors in UK and British Action Learning SETs could learn from this with effect; the power of the telephone in supporting early constructive actions for change, stimulated by Set members, is also seen to be valuable. The use of Action Learning minutes to give immediate feedback of lessons learning directly from the meeting themselves is further seen by the facilitator, as in our experience, to be constructive in support of SME change.

5. Conclusion

This case study provides a powerful benchmark revealing the value of an “action learning type” approach to engaging and empowering construction SMEs, with a whole range of capabilities and levels of knowledge, to learn from each other, and their supply chain corporates, for mutual benefit. The similarities of the underlying learning process between the UK, Brazil and South Africa in implementing such an approach is clear and reinforce other evaluations of its overwhelming success in engaging busy managers to learn how to participate in many new ways both tactically and strategically. Their new skills developed include learning how to question others in a penetrating and useful way, to actively listen to peers, bosses and subordinates equally and act with understanding as a result and to learn from all their actions, these now seem to have been embedded in useful ways to the benefit of their mainstream working. Interesting other detailed learning points have arisen when comparing the more proactive, professional disciplinary and advisory role of facilitators. These learning points have been fed into the educational packs developed for the training of future coach facilitators for “education micro networking” in the North West and beyond; these packs are available from the author.

Abstract

Quantity Surveyors are the cost consultants in construction. They possess expert knowledge in construction costs, material usage, and labour norms. Quantity Surveyors have their expertise in project finance, project cash flows, contractual procedures and legal aspects pertaining to construction. Due to the present scarcity of labour, material and finance, Quantity Surveying profession has got recognized in both domestic and international markets.

Sri Lankan construction sector has shown 6.7 % growth as per central bank bulletin in the third quarter of 2005. Tsunami reconstructions also contributed to the above growth. Simultaneously demand for Quantity Surveyors has also increased significantly.

This research is focused on analyzing the demand and supply of Quantity Surveyors to the Sri Lankan construction industry. Several demand factors were identified for the period of last five years, which has caused to increase the number of job opportunities.

Supply sources of Quantity surveyors were also identified and compared for the contribution. As per this study on evaluation and forecast of demand and supply, Supply of graduate and non graduate Quantity Surveyors is insufficient to cater the future demand. Therefore, supply sources are to be stimulated to meet the demand of the industry.

Key words: Quantity Surveying, Demand, Supply, Graduates ,Non-Graduates

1. Background

1.1 Introduction

The construction industry, being the means by which society shapes the built environment, carries considerable responsibility in ensuring that building and civil engineering work of the highest standard is achieved in prevailing constraints. Historically, the construction industry has played an important part in meeting the social, economic and technological demands of developing civilization. The role can therefore be defined as being the management of resources in the development, production, maintenance and disposal of capital assets [3].

But with the likely changes in society, the role of the Quantity Surveyor has been evolved constantly and the present Quantity Surveyors practice their competencies in diversified paths within the construction industry and as well as beyond the boundaries of the construction industry [1].Since the construction industry becomes more significant in the economy and it has created more employment opportunities to the nation [8].

The market forces regulate demand and supply for the labour which decides the price of the labour which has a greater impact on the business, government policies, general education and the technical and vocational education. Demand for labour is the number of employment opportunities available in the public and private sector institutions within the country and overseas as well. Supply of the labour represent the number of workers enter into the world of work from schools, universities, and technical and vocational training institutions.

The visible changes and growth of Sri Lankan construction industry have forced the Sri Lankan Quantity Surveying profession to evaluate its demand and supply.

1.2 An overview of the Quantity Surveying Profession

A Quantity Surveyor is the person controlling the financial aspects of a building project. They are the 'accountants' of the building industry does planning and managing the cost of building projects from start to finish. More descriptively, the Quantity Surveyor is the one who “ensures that the resources of the construction industry are utilized to the best advantages of society by providing, inter alia, the financial management for projects and cost consultancy services to the client and designer during the whole construction process”. (Ashworth and Hogg 2002 cited by [4]).The role of the Quantity Surveyor is currently more vital than the profession when it was originally established in England in 1785.

The Quantity Surveyors work in conjunction with architects, consulting engineers and contractors safeguarding the client's interests as an independent professional with specialist skills. Once the Quantity Surveyor has been employed or commissioned by a client, Quantity Surveyor turns considerable expertise to ensure that the client gets full value for money. So that they have to keep in touch with appreciate and understanding all aspects & disciplines of building, construction practice, design and engineering combined and be able to cost fairly, accurately and precisely [7].

The origin of Quantity Surveying in Sri Lanka can be traced back to the British era. British Quantity Surveyors were employed during colonial period in the Public Works Department of Sri Lanka. During World War II these Quantity Surveyors left the country. Later, Sri Lankans who had the opportunity of obtaining foreign education returned and practiced as Quantity Surveyors [5]. As per Miskin 1993 [3], in the past the only course available in Quantity Surveying was the Builders' Quantities course at Ceylon technical college. Today, there are number of Quantity Surveying programmes, in Sri Lanka such as a four year BSc honors degree course in Quantity Surveying at University of Moratuwa (started in 1985), a three year part time National Certificate of Technology course conducted by technical colleges throughout the country and other courses conducted by private sector organizations.

1.3 Significance of Quantity Surveying Profession in Sri Lanka

Labour as a factor of production plays an important role in the socio economic development of the country. A labour market is the place where both suppliers and buyers of labour meet together. In the case of Quantity Surveying profession, it has a significant importance in the construction industry both in local and international labour market. Following data (Refer table 1 and 2) represents the fact that, how much Quantity Surveying profession is significant in the industry. The data have been obtained through LABOUR MARKET Information Bulletin published by the Tertiary and Vocational Education Commission, Ministry of Vocational and Technical Training.

Table 1-Ranking for High Demand Foreign Jobs

Occupation / Jobs	**Rank**				
	2001	**2002**	**2003**	**2004**	**2005**
Nursing	1	1	1	---	1
Computer operator	2	2	---	4	2

Due to the continuous changes in the industry and development of technology, the profession has faced many, threats and opportunities. In whatever the dimension profession shapes, the financial management expertise of the Quantity Surveyor remains in the demand [8].

1.4 Aim

The ultimate aim was the assessment of demand and supply of Quantity Surveying professionals to the Sri Lankan construction industry.

1.5 Research Methodology

Research methodology was mainly divided into two sections as far as there are two main categories in this research. The two main categories are Demand and Supply Measures of Quantity Surveying profession.

In order to identify the factors that are being demanded by industry, news paper survey was done by referring weekend papers from January 2002 to December 2006. All the local Quantity Surveying advertisements were taken into consideration monthly wise when analyzing the factors. When the sample of Quantity Surveying vacancies in the news papers was selected, convenience sampling method was used since this research is under exploratory category. Forecasting was done using Time Series Analysis.

In the supply measures, it was mainly done to establish the number of Quantity Surveyors passing out from relevant institutions from January 2002 to December 2006. Three sources of evidence were used for data collection in this study. They were documentation, archival records and semi structured interviews. The table 3 provides variety and mix of interviewees comprising the respondents from Universities Grants Commission Sri Lanka , University of Moratuwa, Vocational Education Commission, Ministry of Vocational and Technical Training.

Table3-Variety and Mix of Interviewees

Name of the organization	Nr of Interviewees
University Grants Commission Sri Lanka	2
University of Moratuwa	3
Tertiary and Vocational Education Commission	3
Ministry of Vocational and Technical Training	3

2. Research Findings and Analysis

2.1 Demand Side

The figure 1 illustrates number of job advertisements published in news papers for gradates and non graduates since 2002. Compared to year 2003, year 2004 has shown 140% growth. Reason for this hike in year 2005 is tsunami reconstructions and there are number of preferred fields specified in advertisements.

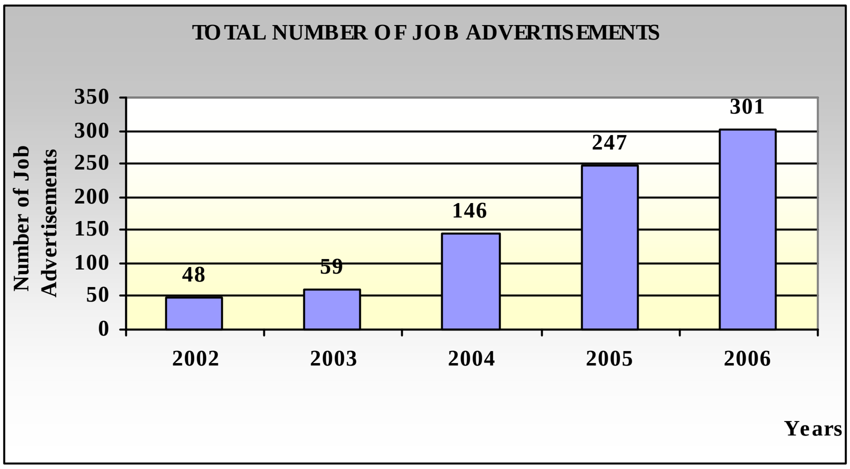

Figure 1- Total Number of Job Advertisements

2.2 More Preferred Fields

In this research, major areas/fields of preference were identified as building, civil, both building & civil and mechanical, electrical, plumbing (MEP) work. The percentages were taken considering total number of advertisements. According to the findings, employers are looking for specialize Quantity Surveyors for relevant field. There are many opportunities available in building sector rather than civil engineering sector. However, Quantity Surveyors who have both civil engineering construction and building construction experience shows increasing demand. Quantity surveyors in MEP sector is minimal, because its complexity or unavailability *of Quantity Surveyors in the market. Category "field unspecified" is for open ended advertisements which are advertised without the required field. However, field unspecified advertisements have been reduced over the period (refer figure 2).*

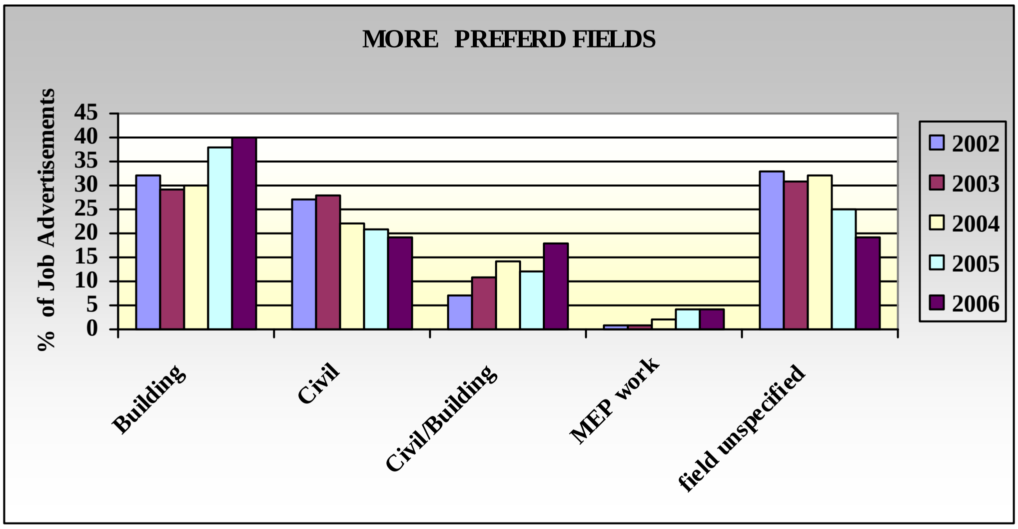

Figure 2 - Graphical Representation of More Preferred Fields

2.3 Experiences Requested

Most of the advertisements used to request work experience (refer table 4 and 5). In graduates category 1 – 3 years experience is the popular request.14 % - 17 % of advertisements have invited without any experience for graduates. In non graduates categories 5 – 7 years group is in better side. It is only 4% - 7% of non graduates are invited without experience. However, "field unspecified" has diminishing over the years.

Table 4 - Percentage Experiences Requested for graduates

Category	**Year**				
	2002	**2003**	**2004**	**2005**	**2006**
Without Experience	14 %	14 %	12 %	15 %	17 %
1 - 3 Years	**25 %**	**33 %**	**31 %**	**34 %**	**37 %**
3 – 5 Years	22 %	24 %	23 %	22 %	21 %
5 – 7 Years	14 %	12 %	16 %	13 %	10 %
More than 7 Years	9 %	7 %	8 %	7 %	7 %
Field Unspecified	16 %	10 %	10 %	9 %	8 %

Table 5 - Percentage of Experiences Requested for Non Graduates

CATEGORY	YEAR				
	2002	**2003**	**2004**	**2005**	**2006**
Without Experience	4 %	7 %	5 %	4 %	4 %
1 - 3 Years	4 %	6 %	10 %	14 %	16 %
3 – 5 Years	18 %	21 %	21 %	22 %	21 %
5 – 7 Years	**30 %**	**33 %**	**30 %**	**29 %**	**31 %**
More than 7 Years	23 %	15 %	16%	17 %	16 %
Field Unspecified	21 %	18 %	18 %	14 %	12 %

2.4 Graduate and Non Graduate Share in the Market

According to the data collected on market share of graduates and non graduates (refer table 6), market share of graduates have been reduced during the last five years. Only in year 2002 they have higher market share. Rapid incensement of non graduate supply, constant graduate supply, employment boom for graduates in middle east and low return from overseas, are the reasons for the decrease in graduate share.

According to the above table 6 , it can be undoubtedly seen that share of the graduates has been decreasing. Since 2003, share of non graduates has been increasing while maintaining a 60 % average mean. This may be due to several issues as such availability, high salary rate and increases in supply.

Table 6 - Graduate & Non Graduate Share

CATEGORY	YEARS				
	2002	2003	2004	2005	2006
Graduate	53%	42%	40%	35%	34%
Non Graduate	47%	58%	60%	65%	66%

According to the above table 6 , it can be undoubtedly seen that share of the graduates has been decreasing. Since 2003, share of non graduates has been increasing while maintaining a 60 % average mean. This may be due to several issues as such availability, high salary rate and increases in supply.

2.5 Graduate and Non Graduate Demand Forecasts

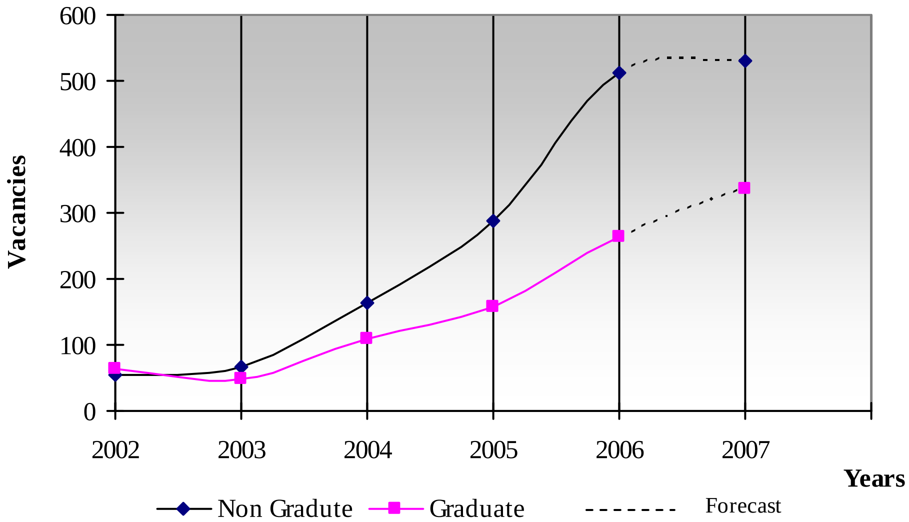

Figure 3 - Graduate & Non Graduate Demand forecast

This section mainly focuses on detail evaluation of demand and forecasting the future demand of both graduates and non graduates by analyzing Quantity Surveying vacancies appeared in last five years. More precise forecast was done for year 2007 using time series analysis. In order to identify the variation of this time series, vacancies are counted yearly and shown in the figure 3. It can be stated that still graduates have increasing trend in their graph while non graduates are proceeding with small variations. In between 2005 and 2006 the rate of increase has changed. The more information regarding those scenarios has been elaborated in demand and supply evaluation.

2.6 Evaluation of Demand & Supply

2.6.1 Graduate demand and supply

When comparing the demand and supply for Quantity Surveyor's, the supply is not keeping with demand (refer figure 4 and 5). According to the figure 4, the gap between the two graphs is increasing. Even though supply is not up to satisfactory level still demand has been continuing to increase. It can also be clearly seen by the forecast. The demand in year 2005 and 2006 has increased significantly due to Tsunami reconstruction works. Figure 4 has been presented using all pass out graduate students. However the average supply of graduates to the Srilankan market is still lower than shown in the graph since most of the graduates are leaving the country after six months time from their graduation.

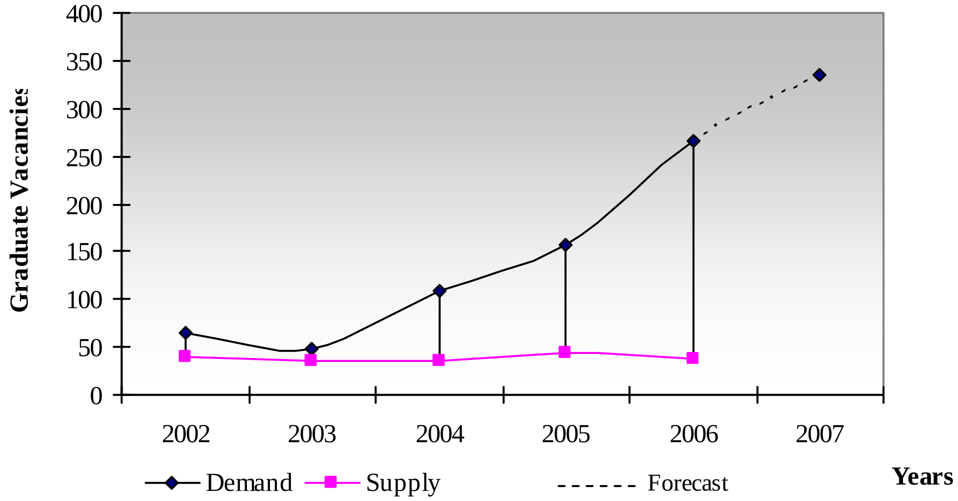

Figure 4 - Graduate Demand and Supply Forecast

2.6.2 Non Graduate demand and supply

The figure 5 illustrates the demand and supply curves for non-graduates. The year 2002,2003 shows the higher supply than the demand. But since 2003 the trend has reversed and the gap between demand curve and supply curves are increasing significantly with a similar trend to the graduate graph. The Figure 5 also illustrates the impact of Tsunami reconstruction work, where there is a significant raise in demand between 2005 and 2006.

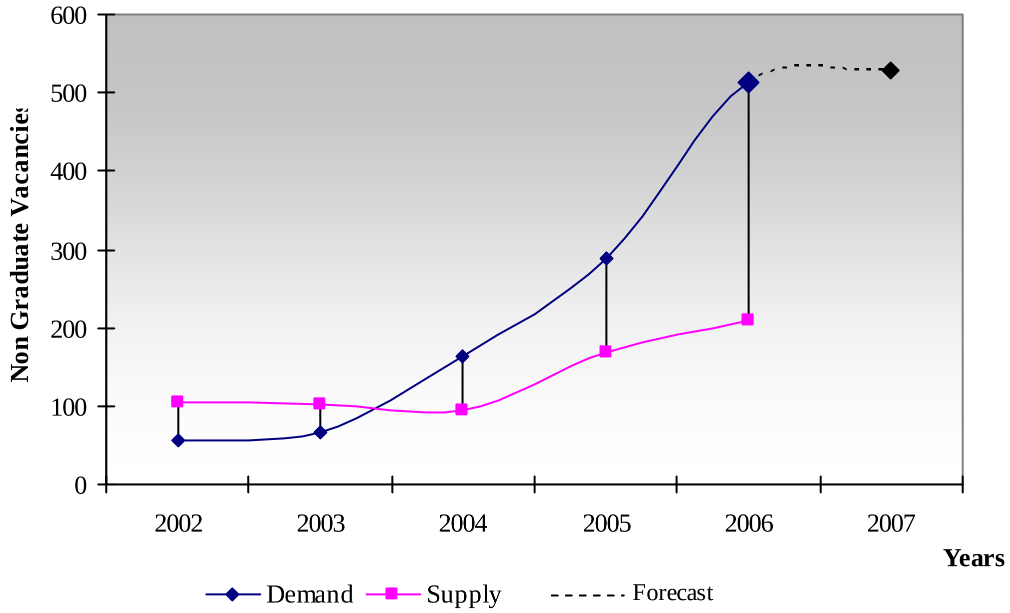

Figure 5 - Non Graduate Demand and Supply Forecast

3. Conclusion

The profession of Quantity surveying has to meet demands of the market as all other professions. Quantity Surveying profession explored opportunities and expanded today due to scarcity of economic goods, improved living standards, and advancement of the technology in Sri-lanka. In order to forecast the future demand, it was required to assess the demand and supply situation of the profession in the present market.

According to the identified demand factors, Quantity surveyors who have experience in civil engineering construction and building construction are the individuals who have highest demand. When considering the professional qualifications and experience, graduates who have minimum two years experience and non graduates with more than four years of experience are the most attractive range for employers. Further for the period under review the market share of 60% has been filled by non graduates due to the non availability of graduates in the domestic market.

To fulfill the above demands, most of the non graduates are produced by technical colleges. An average of 235 students sat for the final year examination of each year and 60% of them have passed out from technical colleges at the end of each year. The University of Moratuwa is the sole supplier of graduates, where it produces 40 students per annum.

As per the market demand analysis and the supply side assessment, it can be recommended to significantly increase the supply of graduate and non graduate Quantity Surveyors and further to acquire experience in civil engineering construction. This would definitely enhance the quality of Quantity Surveying practice in Sri Lanka as well as reap higher financial benefits to the individuals with both civil and building experiences.

Abstract

This paper endeavours to explain the methodology for researching the contribution of women managers to the construction industry development. The research is concerned with gender segregation in the industry and its impact on skills shortages. It further identifies how an increased number of women managers in the construction industry will help to change the gender segregation pattern and how this may contribute to the development of the industry by resolving the problems within it. This paper therefore mainly focuses on the research methodology that has been adopted in this research. Justifications are made for the most appropriate choice of methodology in terms of its philosophy, strategy and techniques. This paper further elaborates the chosen methodology, by explaining the data collection and analysis techniques, the research design and the design tests.

Keywords: Research philosophy, Research strategy, Research techniques, Research design, Research tactics.

1. Introduction

A research, in simple terms, is defined as something that people undertake in order to find out things in a systematic way, thereby increasing their knowledge [1, p.3]. The overall research process contains several activities such as topic selection, literature review, scoping, choice of research methodology, data collection, data analysis, provide findings and drawing conclusions. The appropriate selection of research methodology is very important in order to achieve valid and reliable findings. Thus, the choice of methodology plays a vital role in the overall research process. This paper endeavours to justify and explain the methodology for researching the contribution of women managers towards the construction industry development. The first section provides the overview of the study within which the background, research problem, aim, and research questions are briefly discussed. The next section justifies the selection of appropriate methodology followed by a further elaboration on the chosen methodology including the design tests.

2. Overview of the study

This section provides an overview of the research study. Before deciding the methodology it is important to understand the subject area as it will help us to choose the appropriate methodology. In this context, the background for the study, research problem, aim, research questions, focus of the research and the conceptual framework are detailed in this section.

2.1 Background for the study

Construction in the UK is one of the pillars of the economy. UK construction at its best, including its capability to deliver the most difficult and innovative projects, matches that of any other construction industry in the world [2]. Nonetheless, there is a deep concern that the industry as a whole is under achieving. It needs to modernise in order to tackle the severe problems such as low and unreliable rates of profitability, little investment in research and development, crisis in training, dissatisfaction among clients, and fragmented culture [2, 3]. With all these, the shortage of people with the technical and managerial skills to fully utilise the new technologies has been a problem in the construction industry for many years [2, 4, 5]. This skill and labour demand may be a threat to the long term growth of the industry and it may also challenge the industry's capability to deliver the projects on time, within budget and of the desired quality. Gender segregation within the construction industry could also be seen as a problem as it restricts individual's choices. This gender segregation damages the UK's economy by contributing to skills shortages and to the gender pay gap [6].

Although, the issue regarding the lack of women in construction has been a concern for many years, it has been made more prominent due to the potential skills shortage facing the industry. The constant reliance on a limited recruitment base, disadvantages the industry by disregarding half the population and the diversity of skills these people have to offer. By restricting the possible workforce, the industry is limiting the choice of applicants, which in turn may lead to the recruitment of lower quality employees. Currently, construction employers recruit and rely increasingly on workers from overseas, either inside or outside the European Economic Area (EEA) giving rise to immigration issues and an increasingly diverse labour force [7]. Increasing the number of women in the construction workforce may also contribute to solving the skills and labour shortage problems. Davey et al. [8] identify that increasing the number of women working in construction may go some way to improving the current status of the industry, firstly by utilising the full range of skills available in the population, and secondly by assisting construction organisations to become more efficient and adaptable to the needs of its customers. Women are of benefit to construction organisations because they are, by nature, good with people, less confrontational and are more likely to listen to the opinions of others, which will be beneficial when dealing with clients [9]. More women working in construction will improve the industry's image and will go towards improving the current skills shortage by also aiding the recruitment of other under represented groups, not just women [10].

The low number of women in the construction industry illustrates the under utilisation of human resources based on gender patterns. As per the CITB [11], women account for 9% of the construction workforce, of which 84% hold secretarial posts, 10% are employed in a professional capacity in design and management areas and the rest are craft and trade level employees. In this regard, women who really perform construction specific jobs fall under either managerial jobs or craft and trade level jobs. The under-representation of women in managerial positions may discourage potential female candidates who want to choose a career in construction by limiting the number of role models. It may also be a challenge to convince employers to consider the recruitment or promotion of women in the industry. Women gaining managerial positions will be a clear evidence to show that their career progression occurs in construction. Their presence in managerial positions is one of the most effective ways of ensuring their participation in decision-making. Thus, having more women managers will provide much inspiration for young girls interested in construction careers, reduce some of the barriers associated with recruitment practices and improve the culture in the long run. Further, women's characteristics may be used to tackle the problems in the industry as they possess more diverse skills than the traditional male workforce.

2.2 Research problem

The background of this study highlighted the problems in the construction industry and indicated the importance of having more women, and women managers in particular. These two concepts can be combined to investigate the ways women managers can contribute towards the construction industry's development by tackling the problems that the industry faces. Organisations have paid attention to the leadership styles of the people who occupy managerial positions, holding the belief that leadership is an important factor in achieving business success [12]. One of the major issues raised by Egan [2] is the shortage of people at top management level with the commitment to being best in class and with the right balance of technical and leadership skills to manage their business accordingly. The real issue in leadership differences lies in the equity in selecting the right person with the appropriate skills and qualities to ensure the effectiveness and success of the organisation [13]. A very recent article by Stevens [14] proposes a leader-manager model as the effective one for construction. He believes the leader-manager skill is the new driver in the industry, as the reality of the construction industry demands dual roles. Thus, he concludes that in order to better serve the construction industry the leadership role is to be redefined as having a business management component. In view of that, the contribution of managers can hardly be studied without considering the leadership component. In this context the leadership component has been identified as the primary area to be studied. The following sub-section provides the aim, objectives and the research questions of the research.

2.3 Aim and the research questions

The aim of this research is to explore and investigate the ways in which the leadership styles of women managers may contribute to the UK construction industry's development. To achieve this aim the following research questions have been formulated.

1. What are the characteristics of women managers?

2. What roles do women managers play in the construction industry?

3. What are the leadership styles exhibited by women managers in other sectors?

4. What are the leadership styles exhibited by women managers in the construction industry?

5. Whether or how may the leadership styles exhibited by women managers help to resolve the problems in the construction industry?

6. What benefits may women managers bring to the UK construction industry?

2.4 Research focus

Managers and professionals in industry can be categorised under four types as outlined below [9]. Women managers who fall under category 3 and 4 below will be taken into consideration for the purpose of this study.

1. Non management role: These positions are generally self-directed.

2. Supervisory role: These positions typically fulfil a supporting role to middle management.

3. Middle management role: These positions are mainly responsible for managing the whole process of a project and leading a project team.

4. Senior Management role: These positions are often the ones of power where company-wide decisions are made.

With an emphasis on leadership, the people recruited into construction, women managers in this case, need to demonstrate a strong base and offer the abilities that construction needs from them. Lack of empirical evidence on leadership styles of construction women managers shows the necessity to study it, in order to make a contribution to the existing body of knowledge. Hence, this research will focus on whether or how the leadership styles of women managers, at the top and middle level management in construction organisations, may contribute to the UK's construction industry development. This in turn may highlight the necessity to have more women managers in the construction industry.

2.5 Conceptual framework

A conceptual framework explains, either graphically or in narrative form, the main things to be studied – the key factors, constructs or variables – and the presumed relationships among them

[15, p.18). The study aims to explore and investigate the ways the leadership styles of women managers may contribute to UK's construction industry development. The primary objectives are to identify the characteristics and leadership styles typically exhibited by women managers and investigate the same in order to explore their contribution towards the development of the construction industry. It further identifies the appropriate leadership styles for construction women managers by learning lessons from other sectors. Figure 1 shows the conceptual framework of the study.

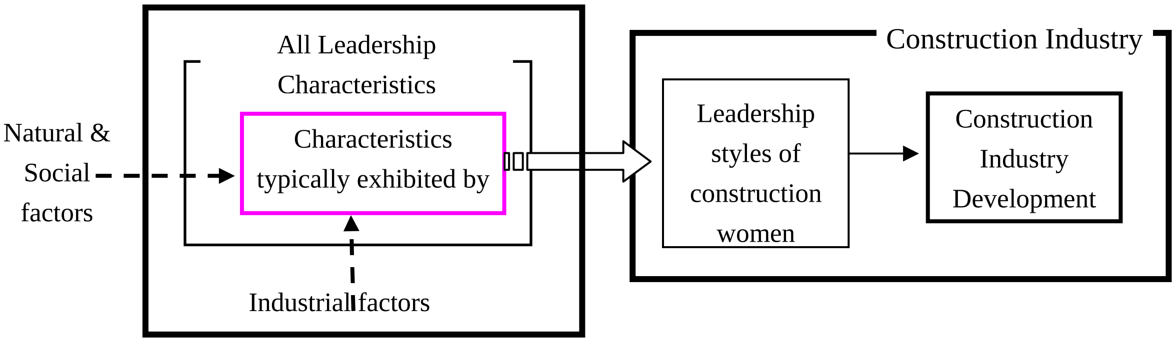

Figure 1: Conceptual framework of the research

This section briefly introduced the research study. The following sections, which are the core of this paper, deal with the methodology that could tackle the above-mentioned research problem and could answer the formulated research questions.

3. The justification of the methodology selection

Research methodology refers to the overall approach to a problem which could be put into practice in a research process, from the theoretical underpinning to the collection and analysis of data [16, 17]. There are many factors that determine the most appropriate methodology. The topics to be researched and the specific research question are the primary drivers in the choice of methodology [17]. In order to choose the most appropriate one it is important to understand the philosophical underpinning of this research. This section, which comprises three sub-sections, justifies the choice of methodology adopted to this research. Firstly, the positioning of this research within the overall philosophical continuum is explained. Secondly, the reasons for the appropriateness of a particular approach are illustrated. Thirdly, the techniques to be used with the data collection and data analysis are discussed.

3.1 Research philosophy

The basic beliefs about the world will be reflected in the way the research is designed, how the data is collected and analysed, and even the way in which the findngs are presented. Therefore, it is important to recognise and understand the personal paradigm as this will determine the entire course of the research study undertaken [16]. The term paradigm refers to the progress of scientific practice based on people's philosophies and assumptions about the world and the nature of knowledge [16].

The two contrasting views on how a research should be conducted can be labeled as positivism and social constructionism/phenomenology [18, 16, 17]. The key idea of positivism is that the social world exists externally, and that its properties should be measured through objective methods, rather than being inferred subjectively through sensation, reflection or intuition [18]. The positivist philosophical stance assumes that the researcher is independent of, and neither affects nor is affected by, the subject of the research [17]. Unlike the positivist, the phenomenologist does not consider the world to consist of an objective reality instead focuses primarily on subjective consciousness. Thus, the phenomenological paradigm assumes that the reality is not objective or external but is socially constructed and given meaning by people [18]. This research intends to explore and investigate the ways leadership styles of women managers may contribute to the UK's construction industry development. Leadership characteristics and styles mean different things to different people [19] and the extent of women's contribution towards industry development is highly subjective. Thus a socially constructed idea should be obtained in order to explore the contribution of leadership styles of women managers towards the construction industry development. In this context, it could be argued that this research takes the overall phenomenological stance.

The research philosophy that is adopted contains important assumptions about the way in which one views the world. These assumptions will underpin the research strategy and the methods a researcher chooses as part of that strategy [1]. The three major ways of thinking about research philosophy are ontology, epistemology and axiology [1, 16]. These ontological, epistemological and axiological assumptions are concerned with the nature of reality, the acceptable knowledge in the field of study and the values respectively. These three assumptions will help to position the research within the philosophical continuum.

3.1.1 Ontological assumption

Within the ontological assumption, the researcher must decide whether to consider the world is objective and external to the researcher or is socially constructed and only understood by examining the perceptions of human actors [16]. The first aspect is objectivism or realism and the second is subjectivism or nominalism [1, 20]. Within these two extremes the intended study could be positioned more towards the subjectivism because the perceptions of people in the society have a greater influence over the behaviour of leadership. Therefore the meanings given to leadership behaviour and the ideas on its effectiveness in addressing the problems in the construction industry are subjective. But this research does not take the extreme subjectivist view where there may be no social world apart from that which is inside the individual's mind [16]. Thus it takes the ontological positioning where the social world is created by individuals, through language, actions and routines, and the meanings sustained through process of human actions and interactions.

3.1.2 Epistemological assumptions

The epistemology involves an examination of the relationship between the researcher and that which is being researched. On one hand, being a positivist the researcher is working with an observable and measurable social reality by taking an independent and objective stance. The positivist assumes that there is a reality that exists independently of the observer and the job of the researcher is merely to find out this pre-existing reality. On the other hand, the social constructionist viewpoint does not assume any pre-existing reality; the aim of the researcher is to understand how people invent structures to help them make sense of what is going on around them [18]. Accordingly this research takes up the social constructionist viewpoint where it intends to find out how may the leadership qualities of women can contribute to the development of the construction industry. However it considers only the leadership practices as an issue for industry improvement, though there are several other factors contributing. In this regard this research avoids the extreme constructionism perspective of the epistemological continuum where the multiple realities are taken into consideration.

3.1.3 Axiological assumptions

In axiological assumptions, positivists believe that science and the process of research is value free, where they further believe that the objects they are studying are unaffected by their research activities [16]. These assumptions are less convincing in the social sciences research which is concerned with the activities and behaviour of people. Thus at the other extreme, phenomenologists consider that the researchers have values which help to determine what are recognised as facts and the interpretations which are drawn from them [16]. The understanding about axiology, positions this research more close to the value-laden end as the researcher is involved with that which is being researched and the researcher's own values play a role in all stages of the research process.

3.1.4 Research positioning

Based on the foregoing discussion, Figure 2 shows the positioning of this research within the philosophical continuum in terms of ontological, epistemological and axiological assumptions.

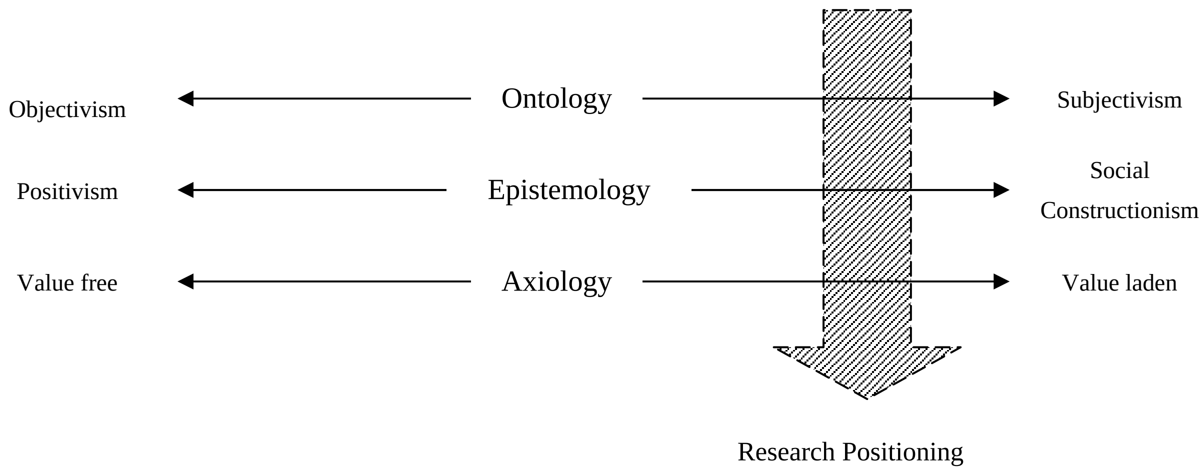

Figure 2: Positioning the research within the philosophical continuum

3.2 Research strategy

A research strategy may be thought of as providing the overall direction of the research including the process by which the research is conducted [17]. The type of research questions posed, the extent of control an investigator has over actual behavioural events and the degree of focus on contemporary as opposed to historical events are the three conditions that govern the choice of an appropriate strategy [21]. In addition to the research questions and objectives, the choice of research strategy will be guided by the extent of existing knowledge, the amount of time and other resources available and our own philosophical underpinning [1]. The commonly used research strategies in business and management research are experiment, survey, case study, action research and ethnography [1, 17, 18]. This section justifies the choice of research strategy used for this study.

The overall philosophical positioning of this research, as outlined above, takes a social constructionism stance. Experiments are generally governed by positivist epistemological undertakings and an ontological assumption tilted towards objectivism with value neutral research. Ontological assumptions of strong 'pre-existing reality' in experiments, require a high extent of control over the environment by which the investigator directly, precisely and systematically manipulates the reality [21]. These can basically be conducted in a laboratory where the extent of control the researcher has over the environment is high. The leadership styles cannot be manipulated in a real life context. Therefore, this strategy is not compatible with this research. In action research, the researcher tries to solve the problem by becoming a part within the problem environment, with the goal to change the status quo of the participants [22]. The action research operates in a partly controlled environment and the aim of the research may be to have a direct and immediate impact, and hence it attempts to change the environment. Ethnography is defined as the study of people in naturally occurring settings or 'fields', by means of methods which capture the social meaning and ordinary activities, involving the researcher participating directly in the setting, if not also the activities, in order to collect data in a systematic manner [23]. According to the aim of this research, an immediate change does not need to be incorporated into the research process as it merely intends to explore and investigate the contribution of leadership styles of women managers to construction industry development. Further, both these approaches need high participative observation from the researcher. As this research doesn't take these qualities, it disqualifies actions research and ethnography from being an appropriate strategy.

Hence, it leaves both survey and case study strategies as the suitable choice for this research. The survey does not require high control over the environment and it is designed to address the 'what' type of exploratory questions and they can be applied in social science research [21]. This research intends to explore the contribution of women managers towards the UK's construction industry development and identify the appropriate leadership styles for construction women managers by learning lessons from other sectors. It also intends to explore whether or how the leadership styles exhibited by women managers can address the problems that persist in the construction industry. The perceptions of subordinates, superiors and peers towards the women's leadership characteristics and styles within their real life context, are also to be captured in order to make sure that their contribution is beneficial towards the construction industry's development. Accordingly this research requires an in-depth analysis of the construction industry. Therefore case study approach is more suitable compared to the survey.

Thus this research proposes the case study is the most suitable strategy. The case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between phenomenon and context are not clearly evident [21].

3.3 Research techniques

Research techniques refer to the specific methods used to collect and analyse the data. Data collection and analysis are developed together in an interactive process in a case study [24]. The following sub sections discuss the data collection and data analysis techniques used within the case study approach.

3.3.1 Data collection

According to Yin [21], evidence for a case study may come from six sources; documents, archival records, interviews, direct observation, participant observation and physical artifacts. In order to identify the leadership styles of women managers, a questionnaire will be distributed among the women managers, their superiors, peers and subordinates. For this purpose the Multifactor Leadership Questionnaire (MLQ) will be used. The MLQ offers researchers the most validated and efficient measure of transformational leadership, as well as a full range of leadership behaviours [25]. MLQ, which measures, explains and demonstrates a broad range of leadership styles, has been widely used throughout the world in many, diverse cultures and organisations, and has shown to be reliable [26]. Further, the Personal Attributes Questionnaire (PAQ) by Spence et al. [27] will be used to measure the degree to which a person can be classified according to masculine or feminine adjectives. It is a 24 item self-report questionnaire in which people are asked to indicate the extent to which they can be characterised in terms of various adjectives. The analysis of the PAQ will help to find out the personal characteristics of an individual in terms of masculine, feminine, or androgynous qualities. These characteristics will also help to determine the leadership styles. Semi-structured interviews have also been chosen as one of the techniques to get the perceptions of the industry personnel to explore and investigate the ways the leadership styles of women managers may contribute to the UK's construction industry development. This has the advantage of being a 'halfway house' between the rigid layout of a structured interview and the flexibility and responsiveness of an unstructured interview [28]. In addition to these, expert interviews are preferred to identify the leadership styles that could address the problems that persist within the construction industry. These expert interviews are not covered within the case study approach.

3.3.2 Data analysis

Data analysis consists of examining, categorising, tabulating, testing or otherwise recombining both quantitative and qualitative evidence to address the initial propositions of a study [21]. The objectives and the research questions of this research are developed through the identification of theoretical propositions. It is important to have a data analysis strategy as it will guide the researcher to select the appropriate data analysis tools, to make sure that the evidence is treated well, and to generate sound and convincing analytical conclusions while discarding the alternative interpretations [21].

The data collected through expert and semi-structured interviews will be analysed using content analysis. As per the process outlined by Miles and Huberman [15], qualitative analysis involves three activities: data reduction, data display, and conclusion drawing. The first stage of analysis identified is data reduction, which is the process of selecting, focusing, and simplifying the interview transcripts by extracting the most relevant data for all of the questions and from the responses to additional probes. This process will identify a number of issues addressed under the major subjects of the research. The second stage in the analysis process is data display. This will be done by producing a data matrix through tabulating the interview data; with the respondents listed as columns and the questions as rows. The final stage of analysis will be to display the data and draw conclusions. In addition, the quantitative analytical techniques adopted with the MLQ and PAQ will be used to analyse the data collected through MLQ and PAQ surveys respectively.

This section provided the justification for the selection of research methodology in terms of its philosophy, strategy and techniques. The next section further elaborates the chosen research strategy explaining its design together with the tactics used in order to ensure the quality of the research.

4. Case study design and tactics

4.1 Case study design

In the most elementary sense, the design is the logical sequence that connects the empirical data to a study's initial research questions and, ultimately, to its conclusions. It can be understood as a logical model that helps the researcher to collect, interpret and analyse the relevant data in order to effectively find out the answers for the research questions. The case study approach may potentially fall into at least four basic types of study, in terms of the differences in design within each type [21]. They are single (one case) or multiple (more than one case) studies and can be holistic (single unit of analysis) or embedded (multiple unit of analysis) design. Case studies can also be classified as exploratory, descriptive or explanatory.

A research design should include three basic components: 'study questions', 'its propositions' and 'its unit of analysis'. This section explains the research design for the case study bearing these components in mind.

The first component - the research questions - sets out in this research to cover both 'what' type of exploratory questions and 'how' type of explanatory questions. However, the overall objectives are of an exploratory nature. Thus an exploratory type of case study is adopted for this research. The second component - study proposition - directs attention to something that should be examined within the scope of study. In this regard, it is assumed that the leadership styles of women managers may contribute to the construction industry development. The third component - the unit of analysis - is related to the fundamental problem of defining what the 'case' is. A case can be an individual, an entity, an issue, or an event. As this research focuses on the women managers' contribution, it takes the 'individual' as the case for the purpose of this research. The rationale for a single case is when it represents the critical case, extreme case or a unique case or when the case is the representative or typical, revelatory or longitudinal case [21]. Since the case in this research is the 'women manager', the selection of a multiple case design is preferred over single-case designs as it provides analytic benefits from having two or more cases. Analytic conclusions independently arising from two cases will be more powerful than those coming from a single case alone [21]. Furthermore, the proposition would still be needed to help identify the relevant information about the individual, as it is simply impossible for a researcher to cover 'everything' about an individual. The more a study contains specific propositions, the more it will stay within feasible limits. Accordingly this research considers the 'leadership styles of women managers' as the unit of analysis in order to analyse their contribution to the construction industry. Hence it takes a holistic type. All in all, this research adopts an exploratory, multiple, holistic case study design.

4.2 Case study tactics

This section identifies the case study tactics that are used to judge the quality of the research design. Table 1 lists the four widely used tests and the recommended case study tactics, together with the respective phase of research when each tactic is to be used.

Table 1: Case study tactics for four design tests (adopted from Yin, 2003 Page 34)

Tests	**Case Study Tactic**	**Phase of research in which tactic occurs**
Construct validity	Multiple source of evidence	Data collection
Internal validity	Pattern matching	Data analysis
External validity	Replication logic	Research design
Reliability	Case-study protocol and database	Data collection

Construct validity and reliability are tested during the data collection stage. In order to satisfy the construct validity, which is concerned with establishing the correct operational measures [21], multiple sources of evidence will be used. Any findings or conclusion in a case study will be much more convincing and accurate if it is based on several different sources of information. This will be achieved by using theory triangulation and methodological triangulation. Theory triangulation uses the 360 degree review method in order to get different perspectives to the same data set. Accordingly, the information about the 'women manager' would come from her subordinates, peers, and superiors in the organisational hierarchy, as well as from any other external stakeholders who can provide the relevanet information about her. This will ensure that the data is from a rich pool of people from different levels. The use of both quantitative (MLQ, PAQ) and qualitative (semi-structured interviews) data collection methods ensures the methodological triangulation. Further, the principle of the case study protocol and developing a case study database will be employed to address the reliability of the design test and to demonstrate that the operation of the study can be repeated with the same results. Internal validity refers to establishing causal relationships, whereby certain conditions are shown to lead to other conditions, as distinguished from spurious relationships [21]. This is tested during data analysis stage by using pattern matching; a technique which compares the theories and observed data [21]. Accordingly, this research will compare the data collected through expert interviews and semi structured interviews with the theoretically predicted one. If the patterns coincide, the results can help a case study to strengthen its internal validity. External validity means establishing the domain to which a study's findings can be generalised and it is to be tested during the research design stage. The findings from one case study will be replicated by conducting the second, third and additional studies. The cases could either predict similar results or contrasting results but for predictable reasons. Hence, using replication logic in multiple-case studies satisfies this external validity.

5. Conclusions

This paper explains the methodology for researching the contribution of women managers to the construction industry development. It introduces the subject area in which the researcher intends to undertake a study. It further justifies the selection of the appropriate methodology to achieve the objectives of the study. The topic to be researched and the research questions are the primary drivers in the choice of methodology. In addition, the researcher's knowledge, availability of time and other resources, and accessibility of information sources are also to be considered as they have an influence over the choice of methodology. Based on these factors an exploratory, multiple, holistic case study has been chosen as the most appropriate research strategy. Semi-structured interviews, expert interviews, questionnaire survey are the data collection methods adopted for this research. The data collected through interviews will be analysed using content analysis whereas quantitative analytical techniques associated with MLQ and PAQ will be used to analyse the data collected through MLQ and PAQ respectively. Multiple sources of evidence, pattern matching and replication logic in multiple case studies will satisfy the construct, internal and external validities respectively. Case study protocol and a case study database will be developed in order to ensure the reliability of the research. In summary, this paper will be a supportive resource to any reader interested in defining a methodology for a specified research study.

Abstract

The teaching profession both in this country and internationally is, with few exceptions, dominated by women as it has traditionally been seen as a 'suitable' job for women. However, a look at the statistics reveals that despite the large number of women in the profession, they are greatly under-represented in positions of management in higher education (HE). Thus this under-representation of women continues to be a matter of some concern. The background of this paper identifies the status of women managers within the higher education sector. The leadership styles typically adopted by women managers are then discussed. These styles are taken into further analysis in order to find out whether any such styles are of use in terms of filling the leadership gaps in higher education. In this context, this paper examines the literature relating to gender, leadership styles and higher education in order to explore how the leadership qualities of women managers will have a contribution towards the higher education sector.

Keywords: Higher education sector, leadership, women managers

1. Background

The higher education sector is characterised by specific aspects that make it distinguishable from the business world. However, in higher education, as well as in business, men and masculine values are dominant [1]. According to the Higher Education Statistics Agency (HESA) female students in higher education institutions in the UK reached nearly 45% in 2001. Research revealed that the women entering higher education in the UK has continued to increase over recent years and now account for over 50% of students [2]. However, the participation rate of women at senior management level in higher education is relatively low. The senior management level, in this paper, refers to academic professionals such as professors, senior lecturers and senior researchers in higher education institutions. Table 1 below shows the status of the academic professionals by gender.

Table 1: Full-time academic staff by grade and gender in 2005/06

Tests	Female	Male	Total	Female 2004/05 (%)	Female 2005/06 (%)
Professors	2320	11730	14050	15.8	16.5
Senior lecturers & senior researchers	7575	17015	24590	29	30.8
Lecturers	14900	20075	34975	41.8	42.6
Researchers	12330	16930	29260	42.2	42.1
Other grades	3620	4915	8540	42.5	42.4
Total	**40745**	**70665**	**111410**	**36.1**	**36.6**

Source: Higher Education Statistics Agency (HESA)

The proportion of full-time female academic staff has risen slightly from 36.1% in 2004/05 to 36.6% in 2005/06. Full-time female academics account for around 42% of staff members at lecturer, researcher and other grades. At the grade of 'senior lecturers & senior researchers’, females represent 30.8% of full-time staff, while at professorial level, just over 1 in 6 full-time staff are female. Compared to 2004/05 there has been a small increase in the proportion of females at ‘professor’ and ‘senior lecturers & senior researchers’ levels, while at other levels the split in gender has remained almost static. However, managers in education are predominantly male though there is some evidence of a growing willingness of women to take up leadership positions in higher education.

The major reason for this under-representation of women at senior management level in higher education is the barrier women face to progress their career in educational leadership [3, 4, 5]. Socialisation and stereotyping are the major barriers for women seeking a senior position in education. Some internal barriers such as lack of confidence, lack of competitiveness and fear of failure have also been identified for women’s entry into leadership positions [3, 4].

In this context, this paper reviews the employability of women at senior management positions in the higher education sector. The leadership concept cannot be entirely discounted when discussing the employability of women at managerial level as organisations have paid attention to the leadership styles of the people who occupy managerial positions, holding the belief that it is an important factor in achieving business success [6]. In recent years, both mainstream management literature and organisational policy show evidence of a marked turn to leadership rather than management as the means to enhance organisational performance in contemporary organisations. This is matched by a growing trend in the UK to attribute ever-greater significance to leadership as a way of solving organisational problems not only within the private sector, but also within the public sector in general, across education (in schools and in universities), health and local government organisations [7].

Accordingly this paper first identifies the leadership gaps in higher education and then the leadership styles typically adopted by women managers. These finding will lead to the discussions on the employability of women managers within the higher education sector.

2. Leadership in higher education

Leadership is defined as ‘the ability to influence – either directly or indirectly – the behaviour, thought, and actions of a significant number of individuals’ [8]. Educational leadership refers to “leadership influence through the generation and dissemination of educational knowledge and instructional information, development of teaching programmes and supervision of teaching performance” [9, p166]. The real issue in leadership differences lies in the equity in selecting the right person with the appropriate skills and qualities to ensure the effectiveness and success of the organisation [10].

The number of students studying at universities and colleges has increased dramatically, with over 2 million students at higher education institutions today. Higher education is part of ‘lifelong learning’, which is not limited to the compulsory school years, but extends through an adult’s working life and sometimes into retirement [11].

The main purposes of higher education as per the Higher Education Funding Council for England- (HEFCE) [11] are to:

- enable people to develop their capabilities and fulfil their potential, both personally and at work;
- advance knowledge and understanding through scholarship and research; and
- contribute to an economically successful and culturally diverse nation.

The nature of higher education in the UK has changed significantly over the past years. During the last 5-10 years UK Higher Education Institutions (HEI) have been developing and implementing significant levels of structural change, influenced by both internal and external policy and environmental developments [12]. These changes appear to have been made in the formal and informal structures. The senior management structure of many institutions is being re-framed or conceptually restructured. As a result the balance of power between groups at different levels is changing and identifying the focus of power and influence within senior management has become more difficult and complex [12]. Consequently it may affect the efficient functioning of senior management in higher education.

Birnbaum [13] argues that, in general, interventions from leaders should be limited in order to allow the self-correcting mechanisms of the institution to operate effectively. In relation to that, Kathleen [14] also argues that the traditional sense of providing direction in the carrying out of tasks was likely to be less significant for professionals like university employees than for some other occupational groups. Supporting these arguments, Bryman [15] revealed that the traditional form of leadership may sometimes be more significant for the problems it can foster than for its benefits. This suggests that a key issue in higher education is not so much about what leaders should do, but what they should avoid doing.

Mumford [16] identified some of the characteristics of the managers who are good developers of their staff. These characteristics include: “drawing out the strengths and weaknesses of their staff rather than suppressing them; rewarding their people both materially and psychologically for the risks that they take in attempting to develop themselves; positively seek to identify learning opportunities for staff; giving personal time to the development of staff; involving their subordinates in some of their own tasks and not simply delegating tasks they do not wish to do themselves; share some of their problems and anxieties with their staff as one way of enhancing staff development; listening rather than talking; not seeking to shape individuals as replicas of themselves; and taking risks on the desired results of the departments in pursuit of relevant learning opportunities for their people”. These characteristics could be closely linked to that of a leader in the centre of the organisation and not at the top.

Effective leadership is a success of any organisation and academia is no exception to this. In a recent research, Spendlove [17] identified the competencies for effective leadership in higher education as shown in Table 2.

Table 2: Competencies for effective leadership in higher education

Attitudes **What good leaders are**	**Knowledge** **what good leaders know**	**Behaviour** **what good leaders do**
Self-aware Flexible Open Honest Discrete Visible, outgoing Willing to be wrong/accept advice/support Sensitive to the views of others	Knowledge of university life Understand how the university system works Understand academic processes	Work to maintain academic credibility/respect Act as role models Think broadly/strategically Engage with people Listen to others Consult with others Negotiate Communicate clearly Delegate Motivate others Act as mentors Build

The above table illustrates that the attitudes and behaviours for an effective leadership in higher education tends to lean more towards people-oriented than task-oriented. Thus, leadership in today's academia must take into account the needs and demands of various stakeholders and to include these major stakeholders in the change process [18]. The practice of transformational leadership by the department Chair, has been found to be related to faculty satisfaction and a willingness to expend the extra effort required in the change process [19]. However, Pounder [20] found that the styles of leadership that reflects a combination of transactional and transformational dimensions may be most effective in providing the university with the flexibility it needs to make subsequent changes. New systems of management that emphasise behaviours such as nurturing and caring, interpersonal sensitivity and preference for open and cooperative relationships, have been advocated as the most effective response to change in an organisation's environment [21]. Nevertheless, the traits and behaviours of the individual leader matter in terms of determining the effectiveness of the leadership styles that are practiced.

The following sections discuss the influence of gender over the leadership styles and the leadership styles typically adopted by women managers.

3. Gender and leadership

Although mainstream research on leadership generally continues to ignore gender relations, over recent years there has been a major expansion of international research on gender relations in leadership, organisations and management [22]. Fitzgerald [23] suggests that it is impossible to create conceptualisations of leading and managing without taking into account issues of gender. The way gender is defined by society determines how a male or a female should behave within a society. This also seems to affect the leadership characteristics men and women exhibit. These gender role definitions can be discussed in two broad perspectives. One perspective assumes gender as a social institution and thus the role that men and women perform are defined by society. The second perspective argues that gender is a biologically determined element, and thus, the gender role is determined by the biological nature of the male or female. Researchers have tried to find out the relationship between gender role and leadership style as they assume that gender role is an important personality trait that influences leadership style. Some researchers found differences in leadership styles between men and women, whereas others argue that there are no significant differences [24].

Discussions on the gendered differentiation of leadership have centered on the different qualities and styles of leadership of men and women; that is, the so-called masculine and feminine styles of leadership [25]. While men still dominate leadership positions, research suggests that when women do occupy leadership positions, they display different leadership styles compared to men. The presence of feminine or masculine characteristics in leadership styles is related to the construct of gender [26]. Thus, they have related masculinity with task-oriented leadership style and femininity with relationship-oriented leadership styles. Male gender qualities are characterised as aggressive, independent, objective, logical, rational, analytical, decisive, confident, assertive, ambitious, opportunistic and impersonal. These are distinguished from female gender qualities that are characterised as emotional, sensitive, expressive, cooperative, intuitive, warm, tactful, receptive to ideas, talkative, gentle, empathetic, and submissive [27].

Contrary to the above discussion, some researchers argue that there are no significant differences in leadership styles between men and women. Powell [28] in his analysis of a number of research studies found that male and female leaders exhibit similar amounts of task-oriented and people-oriented leadership characteristics. Further to this, Pounder and Coleman [29], citing a number of studies undertaken by various researchers (Davidson and Bruke, 1994; Brenner, 1982; Carless, 1998; Komives, 1991; Maher, 1997; Vilkanas and Carton, 1993, Thomson, 2000; Evetts, 1994) have summarised the idea of ‘little or no difference’ and ‘no evidence for any dissimilarity’ in the leadership styles, leadership effectiveness and competencies of men and women. Further, a study by Oshagbemi and Gill [30] examined gender differences and similarities in the leadership styles and behaviour of UK managers. Their study found that women managers delegate less than their male counterparts but their directive, consultative and participative leadership styles were similar. There are more similarities than differences found in their study on the leadership styles and behaviour of their managers, unlike the findings in other research studies where there are significant differences between males and female in the leadership styles and behaviour of their managers. However, the authors suggest that although women are relatively similar to men in behaviour and effectiveness, women leaders tend to be more participative and less autocratic.

4. Leadership styles typically exhibited by women managers

This section examines the leadership styles typically exhibited by women managers. The growing numbers of women in managerial positions have created interest in the concept of women as leaders [31]. As women increasingly have a more prominent presence as managers and executives in organisations, more attention has been devoted to the possible differences between the leadership styles of women and men. Intuitive reasoning suggests that early socialisation patterns develop different qualities in women and men that would likely result in variations in leadership styles [32].

Hey/McBer, a consulting firm, has leadership style typology which is based on the work of David McCleland [7]. Hey/McBer categorises leadership into six distinct styles based on two major classes: they are transactional and transformational [33]. Under transformational leadership, the most prominent behaviour used is inspirational motivation, followed by idealised attributes, intellectual stimulation, idealised behaviours, and individualised consideration. Under transactional leadership, the most prominent behaviour used is contingent reward, followed by management-by-exception active, and management-by-exception passive [34]. In this regard corrective style (‘do what I tell you’) and authoritative style (‘come with me’) fall under transactional style whereas affiliative style (‘people come first’), democratic style (‘what do you think’), pacesetting style (‘do as I do, now’) and coaching style (‘try this’) fall under the transformational leadership styles [33].

Female leaders seem to prefer a transformational leadership style [35]. Another research carried out by Rosener [36] revealed that women are more likely than men to use "transformational leadership", i.e. motivating others by transforming their individual self-interest into the goals of the group. The characteristics of transformational leadership relate to female values developed through socialisation processes that include building relationships, communication, consensus building, power as influence, and working together for a common purpose. This is supported by Shane et al [37], stating that femininity is found to positively correlate with transformational leadership. Further several studies focusing on transformational leadership indicated that women are perceived, and perceive themselves, as using transformational leadership styles more than men [38]. Bass [39] and Bass and Stogdill [40] also suggest that women are slightly more likely to be described as charismatic, as women scored higher on transformation factor than men. This is further supported by Comer et al [41] where they noted that female business managers tend to be rated higher than male managers on the 'individual consideration' dimension of transformational leadership styles. Yammarino et al. [42] also noted that female leaders rather than male leaders tend to develop the individualised, unique relationships with subordinates necessary to effect the transformational leadership style. In describing nearly every aspect of management, women made reference to trying to make people feel part of the organisation from setting performance goals to determining strategy [36]. Men, on the other hand, were found to be more likely than women to: adopt "transactional" leadership styles (exchanging rewards or punishment for performance); use power that comes from their organisational position and formal authority [36]. Likewise, many authors refer to transformational leadership as a feminine leadership style. However, research by Hackman et al. [43] show that transformational leadership is a stereotypically gender-balanced style.

The notion of male and female gender qualities facilitates the argument that male gender qualities are oriented towards the more impersonal, task oriented or transactional approach to leadership, whereas female gender qualities tend towards more nurturing, relationships oriented style of leadership that underlies the transformational leadership approach [29]. Rigg and Sparrow [44] state that female leaders emphasised the team approach more than men and were regarded as more people oriented than their male counterparts, while male leaders were considered more paternalistic and authoritarian than female leaders. The empowering and collaborative style of leadership associated with women is also compared with the more directive and authoritarian style traditionally associated with male leaders. In other words, women seem to lead in a rather democratic way, while men show a more autocratic leadership style [45]. Research findings of Trinidad and Normore [46] show that women adopt democratic and participative leadership styles in the corporate world and in education.

Apart from these leadership styles women are said to be better than men in terms of multi-tasking. In a research carried out by Priola [47] almost all of the participants interviewed referred to multi-tasking, presenting it as a female quality and ability. The belief that women are better at managing different activities simultaneously finds its origins in the role of women in various societies. Priola's research further identified four major discourses that refer to aspects generally associated with femininity when identifying female traits within educational institutions. These are: the ability to manage multi-tasks (including administration); people and communication skills; the ability to focus on support and care for the staff; and the implementation of a team-based approach rather than an authoritarian style approach. The ability to juggle several things at once was reported as one of the differences between women and men in Deem's [48] study of 137 manager-academics (women and men). Helgesen [49] argues that women's central involvement in managing households, raising children and juggling careers gives them a capacity for prioritisation in a leadership role that men typically do not possess. Women are often carers of the family and the household in addition to external employment. Women are good in interpersonal and communication skills. Rosener's [36] study found that women managers put effort in building relationships and understanding the people they work with, so that they can adapt their style to each individual. Rosener [36] also found through her study that women use "interactive leadership" styles by encouraging participation, sharing power and information, enhancing peoples' self-worth. She further justified that women are much more likely than men to ascribe their power to interpersonal skills or personal contacts rather than to organisational stature. Women as leaders believe that people perform best when they feel good about themselves and their work, and the leaders try to create situations that contribute to that feeling. Earlier thinking emphasised that women who had achieved leadership positions were imitators of male characteristics, but later theories recognised feminine leadership styles [50]. Research into the feminisation of management suggested that contemporary managers were moving towards substituting the "masculine power" of decision-making, giving orders and being obeyed, with the power to give others (the work force) sustenance, nurture their growth and care for them [51].

5. Discussion

The issues related to the status of women in senior management positions in higher education, leadership styles in higher education and the leadership styles typically exhibited by women managers are discussed in this paper. It is the fact that women are under-represented in managerial positions in higher education. In order to study the employability of women in managerial positions, the leadership style has been taken as the primary area of the research.

From the previous sections, it is apparent that the management structure within higher education has become more difficult and complex. More than just the activities involved, it is the people who are to be motivated and to be trained in order to promote them into a state of self-correction. Accordingly it is understood that the higher education institutions should be friendlier and more accommodating for employees and the gaps between people at different levels are to be minimised to achieve this. Thus maintaining a personal relationship is vital in higher education. This cannot simply be achieved by placing the whole responsibility on the shoulders of one single leader. Leadership in higher education is therefore more complex as people in these positions should have the ability to motivate employees to excel beyond what is expected through the use of individual consideration. This could closely be linked with the typical characteristics of women managers such as empowering employees, caring for others and listening to others.

Teamwork is also an issue that is to be encouraged in higher education in most instances, especially when undertaking research projects. Furthermore, the leadership role should include the establishment of priorities, the design of appropriate early warning and communication systems, the coordination and balancing of the various subsystems within the institution and the directing of attention, symbolically and actively, towards the priority areas. Women are good at multi-tasking and have the ability to prioritise. Female leadership styles encourage teamwork, personal relationships, caring, and nurturing qualities, as they tend to lead in a democratic and participative way.

In summary, we could see that the transformational leadership, which is largely used by women managers, could be the preferred leadership style in higher education.

6. Conclusion

The higher education sector in the UK is changing and facing greater scrutiny and accountability from outside agencies that impact accreditation, funding and financial aid resources. The traditional sense of providing direction in the carrying out of tasks is likely to be less significant for professionals such as university employees. Therefore the idea of placing a traditional form of leadership in higher education sector is less convincing.

In summary, the democratic participative styles of consensus building, power as influence, working together for common purpose, ability to manage multi tasks, excellent interpersonal skills, caring and developing personal relationship are said to be the qualities typically exhibited by women managers. These qualities largely fall under the transformational approach of leadership.

However, leadership purely based on transformational style may not be sufficient. There could be instances where the leader has to use transactional style, for example when motivating people to perform in exchange of specific rewards. Similarly, when there is a situation where a job is required as a matter of urgency, the leader may have to use an authoritative style. Considering these, it cannot be concluded that higher education is effective merely with the transformational style of leadership. The managers, therefore, should be able to switch from one style to another depending on the situation.

Nevertheless, the authors intend to say that transformational leadership, which is largely used by women managers, could positively contribute to improve the higher education sector. Through this paper it could be concluded that the women have a greater potential to be employed in managerial positions within the higher education sector. An increase in the number of women managers in higher education will possibly help to reduce barriers in the long run and in turn may enhance the sector. This study will be a supportive resource to any reader interested in identifying women's leadership qualities to manage the higher education sector.

Abstract

Leadership research in the construction industry has been dominated by positivist methodologies resulting in a much larger proportion of quantitative studies than qualitative approaches. Thus, the richer interpretations which could be possible through the latter are not realised. With growing research focus on leadership in construction, it is pertinent for studies to utilize the grounded theory approach to uncover the basic social processes that drive the leadership phenomenon in construction. Research in the mainstream social sciences has recognized the vital benefits that the grounded theory approach offers. There is dearth of grounded theory application in the extant body of knowledge on leadership in construction. A case is presented here to advocate the strengths of grounded theory and the potential benefits it can offer to research on leadership in the construction industry.

Keywords: Leadership Research, Grounded Theory Methodology, Construction Industry

1. Background

The field of leadership research has changed considerably in how one thinks about, studies, and defines leadership [1,2]. This is mainly because of greater optimism about the field and greater diversity in the methodological approaches being employed by the researchers to study leadership [1]. Bryman [1] further notes the factors that have contributed to this increased optimism and greater methodological diversity, including: improved measurement and analytical methods; greater use of meta-analysis for developing systematic reviews; the surge of interest in transformational leadership and charismatic leadership; more and better cross-cultural studies; and greater diversity in the types of leadership and organizational contexts that became the focus of attention. However, many other researchers have argued that leadership remains a difficult phenomenon to capture and measure.

Research on leadership in construction has particularly been restricted to the use of positivist or quantitative methodologies. Very few studies have utilized qualitative methods to analyze the nature of leadership in the industry. This is ironical. Many have recently argued that leadership must be regarded as a social process [1-6]. Similarly, scholars have argued that construction is a social system in which people are the principal actors [7]. In order to uncover the dynamics of leadership and complex details of the social processes that take place among people in construction, there should be increased use of analyses suitable for studying social processes. This paper underlines the need for the application of more qualitative methodologies to study leadership in the construction industry. It focuses on three issues: (i) the current methodological trends in leadership research; (ii) why qualitative methodologies are more useful for leadership; and (iii) how the grounded theory framework can help to capture the basic social processes of leadership in construction.

2. Which research method?

Goulding [8] notes that choosing a research methodology is not an easy task. It is time-consuming, laborious and difficult. However, it is personal and reflective process. It also requires evaluation of oneself in terms of convictions, beliefs and interests. Goulding [8] views research as a part of an integrated process involving researchers, their beliefs and experiences, the cooperation of various stakeholders of the research, and suitability and implementation of a chosen methodology which results in an answer that is a single perspective and not an absolute explanation of the problem. In this process, Guba and Lincoln [9] suggest that researchers should address a few questions in relation to their own philosophy, including: (i) the paradigmatic question—"What is the basic belief system or world view that defines the nature of the world, the individual's place within it and the range of possible relationship to that world?"; (ii) the ontological question—"What is the relationship between the researcher as the would-be knower and what can be known?"; and (iii) the methodological question—"How can the enquirer go about finding out what he/she believes can be known?".

Buchman and Bryman [10] highlight a number of issues which play an important role in the choice of research methodology such as: aims of research, epistemological concerns, and norms of practice of the researcher who is also influenced by organizational, historical, political, ethical, evidential, and personal factors. Simply put, research method is an integral component of a wider, iterative, and coherent research system in which a number of unavoidable influences need to be accommodated in decisions concerning the choice of method. Buchman and Bryman [10] suggest that the design of organizational research work and the choice of data collection methods remain in part a creative process despite a number of constraints and influences. Therefore, it is important to recognize the role of personal interests, preferences, biases, prejudices, and creativity in addition to technical skills, knowledge, and competence of the researcher. This competence, as Buchman and Bryman [10] conclude, must encompass the ability to address, systematically and coherently, the organizational, historical, political, ethical, evidential, and personal influences on the choice of research methods.

3. Research approaches to study of leadership

3.1 Quantitative approach in leadership research

Quantitative research methods are characterized by the assumption that human behaviour can be explained by social facts. Such methods employ the deductive logic of the natural sciences [11]. Quantitative methods were mainly used for leadership studies during the 1960s and 1970s, due to the bend of leadership research towards psychology, giving rise to the use of the positivism and quantitative methods associated with research in psychology, especially in the US (Parry, 1998). House and Aditya [12] observe that about 98% of the empirical evidence in leadership research is American in character; empirical research on leadership has either been conducted within the US, America or been carried out by those who have studied or have some affiliation to American educational institutions. Other researchers confirm that the vast majority of empirical research on leadership originates in North America [13-15]. Reviewing 10 years of publications in "The

Leadership Quarterly", Lowe and Gardner [14] found that 64% of studies employed a questionnaire-based method of collecting data. They also reported that around one-third of all the articles were based on a qualitative methodological approach. Reviews by Bryman [1] and Lowe and Gardner [14] show that the number of qualitative studies on leadership is significantly lower than those using quantitative methods. Conger [15] also highlighted the dearth of qualitative studies on leadership.

There have been many criticisms of quantitative approaches for studying leadership. Bryman [1] observes that leadership research has been dominated by a single kind of data gathering instrument—the self-administered questionnaire. Most studies in the literature on leadership employed questionnaires in various contexts including experimental settings, cross-sectional designs, and longitudinal investigations. A few standard sets of questionnaires have been used in a large number of studies. These include: Leadership Behaviour Description Questionnaire (LBDQ), Multi-Factor Leadership Questionnaire (MLQ), Multi-Culture Leader Behavior Questionnaire (MCLQ), Leadership Practices Inventory (LPI), Least Preferred Co-Worker (LPC), Leader Effectiveness and Adaptability (LEAD), and Ethical Leadership Scale (ELC).

Surveys and questionnaires mostly measure attitudes towards behaviors and not the actual behaviors due to social desirability. Such surveys are also not useful as they mostly measure the static situations and do not explain the processes behind them. Such descriptions of leadership fail to help us understand the deeper structures [15] and dynamism of leadership phenomena. Moreover, Bass and Avolio [16] note that the inability of quantitative research to draw effective links across the multiple levels to explain leadership events and outcomes has been a major shortcoming. Yukl [17] shares this perspective and argues that quantitative approaches mostly focus on a single level of analysis and hence ignore several other mediating factors, such as the influence of groups or organizations. Alvesson [4] observes that the inadequacies of quantitative and hypothesis-driven approaches have encouraged researchers to look for alternative qualitative methods. Conger [15] argues that the symbolic and subjective components of leadership have serious implications for research methods [3]. Quantitative methods focus on objectivity and attempt to capture the reality. On the other hand, they are unable to explain the subjective and ever-shifting realities of the leadership process. Other criticisms of the quantitative approach in the social sciences is that it is pseudo-scientific, inflexible, myopic, mechanistic, and limited to realm of testing existing theories [8].

3.2 Qualitative approach in leadership research

Jones [18] observes that qualitative methodologies are strong in those areas that have been identified as potential weaknesses within the quantitative approach. For example, interviews and observations provide a deep, rather than broad, set of knowledge about a particular phenomenon. In a review of qualitative studies on leadership, Bryman [1] selected a total of 66 qualitative studies from social sciences journals from 1979 to 2003. He found that only 10 studies were based on qualitative methodology between 1979 and 1991 whereas 56 studies were published between 1991 and 2003. This increase in the number of studies shows soaring interest of researchers to employ qualitative approaches to research leadership. Bryman [1] observes that the upward trend in qualitative research on leadership did not begin until 10 years after an influential issue of "Administrative Science Quarterly" in 1979. He also found that a large number of studies employed the case study approach. With regard to the data collection method, Bryman [1] found that 56 studies (more than 80%) employed qualitative interviewing (semi-structured, in-depth, unstructured, and biographical interviewing). Interviewing was the sole technique of data collection in 25 studies. It is ironic that qualitative researchers tend to use interviewing when other techniques of data gathering (such as document analysis, observation and anthropology, discourse and conversation analysis, visual data, and case studies) could be used to complement interviewing. However, a number of issues often make interviewing the only option available. Particularly, observational techniques are hard to use for several reasons such as the need for greater investment of time; observing acts of leadership is a complex matter; observation involves a large expenditure of time for relatively little return in terms of data; problems finding gaining access to leaders who are willing to allow the observation; and potential of contamination of observation due to presence of the participant observers. There are also several ethical and methodological dilemmas in being an observer in a research setting associated with entering the field, positioning and disclosure, shared relationships and disengagement [19].

Conger [15] recognized that qualitative approaches may be intensive, complex, expensive and time consuming. However, they are rich in detail and illuminating in new ways to explain the complex phenomenon of leadership. Conger [15] also notes that qualitative research studies are particularly important during exploratory phases of researching a new area. However, he argues that, in leadership research, qualitative research plays an important role at all stages of investigation because of the extreme and enduring complexity of the leadership phenomenon itself. Parry [20] shares this sentiment and observes that qualitative approaches, due to their painstaking data collection and analysis techniques, have been under-utilized by leadership researchers. Parry [6] observes that greater use of qualitative approaches in the recent past is resulting in a fuller and richer understanding of the nature of leadership. Similarly, Martin and Turner [21] argue that qualitative approaches allow richer descriptions, sensitivity of ideas and meanings of the individual concerned, and increased likelihood of developing empirically supported new ideas with practical relevance. Qualitative approaches help in discovering new ideas and phenomena rather than verifying the old and existing theories [22]. Conger [15] advocates that qualitative methods offer a number of benefits, including: greater opportunity to examine the process in depth; the flexibility to discern other contextual factors; and more effective means to investigate symbolic dimensions.

However, qualitative research is not without shortcomings. Alvesson [4] suggests that qualitative research is as superficial as quantitative approaches; however, the shift to the use of qualitative methods should be welcomed. One of the most often mentioned limitations of qualitative research is its over-reliance on interviews as a principal methodology [15]. The qualitative approach to research methodology has been criticized as being exploratory, filled with conjecture, unscientific, and a distortion of the canons of ‘good’ science [8]. The approach and its results are also viewed as being soft hearted, pitying, and even too foolish to be taken seriously [23]. In opinion of Morse et al. [24] qualitative research leads nowhere and predominantly relies on inference, insight, logic and luck. Qualitative research is also accused of being novelistic, entertaining, descriptive, not sufficiently rigorous, incapable of explaining why things happen, and having no hard and fast rules of procedures [8]. Table 1 shows the differences and similarities between qualitative research and the quantitative approach.

Table 1: Characteristics of qualitative and quantitative methods

Characteristics	Qualitative Research	Quantitative Research
Goal/purpose	Understanding/meaning from the participation	Explanation/prediction from data
Theory	Generation	Testing
Sample	Participants	Subjects
Researcher/sample relationship	Direct involvement	External involvement
Instrument	Research is "tool"	Established, pre-tested tool
Findings	Narrative/inclusive for depth	Data/exclusive and limited to narrowed focus
Analysis	Meaning from findings	Numerical interpretation and significance
Significance	Applicable only to the sample	May be generalizable to the population

3.3 Combining qualitative and quantitative approaches in research

The debate about quantitative and qualitative research at the epistemological level originated in the mainstream of the social sciences and was also known as 'the paradigm wars' [25]. 'Paradigm wars' refers to the competing perspectives of proponents of quantitative and qualitative research which are considered to be distinct and based on fundamentally different principles. The debate was predominantly initiated and extended by qualitative researchers who purported a distinctive philosophical position for their approach and presented an intellectual rationale for it in the face of the hegemony of quantitative investigations in journals and elsewhere. As a result, awareness of qualitative approaches grew and peace was slowly restored among the researchers. Bryman [26] observes that research that involves the integration of quantitative and qualitative research has gained popularity in recent years. Such approaches have been given numerous names, such as multi-methods, multi-strategy, mixed methods, or mixed methodology research. Bryman [22] suggests that more abstract philosophical issues should be linked with questions of research practice. This would be a more sophisticated way of treating the comparability of different methods of investigation than direct juxtaposition in terms of relative superiority. Rocco et al. [27] argue that 'mixing methods that bring together the strengths of both quantitative and qualitative methods will enhance research in the field' [27, p. 604]. Bryman [1] suggests that qualitative research on leadership can serve the area better by engaging much more with quantitative research in terms of its findings and literature. This way, it would become integrated into the field while simultaneously maintaining a distinctive approach to designing research and gathering data.

In the literature, several researchers have combined qualitative and quantitative approaches in their studies to achieve the research objectives [29-35]. For example, Rosner [32] studied women leaders and employed questionnaires followed by interviews. Egri and Herman [29] in their study of leaders in non-profit organizations, used both questionnaires and interviews to study the transformational and transactional behavior of leaders. Such studies are mostly cross-sectional in design, and use qualitative interviewing as the data collection tool. There are many reasons why researchers combine qualitative and quantitative research. In most cases, it is done to achieve triangulation of data and to examine how far the results from both methods are similar. Although there is no hard and fast rule about the sequence in terms of the method which should be used first, most researchers use qualitative research studies to prepare for quantitative data collection. However, many studies employ interviews to validate their quantitative findings. Moreover, the combining of quantitative and qualitative methods is also done to achieve different objectives and address different research questions.

Bazeley [36] and Bryman [26] discuss why and how quantitative and qualitative approaches can be combined to achieve the desired results. Bazeley [36] asserts that mixed methods research has several benefits including greater validity of results. However, the mixing quantitative and qualitative methods also has its problems in terms of definitions, paradigms, and methodology. Moreover, issues such as the nature of design, sampling techniques, research instrument, analysis techniques, financial and time constraints, and finally, adequate skills required to mix the research continue to find critique in research works. Bazeley [36] discusses triangulation. He argues that, as opposed to its original meaning, triangulation has recently been used loosely as a synonym for mixed methods without regard to either of the conditions inherent in the original concept. Triangulation was originally conceived as the conduct of parallel or otherwise duplicated studies using different methods to achieve the same purpose. This was mainly done to achieve the same results from different methods and find a stronger support for the conclusions. It was more like a validation technique. There has been criticism of the ability of triangulation to provide validation as each source must be understood on its own terms [37]. Bazeley [36] also argues that “Mixed methods are inherently neither more nor less valid than specific approaches to research. As with any research, validity stems more from the appropriateness, thoroughness and effectiveness with which those methods are applied and the care given to thoughtful weighing of the evidence than from the application of a particular set of rules or adherence to an established tradition.” (p. 9). Jones [18] observes that the vital feature in justifying a mixed methodology research design is that qualitative and quantitative methodologies have strengths and weaknesses. Adequate mixing both methodologies can be useful for combining the strengths of both methodologies. Hence, the researcher should aim to achieve the situation where mixing both qualitative and quantitative methods can produce a final product which can highlight the significant contributions of both [38].

4. Trends in leadership research in construction

In their review of empirical studies of leadership in the construction industry, Toor and Ofori [39] note that most of the studies utilized quantitative methodologies, using survey questionnaires to collect information. Few studies used qualitative methodologies based on interviews and case studies. However, such qualitative studies did not extend beyond interviewing the subjects or analyzing some official documentation to develop rigorous analyses. They also found that the studies were cross-sectional in nature. Thus, there was a heavy bias in static, cross-sectional analysis, and comparative statistics [2]. It is, therefore suggested in the mainstream literature that leadership, being temporal in nature, must be examined through longitudinal studies [40]. Particularly, in construction projects, some researchers have argued that project managers tend to employ different leadership styles during different stages of the project [41]. This conclusion should be further explored through longitudinal studies which can also investigate how project managers adapt their styles and approaches to new projects and what influences their leadership styles in a new environment. Toor and Ofori [39] also suggest the use, in leadership research, of more qualitative techniques such as the grounded theory approach; observational techniques [15]; narratives, personal writing, stories, or biographies [42]; ethnographic studies [43]; and psychometric neuro-scientific methods.

5. Leadership as social process

An important issue to address is whether leadership is solely about qualities, behaviors, and attributes of the leader, as advocated in many classical theories, or it is actually a social process comprising the leader, followers, and situations. Yukl [17] also claims that, after thousands of studies on the subject, a general of theory of leadership that can explain all aspects of the process adequately has not been developed. Most leadership studies have also focused on a single level of analysis, ignoring the influence of intra-psychic, group, or organizational factors. There seems an excessive focus on 'the leader' rather than leadership [44], especially in North American research [1, 44, 45]. Meindl et al. [46] share this sentiment, and note that outcomes are often linked to the leader, forgetting that many other factors also play a significant role. On the other hand, many scholars view leadership as a relationship between leader and led that can energize an organization [47]; an art of creating a supporting work environment [48]; a phenomenon that works on the system [49]; an inspiration and support of people to do things [50]; and creation of a common vision to achieve results by persuading others [51] in a trust-based environment [52]. It is primarily about influencing others [53]; it is not only the influence of a leader on followers but the collective incremental influence of leaders in and around the system [54].

Conger [15] views leadership as a complex and dynamic process which is a social construction, and exists at multiple levels of organizations. These views indicate that leadership is a social process of influence [6, 15, 17, 20, 55, 56] that engages everyone in the community [57]. Therefore, leadership is a function of the social resources that are embedded in relationships, the environment, structure and technology of organizations [54]. It is about bringing people together around a shared purpose and empowering them to step up and lead in order to create value for all stakeholders [58]. Others share the same perspective, noting that leadership is a process [1-4]. In this process, leaders interact and communicate with, and influence others. Parry [20] explains that a process involves change (which occurs over time), and the linking of interactional sequences. This implies that the relationship between leaders and followers is also a process which involves changes in beliefs and motivations of followers that occurs within organizations which act as communities.

Many consider leadership to be about the future [59], about creating and coping with change in organizations [60, 61]. Others note that change is inherent in leadership [5, 20, 54, 59]. Change incidents may form the basis for investigating the leadership process. Bass [55] noted that leadership involves restructuring of the situation. Kotter [61] argued that leadership can be differentiated from management due to the inherent notion of change in leadership. Conger [15] noted that achievements, failures, crises, changes, always reshape the experiences of the leader and the led. Leadership occurs within a group context as well as within a dyadic relationship [53, 62]. However, the effectiveness of leadership is largely dependent upon the context. Osborn et al. [53] argue that leadership "is socially constructed in and from a context where patterns over time must be considered and where history matters" (p. 798). The concept of context is similar to what contingency theories of leadership advocate, that leadership style cannot be separated from the conditions under which leadership is exercised [63]. Osborn et al. [53] suggest that contextual macro views need greater recognition than they receive currently. They suggest four contexts—stability, crisis, dynamic equilibrium, and edge of chaos—to explain the context of leadership in organizations. They consider leadership as a series of attempts, over time, to alter human actions and organizational systems.

From the above discussion, there is a conceptual basis for the conclusion that leadership is a process in a social context [20]. Therefore, researchers have purported that analysis of leadership as a process can enhance one's understanding of it [2, 20]. This is a conception of leadership which departs from "role" to "process". Kan and Parry [5] observe that defining leadership as a process supports the notion that leadership is not a linear or mono-directional phenomenon; it is rather multi-directional, involving formal leaders, informal leaders, and followers. Thus, Parry [20] argues that leadership research should focus on the social processes that go on between people and which have a leadership impact. This is because irrespective what behaviors people employ in leadership roles, many other variables influence the impact which these leadership behaviors have upon followers and upon the context of work.

6. Construction as a social system

The nature of leadership as a process which takes place within a social system—comprising groups, organizations, and so on—is further strengthened when it takes places in the construction industry. Love et al. [7], in their critique of methodologies in construction research, argue that construction is a social system and people are the principal actors in construction projects. They note that the social system that exists in a construction project is no more than the sum of individuals. Since humans change over time, undergoing different circumstances, their behaviour and the resulting structure of the social system they construct is also open to change. After it has been established that construction is a social system and humans are principal stakeholders in this social dynamics, it is pertinent to evaluate what research methodologies are adequate for construction leadership research.

7. Grounded theory as a potential research method

Originally developed in medical research [64], grounded theory is a method well suited to enhancing the development of knowledge on leadership. Grounded theory uses qualitative research methods with the aim of generating theory which is grounded in the data, rather than testing existing theories [65-67]. Glaser [[66] noted that grounded theory is useful for research related to human behaviour in organizations, groups, and other social configurations. Parry [20] suggests that as leadership is a process of social influence, this makes grounded theory a relevant method of analysis as it emphasizes theory development rather than testing an existing theory. In the opinion of Hunt and Ropo [2], grounded theory discovers the underlying social processes and forces that result in a particular activity or phenomenon.

7.1 Support for Grounded Theory for Leadership Research

Researchers in the mainstream social sciences research have employed, and called for the application of, qualitative methods to study leadership style and behavior [15]. Many researchers have also emphasized the application of the 'grounded theory approach' [64, 67] to theorize leadership [2, 3, 5]. The key argument here is that leadership is a basic social process [6, 15, 17, 20, 56, 68] with a number of intervening variables which makes it dynamic and complex. This, therefore calls for more grounded qualitative approaches that can dig deep into social realities and can uncover the intervening variables and forces that influence leadership [69, 70]. It can also be used to examine leadership incidents in various organizational contexts [5, 20, 71, 72]. The grounded theory approach will also be helpful to refresh and considerably compliment the existing works on leadership [8]. In the opinion of Kan and Parry [5], the grounded theory approach is capable of capturing the complexities of the leadership process without discarding, ignoring, or assuming away relevant variables. The richness of the data in the grounded theory approach ensures that the resulting theory is fully able to elaborate upon the leadership process for participants and fellow researchers alike. Many researchers agree that a full grounded theory approach can provide valid and reliable findings explaining the leadership phenomena under a given context [2, 3, 15, 20].

In addition to a detailed account of how grounded theory can be useful for leadership research, Parry [20] also underlines a number of aspects one should consider while using the grounded theory approach in leadership research. He observes that one must observe or undertake interviews in depth about the process of social influence. To do this, one must have a definition of leadership to ensure that the phenomenon under consideration is leadership and not something else. Also, such research should be more concerned with the leadership process rather than leaders themselves. The interview subjects for this purpose should be statistically random. Therefore, the interviews can come from a range of levels in the hierarchy, various functional areas and from different stages of the change process. During this whole process, until the grounded theory has been generated, it is not appropriate to consider any existing leadership theories. However, after the generation of grounded theory, its comparison with extant theories is useful.

The grounded theory approach for leadership research is not without weaknesses and limitations. These weaknesses mostly pertain to the validity and reliability of the generated theory. Parry [20] suggests that multiple sources of data collection are useful to improve the validity of the findings. However, in addition to multiple sources of data, an interviewing strategy should be the core of the data gathering approach for grounded theory research in leadership.

7.2 Application of Grounded Theory in Leadership Research

A number of studies have been conducted in leadership research using the grounded theory approach. These include Fernando and Jackson [73], Harchar and Hyle [74], Hay and Hodgkinson [75], Hunt and Ropo [2], Irurita [76], Jones and Kriflik [77], Kan and Parry [5], Kempster [72], Lakshman [78], Parry [79], and Sjoberg et al. [80]. Table 2 shows characteristics of selected studies that have used the grounded theory approach. These studies have been conducted across a wide spectrum of organizations, contexts, and leadership situations. They explore a number of topics related to leadership, such as administrative instructional leadership, leadership in turbulent change, indirect leadership, role of spirituality in leadership, leadership learning, and leadership in stressful and complex rescue operations. The studies have been conducted in manufacturing, the health, educational, and government sectors, the military, and rescue-services organizations. Unlike quantitative research, which is predominantly North American in nature, the grounded theory approach has been used in America, and many countries in Europe, and Asia-Pacific.

From Table 2, qualitative interviewing has been the primary data collection tool in the application of grounded theory in leadership research while some studies have used informal interviewing, observational techniques, and document analysis. Kan and Parry [5] used both qualitative and quantitative data for triangulation purposes. They used Multi-factor Leadership Questionnaire (MLQ) to bring quantitative psychometric data into grounded theory analysis. This innovative way of using quantitative data in grounded theory analysis is quite rare in leadership studies. Table 2 shows that several researchers have effectively used the grounded theory approach to research various topics of leadership. It also shows that researchers have predominantly used qualitative interviewing for data collection. This feature of qualitative research on leadership has been mentioned by some authors [1, 15, 5]. Kan and Parry [5] observe that leadership research traditionally tends to control for variables, such as hierarchy or groups, to comply with the positivist nomothetic tradition. On the other hand, the grounded theory method attempts to develop new theories and propositions rather than testing the existing theories. However, adequately mixing quantitative data with qualitative data helps to better understand the leadership phenomenon in more depth.

Table 2: Application of grounded theory for leadership research

Author(s)	Country	Sector	Nature of study	Research methods
Hunt and Ropo (1995)	USA	Manufacturing Industry	A CEO's tenure at General Motors	Document Analysis Interviews relating to Roger Smith's tenure as CEO at General Motors
Harchar and Hyle (1996)	USA	Educational Sector	Understanding administrative instructional leadership in the elementary school	Qualitative Interviewing
Parry (1999)	Australia	Local Government	Organizational turbulent change in local government settings	Qualitative Interviewing Participant Observation Document Analysis
Kan and Parry (2004)	New Zealand	Health Sector	Understand the leadership processes operating within the nursing environment of a hospital undergoing organizational change	Non-participant observation Qualitative Interviewing Document Analysis Multifactor Leadership Questionnaire (MLQ)
Bjorkman (2005)	Sweden	Military	Understanding of how indirect leadership is done in a military context	Qualitative Interviewing
Fernando and Jackson (2006)	Sri Lanka	Business	Workplace spirituality and leadership	Qualitative Interviewing Participant Observation Document analysis
Hay and Hodgkinson (2006)	UK	Educational Sector	Conceptualizing leadership afresh	Qualitative Interviewing
Jones and Kriflik (2006)	Australia	Public-Sector Organization	Leadership process within the substantive setting of a cleaned-up bureaucracy	Qualitative Interviewing Conversational-type Interviewing
Kempster (2006)	UK	Multinational Public Company	Understanding of underlying influences shaping leadership	Qualitative Interviewing

Author(s)	Country	Sector	Nature of study	Research methods
			learning within a single organization	
Sjoberg et al. (2006)	Sweden	Rescue Services	Understanding of leadership in stressful, complex rescue operations	Qualitative Interviewing
Lakshman (2007)	USA	Business Organizations	Role of leaders in knowledge management	Qualitative Interviewing

8. Conclusion

Leadership research in the mainstream social sciences as well as in construction continues to utilize positivist methodologies. However, there is evidence that qualitative or interpretivist methodologies have the potential to take leadership research in a new direction and to a high level by discovering the basic social process that drives the dynamics among leaders and followers under given circumstances. The grounded theory approach can be useful in helping to uncover the social processes that are fundamental to leadership. While mainstream researchers have already recognized the significance of grounded theory for leadership research, its use remains scarce in construction research. No evidence of grounded theory approach for researching leadership is found in the construction literature. Given the importance of leadership in construction, it is a timely for scholars to use grounded theory methodology to develop richer interpretations, frameworks, and theories of leadership in construction. It would be beneficial if a network of researchers could be formed comprising those interested in leadership and those who have previously used the grounded theory approach in their past research. This can be helpful in training potential grounded theory analysts who can then use this approach to study leadership and other related disciplines in the built environment.

CURRICULUM DEVELOPMENT

The changing role of universities and flexible course re-development

(email: s.savage@qut.edu.au)

Abstract

This paper reflects upon the development of a suite of new courses in the Faculty of Built Environment and Engineering at the Queensland University of Technology in Australia. It describes the theoretical framework upon which these courses are founded and the broader pedagogical and structural implications and opportunities. It relates a model of transformative learning to the large scale issues of course design and contemporary course relevance. The paper illustrates such a relationship with a suite of courses in which the student takes a greater lead in the shaping of his or her own education. Notions of change and transition are presented as opportunities for continued renewal of course offerings, and as the catalyst for transformative learning wherein students become more active members in the teaching and learning process. What we find is that good pedagogical course design aligns with the changing role of universities in contemporary society.

Keywords: Cross-disciplinary, Curriculum, Design, Education, Multi-disciplinary

1. Introduction

“Universities are products of the late 19th and early 20th centuries… The question is how do you break them up in some way… How do you make them free to do something new and different?” Everett Hughes [1].

This paper explores and illustrates how university undergraduate courses can be designed and developed to respond to the changing role of universities within the broader social context. Further to that, it illustrates how a model of transformative learning [2] can be used to inform such course design and development. Universities need to prepare students for the real-world demands of professional practice, and classroom knowledge is increasingly seen as only a part of the knowledge needed to operate in practice. New courses need to adapt and embrace a broader more flexible approach to what constitutes disciplinary scholarly knowledge.

2. The changing role of universities

“Current changes in Western universities which are attributed to global and other international economic, social and cultural developments are variously referred to in a number of different ways including new managerialism, academic capitalism and academic entrepreneurialism” [3].

The purpose for the existence of higher education is changing. The role of universities within society has changed. One of the significant issues about this is that different stakeholders still have different perceptions of that changing role. For example, university is no longer seen as being as elitist as it once was, it is much more ‘normal’ to attend university with an increasing percentage of the population now studying at tertiary level. Higher education is now seen as an expected part of the process of getting a job or developing a career. This has not only affected the types of courses that universities offer, but more significantly the ways in which those courses are delivered. There is also increasing influence from industry and professional bodies with respect to student graduate attributes (employability skills), and within the disciplines of design, engineering and built environment, many courses are externally accredited by such professional bodies, whose influence on curriculum development is significant.

Many practitioners in the design, engineering and urban development industries require a period of formalised workplace training, either during or after university study, before being eligible to apply for statutory registration. This arrangement sees three significant stakeholders involved in, and influencing, education in these fields:

- Governments who are responsible for registering professionals, and administering registration examinations, and who control higher education policy and funding

- The professional industry bodies, who increasingly lobby governments and have their own education policies

- The higher education sector itself, responsible for curriculum development and delivery, often within guidelines provided by government and industry

This complex arrangement is fraught with all of the expected conflict between academia and industry and the ongoing differing visions of the role of professional education. In the example of architecture, the industry and professions have a vocational view and see the architecture course as “training for operation in the profession” [4], while many academics still see their role as “developing individual star architects as unique and gifted designers” [5].

2.1 Changes within society and Government

Until fairly recently university was considered as one stepping stone on a life-long career path. More recently however the notion of multiple careers in any one lifetime has emerged and university education is thus seen in a range of different ways, with multiple entry points, exit points and reasons for attending. This change in societal attitude has been driven by, among other things, significant changes in skill level in the workforce. Increasing internationalisation and automation in the 1980's saw increasing numbers of students attending university to raise their skill levels and improve their employability [6]. The new post-industrial society of that time was experiencing the rise of the information industries and the service sectors and Richard Florida's "creative class" were on the rise [7].

This increase in student numbers was primarily within the professional and technology sectors, not the arts and pure sciences, as students trained for changing career opportunities. This shifting focus towards employability also saw increasing concern among governments about the quality of higher education, and the balance of academic knowledge and practical (employability) skills. Many higher education providers, prompted by government, revised courses to incorporate graduate capabilities (employability skills) such as communication, teamwork, creativity, problem solving, and life-long learning [8].

2.2 Changes within the professions

On a professional level the building industry, and the roles of professional within it, has changed dramatically in the past few decades. What was once seen as a series of hierarchical industrial relationships, has changed to a team based industry with patterns of shared responsibility. These changes in professional practice have resulted in building industry professionals who need different sets of capabilities and skills, and more importantly who have a different view of themselves within their professional context. Such professionals must now see the value in participatory teamwork, client involvement, cross-disciplinary activity, multiple perspectives, and the capabilities for lifelong learning.

Problems in contemporary society are characterised as complex and not limited to one discipline, and our graduate must similarly work in multi-disciplinary or trans-disciplinary ways [9]. In particular our graduates need to be: outward-looking and connected, enterprising and innovative, community and society responsible, and providing and focussing on leadership [10]. This need for our graduates to be more focused on societal values rather than technical solutions means that university courses must respond to develop mode deeply a broader range of capabilities in our graduates. Together universities and the professions must develop policy and direction to assist in the development of higher education in this direction.

Professional organisations, as representatives of employers, "have been remarkably successful in influencing government policy on higher education" [11]. Such professional bodies develop education policies that rely heavily on performance criteria, employability skills, or graduate capabilities; all of which are permeating higher education. It is clear that such policies seek to make graduates more immediately employable, often at the expense of a more liberal education.

2.3 Changes within the higher education sector

Contemporary universities are "rapidly changing legal, social, economic and technological environments" characterised by the conflict they are experiencing between corporate and academic cultures [12]. With significant changes in the past few decades to society's attitude to higher education, universities have changed their management structures to become more entrepreneurial, competitive, strategic and bureaucratic [13]. The contemporary university-as-business may however be more concerned with responding to market demands than with the public good [14]. The need to capture a fair share of the student market is now a significant driving force. As long ago as 1980 David Riesman was investigating the effects of rising student consumerism on the higher education sector [15]. He talks of the decline of faculty (academic staff) dominance and the corporatisation of universities. More recently Sharon Beder [16] has noted the external demands on universities, and an increasing need to form partnerships with corporate employers, resulting in "university education… being increasingly turned into vocational training".

Such partnerships in BEE have been used to develop new commercial postgraduate courses, but such partnerships also manifest themselves in activities within the undergraduate program. Integrated projects may see undergraduate students working on research projects for external community groups, or commercial clients. Students may gain academic credit for work place learning with any of the Faculty's commercial partners.

3. Building a new Faculty framework

Within this complex and changing context, the Faculty of Built Environment and Engineering (BEE) embarked on a major process of renewal in the latter half of 2004. The process was guided in part by the works of two significant scholars in the field of higher education; Ernest Boyer's [17] work on scholarship and Burton Clarke's [18] work on successful entrepreneurial universities. The Faculty identifies its activities within the scholarly fields of teaching, discovery, and application. The Faculty conceives of Boyer's scholarship of integration as the role which academic leaders bring, at all levels of the faculty's organisation, to working these fields together (see Figure 1) [19].

Within the Faculty of Built Environment and Engineering at QUT, such partnerships have become an increasingly common mode of operation as guided by the Faculty White Paper [20] which draws much overt inspiration from the work of Burton Clark. The features of entrepreneurial universities identified by Clark, and reviewed by Deem [21], have been used to steer the Faculty to a more global, entrepreneurial, and integrated future, with industry partnerships, international activities, transdisciplinary courses, and a developing third funding stream.

We find that our courses must also fit this model of a contemporary faculty, sitting at the integration of teaching and learning, discovery, and application.

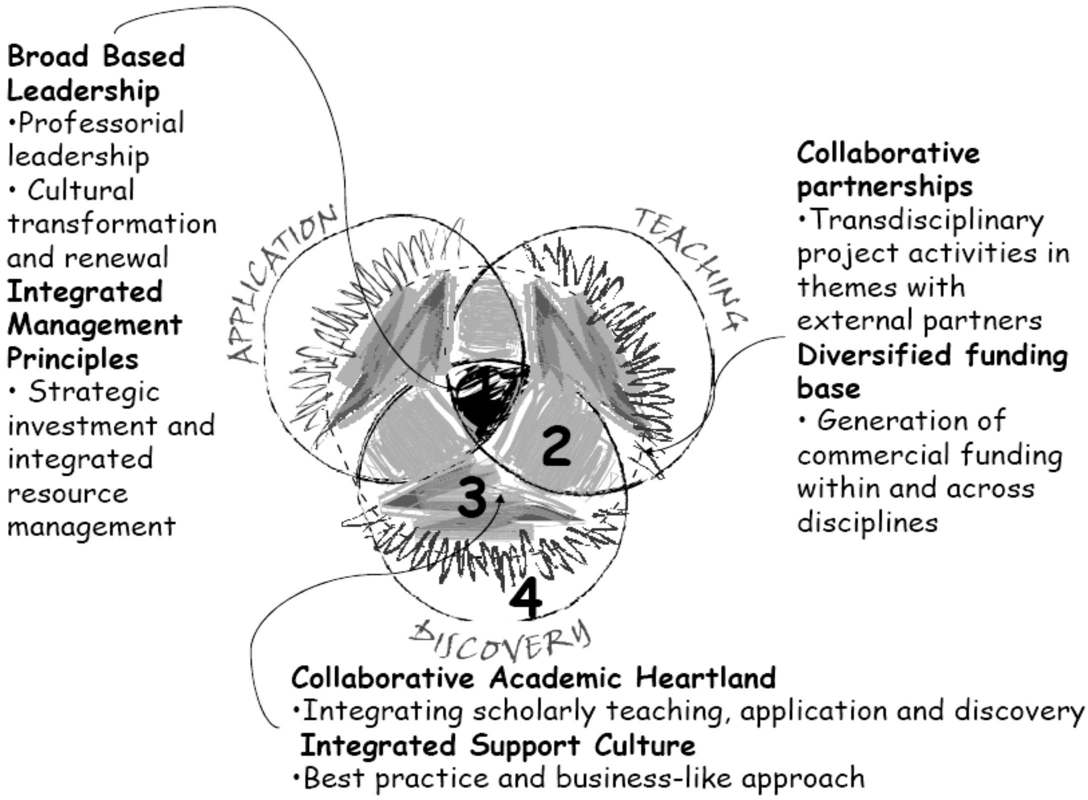

Figure1: Mapping Clark over Boyer; three areas of integrated scholarship ('Teaching, Discovery and Application') with an 'Integrated' core leading transformation of the Faculty.

The role of the contemporary university is to deliver education that responds to the changing needs of society, so different to just twenty years ago, within an increasingly global and entrepreneurial higher education environment. We must balance commercialism with social responsibility, while seeking the answer to "how an institution can be publicly funded, accountable and independent" [22].

4. Building a new course model

4.1 Up-scaling good practice

Closing the gap between outdated learning experiences and the changing societal expectations of the professions, and the changing role of universities, requires a shift from an educational model based on persuasion to one based on dialogue [23]. Where in the past, education has been seen as a process of doing it to them, to *turn* them into practitioners, it must now be about *enabling* them to become professional life-long learners by their own processes. This notion of 'becoming' suggests a transformative pedagogy as exemplified in the work of Jack Mezirow [24] [25].

The value of dialogue as opposed to persuasion is well explored by Mezirow in his work on transformative learning. Among other attributes, the communicative and participatory learning that Mezirow proposes is learning in which a student will be “free from coercion, distorting self deception or immobilizing anxiety... open to alternative view points… and have equal opportunity to participate in the various roles of discourse” [26]. This form of transformative learning involves critically questioning the assumptions of the professional and educational contexts around us, therefore a new educational context that embraces transformative learning will require students to have opportunities to question, and to play a greater role in shaping and forming their own educational environments, and this can certainly extend to large scale curriculum design.

BEE’s course development concepts stem from an understanding that Mezirow’s ideas of dialogically based learning environments can be used to conceive whole courses as well as classroom encounters. Within such a model of educational dialogue, students and teachers develop an understanding through conversation. The Faculty of Built Environment and Engineering has, in order to conduct that dialogue at a course scale, designed course structures that are not imposed upon students but rather developed individually by students, through their own choices, such that students can respond to changes in society, the professions, the higher education context in general, and changes in the role of universities.

The value of such student choice in not limited to transformative learning and professional alignment. Students who make their own choices are also more likely to use a “deep approach” to learning [27] due to higher levels of motivation and feelings of ownership. Such a deep approach, as opposed to surface learning, is one of improved understanding and application.

Engaging with transformative learning and preparing students for contemporary professional practice in the building industry will require an educational context with the following characteristics [28]:

- Divergent learning and teaching
- Dialogical learning and teaching
- Transformative learning
- Participation in practice
- Perspectivalism
- Revisability
- Creativity, inventiveness and innovation
- Self-construction and self-reliance

Courses in the contemporary university should therefore offer students opportunities for divergence, dialogue, and self-construction, along with opportunities for participation in practice and flexibility. Such courses will allow students to become different *types* of graduates with different types of capabilities more suited to contemporary circumstances.

4.2 Building course structures for dialogue

With these goals in mind, one of the major parts of the Faculty's transformative process was the development and introduction of a suite of new undergraduate courses to replace all existing ones. These courses broadly cover the fields of design, engineering, and urban development. Further to the pedagogical goals described above, these new courses were designed to integrate the scholarly activities of teaching, discovery and application, as described in the new structure of the Faculty. No longer would teaching and learning activities sit in isolation, rather students would engage with discovery (research) and application (external service) as structured parts of their programs of study.

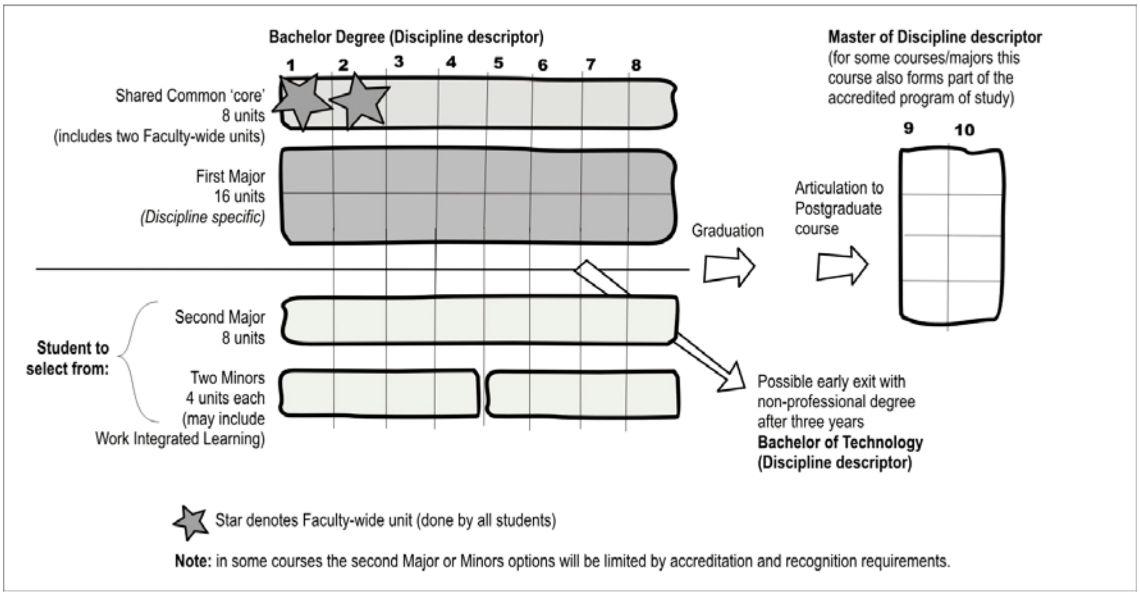

Figure 2: Model of the course structure of the Faculty of Built Environment and Engineering.

With a coming together of these Faculty goals, and ideas of transformative learning, it was possible to develop a common course structure (model) that would allow for the individuality of the disciplines to prevail, while also providing, and indeed encouraging, transdiciplinary activity. These two notions of discipline focus and flexibility/choice exist as shared possibilities that promote self-constructed, divergent learning. The courses (Figure 2) would provide the students with:

- Opportunities for self-construction and divergence
- Opportunities for integrated transdisciplinary study
- Opportunities to learn through and in practice (work place learning)

- Opportunities for articulation

- Opportunities to engage in discovery (research) and application (external and community service) activities through a thematic approach to faculty activities

The new courses all share a common model of a four year full-time structure (Figure 2, note that this diagram is not temporal but simply proportional), in which students self-construct one quarter of their studies to suit their own divergent paths. Further to this all students share a further quarter of their course with students from cognate disciplines, to enhance their broader professional capabilities. This commonality allows such groups of cognate disciplines to come together within single courses within which they share common subjects while still retaining individuality and diversity. This allows the Faculty's nineteen disciplines to form just three undergraduate degrees:

- Bachelor of Design (with majors in: Architecture, Industrial Design, Interior Design, and Landscape Architecture)

- Bachelor of Engineering (with majors in: Aerospace Avionics, Civil, Civil and Environmental, Civil and Construction, Computer Systems, Electrical, Infomechatronics, Mechanical, Medical, and Telecommunication)

- Bachelor of Urban Development (with majors in: Construction Management, Property Economics, Quantity Surveying, Spatial Science, and Urban and Regional Planning)

One useful way to think about the general model of these undergraduate courses is that they will contain three types of knowledge, or three types of units or subjects (Table 1).

Table 1: Three types of knowledge/unit within the undergraduate degree.

1	**Shared Core** (common to one degree)	A coordinated group of units (8 units in a 4 year degree) done by all students in the course. These are units of common content that are 'core' to all disciplines and therefore shared. Two of these units are also shared across the entire Faculty (*Introducing Professional Practice*, and *Introducing Sustainability*).
2	**Major** (the discipline that the student chooses to enter)	A coordinated group of units done only by the students of one discipline, to obtain a focused view of that field of knowledge.
3	**Self-selected units** (a coordinated suite of units structured as: second Major,	A selection from a range of coordinated groups of units (8 units in a 4 year degree). Students elect at the completion of their first year, a secondary field of specialisation (second Major), or two fields of specialisation (two

	two Minors, or Work Integrated Learning	Minors), or Work Integrated (workplace) Learning, or some combination of these. Students self-create their own divergent education, and career path.

The options for students to self-construct their course are wide and varied. They may select from as divergent areas as, cognate fields (within the Faculty), non-cognate fields (from other Faculties), work-integrated learning (learning in the workplace), research activities (engaging in the themed discovery activities alongside academic staff), and external services (community service and commercial application activities). Students are therefore able to construct courses in which they themselves also integrate the Faculty's scholarly activities of teaching and learning, discovery, and application (refer to Figure 1).

While this structure has been developed around nineteen existing majors (or disciplines) it is expected that new majors in emerging fields will be comfortably accommodated within the model proposed here. New disciplines of Design, Engineering, and Construction will be easily accommodated within the existing model. While notions of what such future disciplines might be will be led by changes in the professions, our students will also take an active role in such development.

New course Majors (disciplines) can be firstly tested, before full implementation, as Minors or Second Majors in which our students may take an active role in developing our education context, already characterised as 'innovative, creative, dialogical, and revisable'. The pathways that our students make for themselves, pathways that many of them will develop while participating in professional practice through workplace learning, will show us desirable and sensible course options for further development. Such pathways will not be restricted within the Faculty, but may stretch across the whole university to explore new professional career paths such as Sustainable Environment Design, Chemical Engineering, Design Education, Social Project Management, and Built Environment Law.

This larger scale flexibility, at a course level rather than at a student level, positions the Faculty where it can respond to an uncertain future, in the professions, in the higher education sector, and within the broader society.

5. Conclusions

The courses described here can be seen as a direct response to the changing role of universities, while implementing sound practices of transformative and dialogical learning environments. These courses have been running for two years now, and all evidence suggests that the aims of self-construction and divergence have been well received. The courses have been recognised by a university award for curriculum development; the model described here is now being copied by other faculties; student demand is high and rising in a climate of falling demand; and anecdotal evidence from student recruitment events shows that prospective students are highly interested in, and attracted to, the flexibility and self-directed possibilities that these courses offer.

Self-directed flexibility on this scale is not usual for ‘professional’ degrees, such as engineering and architecture; courses where so many stakeholders drive the agendas of curriculum, content, graduate capabilities, and course structure. This model shows however that the most important stakeholder, the student, can be given greater levels of involvement in their own course development with both desirable and successful outcomes. These courses offer students the opportunity to develop into different *types* of graduates, appropriate to changing professional and social context. “Adults do not learn for the sake of learning; they learn to perform a task, solve a problem, or live a more satisfying way” [29]. These courses seek to provide educational possibilities for the broadest range of tasks, problems, and ways of living.

Shifting the Engineering Education Paradigm - Challenges and Experience in Curriculum Development and Delivery

Saman de Silva,
RMIT University
(email: saman.desilva@rmit.edu.au)

Abstract

It is being recognised around the world that educating future professionals as building practitioners requires a fresh approach. This school of thought stems from the fact that the industry puts higher value on efficient knowledge managers armed with emotional intelligence as compared to traditional knowledge sinks. Especially in the field of engineering, on the one hand engineered proprietary products, new construction materials and processes are becoming globally competitive and therefore technical data and design guides are readily accessible. This inevitably questions the prominence, teaching and learning effort and time invested gaining skills in numerically deductive reasoning in the traditional manner. On the other hand in the building industry, digital architecture, form finding techniques and computational mechanics skills are being complemented or replaced by ultra efficient software tools. In this fast moving and globally competitive environment, the industry recognises that what has been perceived as "know-how" can become stale in a much short time than the time required to acquire and preserve it. Forward thinking building education thus bears the challenge of training a new breed of practitioners who are robust self learners relentlessly in pursuit of skill transformation within short life cycles. This paper presents the teaching and learning paradigm which is aligned to the above school of thought.

Keywords: Engineering education, WIL, PBL, Co-rational design, PBL, Curriculum development

1. Background

1.1 Need for shifting the paradigm

The modern practice of building and construction engineering is evidence-based critical decision making achieved through team networks. However, engineering was traditionally taught in a content intensive, compartmentalized and prescriptive manner, focusing on numerically deductive reasoning. That approach had little focus on generic graduate attributes expected of the future engineering practitioner. There is an increasing trend to suggest that the professional and the tertiary education institutions are jointly addressing the concerns of this widening gap. For example, The Engineers Australia manual for the accreditation of professional engineering programs [1], issued in 1999, called for a major shift in the way universities train engineering graduates. This demanded the inclusion of generic graduate attributes in all programs, driven by capability agenda which was linked to re-accreditation in 2004. In a way, this was the first formal acknowledgement of the widening gap between engineering education and industry expectations mentioned above in Australia and the strategy adopted to address the issue. Those who have been practicing engineers involved in the graduate recruitments and mentoring schemes around the world no doubt would have great insight into the issue and appreciate the need for such a paradigm shift.

In response to this and also as a part of the general quality assurance process, the faculty of engineering at RMIT University issued, in 2002, a project plan titled: 'Renewal of the Bachelor of Engineering 2002-2004' [2], encouraging project based learning methods in teaching practices at RMIT. The paper discusses the challenges faced and the experiences gained transforming a prescriptive type teaching and learning paradigm in the field of civil engineering design stream aligning to a capability agenda. The curriculum development and the delivery presented here evolved over five years (2002-2007), and the first batch of engineering students benefited from this undertaking is graduating at the end of 2007.

1.2 Essential elements of change

In line with the Engineers Australia recommendations and the faculty directive, the author undertook creating and developing work integrated learning (WIL) environments using project based learning (PBL) methods to align the civil engineering degree program towards the set objectives. Six civil engineering design and analysis courses were created [3], and arranged in a scaffold-like, verticially integrated stream. By immersing students in realistic and team oriented integrated learning activities, analysis and problem solving skills were simultaneously developed with teamwork and communication skills (our core graduate capabilities). As demonstrated here through a sample of project descriptions and outcomes, the author managed to arouse enough curiosity and enthusiasm in them to foster independent learning which, in our view, would encourage them to become reflective practitioners later in their careers [4].

The fundamental difference we made was changing the mind set of the teacher and the student. To get more insight to the teaching and learning philosophy and the course development models influencing this change, the reader is directed to a 2004 publication [5]. The desired paradigm shift was achieved affecting the following three areas,

- Acknowledging, in principle, the problem or project based approach to teaching and learning (PBL) as the preferred method to simulate work integrated learning (WIL)

- Creating student centeredness within both teaching and learning opposed to content and teacher centeredness

- Acknowledging the engineering design as a multi disciplinary, evidence based decision making process where know-how of the whole of design process, negotiated compromise and project delivery capabilities are as equally as important as numerically deductive reasoning.

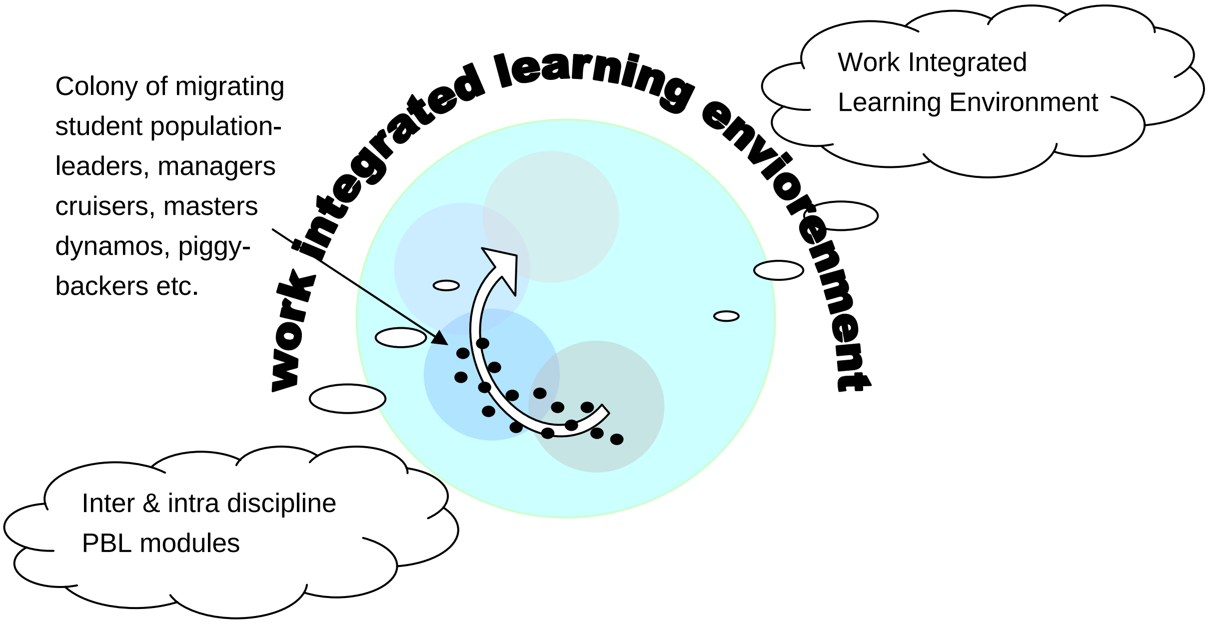

Figure 1: Model Illustration of Paradigm Shift

Figure 1 illustrates, conceptually, the new paradigm, its influence on our student population and our observations in seeing them grow. The important thing in student centeredness is that it is up to the student to reflectively and relatively evaluate how he/she travels within the population. More importantly, this is the best way we can observe them closely at play in a simulated work environment. We are convinced that this way, students have a far better opportunity to get feedback and seek suggestions in order to develop as rounded personalities in professional practice.

We give equal emphasis on the key skills discussed in sections 4.1-4.3 to their comprehension in technical content, in assessing engineering excellence.

2. Work integrated learning and audit readiness

Unlike a couple of decades ago, the current marketplace demands work ready graduates. Therefore the key focus of the forward thinking educational institutions in our view, striving for quality value added delivery, is to ensure students' readiness to work at different stages of their growth, even before they complete their degree.

Work Integrated Learning (WIL) basically refers to the institutions' ability to simulate or mimic workplace process mechanisms and emotional/behavioural intelligence within the constraints of the "class room" or learning environment. Audit readiness here refers to students' ability to be competitive in seeking a placement as early as possible in their undergraduate program. These two objectives require a significant departure from training graduates through text books, tutorials and exams. WIL can vary from designing a simple learning activity, a single course or an entire degree program. Problem or project based learning is increasingly being recognised as the means to that end. In a more provocative approach one can create functioning virtual communities where multi disciplinary student teams work in collaboration to solve simulated real life scenarios. For example, challenging students by engaging them in university capital development project initiatives or university asset management strategies where students offer solutions on competing teams can become a refreshing experience. In many cases we find that the solutions proposed by them are exciting and innovative to the extent that all involved exceed their own expectations.

Audit readiness is a concept we introduced to encourage our students to be confident and upfront in sharing and discussing their work in progress. This concept was introduced in 2004, after careful monitoring of students' lack of confidence and transparency in sharing and discussing their work in progress. I found this reluctance to be not very healthy from a professional education standpoint. Audit readiness and transparency at work are undoubtedly the pillars of quality and safety assurance mechanisms in the building industry. My concerns were further accentuated with the observation that even our best performing students had this reluctance. The concept of audit readiness was therefore introduced to reverse this bad habit, apparently a wrong perception of assessment inherited through traditional education.

To put this succinctly, our endeavour is to transform "student hours" to "engineering hours" as early as practically feasible within the degree program so that our students are highly sought after within the workplace.

3. Teachers' role

Obviously, re-defining teachers' roles and teachers' mindsets is fundamental to shifting an education paradigm, especially in creating student centeredness. This requires significant commitment, resources and bold decision making at the institution level. We acknowledge that the future role of quality educational institutions would need to change from being the "centre of knowledge" to being the "centres of opportunity/experience". In this regard the teacher's role would shift from being the knowledge provider to a facilitator's role in knowledge management. Although the volume of information available and the speed of accessing it have reached phenomenal levels of efficiency, the obsoleteness and the lack of credibility of the knowledge that is within reach are also on the rise. As a result, the teacher's role as the sole guardian of knowledge and the ability to police students' leaning is going out of fashion. In the new paradigm shift, the teacher can command respect only if she/he possesses great motivational skills, vision, reach, can interpret information in a speedy manner and is capable of real time responses to students' enquiries regarding various sources of information. In other words, building education is moving from having a pseudo-static status to a dynamic mode. It is certainly challenging and for many, it is outside their comfort zone. That is where institutional level intervention is required, and adequate resources should be utilised in ensuring that the teaching resources are continually groomed.

4. Curriculum, learning outcomes and performance indicators

In this endeavour work integrated learning (WIL) environments were created in a scaffold-like manner by a vertically integrated stream of engineering design and analysis courses offered from second year through to final year. By immersing students in realistic and team oriented integrated learning activities, analysis and problem solving skills were simultaneously developed with teamwork and communication skills (our core graduate capabilities). As demonstrated here through a sample of project outcomes, the author managed to arouse enough curiosity and enthusiasm in them to foster independent learning which, in our view, would encourage them to become reflective practitioners later in their careers. A brief sampling of curricula and learning outcomes is presented to support the conceptual model illustrated in Figure 1. They are discussed under three key performance indicators which are of great importance to future engineers and highly valued by the Australian building industry. Namely, gaining skills in co-rational decision making, skills in virtual mobility and work ethics are all required to succeed in inter-discipline and intra-discipline engineering services.

4.1 Skills in co-rational design

In a traditional structural engineering design office setting, there were two general process mechanisms evident – the pre-rational approach and the post-rational approach. In a pre-rational design process engineered structural solutions precede the architectural form. This approach is seldom used in current practice. In a post-rational design process architectural form finding precedes the engineering design process. This is probably the most common practice today. In both these traditional approaches process becomes inherently problematic and defeats the purpose as the architect or the engineer is in a reactive mode. This is especially the case when one considers the advances in digital architecture and its impact on engineering [6]. The co-rational design approach, which seems to be the future trend in the building industry, is more synergistic, encouraging the optimal outcome for stakeholders. In fact, from a constructability point of view, such co-rational design teams should also include building services and construction experts as well.

It is believed that during the Roman era the person in charge had a good understanding of engineering aspects such as the strength of material, structural stability, constructability as well as the architectural aspects such as form and aesthetic. Ardill [7] argues that this was the idea on which the “Master Builder” concept was evolved. Although this is still the reality, as discussed above, in practice universities around the world chose to educate and train the student counterparts in these complimenting fields in a number of different discipline specific silos which provide few opportunities for interactive team play. We observe this as a major anomaly which, in our view, warrants attention of the building educators. Our response is to bridge this apparent intra-discipline gap by engaging students and staff in simulated co-rational design projects.

A project based learning module was therefore developed under the theme “long-span and high-rise structures”. There is an ever increasing trend in constructing all-weather multi-purpose venues and tall buildings where state-of-the-art structural concepts and the new generation of materials and analysis tools are involved. Information on such high profile structures, designed and developed by the well known architect/engineer syndicates around the world on a competitive basis, serve as great case studies and learning resource for our students and staff. By engaging students and staff from engineering and architecture, we managed to mimic and enrich their learning and insight into how complementing fields can learn from one another. Figures 2(a) – 2 (d) present a representative sample of student projects developed through this course.

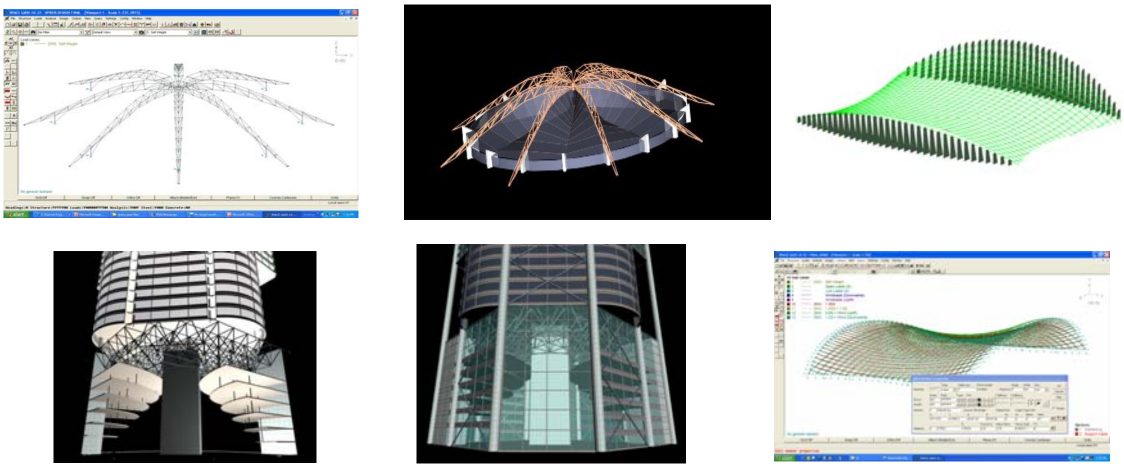

Figure 2: Students Co-rationally Design Long-Span and High-rise Structures

4.2 Skills in virtual mobility

Virtual mobility here refers to gaining communication and collaboration skills in order to transcend cultural, geographic, language and discipline barriers to establish new professional affiliations. We strongly believe our civil engineering graduates need such skills in the future, especially because the building industry is an increasingly globalising market. We have simulated a learning environment to provide experience and the gaining of such skills by engaging them in an internationally collaborated project. In this particular course our students have to engage with their counterparts, whom they have never met, from an international university to conduct a collaborative joint project. Our initial motivation was to provide an opportunity to expose students to international collaboration in order to gain skills in virtual mobility. The author has developed the pedagogy and provided the leadership for this ambitious project initiative, the first of it’s kind, between RMIT University, Melbourne, Australia and the Ecole Spéciale des Travaux Publics du Bâtiment at de L’Industrie (ESTP), Paris. In this course each project team comprised of two RMIT students and two ESTP students. The course, named “sustaining historical structures”, was designed in content to teach structural pathologies and structural forensics involved in extending the life of aging structures. There is limited opportunity for Australian students, being educated in a relatively young country, to investigate and learn about these aspects and how world renowned monuments are normally preserved beyond their designed life. Students from each university have met and communicated in a virtual class room environment over two months in scoping, researching and jointly investigating a monument in Paris of their choice. This was followed by a visit to Paris for two weeks where students were to meet their team members in person for the fist time and to finalise their project and make a presentation to an international academic panel. The idea was successfully launched in the summer of 2004/05 involving nine such teams. A total of 36 students took part from both universities, investigating nine world renowned monuments. All involved - students, the ESTP academic team and the RMIT team – were unanimous in their enthusiasm as to the success of the program. This success was measured in both the quality of the academic program and the interaction between students on an academic and social level. It is refreshing to see how such an ambitious and far reaching project can speed up their process of maturing to international arena.

4.3 Skills in negotiating more than one solution with intra-disciplinary and inter-disciplinary work environs

To our great disappointment, engineering students who are meant to be inherently pragmatic, logical thinkers with excellent numerical and reasoning skills appear to in fact be educated and trained to become "single solution" seekers. It is intriguing to see that within our traditional education paradigm, significant class time, effort and rewards appear to be granted in calculating a "decision", to a third decimal accuracy where as a rough estimate leads to the same outcome. More interestingly, students have no appreciation whether their solution could be acceptable to other stakeholders. It appears to us that we need to provide enough learning experiences within the classroom for our students to learn this reality and when and how to arrest obsession of over engineering, and to demonstrate that although the intent is good such endeavours can be perceived as being inefficient.

We were also keen to establish a leaning environment within which inter-disciplinary skills can be sharpened and students could experience how interface issues can become critical during the design and developing stage of a project. Here inter-disciplinary refers to the major specialization streams within the field of civil engineering such as water resources, structural, geotechnical and project management. This project based learning module was also intended to integrate three years of learning in different course to come together in a major project outcome.

The same group of students were again rallied, this time under the theme "re-imagining Australian suburb" to develop a medium density township with a sustainability focus. Such a task obviously demands a wide spectrum of expertise and skills and needs to work within a well coordinated complex organization structure. The Green Suburb Project is a 30 hectare development project to cater for a population of 2000 with 1-2% growth over a 50 year planning horizon. The project evolves in three phases. The first phase is to engage students through the competition between design consortia for the project, and through them conceiving and developing a master plan. A typical design consortium comprises of a mix of 8-10 students from different specialisation fields. The second phase is to engage students as part of a chosen specialist sub-team engineering and documenting civil works within the consortium; namely earthworks, roads, storm water drainage, and water supply and wastewater treatment. The third phase is to engage students, as individuals, in designing and documenting a building structure of their choice. The key motives are to simulate an environment where students see the "big picture" issues. That is, to experience and resolve typical interface problems for a coherent design, as mentioned, integrating their prior learning in water resources, geotechnical engineering, surveying, project management, transport, and structures. Figures 3 provide a representative sample of student project outcomes achieved through this course.

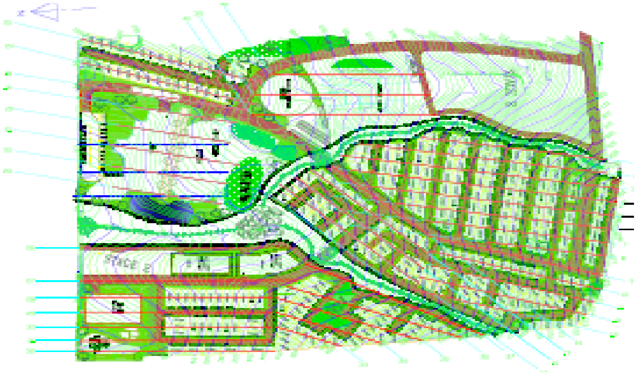

Figure 3: Inter-disciplinary Green Suburb Project Involving Specialising Streams of Civil Engineering

It is refreshing to note that in 2005, we used the tsunami as a catalyst to positively engage students in developing planned townships for tsunami affected regions. Instead of "Re-imagining the Australian suburb" students were engaged in developing a master plan for a new township to replace washed away unplanned cities in the region including in Sri Lanka. This demonstrated the strength of using a "theme" as a backdrop in curricular development, where real engineering issues can be taken on board with least effort. I was amazed at the vigour and commitment students showed in completing and documenting the task in 2005. The most interesting aspect was how swiftly students adapted themselves to think globally and their sense of a 'duty of care'.

One intra-disciplinary example is presented under the co-rational design section. Figures 4 illustrate a recently concluded intra-discipline pilot study where a team of thirteen students from engineering, social planning, architecture and management came together to propose a modern, responsive community centre for the Victorian Growth Authority, which was ultimately well received and commended by the client.

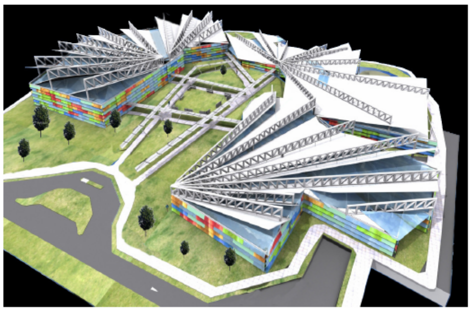

Figure 4: Intra-disciplinary project involving engineering, architecture, social planning and management disciplines.

5. Conclusions

- The tertiary education paradigm is currently being revived in many universities around the world which are aligning to a capability agenda. The need to create Work Integrated Learning environments in professional education is gaining recognition and Project Based Learning is regarded as the best form of delivery of a capability driven agenda. However, it must be emphasised that the intension is not to undermine basic and fundamental discipline specific skills but to enhance its application by creating exciting learning environments simulating the real work place. In other words, content is taught within the context of processes, emotional and behavioural patterns of the real workplace, providing students the opportunity to experience first hand.

- The skills needed by the quality educators and the future graduates for success are changing rapidly and can no longer be regarded as pseudo-static.

- Knowledge is widely and freely accessible. Training opportunities and experiencing first hand how to apply know-how in the working life are the reasons for students attending educational institutions. This can be achieved while safeguarding and nurturing tertiary institutions' traditional position as the institutions of scholarly learning.

Abstract

Dissertations are used in many disciplines as the flag ship document for honours graduates. The skills developed help in completing work in other modules and are valued by potential employers. Bespoke research methods modules are used in some degree programmes to foster improvements. It could be argued that built environment dissertations still lack rigorous analysis. Students who have a dislike of mathematics will avoid quantitative techniques that involve statistics. Students who take a qualitative approach rarely do little more than content analysis. The methodology for the study is a literature review and survey of students in two segments (i) those who have completed a research methods module and about to embark upon dissertations (level two students), and (ii) those who have completed their dissertations (level three students). There were 50 replies. The survey measures 'student perception of success of learning outcomes' in research methods and dissertation modules. Overall mean scores were 68.4% for level two students and 72.1% for level three students, indicating 'good to very good' achievement in learning outcomes. The study finds that a research module is highly valued by most students. There are several areas where students need to improve, including analytical skills, time management, citing techniques, and the use of hypotheses and variables. It was found that tutors sometimes give contradictory advice about research methodology.

Keywords: Research methods, dissertations, analysis, teaching

1. Introduction

In the early 1990s, there was concern in the built environment that student dissertations were not of the appropriate quality. Holt [1], Fellows and Liu [2], and Naoum [3] published their first editions of research methodology texts for construction students in the late 1990s. Consequently, dissertations improved, and consensus was established about structure and content. Historically, students have not used robust analytical techniques, and academics did not agree on what constituted a 'good' dissertation. Dissertations skills 'spin-off' into other modules by encouraging students to take a more analytical approach to all their studies, and also to ensure that all material used is evidentially based. Some degree programmes prepare students for dissertations with formal teaching in the dissertation module itself, whilst others prefer to nurture research skills in all modules. There has been a trend to increase the weighting of final year dissertations on some programmes, perhaps constituting as much as one third of a final year programme. A case study which illustrates how dissertations are dealt with at the University of Ulster, Jordanstown, is articulated by Taylor [4]; research methods and dissertation are integrated into one module worth 40 credit points. Amaratunga and Senaratne [5] state that there is a need to enhance student learning and research skills. Students often avoid statistics to analyse data such as those illustrated in Ruddock [6]. Since there can be some complexity in understanding the intrinsic meaning of inferential statistical tests, there may be a danger that those students who do take-on the statistical challenge may not have real understanding of their results. Qualitative analysis is often limited to content analysis, and does not demonstrate the rigour illustrated for example by Taylor and Bogden [7]. It is probable that few construction undergraduate programmes use sophisticated software programmes to analyse qualitative or quantitative data. Such programmes are used in other disciplines, for example QSR International qualitative software XSight and NVivo7, used at the University of Southampton in the marketing profession [8], and SPSS quantitative software as illustrated by Bryman and Cramer [9]. There may be a feeling by tutors that they are unnecessarily complex for construction. It is unlikely that students will have the resource to take-on both quantitative and qualitative analytic methods within their work; that is triangulation or mixed-methods approach as suggested by Somekh and Lewin [10, p. 274]. Consequently as Strauss and Corbin state [11, p. 28] without at least appreciation of both, there is a danger that students will take into their careers 'dogmatic positions … in favour of either'. There is probably a tendency for students to design objectives around a data collection exercise and analytical method they are comfortable with, rather than, as Patton [12, p. 585] states 'to appropriately match methods to purpose'. Real understanding of the concepts of reliability and validity by students is arguably a challenge still to be addressed. Dissertations are often weak in the latter sections, because students do not understand the importance of well developed conclusions, and they also run out of time. A survey is undertaken of students who have completed their dissertations and those who are about to embark upon the process. The study explores whether research methods modules, in preparation for dissertations, are of real value, and seeks areas for improvement.

2. Literature review

Holt [1], Fellows and Liu [2], and Naoum [3] illustrate loose consensus about structure and chapters for dissertations, thus (i) introduction, (ii) review of theory and the literature, (iii) description and defence of methodology employed, (iv) data analysis, results and findings, (v) discussion and interpretation of results and findings with the literature, and (vi) conclusions and recommendations against objectives. However, Holt [1], and Naoum [3, p. 132] place little emphasis on the need for a separate discussion chapter.

Language used to describe research goals is consistent, that is aims, research questions, objectives and hypotheses. Aims and objectives are always stated as being key, and Fellows and Liu [2, p. 46] suggest one aim and three objectives. There is agreement that research in construction is often problem based, and this is supported by Creswell [13, p.74] and Silverman, [14, p.5] in the fields of human and social sciences. However, some terminology in texts is variable, for example according to Hart [15, p. 9] the first part of a dissertation should be a rationale; Holt [1, p. 9] asks for a broad discussion, Naoum [3, p.14] suggests a purpose, and Fellows and Liu [2, p. 9] a proposal. Also, there does not appear to be consensus about the rigour of analysis that should be present in undergraduate dissertations. This can stem from emphasis which is (or which is not) placed on the need to identify variables, explain influence between them and formulate hypotheses. Blaike [16, p. 35] states that this analysis is the ultimate objective in social research and is the most complex. Naoum [3, p.46] states that if sample size is small, relationships can be discussed intellectually, 'which is acceptable for the level of students reading this book'. But Holt [1, p. 100] states that a basic grasp of statistics is a pre-requisite to almost any successful dissertation. Fellows and Liu [2, pp. 9 and 28] argue that sometimes qualitative research is assumed to be an easy option for persons who do not excel in mathematical techniques and that qualitative approaches are actually considerably more difficult than quantitative, requiring a lot of filtering, sorting and manipulations. The danger is that students who undertake qualitative approaches do not do rigorous analysis, and that dissertations become what Holt [1, p. 15], describes as simply a comprehensive assignment. It is not helpful that construction research methods texts do not give examples of robust qualitative analysis, particularly that is in the context that as Creswell [17, p. 140] points out 'undoubtedly, no consensus exists for the analysis of … qualitative data'. Creswell [13, p. 4] also states that the issue is not quantitative or qualitative, but more how research practices lie somewhere on a continuum between the two.

The need for reviews of theory and literature to be critical is emphasised in all texts. Similarly, it is agreed that conclusions should be written against aims and objectives, and Holt [1, p. 126], reminds us that the length of time to compile them can be substantial in comparison to the volume of work produced. Holt [1, p. 29] and Naoum [3, p. 164] give typical programmes or work schedules to assist students with their time management.

Reliability and validity are arguably very important issues for students to grapple with, otherwise the whole basis of their research can be flawed. It is acknowledged they can be very difficult concepts to understand and particularly to apply to one's own work. Fellows and Liu [2] examine both; however Holt [1] and Naoum [3] are both silent. It is therefore questionable whether it can reasonably be expected that undergraduate students should display knowledge of reliability and validity in their dissertations.

3. Methodology

A questionnaire was used to collect primarily quantitative data. Useful qualitative information was obtained from a section at the end of the questionnaire under the heading 'please add further comments … constructive criticism welcome'. The population for the study was built environment students studying BSc (Hons) programmes in UK universities. The sample was one of convenience, that is full and part-time construction students attending The University of Bolton, UK. They were studying either Architectural Technology, Building Surveying, Construction Management or Quantity Surveying. A key feature of student intake was that many are mature students with non-standard backgrounds. This sample was in two segments: (i) level two students who had just completed a level two research methods module (10 credits) as preparation for their dissertations, and (ii) level three students who had successfully completed the research methods module and subsequently their dissertations (30 credits). Questionnaires were distributed by post to home addresses with pre-paid envelopes. There were 52 students in segment (i) and 50 students in segment (ii); these generated 23 and 27 replies respectively. The questionnaires sent to each group or segment were of a similar structure. For each group there were five questions collecting data about the following subject variables: degree discipline, age, whether studying full or part-time, gender and whether qualitative or quantitative analysis was used in their documents. A basket of statements was used to measure the variable labelled 'student perception of success of research learning outcomes'; there were 28 statements for level two students and 30 statements for level three students. A Likert scale as illustrated by Oppenheim, [18, p. 196] was used, whereby students were invited to indicate whether they strongly agree, agree, uncertain, disagree or strongly disagree with each statement. The five possible student replies were scored in the range of 0 to 4, with 4 indicating a positive perception of success and summed totals were calculated from the basket of questions. The minimum score was therefore 0 for level two and three students, and the maximum score 112 for level two students and 120 for level three students; results were converted arithmetically to a percentage scale, whereby for example a score of 60 out of 120 became 50%. Seven questions were reversed in the survey to improve the internal reliability of the question scale, but for the purposes of clarity in table 3 all questions are written in the same direction e.g. Q. 24 '*I am sure about how to cite other work Harvard Style'* was actually presented to students as '*I am still uncertain about how to cite other work Harvard Style*' [18, p. 197].

Inferential tests were undertaken to detect for differences in the perception of success scores for the five subject variables. Tests of internal reliability were undertaken; the p value was set at 0.05. Actual student marks from tutors were considered to help improve validity of the study.

4. Quantitative Results and Analysis

Table 1 indicates the profiles of those students who responded to the survey. There are approximate equal numbers in each of the four disciplines. The most popular method of analysis is quantitative for level two students, but qualitative for level three students. The gender profile is typical of that in the built environment in the university; that is 84% male, 16% female. It is perhaps to be expected that the mean age of full-time students at 25 years is below that of part-time students at 30 years.

Scoring scales used to convert the qualitative student responses (disagree/agree etc) into quantitative data are shown in table 2. Percentage scales are used to express the results with greater clarity, and adjectives or labels are also ascribed to assist summative qualitative judgements to be drawn.

Table 3 details all statements used in the main research instrument. Statements are listed in the order of highest scores for level two students in measurement of the variable 'student perception of success of research learning outcomes'.

Table 1: Demographic data

Level two students, n = 23				
Discipline	Architectural Technology 6	Building Surveying 7	Construction Management 3	Quantity Surveying 7
Type of analysis	Quantitative 14	Qualitative 5	Other4	
Gender	Male 20	Female 3		
Mode of study	Full-time 10	Part-time 13		
Mean age	25 years			
Level three students, n = 27				
Discipline	Architectural Technology 8	Building Surveying 7	Construction Management 8	Quantity Surveying 4
Type of analysis	Quantitative 6	Qualitative 12	Other 9	
Gender	Male 22	Female 5		
Mode of study	Full-time 11	Part-time 16		
Mean age	30 years			

The overall mean scores of 68.4% for level two students and 72.1% for level three students indicate good to very good achievement in measurement of the variable 'student perception of success of research learning outcomes'. The research methods module at level two was highly valued by students (item 1), and graduates found the dissertation process challenging (item 6). In the context that the research seeks to identify areas for corrective action, inferences are sought and interpretation undertaken below for all measures of success that fell below the mean score of 60% (those statements indicated by italics in table 3).

Items 22 and 23 indicate that students were not able to use quantitative or qualitative analytical tools appropriately at the end of their level two studies. This is important because a key learning outcome in the research methods module is that students should be able to use 'robust' analytical tools in their work. Also historically, external examiners on the programmes have criticised dissertations for their 'lack of analysis', and to the extent that analysis was present in dissertations it was superficial and not academically rigorous. There is reluctance for some students to grasp the challenge of mathematics or statistics in their analysis. Similarly robust qualitative techniques are avoided. Whilst on the one hand scores of 59.7% and 58.7% from table 4 for level two students may be disappointing, it is pleasing that student skills improved (70.3% and 72.2%) as they undertook further more in-depth analysis in their dissertations.

Table 2: Scoring scales

Possible student response	**Allocated score**	**Allocated score converted to a percentage scale**	**Adjective / label to describe achievement against learning outcomes**
Strongly disagree	0	0%	Highly unsatisfactory achievement
Disagree	1	25%	Unsatisfactory achievement
Uncertain	2	50%	Satisfactory achievement
Agree	3	75%	Good to very good achievement
Strongly agree	4	100%	Excellent achievement

Scores for item 24 (citing work Harvard Style) are 55.4% and 77.7% for level two and three students respectively. The improvement between the levels is noted, but both scores can be considered disappointing. Citing Harvard style is a concept introduced in a communication studies module at level one; it is emphasised to students that citing other work with precision is a fundamental concept underpinning academic work. It may be expected that even students who graduate with third class honours will be able to cite correctly.

Being able to include a clear hypothesis in work (item 20, 64.1% and 58.3%) and the identification of variables (item 25, 51.0% and 59.2%) are concepts that many students find difficult to grasp, and are reluctant to conquer. Many students who are able to give examples of variables cannot identify which are the independent variables (IVs) and which the dependent variables (DVs).

There are two items Nos 26 and 28 related to working independently and working in teams. Working independently scored only 31.5% and working in teams scored only 34.7%. It is observed that it would be excellent for students to work almost entirely independently and obtain excellent dissertation scores. However this is rare; those students who work very closely with supervisors often obtain better marks than those students who do not. The level two research methods coursework is a task set for pairs of students; many students do not like this on the basis that they become reliant on colleagues who may be less capable, and part-time students particularly can be difficult to get hold of especially when they are working in busy full-time jobs.

Table 3: Survey statements: mean scores for 'student perception of success of research learning outcomes'. High mean scores indicate high perception of success. Statements in italics indicate results below 60%

Item No	Basket of statements to measure the variable 'student perception of success of research learning outcomes' – possible responses strongly disagree, disagree, uncertain, agree, strongly agree	Mean % scores level two students	Mean % scores level three students
1	I found that the research methods module was valuable in helping me to prepare for my dissertation / coursework	86.9	74.0
2	I found that the dissertation gave me good insight into the world of research	84.7	76.8
3	I became aware of literature sources that otherwise I would not have known about	82.6	75.0
4	I understood that establishing clear objectives is a key premise for good dissertations	81.5	88.8
5	I was able to develop my skills in searching for information using electronic and other means	80.4	83.3
6	I found that the dissertation / coursework was really challenging	78.2	86.1
7	I understand the need to write conclusions against all my objectives	78.2	80.5
8	I was able to develop my knowledge of research methodology	78.2	78.7
9	I understand the limitations of my dissertation in the context of the 'real world'	78.2	78.7
10	I found the research methods class notes very useful	77.1	70.3
11	I was able to appropriately manage my own time in completing my work on time	76.0	75.9
12	I developed the skills necessary to write a literature review.	73.9	80.5
13	I was able to develop ideas about how to collect data	73.9	73.1
14	I understand the relationship between the aim, objectives and hypotheses	71.8	83.3
15	I was able to develop my specialist knowledge in my chosen topic area	71.7	75.0
16	I am very proud of my dissertation / coursework	65.2	75.9
17	I was sure what the concept of reliability means in the context of research	64.1	73.1
18	I found the key recommended text book by Naoum very useful	64.1	72.7
19	The modules helped me to develop my writing skills	64.1	72.2

Table 3 (continued):

20	*I was able to include a clear hypothesis in my dissertation / coursework*	*64.1*	*58.3*
21	I was sure what the concept of validity means in the context of research	61.9	72.2
22	*I had sufficient knowledge to be able to use quantitative techniques (numbers) in my dissertation / coursework*	*59.7*	*70.3*
23	*I had sufficient knowledge to be able to use qualitative techniques (words) in my dissertation / coursework*	*58.7*	*72.2*
24	*I am sure about how to cite other work Harvard Style*	*55.4*	*77.7*
25	*I was sure how to identify independent variables (IVs) and dependent variables (DVs) in my dissertation / coursework*	*51.0*	*59.2*
26	*I preferred to work independently in my dissertation / coursework without much help from my tutor*	*31.5*	*46.3*
Questions only to research methods students			
27	I was able to concentrate, to an appropriate extent, on research methodology in my coursework, rather than learn about the specialist subject area that I chose	68.4	-
28	*I would prefer to complete the coursework alone rather than working in pairs*	*34.7*	-
Questions only to dissertation students			
29	I think research has application to practice in the construction industry*	-	74.0
30	I was able to get further appropriate advice from my dissertation / coursework tutor about research methodology	-	61.1
31	*I found that tutors gave contradictory advice about research methodology**	-	*54.6*
32	*I think I learned more about research methodology in my dissertation than I did about my specialist subject area*	-	*44.4*
Mean percentage scores; 'student perception of success of research learning outcomes'		68.4	72.1

Tutors giving contradictory advice about research methodology is clearly a problem (item 31, success score 51.6%). It is expected that approaches to research can be different, and indeed the authoritative texts can be contradictory. Tutors may have their own preferred methods they may encourage students to use, and even discourage students to use some methods of analysis that they are not familiar with. Not all academics are researchers; some are 'merely' excellent ex-practitioners with a flair for teaching their own subject specialism. But as these practitioners become embedded in academic communities, there may be a need to ensure that departments provide seminars and staff development opportunities to ensure consensus exists as far as is possible. Finally item 32 (success score 44.4%), learning more about research methodology than about specialist subject areas, can be viewed in two ways. If the key learning outcome in the dissertation is to develop research skills that are transferable into all aspects of the workplace, this score is unsatisfactory. If however, the key learning outcome is to become an expert in a narrow specialist field, then this score may be construed as being satisfactory. In the context of this paper, the score is considered unsatisfactory, and it does warrant further discussion amongst academics.

Unrelated parametric ‘t’ tests were used to detect if differences occurred in the perception of success scores for the five subject variables (degree discipline, age, whether studying full or part-time, gender and whether qualitative or quantitative analysis was used in documents.); no such differences were found, and for all tests $p \geq 0.05$ (the lowest p value was 0.10). Tests of internal reliability on the basket of questions were undertaken, whereby each individual question was correlated against the total score for the basket. Spearman’s non-parametric correlation coefficients were calculated; the range for these coefficients was 0.40 to 0.90 and in all cases $p \geq 0.05$. It is therefore argued that the questionnaire was internally reliable.

The mean scores for the research methods module and dissertation for 2006/07, obtained from the university database, were 54.7% and 58.10% respectively.

5. Qualitative results and analysis

Part-time students have a one year gap between finishing the research methods module and starting dissertations. It was felt that this gap was not desirable, since students preferred to start their dissertation with research methodology fresh in their minds. Part-time students also felt that the period of time to complete their dissertations (September to March) was too short. Given that programmes are taught in semesters, level two students thought time to complete the research methods coursework was too short

Students reflected that they tried to do too much in the time available and time management was identified as being the most challenging aspect of completing dissertations. If students fell behind in their dissertations, this had a knock-on effect for their work in other modules. Interim targets and meetings with supervisors were thought helpful, particularly in development of dissertation problems and establishment of objectives. Some tutors were strict in the supervision process, setting tough interim targets for students and insisting on regular meetings. Other tutors were more laissez-faire. Some students emphasised that to maintain enthusiasm there is a need to select topics that students are really interested in. Collecting data was thought to be difficult, and it was suggested this should be done at a very early stage in the process.

The research methods coursework is set as a ‘pilot’ for the dissertation; students select their own problems to investigate. Some students felt that alternatively they should be ‘merely’ given sample data sets to analyse. Completing the research methods coursework in pairs was thought by many to be a ‘bad idea’; logistical problems and falling out between students being common. Working in pairs was also noted as being frustrating at times and some students completed the majority of the work whilst their partner did very little. There was concern that marks suffered as a result of poor performance by colleagues. However, some students did recognise paired work as being challenging and good preparation for inter-disciplinary working in industry.

Most students spoke very positively about the research methods module. They found it interesting, challenging and valuable preparation for the dissertation; one student questioned whether alternatively it would be adequate to have two or three lectures at the commencement of the dissertation process, and replace the research methods module with something more practical like land surveying. Also, one student reflected that more was learned about methodology in the research methods module, than in the dissertation. There was a request for more one-to-one tutorials within the module.

Differing and contradictory advice from dissertation tutors was again highlighted as a problem; for example there are different views on the length of literature reviews. Students found contradictory advice confusing and asked for a 'level playing field'. In one case a tutor struggled to advise a student about the design of a methodology that would meet the objective. There was a request for a university proof reading service, and for more copies of paper documents in the library rather than reliance on electronic sources. Some architectural technology students asked that the dissertation be replaced with or integrated with a design project.

The department has a detailed 'house style' for type font style and size etc, e.g. Aerial 12, 1 ½ line space. It is inconsistently applied, and some tutors refer to house style as Aerial 11, whilst others state Times New Roman 12. Also tutors give contradictory instructions about how to cite Harvard Style; and this is despite there being a university library booklet which seeks to promote consistency. More instruction and emphasis on referencing was requested at year one.

One student commented that the dissertation was the 'most joyful module', and wrote very positively about life skills that had been developed. Another looked forward to developing the dissertation idea into a PhD.

6. Conclusions

Trow in Bulmer [19, p. 15] wrote that 'every cobbler thinks that leather is the only thing … scientists have their favourite research methods … but we should try to be less parochial than cobblers … and get on with the business of attacking our problems using the widest array of conceptual and methodological tools'. Not all dissertation supervisors have the knowledge and skills to direct their students to a wide array of tools. It is for debate whether universities should seek to equip academics in this way, or if alternatively it is just a political fact of life that some academics are like cobblers, and students need to be mindful of this when selecting their supervisors. Similarly, it is for debate whether universities should seek to impose rigorous regimes on the supervisory process, or alternatively leave it as a matter for tutors and students to come together (or not) in a manner that reflects their own working preferences.

Time management is clearly a big issue for students. It may be possible for part-time students to do their dissertations over three semesters rather than two. There is a need to emphasise the need for personal plans or work schedules, and ensure that progress is monitored against them. More tuition work is needed in the areas of (i) citing Harvard style, (ii) identification of variables, (iii) house style, and (iv) analytical techniques. There is the possibility that working in pairs for the research methods module could become optional rather than compulsory. The issues about whether students should employ rigorous analytical tools (whether they be qualitative or quantitative) and specify variables etc, is perhaps best solved by ensuring that only students who do these things get the better marks.

An appreciation of the real life limitations of research can only be understood with good underpinning knowledge about the concepts of reliability and validity. The students report that they have 'good' knowledge in these fields (table 3, items 17 and 21, 64.1%, 73.1%, 61.9% and 72.2%). It is doubted that such high scores would be allocated by tutors to students; more work is required in this area. Further, it is argued, that only students who do demonstrate understanding of these concepts should be awarded marks in the first class category.

The overall mean scores of 68.4% for level two students and 72.1% for level three students indicate good to very good achievement in measurement of the variable 'student perception of success of research learning outcomes'. It is recognised that student perceptions about success in achieving learning outcomes is not the same as actual success; a more valid measure is obtained from tutor marks. The tutor marks for 2006/07 were 54.7% and 58.10% for the research methods module and dissertation respectively. These marks are comparable with student performance in other modules. It is argued that using a research methods module at level two improves student performance in dissertations. It is recommended that further work is undertaken to support this position, using samples drawn from more UK universities. Views should also be sought from tutors.

Abstract

The changing market for education in the UK and the growth of the global village has created needs and opportunities to seek alternative business for the education deliverers in the UK, and elsewhere.

This paper reviews the development of a collaboration between a post-1992 university in the UK Midlands and a university with a similar profile in Hong Kong to deliver a top-up programme to BSc (Hons) Construction Management and how this has led to the introduction of a Masters programme with the same partnership.

It considers the reasons for the relationship to be sought and the design of the programme delivered. A review of the internal validation process prior to first delivery, the professional body accreditation of the programme and the implications of this to achieving a viable demand.

The partnership has been in place since 2000 and has had to adapt to changing educational and political environments, greater competition in the local market, changing student cohort expectations, staff illness and travel restrictions (most notably due to the SARS epidemic and a virtual travel embargo on visits to the far east). The paper identifies key events during the partnership and how it has developed to meet these changing circumstances yet remain viable. It will also address how the experiences have influenced the introduction of a Masters programme. The paper concludes with best practice recommendations to assist other institutions in identifying opportunities for similar mutually beneficial partnerships.

1. Introduction

The development of a programme of study overseas was one strand of a School-wide strategy made by the School of Engineering and the Built Environment (SEBE) at the University of Wolverhampton (UoW) some ten years ago. From this strategy a collaborative programme was developed that has been delivered successfully for the last eight years.

UoW has long standing links with a numbers of overseas institutions in various countries including City University in Hong Kong (CityU). It was through an existing business relationship with CityU that areas of mutual interest were identified and potential collaborative opportunities considered. One such development was the introduction of a BSc (Hons) Construction Management top-up programme for graduates from sub-degree programmes at CityU.

The programme has been running successfully since 2000 but has not been without its challenges including internal validation and external accreditation processes, growing competition in the Hong Kong HE sector, resource implications for delivery overseas, international travel vetoes and a QAA collaborative links audit.

The experiences of the design, implementation, growth and development of the programme have been recognised within the university and are being fed into ongoing and planned collaborative links with both UK-based and international partners.

2. History

The commencement of the development of an overseas programme is as much about the relationships between the people that develop them as it is between the institutions themselves [1]. Any proposals for working together tend to evolve as the relationship builds between the staff and they develop as each institution gets to know the other better. The chances to identify opportunities for mutual benefit are more frequent and more easily exploited in the spirit of cooperation rather than by commercial necessity. The relationship between SEBE, City U and their sister organisation the School for Continuing and Professional Education (SCOPE) has developed in this way.

The scheme initially envisaged was one where Diplomats from the host institution's Diploma programme would feed into a programme of study consisting of three semesters to achieve a full honours degree in the UK.

This unfortunately was not successful. At a time when the construction industry in Hong Kong was particularly buoyant it was not possible to achieve a viable recruitment for this type of programme. It was necessary to consider alternative delivery options that met the requirements of students in Hong Kong and at the same time satisfy quite stringent quality assurance processes in the UK. Rethinking of the way the programme was to be delivered was necessary to enable recruitment to progress and it need to be recognised that fulltime delivery on a viable basis was unlikely to be achieved hence a part time programme of study was considered.

There were various obstacles to the development of this cooperative programme, not least of which is the intensive work environment in Hong Kong. There were also issues of Quality Assurance, QA, and agreement over memoranda of understanding and cooperation, which needed to be established to formalise the relationships.

2.1 Developing the relationship

UoW had an existing relationship with CityU and SCOPE as a result of previous international marketing initiatives; an additional initial contact was made between staff at each of the institutions through mutual contacts in HK. Through these two initial contact routes and meetings at various levels within the management of the departments the possibility of a joint initiative were discussed. The choice of the programme to be delivered was largely the product of fortune and of the existing relationship between the staff at the respective institutions.

Once the initial ideas had taken shape the three departments (SEBE, CityU and SCOPE) worked together to agree a viable structure and format for the programme that would satisfy both UK and HK internal and external requirements. All parties were involved at all stages of the design and validation of the programme through face-to-face meetings, via email, post, telephone conversations and videoconferences.

Throughout the years that the programme has run, whilst there have been changes of management and administrators in each of the organisations, communications between the parties have been given the highest priority to ensure that the good working relationships continue.

2.2 Identification of the market

In initial discussions CityU identified, through surveys with their existing cohorts and alumni, that students on the Higher Diploma (HD) in Building Studies would be interested in gaining an honours degree if a 'top-up' programme were made available and that sufficient numbers of students would be willing to travel overseas for 3 semesters to undertake their study in the UK. Despite such a programme being made available at UoW for a September 1999 start and approximately twenty students applying to join the programme none accepted the offers made and the programme did not run. A rethink was necessary!

Additional market research was conducted in HK which showed that there would be sufficient numbers interested in studying in HK in a part-time mode to make the programme viable. CityU identified that an initial cohort of 50 students could be expected with similar numbers in future years.

2.3 Competition

At the time the programme was first considered CityU was one of only two institutions in HK to offer full time degrees in building/construction management recognised by the Hong Kong Institute of Engineers; the proposed programme would be the only part time first degree programme in HK. The market research also showed that there were no similar part time degrees with professional recognition in the locale. The only way in which students from HD programmes in HK could further their studies was by going abroad or taking a diploma programme at HK University to bridge to their Masters degree in Construction Management.

2.4 PR China: handover and influence

In 1997, the former UK colony of Hong Kong had become the Hong Kong Special Administrative Region when sovereignty was returned to the Peoples Republic of China. Schooling, at all levels, within HK has traditionally been delivered in English and the primary language of business was English. Since handover, whilst English is still the main language used in schools and universities other languages have more prominence particularly Putonghua, the official Chinese language [2] and Cantonese, the dialect of Hong Kong and the southern Chinese province of Canton.

Over the time that the programme has been delivered in HK there has been a change in the standard of the students' English and whilst students must achieve an identified qualification in English their confidence in speaking in English in the classroom environment has diminished. This is thought to be due to less English being used in the schools, homes and workplaces.

A second influence of PR China is the increased number of students who are required to travel and work in the mainland for weeks at a time and this impacts upon attendance at taught sessions on the programme and applications for leave of absence and deadline extensions for submission of work.

3. Original Model

Delivery of programmes overseas can be expensive to operate. Taking due consideration of the working culture in Hong Kong which is highly intensive a model needed to be developed for the recruitment of part time students.

The original validated programme (for full-time delivery in the UK) was used as the basis of the design for the HK based programme. However, a formal relationship needed to be established with SCOPE to enable the programme to run. In order to create a viable product that would be financially sustainable for both SCOPE and SEBE a collaborative relationship needed to be created.

Collaborative working is not simply the delivery of a UK programme in an overseas institution using their administrative support. True collaboration needs to utilise all the resources of both institutions in the best and most efficient way. Early discussions on the division of workload suggested use of UK based lecturers, HK based tutors and HK based administration. Local tutors were seen as an effective way of contextualising the content of the UK programme to the overseas situation whilst being able to provided weekly student contact through tutorials.

SEBE had an overseas programme running in Singapore which used an intensive delivery mode to allow delivery of the modules whilst minimising the impact on UK students. This model was used as the basis of the design of the HK programme.

Programme structure

In preparation for the validation and accreditation of the UK based top up programme mapping of the Hong Kong HD programme was undertaken against the UK BSc (Hons) in Construction Management programme to establish where there were equivalences in studies at levels 1 and 2 and where additional subject areas were needed. This mapping was used in designing the part-time HK based programme and it was established that a top up programme consisting of four part time semesters would be sufficient to deliver the modules needed to achieve the honours award.

HK students were required to study 3 modules at level 2 (45 credits) and a full level 3 programme (120 credits). The level 2 modules were delivered in the first semester with the level 3 modules being delivered over the remaining 3 semesters (Figure 1). During the first two iterations students were allowed to vote on which of the two options they wanted to study, only one of the two was delivered.

Programme structure

Semester 1	**CN2248** Construction Technology 3	**CN2251** Integrated Project	**MN2236** Construction Management 1
Semester 2	**CN3331** Construction Technology 4	**MN3301** Construction Management 2	Option - one from: CN3334 Fac Man(O) CV3303 Plant Man(O)
Semester 3	**CN3337** Dissertation 1	**CN3332** Contractual Procedures 2	**CN3338** Development Economics Project
Semester 4	**CN3337** Dissertation 2	**AC3324** Construction Finance	

Figure 1. Original Programme structure for Part-time delivery in HK [3]

3.1.1 Intensive delivery mode

At the start of each semester there was a three-week period when each taught module was delivered by the UK lecturer. Lectures consisted of six 3 hour long sessions between Sunday and Saturday (Sunday 2 sessions; Monday, Wednesday, Friday: 1 session each day starting at 6.30pm; Saturday 1 session starting at 1.30pm); tutorials with local tutors were organised between semester weeks 4 and 11 (2 hours per module per week); UK lecturers returned for 9 hours taught sessions (3 hours on Monday, Wednesday and Friday) in weeks 12 – 14 with examinations being taken in week 15.

UK lecturing staff were also responsible for the provision of all teaching and assessment materials (including tutorials) as well as for grading all assessments (coursework and examination). SCOPE had responsibility for all administrative functions in HK and the appointment of local tutors via CityU. (All tutors were interviewed by the UK programme leader and subject to approval by UoW QA procedures).

A minimum of 1 week prior to the start of each semester the UK lecturers provided their module study materials including module guides, lecture handouts and coursework assessment materials. These materials were equivalent to those delivered in the UK and made available via SCOPE and through the UoW VLE (the Wolverhampton On-line Learning Framework, WOLF).

Assessments were returned to the UK where they were graded by the UK module staff; feedback and grades were returned to HK via SCOPE.

4. Revisions

4.1 Revisions to the programme structure

In April 2002 the programme was reviewed, as part of the ongoing quality procedures at the UoW. It was established that the intensive delivery mode together with the long working hours culture in Hong Kong was disadvantaging the students. People working in the construction industry in Hong Kong work for five and a half days per week, typically starting at 07:30 and finishing at 19:00. In contrast to the UK, Hong Kong construction managers tend to be site based. Feedback from students and staff suggested that students tended to struggle with the number of modules studies, particularly in the final semester when they were completing their dissertation, and there were concerns about the communication and report writing abilities of the students, which was particularly noticeable in the dissertation submissions and results.

As part of the review the award team also looked at extending the entry opportunities to students with HD qualifications in Surveying and Architecture, to students with equivalent qualifications from all HK institutions and to students with Associate Degrees (AD) in Building. Due to the proven success of the programme the UoW’s internal QA processes approved the business case put forward to extend the entry to these additional groups of students.

In order to address the concerns regarding the students’ report writing abilities an additional module was validated for study in semester 1 (*Communication and Research Methods*) and the programme was extended to 5 semesters to reduce the student workload (Figure 2). The revised programme allowed for Semester 3 to run during the summer months and thus the overall time from start to completion on the programme did not alter. (The programme was also fully prescribed: Plant Management was no longer offered as an option).

Semester 1		
Communication & Research Methods	Integrated Project	Construction Management 1
Semester 2		
Construction Technology 3	Construction Management 2	
Semester 3		
Construction Technology 4	Facilities Management	Dissertation
		Introduction sessions
Semester 4		
Contractual Procedures 2	Development Economics Project	Dissertation
Semester 5		
Construction Finance	Dissertation	

Figure 2. Revised Programme structure [4]

5. Quality Assurance

Quality assurance processes within the UoW required that the UK lecturing staff retain control over the preparation and delivery of lecture and tutorial materials and were responsible for all aspects of the design and grading of assessments. This meant that staff who teach the modules in the UK were also responsible for delivery in HK. This requirement had implications on the home programme as timetable requirements meant that lectures had to be covered in the UK when staff were in HK. These ‘overlaps’ were normally covered by visiting lecturers, colleagues or pre-set study weeks.

5.1 Assessment boards

The HK programme has to fit within the UK assessment board structure with module results being presented to subject boards, in the UK, and student transcripts being presented to progression and award boards, again in the UK. The HK programme reports module results to January, June and August subject boards in Wolverhampton and progression and awards to an overseas board convened in September (to cover students in Singapore and HK).

5.2 External examiners

It is also a QA requirement that the external examiner for the UK programme takes responsibility for the HK programme to ensure equivalence of provision and comparability in results. There have been three external examiners who have each visited HK, met with students, overseen taught sessions, by both UK and HK staff, and overviewed the assessment processes. Feedback from all three examiners has always been positive with identification of good practice for dissemination within the school, the university and the wider HEI community.

5.3 Re-validation 2006

The HK programme was internally revalidated in 2006 and was brought into line with the 2004 revalidation of the UK programme. Changes were made to the modules studied with Project

Planning and Control becoming a core module at level 3 and Facilities Management being dropped from the HK programme. There were also minor changes to module content and learning outcomes but the intensive mode of delivery did not need to be altered.

5.4 External Audit

The Quality Assurance Agency (QAA) undertook a Collaborative Audit of the UoW in March 2006 and SCOPE was reviewed by the QAA as part of this audit. The outcome was *broad confidence in the soundness of UoW's management of academic standards* and the *learning opportunities offered to students through its collaborative arrangements* [5].

6. Professional Accreditation

To aid marketing of the course to the Hong Kong construction industry professional accreditation of the BSc (Hons) Degree in Construction Management in Hong Kong was sought from the Chartered Institute of Building (CIOB).

When the top-up programme was originally developed the UK programme had full accreditation from the CIOB and this was extended to the full time UK based top-up programme. However, even though there were quality procedures and external examiners reports available there was a necessity for a full application for accreditation to be made for the overseas programme. At the time there were concerns about franchised programmes particularly with regard to quality control issues and the way control over assessments, marking and teaching was assured.

The model developed was not a franchise model; it was, in effect, a cooperative programme whereby full control over the content and delivery of the programme was retained by the home institution. The full accreditation application required the creation of detailed documentation including the submission of mapping exercises firstly for the entry Hong Kong diploma and secondly for the remaining top up program against the CIOB education framework document [6]. The application also required a visit to the host institution including the inspection of any paperwork records and administration that the programme had generated together with meetings with staff, local tutors and administrators. The part-time delivery in HK was fully accredited by the CIOB.

7. Challenges

Throughout the eight years that the programme has run there have been a variety of challenges that the award team have had to deal with; some of these were considered as potential contingencies in the programme design, others could not have been foreseen but had to be dealt with as they occurred.

7.1 Foreseeable challenges

The first expected challenge was the need for UK staff to deliver modules in both HK and UK, as well as undertake other academic duties. In the earlier days of the programme staff made ad-hoc arrangements to cover sessions when they were overseas; more recently SEBE have identified module teams who have joint responsibility for modules and thus can ‘cover’ for times when staff are overseas.

The second type of challenge that has had to be addressed is that of staff being unable to travel to Hong Kong for personal reasons or illness. There have only been two occasions when staff have been unable to travel for these reasons and these have both been within the last twelve months. As a consequence of the good relationship between SCOPE and SEBE and the use of local tutors the lectures have been covered by the local tutors with additional support from the UK staff via email and through the learner support mechanisms within the VLE e.g. discussion forums. Care was been taken to ensure that students were not disadvantaged when alternative lecturers were used.

7.2 Unforeseen challenges

The most far-reaching challenge to the programme organisation was the worldwide spread of Severe Acute Respiratory Syndrome (SARS) between 2002 and 2003, which resulted in the programme being suspended for several months when travel to HK was vetoed. The management team, in both UK and HK, took the decision to suspend the programme as the travel veto was imposed between semesters, rather than within a semester, and the impact on the students was therefore minimal. Once the travel embargo was lifted the programme restarted.

The majority of the UK based staff hold British passports and travel to HK to work in SCOPE is allowed without any need to apply for additional visas or permissions. However, newer members of the teaching team hold other passports that do not give the same automatic permissions. In 2007, one such member of staff made enquiries prior to travel and confirmed that he was able to teach in HK; prior to arrival in HK the local rules changed and on arrival in HK he did not have the correct permissions to work in SCOPE. There followed a number of phone calls between SCOPE, UoW and HK government to ensure that the lectures could be delivered on schedule and without contravention of visa regulations. It was fortunate that prior enquiries had been made and that the HK government had only recently changed their requirements; because of this they allowed the lecturer to work even though he had not met the new requirements.

7.3 Learning styles

Lecturing staff have experienced different learning styles than those encountered in the UK. Students in western countries, by comparison, have a relaxed educational experience. Students in Chinese countries face higher workloads and are usually more disciplined and offer the utmost respect to their teachers. The learning style normally adopted in the UK is more proactive and lecturers concentrate their efforts in providing student-centred learning experiences through problem solving and active engagement. In the Far East the learning culture tends to be one of learning by rote [7, 8].

The experience on the HK programme has been that initially students shows little interest in participation possibly due to having little confidence in their English language skills and of having been brought up in an education system which tends to rely on rote learning, timed controlled assessments and a degree of diligence in their approach to learning which can only be envied by teaching institutions in the West. However, with persistence and encouragement from the lecturers, students respond to the student-centred methodologies employed by the UK staff and give positive feedback on their new learning experiences.

8. Future developments

The first lesson learned from the development of this programme has been the necessity to forward plan. Despite the programme's success, it is currently delivering to its eighth cohort, the partner institutions must be mindful that the initial motivations for such collaborative programmes is for future development potential for both parties. Naturally for this to be successful the host institution should improve its abilities to deliver the programme and the partners should look for new areas of potential collaboration.

8.1 Competition

Competition in Hong Kong has vastly increased over the eight years that this collaborative programme has been in operation. As previously stated, at inception this programme was the only part-time first-degree programme in HK. This is no longer the case and there is now significant competition in the local market for this and similar awards. The most recent competitor to enter the market is CityU: originally a key contributor to the programme (through local programme management and provision of lecturing staff to work as local tutors) as well as the primary source of students to the programme, CityU has introduced a BSc (Hons) programme of its own, from September 2007. Despite the growth in competition SEBE, through SCOPE, has maintained its student intake at 50-60 students per cohort and the programme remains financially viable. However, this has not led to complacency by either SCOPE or SEBE and new market opportunities are under consideration.

8.2 New market opportunities

A number of alternative are currently being investigated by both SCOPE and SEBE; these include the introduction of a Masters level qualification to introduce a natural progression route to higher level qualification, alternative honours degree qualifications, work-based learning qualifications to enable students and their employers to benefit from experience gained through work, distance learning opportunities (to enable students working in mainland China to gain a qualification) and credit accumulation options (to meet needs of students who want to study at a slower pace than available on alternative routes).

8.3 The English test

A key feature of the programme is that it is delivered wholly in English; use of English, for all learning materials, assessments and taught sessions, is a requirement of the agreement made between the institutions and students much achieve a minimum set standard of in English as one of the entry requirements to the programme. Up until now students have had to achieve the specified standard through an externally recognised qualification e.g. IELTS, but this is not always a precise indicator of ability to undertake the studies on the programme, or to write English at the level needed. From 2008 students will be required to take an internal UoW English test and success in that will satisfy the language entry requirements.

9. Conclusions

This paper has reviewed the introduction and development of an honours degree in Construction Management through a collaborative partnership between a UK HEI and one in HK. It has identified the design of the programme and the delivery methodology as well as changes to the programme and reasons for the changes being made. The needs to meet internal and external quality assurance requirements and to achieve professional body accreditation were discussed. Challenges to the programme team, and how these were overcome, have been identified and potential future developments highlighted.

Abstract

Although Bachelor of Technology (BTech) graduates in South Africa are employed in the construction and allied sectors many employers have expressed dissatisfaction with the abilities of these students to perform effectively in the construction sector. Given the current SA construction boom, and the severe skills shortage in both construction management and site skills almost all construction graduates from Universities of Technology are able to find employment despite their skills being inadequate. Traditional universities that offer a Bachelor of Science Honours (BSc. Hons.) degrees in construction studies, namely construction management and quantity surveying are perceived to produce a better graduate despite the BTech co-operative education and training being the preferred method of training for construction graduates. The offering of a capstone course may be seen as an avenue to achieve a better quality BTech construction graduate that meets the needs of the SA construction sector.

This particular paper presents the views of employers in an exploratory pilot study on their perceived acceptability and value of a capstone course to both students and industry practitioners.

Keywords: Construction, management, capstone course, quantity surveying

1. Introduction

Although Bachelor of Technology (BTech) graduates in South Africa are employed in the construction and allied sectors many employers hold that gaps exist between their academic performance and the importance of various subject areas relative to the workplace where the theory is required to be implemented practically [1]. Given the current SA construction boom, and the severe skills shortage in both construction management and site skills almost all construction graduates from Universities of Technology are able to find employment despite their skills being inadequate.[1]. Traditional universities that offer a Bachelor of Science Honours (BSc. Hons.) degrees in construction studies, namely construction management and quantity surveying are perceived to produce a better graduate despite the BTech co-operative education and training being the preferred method of training for construction graduates. This contrast with a study in the United States of America in their 1996 survey of Associate Schools of Construction members found the co-operative education method to be the preferred method of training construction graduates [2] and [3]. The offering of a capstone course may be seen as an avenue to achieve a better quality BTech construction graduate that meets the needs of the SA construction sector.

Construction education for BTech degrees in South Africa is based on the cooperative education model in terms of which, arguably, the gap is bridged between education and training to produce a graduate or diplomate that is both educated and trained and able to add value to the construction industry. Cooperative education, therefore, involves training and systematically developing students through the acquisition of the requisite skills, attitudes, values and knowledge required to adequately perform in their chosen careers. It incorporates productive work into the curriculum as a regular and integral element of a higher education course [4] and [5].In order to achieve stated national goals [6] universities in South Africa have a responsibility to adjust their programmes where the needs arise.

Capstone courses are designed to merge participatory learning with academic inquiry allowing student interaction in simulated environments organized around activities that require rigid procedures and processes and unique creative solutions [7], [8] and [9]. Where they have been used construction capstone courses are typically structured and focused around the procedures and operations of construction organizations. Management level decision making is emphasized such as development of alternatives, risk assessment, evaluation of opportunities and potential pitfalls, cost control and documentation, and a thorough analysis of cash-flow [10]. Students are expected to identify critical aspects of planning and tendering in a time-constrained environment. Capstone courses allow the assessment of the cumulative abilities of students, and to achieve optimum results the following aspects need to be addressed, namely,

- Clarification of the performance activities;
- Determination of what learning is to take place;
- Establishment of what knowledge is to be applied;
- Agreement of the basis of evaluation and the mastery required;
- Selection of the project teams; and
- Determination and agreement of the project outcomes.

Eight phases of the project life cycle has been identified [11] which include the following project aspects, namely project definition, scope, budget, planning, scheduling, tracking and close out. For capstone courses to be effective students need to be exposed practically to each of these phases. It is similarly argued that students should at least be exposed to the following aspects of construction management through the following broad project phases, namely

- The pre-design phase that includes the agreements with construction consultants and the definition and understanding of the project brief and scope management;

- The pre-construction phase that includes the development of the tender form the estimate stage through conclusion of the contract between the client and the preferred contractor. The contract documentation is included in this phase; and

- The construction phase that includes the management of the project integrating the construction and project management body of knowledge.

Capstone courses allow for the integration of subjects in a way that theory becomes practice [12]. The graduating student is arguably consequently better prepared for the work situation. The current trend of stand-alone subjects where student do not relate one subject to another is counter-productive [13]. Capstone courses provide the opportunity to address this weakness and integrate the learning experience.

2. Current Status

In South Africa the various Voluntary Associations and Professional Registration Councils have to date not recognized the BTech degrees in Construction Management and Quantity Surveying as vehicles for direct Professional Registration. Consequently, to be registered and obtain corporate membership of these councils and associations respectively, BTech graduates have had to satisfy additional and onerous requirements such as board examinations and extended post-graduate training. Recent research by [14] and [15] found that industry stakeholders had serious concerns about the ability of BTech graduates to perform adequately on construction sites and in construction and quantity surveying offices. They also questioned the suitability of these graduates for professional registration. It was found that construction employers in California, U.S.A. regarded students who had successfully completed the CalPoly capstone course as properly prepared for the rigours of construction employment [16]. This particular course integrated the theoretical components of the academic program into a final project that simulated project conditions and involved aspects such as company and job organization, tendering, award adjudication, project planning and scheduling, construction and project completion, and handover. The authors of this paper argue that the introduction of a capstone course could potentially produce similar results in South Africa.

3. Methods of delivery of capstone course

Capstone courses may be delivered in various forms. Typically, these may include any combination of the following, namely

3.1 Case Studies

Typically a record of a business issue, which actually has been faced by business executives, together with surrounding facts, opinions and prejudices upon which the executives had to depend. These real and particularized cases are presented to students for considered analysis, open discussion and final decision as to the type of action that should be taken.

3.2 Structured Interviews

Structured interviews with construction executives asking open questions with regard to specific issues that may have been raised during the study period or from case studies

3.3 Extended site visits

Students spend periods of at least 2 hours per day for three days a week under the guidance of a mentor on site specifically concentrating on a specific management issue. The University reserves the right to approve all management issues.

3.4 Integrated projects

Setting of a real or simulated integrated construction management project where the students are required to act as the project and construction manager in both bidding for the project as well as planning the construction implementation

3.5 Final year dissertation

A research project based on empirical research including the scholarly writing up of the discourse and presenting it as a complete document.

4. The research

An exploratory study was completed to determine the attitudes of construction employers towards capstone courses. The sample comprised of employers who employed BTech Construction Management and BTech Quantity Surveying students from the University of Johannesburg. A structured questionnaire comprising both open- and closed-ended questions was distributed among the 67 employers and 31 completed questionnaires were received, representing a response rate of 46% which was deemed adequate for an exploratory study. The data was analysed using the Statistical Package for Social Sciences (SPSS).

4.1 Sample Profile (Employer organisations)

Of the 31 employers who responded, 23% were construction and/or project management practices, 29% were quantity surveying consultants, 13% were general building contractors, 7% were civil engineering contractors and 26% were in the public sector. The majority (51.7%) of the organisations were medium to large with annual turnovers of more than 2 million Euros per annum and more than 50 full time employees (61.3%). These findings are shown in Tables 1 through 3.

Table 1: Field of activity

Field of Specialisation	Valid Percentage
Construction and /or project management consultants	23.3
Quantity Surveying Consultants	30.0
General Building Contractors	13.3
Civil engineering contractors	6.7
Public Service Employers	26.7
Total	100%

Table 2: Private sector average annual turnover

Turnover	Valid Percentage
≥ 200000<1 million Euros	14.3
≥ 1 million<2 million Euros	9.5
≥ 2 million<7 million Euros	14.3
≥ 7 million<21 million Euros	14.3
≥ 21 million Euros	47.6
Total	100%

Table 3: Average Labour force

Staffing	Valid Percentage
< 5 employees	3.2
≥ 5 employees < 15 employees	22.6
≥ 15 employees < 50 employees	12.9
≥ 50 employees	61.3
Total	100%

4.2 Sample Profile (Employer respondents)

The majority of the respondents (71%) had qualifications in quantity surveying followed by construction management (25.8%), civil engineering (25.8%) and architecture (9.7%). Respondents reported that they held formal qualifications in more than one field of construction. The majority of the respondents had post graduate degrees (61.3%), while 12.9% had National Higher Diplomas and 9.7 % either a National Diploma or undergraduate degree.

In response to whether respondents themselves or their staff had undertaken or presented capstone or co-operative education courses, they responded as shown in Table 4.

Table 4: Exposure to capstone course

	Yes	No	Unsure/ Missing
Have you ever undertaken or presented a capstone course?	16.1%	80.6%	3.2%
Have you ever undertaken or presented a co-operative education course?	29.0%	64.5%	6.5%
Have any of your staff undertaken or presented a capstone course?	12.9%	58.1%	29.0%
Have any of your staff undertaken or presented a capstone course?	16.1%	61.3%	29.0%

All respondents who completed National Diplomas and Higher Diplomas had participated in a co-operative education programme (22.6%). The findings suggest that although capstone courses are uncommon in South Africa they are not entirely unknown.

5. Data analysis

The respondents were requested to rank on a 5 point Likert scale the extent to which certain competencies were required by graduates and also the extent to which graduates possessed these competencies.

The comparative results of the expected and actual competencies are reflected in Table 5 using the means and standard deviations of responses.

It is evident from the findings that in all cases the actual competencies demonstrated by graduates were less than the level expected by employers. The responses were tested for reliability using Cronbach's Alpha test. Both sets of data satisfied the criteria of Alpha scores not less than 0.700, namely 0,795 in the case of expected competence and 0,907 in the case of actual achievement by graduates. By deleting a single item, namely ability to act ethically in business for expected competence the Alpha value increased to 0.813. The data set was deemed to be reliable.

In response to whether graduates were currently satisfactorily trained to enter the industry, respondents reported moderate satisfaction (mean= 2.93). Relative to their level of support for the introduction of capstone respondents were supportive (mean = 3.78).

Table 5: Comparison of expected and actual competencies

Competence	Expected Mean	Std. Dev.	Rank	Actual mean	Std. Dev.	Rank	Diff. in Mean	Rank
Ability to act ethically in business	4.74	.575	1	3.27	.907	3	1.47	1
Recognition that they need to constantly improve as scholars	4.39	.615	5	3.00	.743	7	1.39	2
Ability to adapt to circumstances as they arise	4.32	.653	6	2.97	.928	8	1.35	3
Ability to think critically through problems	4.48	.570	2	3.13	.937	5	1.35	3
Ability to understand a problem in its correct context	4.48	.570	2	3.13	1.042	6	1.35	3
Recognition that CPD is an important part of professional life	4.10	.662	9	2.83	1.060	9	1.27	6
Ability to lead a business	4.00	.775	10	2.80	1.064	10	1.20	7
Recognition of themselves as professionals	4.29	.864	7	3.17	1.117	4	1.12	8
Written communication ability	4.39	.558	4	3.40	.894	1	0.99	9
Oral communication ability	4.19	.543	8	3.33	.711	2	0.86	10
Ability to comment critically on architectural drawings with regard to aesthetics	3.32	1.137	11	2.60	1.102	11	0.72	11

From Table 6 it is evident that the inclusion of an integrated project in the capstone course was the most preferred component (mean=4.32). The extended site visit (mean = 3.970 and final year dissertation (mean = 3.90) were also preferred although to a lesser degree.

With regard to the timing of the capstone the respondents tended to support the capstone course being offered in the last year of the Diploma (mean = 3.93) and the Degree (mean =3.97).

With regard to whether or not the capstone should be throughout the year or only in the last term of the programme respondents tended to support (mean = 3.79) capstone be done throughout the academic year.

Table 6:Components of capstone course

Component	Mean	Std. Dev.	Ranking
Integrated project	4.32	.845	1
Extended site visits	3.97	1.140	2
Final year dissertation	3.90	.944	3
Case studies	3.55	.925	4
Interviews	3.16	.934	5

With respect to the method of evaluation of the capstone course, respondents preferred (mean = 4.10) a combination of a written submission and an oral presentation of the project. Written submission only (mean = 2.67) and oral presentation only (mean = 2.10) were not as popular means of evaluation. Relative to the extent of the industry participation in the evaluation of the capstone course, 68% of the respondents felt that industry should be involved throughout the course offering at every level and 26% felt that industry should only be involved at the final evaluation. With regard to the recommended pass mark for the capstone course the findings are shown in Table 7.

Table 7: Preferred passing grade

Pass Grade	%
50-64%	26%
65%	19%
70%	35%
75%	6%
>75%	13%

Most respondents (54%) reported that a mark of between 65% and 74% was preferred.

With regard to the contribution of the capstone course to the overall final grade, the findings are shown in Table 8.

Most respondents favoured either a 25% (45% of respondents) or 50% (34% of respondents) contribution to the overall final grade.

The respondents were supportive (mean = 3.55) of the capstone course leading to registration as Professional Construction Managers

Table 8: Contribution to overall final grade

Percentage of overall grade	%
<25%	10%
25%	45%
50%	34%
>50%	7%
Other	3%

Table 9: Comparison of expected skills and actual abilities in specific skills

Skills	Expected Mean	Std. Dev.	Rank	Actual Mean	Std. Dev.	Rank	Diff. in Mean	Rank
Estimating and pricing practice and knowledge of software packages	4.48	.580	1	2.95	.844	9	1.53	2
Knowledge, understanding and interpretation of specifications	4.44	.641	2	3.27	1.032	4	1.17	9
Quantity surveying practice and knowledge of software packages	4.44	.698	3	3.05	.899	6	1.39	4
Working in teams	4.37	.629	4	3.55	1.057	1	0.82	14
Financial management knowledge								

	4.22	.801	5	2.77	.869	14	1.45	3
Practical and theoretical knowledge of quality	4.22	.847	6	3.00	1.155	8	1.22	7
Cost engineering practice	4.19	.736	7	2.55	1.057	19	1.64	1
Set up and maintain contract administration procedures	4.15	.770	8	2.77	.922	15	1.38	6
Contract procurement strategies (not purchasing)	4.11	.801	9	2.95	.899	10	1.16	10
Organisational issue on projects	4.07	.730	10	2.68	.995	17	1.39	4
Feasibility studies	4.04	.980	11	2.82	1.140	13	1.22	7
Carry out commercial appraisal and economic analysis of projects	3.89	.698	12	2.82	.907	12	1.07	11
Concepts of Programme Evaluation and Review Technique (PERT)	3.85	.770	13	3.27	.703	3	0.58	18
Work Breakdown Structure (WBS)	3.85	.818	14	3.36	.581	2	0.49	19
Schedule on a project management software								

programme	3.85	.864	15	3.09	.811	5	0.76	16
Familiarity with temporary works required to produce permanent structure	3.78	.892	16	2.73	.883	16	1.05	12
Industrial relations	3.74	.712	17	3.00	.873	7	0.74	17
Knowledge of design and engineering processes	3.67	.734	18	2.86	.774	11	0.81	15
Knowledge of pre-design organogram	3.52	.849	19	2.55	.671	18	0.97	13

Table 9 reflects the comparison of the skills that employers expect construction graduates to possess, and the actual abilities that these graduates possess in the work environment. Apart from working in teams (ranked 4th) the dominant expected skills that a BTech graduate should have were largely related to the financial aspects of construction projects. Knowledge of design aspects was ranked the lowest of the expected skills.

On the other hand, working in teams, WBS, PERT, knowledge and understanding of specifications and ability to schedule using computer software ranked 1st through 5th respectively in terms of actual graduate abilities. This finding suggests some mismatch between the preferred abilities and that which graduates actually possess. However, it is important to note that the mean scores in all cases were lower for the actual abilities than those that were expected.

6. Conclusions

Construction employers employed current BTech Construction Management and Quantity Surveying students despite these graduates completing their final year/s of study and not being in possession of the expected skills to perform adequately in the industry. Both BSc (Hons) and BTech graduates are employed broadly in the SA construction sector. The study suggests that the inclusion and successful completion of a capstone course that includes multiple components such as an integrated projects and extended site visits will contribute to the improvement of the employability of BTech graduates. The course outline needs to cover all phases of the construction process with mastery levels set fairly high around 70% and comprising 25% to 50% contribution to the final overall grade. The gaps between the importance that employers accord certain skills and competencies and the actual perceived performance by graduates must be addressed. Overall construction employers are supportive of the introduction of a capstone course into future construction-related BTech offerings which would lead to professional registration with councils and corporate membership of voluntary associations.

Abstract

In the current 'Decade of Education for Sustainability' universities have responded by implementing initiatives to promote sustainability education. At RMIT University, a one-year action research project was conducted to embed sustainability into the property and construction management curriculum. The project aimed to create lasting change in organisational structure and curriculum content. One of the outcomes of this project was the development of a new course in sustainability for 3rd year students. The course, entitled 'Research and Sustainability' is now a core course in the undergraduate programme. This paper provides the results of a research project that was undertaken to examine student 'perceptions and awareness of sustainability' both prior to and after completion of the new course. As part of this investigation students were asked to complete a paradigm shift exercise both at the beginning and end of the semester in which the course was taught. The exercise asked students to consider four groupings of words. The word choices they made determined whether they had a leaning towards the 'status quo' or a 'green' paradigm. A leaning towards the 'status quo' was characterised by the adoption of a functional analytic *ontology*, an economic individualistic *values* system, the ruling elites as *agents* of change and an instrumental *process* approach to sustainability/change; whereas a leaning towards a 'green' paradigm was characterised by a social ecology *ontology*; a post-materialistic *values* system; community members as *agents* of change; and an experiential *process* approach to sustainability/change. The data collected were analysed to establish whether students' learning over the course of the semester had influenced the overall paradigm within which they operated, which could be either 'status quo' or 'green'. Results show that whilst few students adopted a 'green' paradigm, there was a statistically significant shift towards the adoption of a social ecology and community driven change approach to sustainability from the beginning to the completion of the course. Findings will be used to inform approaches to learning and teaching and improve knowledge of student perceptions so that that this generation of students cross the threshold to new sustainable ways of thinking and working.

Keywords: Education, Green paradigm, Perceptions, Sustainability

1. Introduction

Universities around the world have responded in a number of ways to the UN's 'Decade of Education for Sustainability' [1] which aims to ensure that all higher education curricula include a focus on sustainability and sustainable development. A number of initiatives to promote sustainability education within higher have been implemented in responses to this initiative. One example from the UK is the Sustainable Development Strategy which has identified sustainability literacy as a core competency for all graduates in UK universities [2].

In 2006, at RMIT University, a large dual sector technological university in Melbourne Australia, a one-year action research project was undertaken to embed sustainability within the core curriculum of programmes in three schools across the university (namely, the School of Property, Construction and Project Management, the School of Social Science and Planning, and the School of Management) [3]. Its design was action research based and focussed on curriculum and assessment change based on reflections from a previous study that identified the need for a strategic approach based on change management and supported by staff development [4]. The project aimed to create meaningful and lasting change in the student learning experience [5]. Within the School of Property, Construction and Project Management the project focussed on embedding sustainability capability into core curricula of four undergraduate programmes (construction management, property management, project management and valuations).

A third year core subject BUIL 1217 Research and Sustainability was created as part of the process. BUIL 1217 research and sustainability combined the topic "sustainable construction and green building" with "research methods". Students applied a range of research methods to critically examine a range of sustainability issues in order to facilitate understanding the often-complicated decision making that surrounds both sustainability and research methodology [6].

As part of the course students visited innovative green building projects, undertook building audits, questioned experts in the field, and determined their own impact on the environment using interactive web-based tools. Students carried out group-work research in an area of sustainability. In addition they completed an independent literature review on a topic relating to one or more aspect of sustainability, showing that they had grasped the key concepts and could apply critical thinking in their approach to developing a research question for their final year project. They also spent time in groups, at the end of the course, discussing their responses and what they had learnt about their perceptions and awareness of sustainability issues. During the course students were asked to complete a number of class activities to demonstrate both their tacit and explicit knowledge of sustainability. These were then used to explore the perceptions and awareness of sustainability issues held by students enrolled in construction and property management degree courses [7].

These students are entering an industry which is currently experiencing a significant move towards more sustainable developments. With increased awareness through the written and visual media, clients are 'going green' and starting to ask for elements of sustainability in their buildings, chiefly to reduce their carbon footprint. In addition the construction industry has recognised the need to implement environmentally sensitive and sustainable management policies, practices and operations in order to meet new government policies and legislation.

As a result, the concept of sustainable development is changing the way the construction and building industries operate, and the language of their business. Graduates and individuals working within the construction sector are now required to work within a green paradigm. This in turn must impact on the university curriculum, as it is necessary for educators to ensure that students are made aware of these issues and how to best approach them and engage with them. To produce construction graduates who meet this need it is necessary to redesign built environment programmes so that they integrate and embed sustainable philosophies and techniques for implementing them, across the curriculum.

2. Methodology

As part of the planned class activities students were asked, at the beginning (pre) and end (post) of Semester two 2006, to complete a paradigm shift exercise adapted from ‘A Green Questionnaire’ by Ariel Salleh [8].

The paradigm shift exercise required students to read a checklist of numbered words/phrases subdivided into four paradigm categories: ontology, values, agency and process (see Table 1) and circle the number by any word/phrase which regularly features in their writing or oral communication. These were then scored according to the frequency of odd numbers circled, and the frequency of even numbers circled in each grouping, in order to determine the student paradigms. The paradigm shift exercise therefore aims to assess whether the students are working in or have moved to a new ‘greener’ paradigm (more even than odd numbered words selected); or whether they are still operating in the ‘status quo’ (more odd than even numbered words selected). Students were asked to submit their results as part of the research project. Participation in the research was entirely voluntary (the research was approved by the University’s Ethics Committee).

Table 1: Outline of paradigm categories.

		Choice of Paradigm	
Word Group	**Theme**	**Paradigm 1: Status quo** (associated with odd numbered words/phrases)	**Paradigm 2: Shift to green** (associated with even numbered words/phrases)
Group 1	Ontology	Functional analysis	Social ecology

Group 2	Values	Economic individualism	Post-materialism
Group 3	Agency	Ruling elites	Community
Group 4	Process	Instrumental	Experiential

Salleh [8] suggests that depending on which paradigm students are operating in (‘status quo’ or ‘green’) their underlying *ontology* could either veer towards a conservative fundamentalist one characterised by a functional analysis perspective where societies and environments are treated as mechanical systems (more odd numbered words selected), or towards a more social and ecological perspective (more even numbered words selected). Student *values* could either be consistent with economic individualism which would prevail in ruling class circles (more odd numbered words selected) or veer towards an alternative post-materialistic generation (more even numbered words selected). *Agency* is divided according to whether the students emphasise the role of government and professionals, the ruling elites, as the movers and shakers of social change (more odd numbered words selected) or want to see community-based initiatives as agents for change (more even numbered words selected). Finally, student views about the *process* for change might veer towards an instrumental or manipulative approach (by circling more odd than even numbers) or appear to be more deeply grounded in an experiential or democratic process.

In summation, a student is deemed to be operating in the ‘status quo’ paradigm if he/she indicates a tendency towards piecemeal reforms that could be incompatible with the longer-term green vision (with more odd than even words circled) characterised by thinking that demonstrates a functional analytic *ontology*, an economic individualistic values system, the ruling elites as *agents* of change, and an instrumental *process* approach to sustainability/change. A student is considered to be operating in a ‘green’ paradigm if he/she demonstrates an understanding of how ecological sustainability and social equity are inter-related through his/her choice of words/phrases across all four groups (with more even words circled) [8]; characterised by thinking that demonstrates a social ecology *ontology*, a post-materialistic *values* system, the community as *agents* of change, and an experiential *process* approach to change/sustainability.

3. Data analysis

Data from the pre-post course paradigm exercises were collected and analysed to determine the paradigm in which the students were operating at the beginning (pre) and end of semester (post); and to establish whether there had been any change and whether participation in the course could be associated with this change.

At the beginning of the course 58 of 72 students enrolled in the course completed and submitted the paradigm shift exercise. At the end of the course 37 completed and submitted the exercise. Responses were matched so that only data from students who completed both exercises were analysed. Matching resulted in 28 of a possible 37 student surveys for analysis.

4. Results

The results of the analysis are represented in Figure 1 below. Student responses (n=28) are represented by two points, with a circle (pre-semester) and a triangle (post-semester).

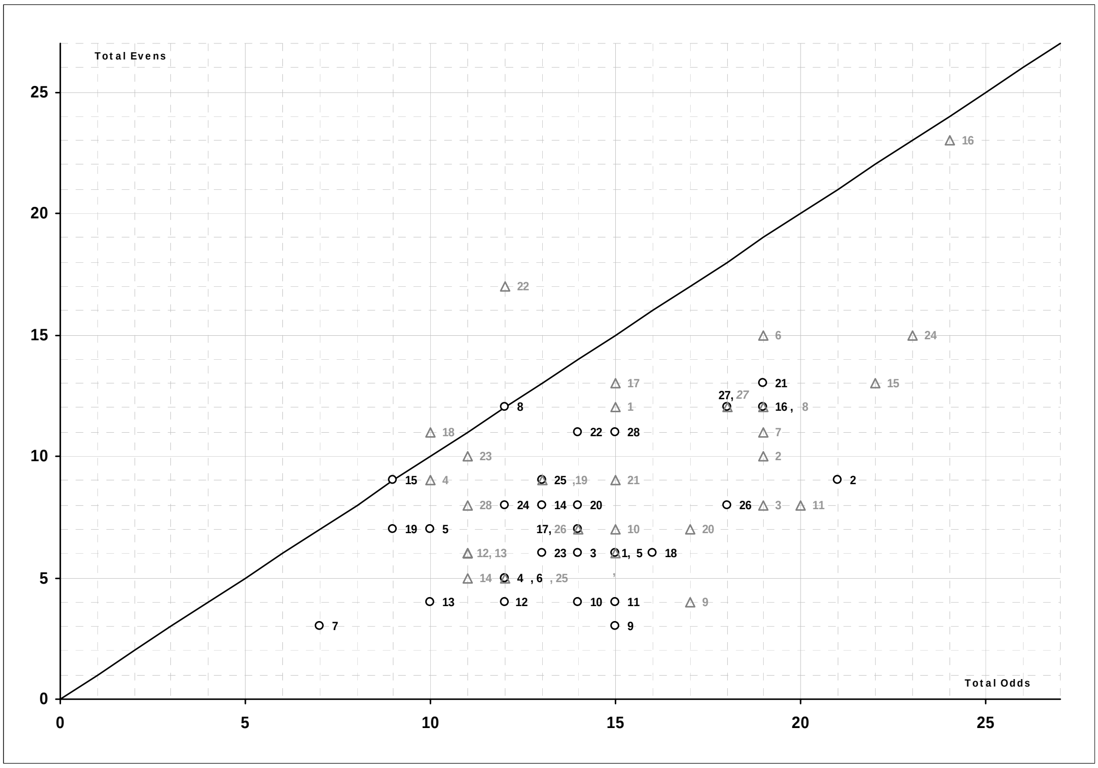

Figure 1: Frequency and distribution of student word choices pre (circles) and post (triangles) module delivery

These points represent the number of odd and even words chosen at the beginning of the course (circles) and on completion (triangles) of the course. The number of chosen *odd* words is graphed on the horizontal axis and the total number of *even* words is graphed on the vertical axis.

The straight diagonal line represents the threshold which must be crossed in order to operate in a ‘green’ paradigm. Points lying above the straight diagonal line or threshold therefore represent a situation where *even* words outnumber *odd* words. Each of these points is numbered in order to see movement pre-post semester.

Figure 1 demonstrates that none of the students were operating in a ‘green’ paradigm at the commencement of the course; however two of the 28 students had adopted a ‘green’ paradigm by the end of the course. In addition, as illustrated in Figure 2, the majority of students (n=15), whilst not crossing the threshold, did demonstrate a definite move towards the threshold, by choosing more even words in the post-semester exercise. Figure 2 graphs, for each respondent, the difference in even word counts denoted △E against the difference in odd word counts denoted △O. Again, number codes identify the individual students.

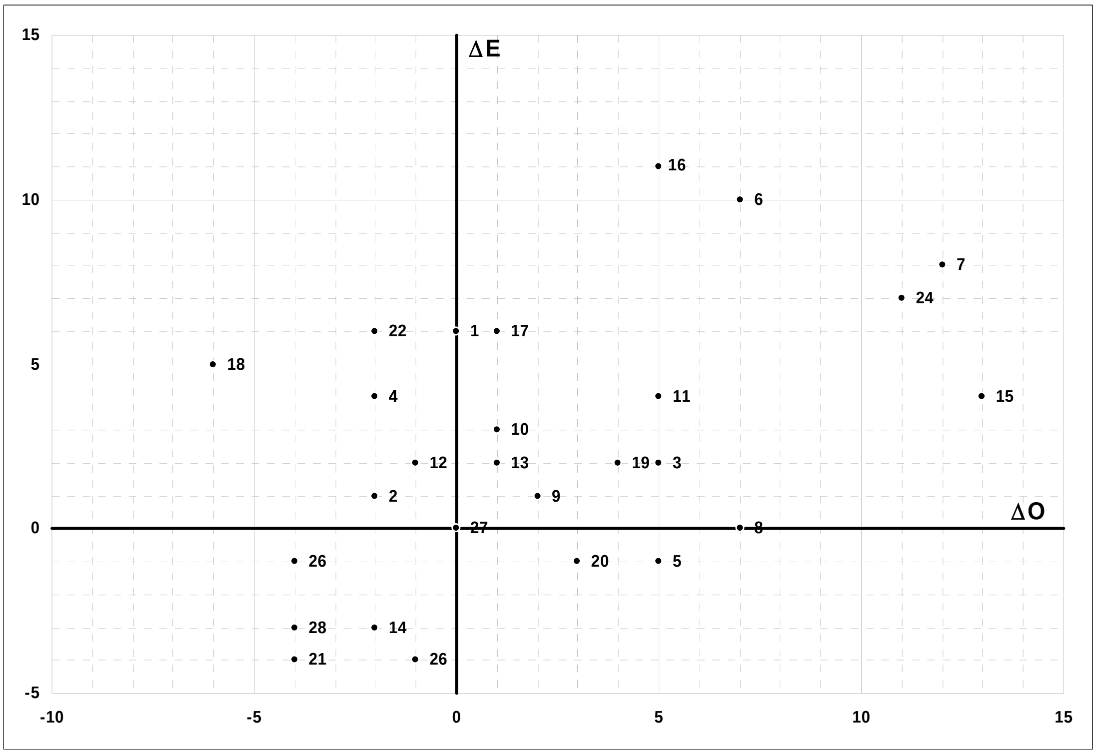

Figure 2: Frequency and distribution of even word counts against odd word counts

Quadrant one (top right) of Figure 2, represents students whose even word counts increased at the same time as their odd word counts increased. Quadrant two (top left) represents students whose odd word counts increased and even word counts decreased. Quadrant three (bottom left) represents students whose odd and even word counts simultaneously decreased and. Quadrant four (bottom right) represents students whose odd word counts decreased and even word counts increased.

An analysis of the difference in the words chosen by the students at the beginning (pre) and end of semester (post) was also undertaken. The results are presented in Tables 2 and 3 below. All asterisked mean differences were found to vary significantly from 0 at the 5% significance-level. The associated standard errors and p-values are also presented.

Table 2: An analysis of the difference between the numbers of even-coded words chosen pre-post semester (to 2 decimal places).

Groups	*Mean difference*	*Standard Error*	*P-value*
Ontology	*0.64**	*0.26*	*0.02*
Values	*1.50**	*0.37*	*0.00*
Agency	*0.29*	*0.33*	*0.39*
Process	*0.11*	*0.27*	*0.70*
Consolidated	*2.54**	*0.76*	*0.00*

The results presented in Table 2 are for even-coded words and show that students who completed the course broadened their lexicon to include words associated with a social ecology *ontology* as well as a post-materialistic *values* system, as opposed to a functional analysis *ontology* and an economic individualistic *values* system, by the end of the course. Whilst there is statistical evidence of a move towards the usage of words associated with a shift to a 'green' paradigm (refer to statistically significant result for consolidated groups in Table 2), there is no evidence of a trend to an increase in use of words associated with those who believe the community should be viewed as the *agents* for change as opposed to the ruling elites, or that the *process* for change should be democratic and experiential as opposed to an instrumental one (refer to statistically insignificant result for consolidated groups in Table 3).

An analysis of the difference between the number of odd-coded words chosen at the beginning of semester (pre) and at the end of semester (post) demonstrate strong statistical evidence that an increasing number of words associated with the 'status quo' were also adopted.

Table 3: An analysis of the difference between the numbers of odd-coded words chosen pre-post semester (to 2 decimal places).

Groups	*Mean difference*	*Standard Error*	*P-value*
Ontology	*0.79**	*0.29*	*0.01*
Values	*-0.21*	*0.37*	*0.56*
Agency	*0.43*	*0.34*	*0.21*
Process	*0.86**	*0.39*	*0.04*
Consolidated	*1.86*	*0.94*	*0.06*

There is strong statistical evidence that the students increased their usage of words associated with the notion that the process for change should be instrumentalist or manipulative.

Micro analysis of the consistency of the word choices pre-post semester was undertaken for each of the four groups of words presented to the students. For the words related to *ontology*, the lexicon nominated by the students was consistent 70.9% of the time. The consistency measure was slightly higher at 73.5% for the odd-coded words associated with the conservative functionalist ontology, and slightly lower at 68.4% for the even-coded words linked to the ontology of social ecology and the green spectrum.

For the words related to *values* the overall lexicon adopted by the students was found to be consistent 59.7% of the time. The consistency measure was 64.3% for the odd-coded words that reflected values associated with economic individualism. 55.1% of the even-coded words demonstrated a consistency with values of the post-materialist generation.

For the words related to *agency*, designed to reveal the students' desired agent of change, the overall lexicon adopted was found to be consistent 70.4% of the time. However the consistency measure for odd-coded words associated with change that is driven by ruling elite (government and professional) was higher, at 74.5%. The consistency measure of even-coded words associated with community-based change was 66.3%.

Finally, for the words related to *process*, the overall lexicon adopted by the students was found to be consistent 64% of the time. The consistency measure for odd-coded words associated with an instrumentalist or manipulative process was 61.2%, with 66.8% for even-coded words linked to an experimental or democratic process.

5. Discussion

On completion of the course, at the end of the semester, the majority of students demonstrated a leaning towards a social ecology ontology as opposed to functional analysis one; a post-materialistic values system as opposed to an economic individualistic one; the ruling elites as agents of change as opposed to the community; and an instrumentalist process approach to change as opposed to an experiential one.

Although only a small number of students were seen to cross the threshold to a 'green' paradigm, a majority of the students did move towards the threshold by the end of the course, particularly in the areas of ontology of social ecology and a post-materialistic values system. This may be associated with the focus of the course that encouraged students to explore their beliefs and values in relation to sustainability and to engage in learning activities that were designed and directed at supporting this.

Students' responses did not show the same pattern when considering agency and process. Responses showed that students still favoured ruling elites and an instrumental approach to change. This is not surprising considering these students are operating within an industry dominated by government regulation and policy, driven by cost and expedience, with a definite hierarchy in place. In addition, students who choose to enter the construction industry and to study in the area have been found to do so with a primary focus on gaining knowledge and skills for how to do the work in industry rather than on gaining academic skills around "…recognising and handling complexity, uncertainty and contested concepts." (p723). They are also more likely to be focused on gaining a professional qualification that is valued in the industry. Further, academic staff teaching this discipline traditionally come from within the industry and value changes that are driven by government policy and new developments originating in the field of practice, rather than those that are driven by empirical and innovative research that is focused on discovery. Therefore, education in the construction discipline tends to focus more on imparting professional skills than on facilitating critical inquiry into the processes of knowledge creation. As Griffiths points out, "…course elements that are concerned with developing research skills, and promoting a more research-oriented ethos, can find themselves out of step with, and not reinforced by, other course elements." [9]

Despite this, micro analysis of the consistency of choices did demonstrate a decrease of words associated with an instrumentalist or manipulative process, suggesting that students' concepts had begun to shift. This may be associated with the students' engagement with this course that introduced them to new ways to approaching the built environment; an approach that is more sustainable.

Findings therefore suggest that it is possible to help some students to change their conceptions, but that this is not easy to achieve through participation in a stand-alone, one-off course experience. Support for sustainability should permeate the curriculum and be aligned to the goals of the programme, learning outcomes and activities, as well as linked to the assessment [10]. Findings from a large body of research in supporting and facilitating understanding and overcoming student mis-conceptions in the areas of probability and statistics, science, mathematics and physics education echoes these findings and suggests a need for more research that is collaborative and cross-disciplinary [11, 12, 13].

Ramsden [14] reminds us that while higher education teachers expect that their students will change the conceptions of the world around them through the subjects they are studying he asks "[why] these changes do not always happen?" and "[w]hy students often obtain quantities of knowledge, yet fail to change their understanding of what it means?..." (p.40). He suggests that in order to facilitate student learning, that is to help learners change the way they conceptualise the world, the answer lies in how learning is facilitated and the context in which it takes place. By ensuring multiple opportunities for students to engage in learning activities that intentionally encourage the making of meaning and learning for understanding rather than recall or memorisation are more likely to result in changes to conceptions. Teaching that: aims to share; ensures that the material is interesting and stimulating; students are engaged at the level at which they are at; it is clear what is to be understood, at what level and why; shows respect and concern for students; supports and encourages independent learning and an ability to adapt to new demands; uses methods that require thoughtful, responsible and cooperative behaviours; focuses on helping overcome misconceptions; is assessed appropriately; ensures feedback is provided; and equally relies on the teacher being willing to learn from the students is more likely to result in deep learning and facilitate conceptual change is teaching [14]. While this is hopeful news for education for sustainable development, it also points to the need for much more connected work aimed at supporting student conceptual change.

Effective student learning that leads to conceptual change involves students actively engaging in learning for understanding, as opposed to memorization; based on experiential approaches that are underpinned by a learner-centred methodology where the focus is on students' experience of learning rather than the teachers' experience of teaching [15]. Whilst this course attempted to address these issues, education for sustainable development needs to be integrated in context across all courses and by all discipline instructors if we are to see lasting change.

6. Conclusions

This paper has described a study which was undertaken in 2006 to examine student paradigms as they relate to the 'green' agenda both prior to and after completion of a new course on sustainable construction and 'green' building. Students were asked to complete a paradigm shift exercise which consisted of choosing words they were familiar with and which regularly featured in their writing or oral communication from four groupings. The choices they made determined whether they had a leaning towards a functional analysis or social ecology *ontology*; an economic individualistic or post-materialistic *values* system; ruling elites or community as *agents* of change; and an instrumentalist or experiential *process* approach to sustainability/change. Their leaning determined whether they operated in the 'status quo' or a 'green' paradigm.

Results show that whilst few students adopted a 'green' paradigm, there was a statistically significant shift towards social ecology and community driven change from the beginning of the course to its completion, demonstrating that the course had a positive impact on student perception in these areas. The next stage of the research is to undertake the same exercise at the beginning and end of the degree programme to establish whether the programme contributes to helping students to cross the threshold to new sustainable ways of thinking and working.

Abstract

The Dearing Report [1] identified that programmes in Higher Education need “to equip graduates with the skills and attributes needed to be effective in a changing world of work and upon which to found and manage a number of careers. Graduates will need to be able to identify their own development needs and be committed to lifelong learning”. Personal development planning is a term used to describe the “means by which students can monitor, build and reflect upon their personal development”. In order that students at Higher Education Institutes within the UK are so equipped the Quality Assurance Agency (QAA) *et al* [2] specified that all students in HE should be ‘given the opportunity’ to engage with Personal Development Plans (PDP) from 2005/06.

This paper reviews the action taken by a post 1992 University in the UK to introduce PDP to students on construction-related courses. The university heads the “league tables” [3] for ‘widening participation’ i.e. entrants to HE from non-traditional and underrepresented backgrounds such as ethnic minorities, students with disabilities, females, mature and first generation HE participants, and this itself brings new challenges in developing curriculum and methodologies to meet Dearing’s and QAA requirements.

The university developed a bespoke web-based PDP tool that is now used university-wide at all levels of sub-degree, degree and post-graduate delivery. The paper will explain how the use of this tool has been embedded in the built environment curriculum, the benefits to the students and how other HEIs can introduce such a tool within their programmes.

There is potential to exploit the tool more widely within general CPD. The paper concludes by identifying how this could be achieved and highlights the benefits to the individual, the professional bodies and the economy of this type of reflective approach embodied within an electronic personal learning system.

Keywords. Personal Development Planning, CPD, ePortfolio

1. Background.

1.1 The introduction of Personal Development Planning to Higher Education in the UK

In May 2000 the Quality Assurance Agency (QAA) *et al* [4] issued a policy statement on the development of a Progress File for Higher Education. This policy statement came from recommendations within the *National Committee of Inquiry into Higher Education* more commonly referred to as the Dearing Report [5]. Recommendation 20 of this report suggests that there should be a way to develop a progress file that has two elements:

a transcript recording student achievement which should follow a common format devised by institutions collectively through their representative bodies;

a means by which students can monitor, build and reflect upon their personal development."

All Higher Education Institutions in the UK were invited to endorse and implement this policy. The Policy Statement set out roles and responsibilities for implementation, (point 16 in the Guidelines for HE Progress files) that clearly state that the institutions are responsible for providing opportunities for students to engage with PDP, however the responsibility for gaining benefit from this process would be with the student but that the institutional stance, policies, support and attitudes would influence this.

The Guidelines gave an implementation date for Progress Files as the start of the academic year 2005/6, from this date the QAA could include PDP in their institutional audit.

Within the Guidelines PDP is defined as:

"a structured and supported process undertaken by an individual to reflect upon their own learning, performance and/or achievement and to plan for their personal, educational and career development." [2].

This definition is now widely used across the HE sector. Prior to the Dearing Report and then the QAA *et al* Policy statement, PDP was not a term that was commonly used. The term PDP is therefore a relatively new term. Grant and Richardson's report *What do we mean by PDP?* [6] tried to establish what activities might be seen as PDP, these included:

- Reviewing strengths and weaknesses (generic/subject specific)
- Stating and reviewing goals (short term/long term)
- Making plans to achieve goals/remedy areas of weakness
- Recording experiences, reflecting on what has been learned

- Recording achievements, reflecting on progress

The output of these activities generating such things as personal development records that might include:

- Initial statement of motivation for programme
- Review of a period of time - what have I achieved?
- Analysis of feedback received – what are my strengths and areas for development?
- Critical incident analysis
- Reflective learning log
- Action plan

1.2 PDP at the University of Wolverhampton

Within the University of Wolverhampton, PDP was strategically placed within the Institutions' Learning and Teaching Strategies 2002-05, 2005-06 and 2006-10 [7].

In the 2002-05 Learning and Teaching Strategy the emphasis for PDP was on development of policy and practice and then implementation. In Strategic Priority 6.3 the following was stated:

to develop our understanding of student independence in learning and our models of delivery in promoting this, so as to improve our retention and employability of students, within a national widening participation agenda.

Objective 6.3.5 was:

to develop the student progress file framework, including the improvement of student skills in reflective evaluation and models to ensure significant student participation

An outcome of this was the development of an institutional framework for the process of PDP which set out that the main outcome should be a formative student-centred process that provided a product that documented a student's achievement and experience at the university. The PDP processes are integrated throughout the whole of the student experience at the university, they are developmental and used by students with tutor guidance. The framework was re-titled from PDP (personal development planning) to PACE (personal, academic, careers and employability) planning and development (Figure 1) to reflect more closely the activities and outcomes that the institution wished students' to achieve.

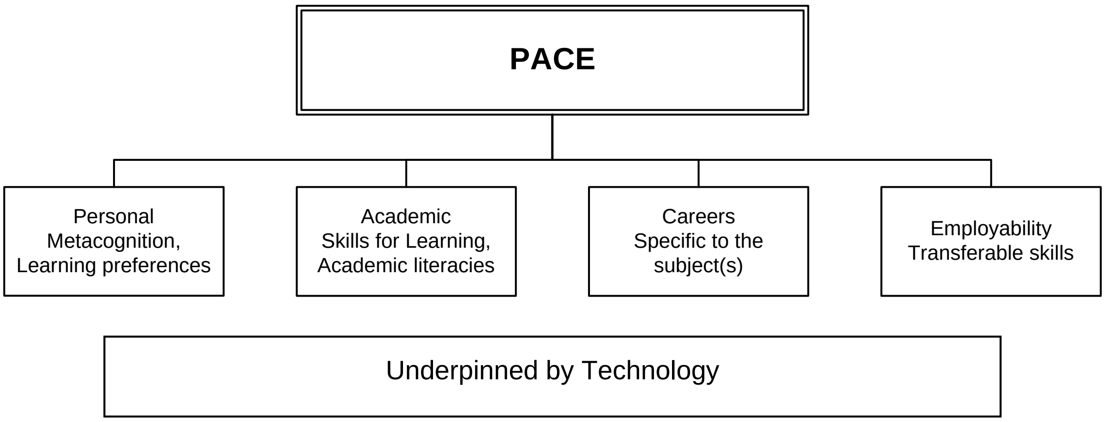

Figure 1. Formative student-centred ***process***

As a consequence of this framework came the development of an electronic tool - PebblePad© - to deliver and support the process.

We are now in the post-implementation phase of Progress Files moving towards embedding processes within the student experience that links directly to the University's Learning and Teaching Strategy 2006-10 [7] the main aim being to:

"*embed the quality, relevance, effectiveness and efficiency of our learning environments into the main stream processes and procedures of university planning and implementation, so to enhance the lives, the educational experience and employability of our students*"

2. ePortfolio.

In the academic year 2003/4 the University undertook a review of PDP practices across all undergraduate provision. That review showed that there were lots of activities that could be classed as PDP. Often this work was documented by paper-based tools that had been developed and used locally. At an institutional level it was decided that for both practical and pedagogical reasons to provide a paper-based system for recording PDP to all students would be inefficient and would go against the institutional ethos of using technology to support learning (for which the university is recognised as a leader) [8].

Best practice was gathered and suggestions were made to find some form of electronic student portal that would, as a minimum function, allow students to access Microsoft Word™-based PDP templates from both their own and other academic disciplines. From discussion between academic staff in schools and in the Centre of Excellence in Learning and Teaching links were made to development work on profiling learning that was happening in a fledging company of ex and part time members of staff from Wolverhampton. The company was developing a generic tool that was based on sound pedagogical practices that did not give one final product but allowed for it to be used in whatever way someone found meaningful.

In 2004/5 the University of Wolverhampton worked with an external company, Pebble Learning [9], to develop and pilot the software PebblePad©. At the start of the academic year 2005/6 this tool was rolled out across the whole of the University. All staff and students having their own personal accounts, icons for short-cut access to the software became a part of all desktops and could be found in the personal management page of the virtual learning environment, Wolverhampton On-line Learning Framework (WOLF).

Over 2005/6 and 2006/7 new communities of users emerged that were early adopters and 'champions' of the new software and an ePortfolio users group was established. This was outside but not exclusively new to the existing technology supported learning community. Over this time period 'Show and tell' events were organised to demonstrate how and why this new tool was being used. Since the University-wide roll out there has been a rapidly increasing use of the tool for staff led learning and teaching activities that ask students to use PebblePad© in some way for both formative and summative assessment. In June 2007 a review of PDP at level 1 [10] showed that all academic schools were using PebblePad© in some way to deliver PDP in the first year (undergraduate) curriculum.

ePortfolio and PebblePad© at the University are often used as interchangeable terms. For example the URL to access the PebblePad© software is http://www.wlv.ac.uk/eportfolio. The concept of PebblePad© is:

"a system which allows users, in any of their learning identities, to selectively record any abilities, events, plans or thoughts that are personally significant; it allows these records to be linked, augmented or evidenced by other data sources and allows the user to integrate institutional data with their personal data. It facilitates self-awareness, promotes reflection, supports enrichment through commentary and feedback from the recipients of shared assets. It grows, develops and matures as the user accesses it, without constraint, over time. It provides tools for aggregating assets in multiple forms; for telling myriad stories to diverse audiences and ensures absolute user-control over what is shared, with whom, for what purpose and for how long. It is a personal repository; a personal journal; a feedback and collaboration system; and a digital theatre - where the audience is by invitation only". Pebble Learning [9].

2.1 What is PebblePad©?

PebblePad© is a system designed to support both formal and informal learning, within the University of Wolverhampton it is defined as a 'personal learning space' as opposed to a 'managed learning environment'. The software allows users to build a diverse collection of items related to their studies, personal development, continuing professional development or any event of personal significance. Those items can then be published or shared with specified individuals or groups or to a public audience through the creation of a URL address. The software promotes reflection and gathering of evidence, any digital file can be linked to the software giving the ability to add such things as video, images and sound.

Within the tool there are a range of templates (Figure 2) that are used to generate items or assets (the term used within the software). As well as providing templates for such things as thoughts, action planning and experiences, Version 1 offers templates to create blogs, CV's and webfolios.

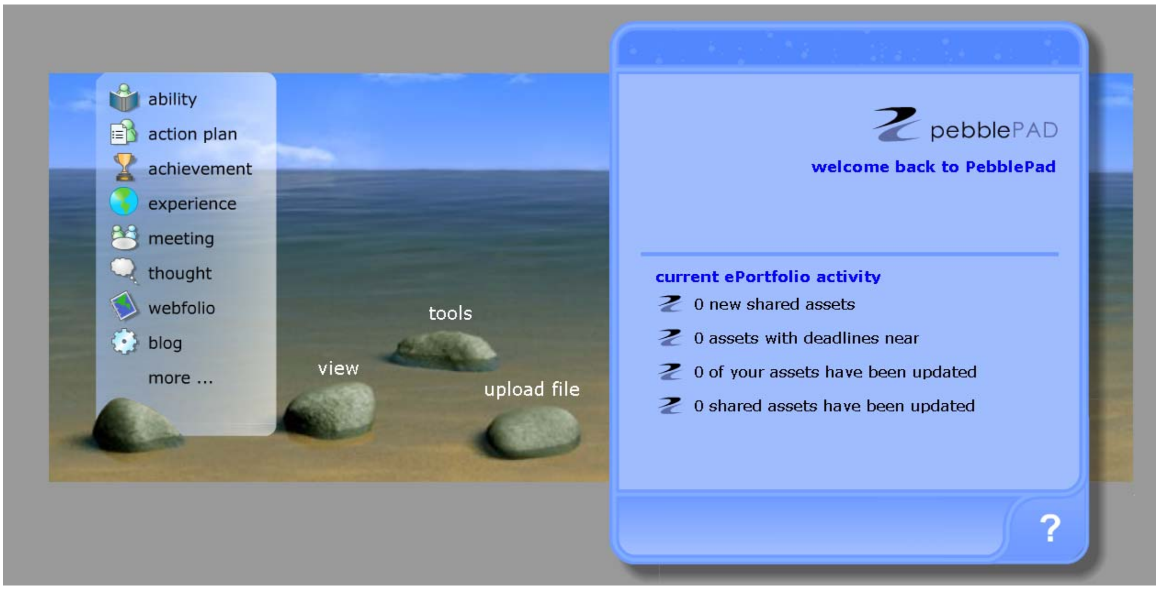

Figure 2. PebblePad© templates

The templates take someone through a stepped process of development and planning (Figure 3).

Figure 3. Creating and Action Plan in a PebblePad© template

The last two 'pages' are the same for any template and ask the users to reflect on what they have learnt by writing and using the template and finally what they would like to do with what they have created (Figure. 4).

Figure 4. Penultimate and ultimate pages in the templates

The templates then generate 'documents' in a user-friendly format (Figure 5) that look very different to the templates, adding headings and subheadings that are already embedded in the template.

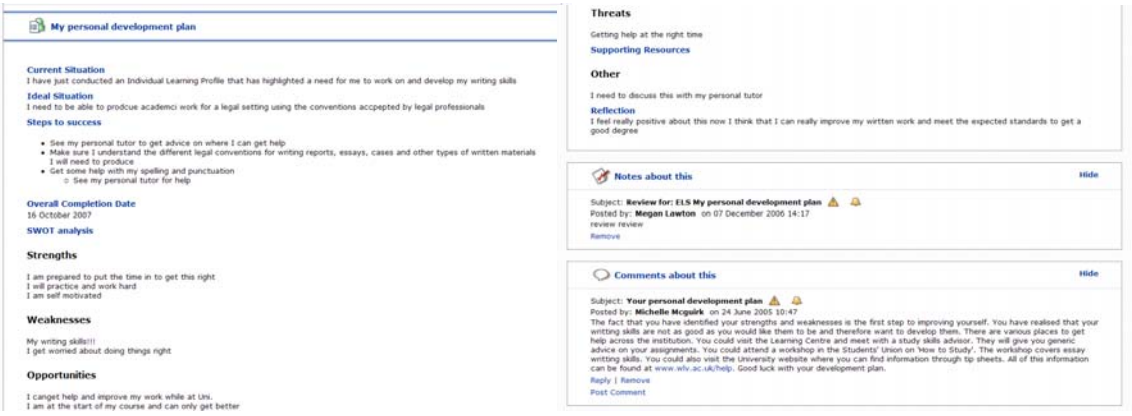

Figure 5. What the information from the template would look like when viewed

As stated previously, the tool has become more widely used members of staff are increasingly using it for formative and summative assessment. For example lecturers have used web folio templates that students can download and copy (Figure 6). They are then asked to personalise the web folio and undertake various assessment tasks. This template is shared with the tutor for comment and formative feedback throughout the module of study. When all tasks are completed the web folio is summatively assessed.

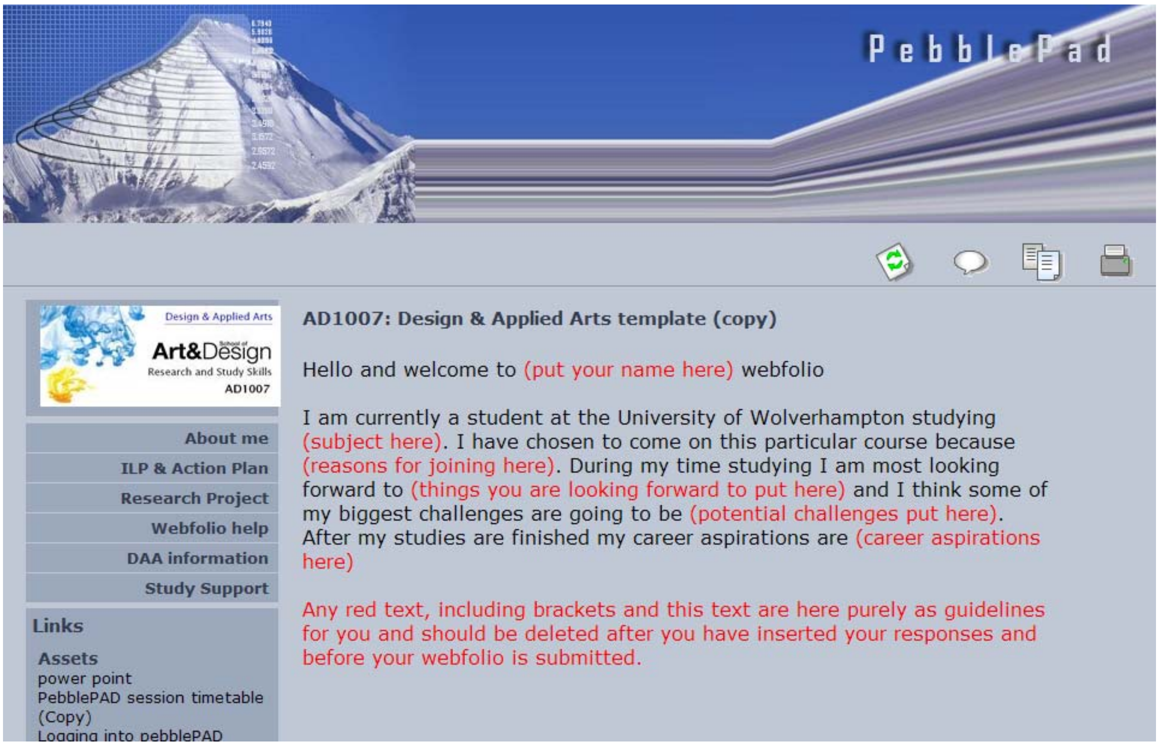

Figure 6. Web folio template for module AD1007 Research and study skills, The School of Art and Design (2006/7)

2.2 Pebble2

PebblePad© Version 2 (released 13th August 2007) offers two major new functions, the ability to create Profiles (self-evaluation questionnaires that staff can create to allow someone to audit their current knowledge, skills and abilities. Profiles can be created based on subject knowledge or skills or they may be based on professional standards from external organisations) and Proformas (forms that can be created for staff and students to fill in and save; files can be attached as evidence to a proforma).

3. ePortfolios within Construction related courses

The university's adoption of an ePortfolio has introduced a vehicle through which students on construction related courses, within the School of Engineering and the Built Environment can engage with PDP throughout their time at the university and on which they can continue to build throughout their professional career, particularly with the development of the Profile tool in Pebble2.

It was stated previously in this paper that use of PDP should be seen as *developmental and be used by students with tutor guidance* and that *PDP processes (should be) integrated throughout* the whole of the student experience at the university. This latter point has been the experience within the university to date: students are more likely to engage and to engage at a deeper level of learning if there is a structure to PDP use and it is integral to a student's programme of study. In addition, employability can be enhanced through PDP where students can "*see a 'pay-off' for the effort that they put in*" [11].

3.1 Embedding ePortfolios

Within the School of Engineering and the Built Environment the course leaders have identified core modules at each level of study for students on undergraduate programmes where there is already a requirement for reflection on personal development within the module. Having identified the modules within which the reflection will be both formatively and summatively assessed the course team develop the existing practice to incorporate engagement with the e-portfolio tool to ensure student engagement at an appropriate level and to show increased engagement and understanding from level to level.

Level One students take a module entitled *Communication and Key Skills* in their first semester. A key part of this module is self-reflection and action planning. Students are given tutor support to reflect on who they are at the commencement of their HE studies and how they change during the course of the first semester. In addition, they create action plans to address key aspects of their approach to study that will help them to develop as a professional in their chosen field. Templates are provided to assist the student in their self analysis and action planning. In previous iterations of the module all documentation was within Microsoft Word™ and was made available electronically through the VLE; with the introduction of the new features in PebblePad© Version 2 the templates are now accessed through this alternative electronic medium.

At level 2 students take a core module *Integrated Project* where they work in a multi-disciplinary team (Civil Engineers, Quantity Surveyors, Building Surveyors and Construction Managers) to put together a project proposal. Within the summative assessment of the module is a requirement for a written reflection on personal development during the module and how existing and new skills have been practiced and developed including positive and negative aspects of working within a team (in the HE context); students are given formative feedback on their PDP during the module.

At level 3 the programmes are more bespoke and there is no module that all students on construction related programmes undertake so at this level a core module for each award has been identified, for instance students on the Construction Management award will be both formatively and summatively assessed on the PDP within the *Development Economics Project*.

By introducing points of formative feedback leading to summative assessment using the ePortfolio tool students are given the opportunity to engage with PDP at each level of their undergraduate programme and are encouraged to expand the use of the ePortfolio tool to all aspects of their study. Key to their engagement is the demonstrable link to their future career and professional body requirements to maintain the currency of any professional qualification through CPD activities. By engaging with PDP within an undergraduate programme graduates will develop the abilities to recognise CPD needs and opportunities, to undertake effective and appropriate action planning and to reflect on their experience for future CPD.

3.2 And so to CPD…

The QAA [2] in their Guidelines for HE progress files state that:

Progress files support the idea that learning is a lifetime activity. The transcript and personal records will be important components of an individual's lifelong record of learning and achievement and the process of personal development planning is intended to strengthen the capacity of individuals to reflect upon their own learning and achievement and to plan for their own personal, educational and career development. This is a core learning process throughout the education system and in many work-based and continuing professional development contexts, and higher education will play a key role in developing this capacity in the context of advanced study

There is a requirement on most professionals to engage with Continual Professional Development; for instance the Chartered Institute of Building [12] state that: e*very member has an obligation under Rule 13 of the CIOB Rules of Professional Competence and Conduct to maintain the currency of the professional qualification through CPD*. And that *CPD is a key part of professional life for any CIOB member and underpins the value of the professional qualification. An institute that cannot demonstrate a firm commitment to CPD undersells its members.*

Individual members of professional bodies are normally responsible for their own CPD planning and achievement, and for the evaluation of the appropriateness and effectiveness of the activities that they undertake. The type and amount of CPD undertaken will depend on the individual, their responsibilities, ongoing development and career aspirations. The individual is normally required to maintain a comprehensive record of CPD activities and can choose how these are recorded. The CIOB [13] offer an on-line facility for keeping records of activity; use of this method is not compulsory and an alternative, such as the ePortfolio used at the University of Wolverhampton would also meet the CIOB's professional requirements.

Students at the University of Wolverhampton will become familiar with the ePortfolio tool during their studies, they will be able to use the tool to create soft copy, or hard copy CVs, to publish blogs and websites and to engage with personal development planning. Alumni will continue to have access to the tool beyond completion of their programme and will find it useful in maintaining their CPD records for both their personal / professional use and to provide evidence to their professional body, if required.

Through the adoption of a reflective approach to a student's personal and professional development an individual is able to identify reason and structure to their action planning to ensure that future activities are undertaken for appropriate reasons and with a particular goal in mind: whether that be for personal or professional needs. Structuring one's activities in this way will show long term benefits to the individual, their professional body, their employer and the economy in general by targeting time and effort to appropriate and effective uses.

3.3 Future developments

The ePortfolio tool used at the University of Wolverhampton (PebblePad©) has shown itself to be an effective and adaptable tool that is used widely within, and outside, the HE sector. As the growth in lifelong learning and development of alternative learning continues PebblePad© can be used as an effective tool within the professional's portfolio. A key potential use is for professionals to create personal learning records against existing professional requirements [14] for use in recording experiential, work-related and work-based learning that could be used towards achievement of a qualification at an appropriate level. The learning record created can be presented in a variety of either electronic or hard copy formats to suit the individual's needs whilst retaining the ability to be developed to reflect the user's changing professional development.

4. Conclusions

This paper has reviewed the introduction of Personal Development Planning within a post 1992 University within the UK and its development, implementation and embedding through PACE files (Professional, Academic, Careers and Employability) to an ePortfolio tool (PebblePad©). It has shown how ePortfolios have been embedded within Construction related courses at the University and offers a model that could be transferred to other HEIs.

The institutional stance, policies, support and attitude to the implementation of PDP influences student engagement with PDP processes through the use of an ePortfolio to enable students to evidence their reflection and personal development.

Through the students' experiences with ePortfolios at the University professional bodies will benefit from the students' ongoing CPD through their ability to target time and effort to appropriate and effective personal development that should be valued by all.

Developments in the curriculum of Environmental Building at the University of Plymouth

Paul Murray, Pieter de Wilde, Steve Goodhew, Susan Turpin-Brooks, Peter Holgate, Steve Donohoe and Michael Riley
Environmental Building Group, School of Engineering, University of Plymouth
(contact email: paul.murray@plymouth.ac.uk)

Abstract

The Environmental Building Group at the University of Plymouth educates students towards accredited degrees in Building Surveying and the Environment, Environmental Construction Surveying and Construction Management and the Environment; close links are in place with the local School of Architecture. The group has been active in this field for 10 years, and has pioneered the theme of environmental building surveying. Teaching efforts have led to national recognition in the form of a National Teaching Fellowship and membership of the Centre of Excellence in Teaching and Learning focused on Education for Sustainable Development (CETL-ESD).

This paper reflects on the strengths and weaknesses in the current curriculum, contributing to an upcoming course review evaluation in 2008. It aims to position the teaching at the University of Plymouth within a changing practice, where sustainability has become a mainstream concern. The paper will review the changes taking place in each of the major disciplines taught on the programme: surveying, building technology, renovation, law/finance, and project management. For each of these disciplines, the paper will discuss initiatives that are planned to keep the curriculum at the leading edge of the environmental building / sustainability field. The paper concludes with an overall analysis of the programme, taking a look beyond individual fields and assessing the overall content of the curriculum.

Keywords: Sustainability, curriculum, SWOT-analysis, future trends

1. Introduction to the Environmental Building Programme at the University of Plymouth

1.1 Programme Structure

The Environmental Building Group at the University of Plymouth offers students a range of courses that help them to prepare for a career in the fields of *Building Surveying and the Environment*, *Environmental Construction Surveying* and *Construction Management and the Environment*. These are offered at different levels: a foundation pathway course, BSc (Hons), MRes, MSc and PhD. The courses are all accredited by the relevant professional bodies, including CIOB (the Chartered Institute of Building) and RICS (Royal Institution of Chartered Surveyors). The programme is part of the School of Engineering, which provides excellent links with related areas of study like Civil Engineering and Mechanical/Marine Engineering. The programme also has close ties with the School of Architecture at Plymouth, with some shared modules and courses.

The programme is strongly related to professional practice in the building industry. Students on the undergraduate track are encouraged to spend a year on placement to gain experience and prepare for their career. While the programme offers all Higher Education Levels that students might undertake, there is a continuous influx of students entering academia at all levels after a period of working in practice. Furthermore, the programme has close ties with practitioners who provide guest lectures and take part in student assessment panels. The intricate interrelation between the courses and the building industry is graphically represented in figure 1.

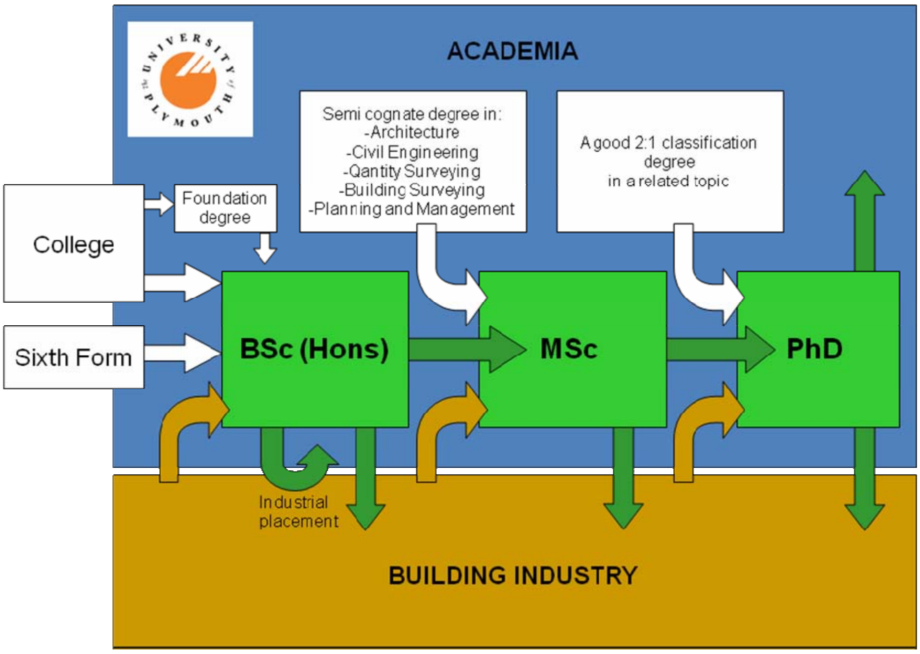

Figure 1: Interaction between Environmental Building Programme and the building industry at the University of Plymouth

The programme has a history that dates back to 1996, and has pioneered the theme of environmental building. Past graduates are sought-after by the industry, and have found their way to positions in the core disciplines but also into other areas like building control, development and historic building preservation.

The Plymouth programme has a strong track record in terms of pedagogical quality. In 1998 the programme was awarded the second highest aggregate grading (23 points out of 24) for teaching excellence in England by the Quality Assurance Agency. This was followed in 2000 by the award of £325000 from the UK government to transfer teaching excellence in flexible learning to other universities. In 2004 a prestigious National Teaching Fellowship was awarded to the then Head of Building Programmes for educational excellence and in 2007 the University of Plymouth received a Green Gown Award from the Higher Education Environmental Partnership Improvement organization for the contribution the Environmental Building Programme made to Education for Sustainability. The Environmental Building Teaching Team were also key contributors to the successful bid to set up a £4.5 million government funded Centre of Excellence in Teaching and Learning focused on Education for Sustainable Development (CETL-ESD). The fruits of these developments have been presented to national and international audiences over the last seven years, see for instance [1], [2], [3].

2. Curriculum development drivers

To stay at the forefront of the discipline the Environmental Building Programme at Plymouth needs to adapt to a constantly changing context. Over the 10 years that the programme has existed, important developments have taken place in the construction industry as well as in education. New technology and information sources have become available; the students starting their education today are different from those of 1996, and the industry has different expectancies of the skill and knowledge base they will be bring into practice. In general the building industry is increasingly aware that the environment and factors related to sustainability have become a major issue. Buildings have a huge impact on the environment in terms of energy use, waste, pollution and habitat destruction. As a consequence, there is a strong demand for graduates that have a background in the environmental aspects of construction. The programme at Plymouth is benefitting from this demand. Yet at the same time it also means that these is an increased offer of similarly oriented programmes from other Universities, and that the unique selling point that set the courses apart when they were launched in the 1990s needs to be reviewed. The changes in industrial practice are rapid, as exemplified by the ambition of the British government to require all newly-built homes to be carbon neutral at a time horizon of 2017. Such changes require the development of a strategic vision to maintain the programme at the cutting edge of ‘environmental building’.

The overall aim of this paper is to provide a position paper that evaluates the context of teaching environmental building at undergraduate, postgraduate and research level, identifying relevant changes and underpinning a vision for future development of the programme.

3. Changes within the major subjects of the programme

The main subjects that are taught within the programme are building surveying, building technology and building science, renovation and refurbishment, law and finance, process management, and land and environmental surveying. These disciplines are taught by a wide range of approaches, which involve student-centred learning [4], traditional lectures, workshops, laboratory experiments, site visits, design project work, and management games.

The following sections discuss the developments per subject, reflecting on changes that are apparent in industry, the implications of these changes for teaching the subject at the different course levels, and developing a view of required changes in the learning and teaching of the subject area.

3.1 Building surveying

The Building Surveying discipline traditionally centres on an understanding of the physical and functional performance of built assets. The central knowledge and skills of the building surveyor relate to building pathology - which involves a deep understanding of building decay mechanisms, analysing building condition and managing remedial works programmes. The discipline is overseen externally by the professional body, the Royal Institution of Chartered Surveyors which maintains standards educationally and professionally. In 2006 the RICS published new guidance on qualifying competencies for newly Chartered Building surveyors [5]; which as can be seen from Table 1 includes sustainability as a mandatory competency.

Table 1 RICS compulsory competencies for Building Surveyors (RICS 2006, p7)

Core competencies for Building Surveyors	**Mandatory competencies particularly relevant to Building Surveyors**
Building pathology Construction technology and environmental science Contract Administration Inspection Design and Specification Legal/regulatory compliance	Sustainability Conflict avoidance Health and Safety

As Table 1 demonstrates, building surveying as a professional discipline embraces a wide range of subjects associated generally with construction and the built environment. The inclusion of a compulsory sustainability competency however, is particularly pertinent development for the Environmental Building Programme as it sets a clear directional steer on educators to engage building surveying students with what is fast becoming a central professional theme. The RICS definition of what constitutes sustainability competency includes the ability to demonstrate how and why sustainability seeks to balance environmental, economic and social objectives at global, local and national levels in a built environment context, as well the ability to demonstrate and apply sustainability to practical and professional situations [5]. Efforts are also being made in teaching Building Surveying at Plymouth to integrate emerging themes such as flood risk assessment and remediation measures within the curriculum in response to the climate change agenda.

3.2 Building technology and building science

The subject area of building technology covers different aspects: it is involved with the systems and components that are used to construct buildings, the assembly and maintenance of the built environment, and last but not least with building science as a prime tool to understand how buildings and their (sub)systems function and perform.

The area of *building systems* and components is subject to rapid change in response to the increasing awareness of environmental problems. Structural systems made of in-situ and precast concrete, structural steel, timber and, mainly for domestic buildings, bricks continue to dominate the industry. Yet even these basic commodities start feeling the impact of high global demand and an increased scarcity of resources, leading to innovation and novel products in the field. Infill and cladding technology is evolving rapidly. Many large and representative buildings now employ active/intelligent/double facades, and increasingly integrate solar technologies and daylighting systems in the building shell. In terms of infill and partition walls industrialised, open systems are replacing traditional stud and sheet partitions. Some innovative buildings even experiment with the integration of phase-change materials in for instance gypsum board. New HVAC technology like micro-CHP units, small scale wind turbines, photochromatic glazing and heat pumps are quickly becoming commonplace in the industry. Interest in environmental friendly materials like cob, strawbale and timber from renewable sources is at an all time high. Within buildings, developments in ICT technology have large impacts, from the ICT connections provided for the occupants to the use of the same technologies for building operation/control and facilities management.

Assembly and maintenance are fast-developing under both economic and environmental pressure. With the decrease of skilled labour and continuous needs to make the construction process ‘lean’ there are continuous efforts to make the process more efficient and increasing quality of the end product. This coincides with the drive to reduce waste, both in terms of unwanted by-products as well as waste in productivity of construction equipment and staff. At the same time facilities management aims to guarantee reliability, maintainability, usability, and serviceability. Furthermore, there is an increased interest in looking at the whole building life cycle, bringing in interest in producibility and disposability and taking a cradle-to-cradle view.

The area of *building science* as an enabling discipline is relatively unaffected by the increased interest in environmental issues: the underlying physical principles like heat and moisture transfer, (day)lighting and acoustics remain the same, and have been the subject of physical research for a number of decades. Some progress is being made by developing new computer programs to evaluate different performance aspects, especially regarding air flow in buildings by means of CFD modelling and regarding daylighting. At the same time increased computational power allows a more holistic performance of processes, for instance combining lighting and thermal issues.

The impact of these developments on teaching in the Environmental Building Programme has different aspects. On the one hand, there is a continuous need to provide a strong scientific basis that allows students to understand and appraise novel systems, techniques and processes. At the same time there is a need to regularly update both the course content and lecturers experience with novel systems, ensuring the students are aware of the latest options available.

3.3 Renovation and refurbishment

Interest in the effective ‘use’ of buildings in the UK has undoubtedly been influenced by the increased ‘customer’ focus within the construction and property sectors within the last ten years, driven by the Egan Report and subsequent industry initiatives (M4i and Constructing Excellence). Coupled with this, the enabling technology within facilities management and maintenance, has ensured that the performance of buildings is mapped more accurately (e.g. BEMS and thermal imaging) and indeed related back to ‘user needs’ through various tools such as Post-occupancy Evaluation [6]. With this growing area of knowledge, more robust decisions about renovation and refurbishment can be made.

To be of most use in business, students need to appreciate the connectivity between science, technology and sustainability or performance assessments (leading to effective changes for buildings. Involvement with the CETL-ESD (see section 1) has enabled the Plymouth Environmental Building students to access real projects and hence gain appreciation of this holistic view in their undertaking of feasibility and refurbishment projects. Such student assignments have recently included final year students evaluating sustainability tools and thermal upgrading options for use on campus building projects, with feedback from this influencing some decisions by the University Estates Department (e.g. fenestration). Additionally, second year understanding of sustainability in this applied context has been achieved through sharing of information and views via a ‘Sustainability Forum’.

3.4 Law and finance

To inculcate “green” issues into the Law and Finance subject areas of the construction curricula, the simple addition of extra lectures “added on” to the programme is insufficient. Instead an approach has been developed that aims at “an active, constructive and cumulative process that occurs gradually over a period of time” [7], employing problem based learning [8]. In this context, , real life situations and problems in the field of law and finance are gradually introduced to students. For example, the first year syllabus includes a module where estimating is studied. Students are required to calculate unit rates for various construction trades. Traditionally this involved detailed calculations for labour, plant, materials, overheads, and profit for concrete work, bricklaying, roofing etc. The examples used in lectures have been expanded to include recycled and environmentally friendly products as well as traditional products. Later students are introduced to comparative estimating and are asked to investigate cost differences between various construction components such as cost differences between different mixes of concrete etc. Students are introduced to the notion that lowest cost might not be the only important factor in selection and are advised to consider the social and environmental costs of decisions. Students’ comparative estimating is expanded to a position where not only initial capital costs are considered but costs over the lifetime of a building are included using complex examples and case studies.

In the subject area of law, students study Environmental Law and Regulations as well as traditional legal subjects such as Contract, Tort, Property Law, etc. In the second year of the undergraduate curriculum, students study standard forms of contract and their applicability to project scenarios. Gradually students are introduced to the RIBA Programme of Work. Eventually The BRE guide to Sustainability is superimposed onto the RIBA Programme of work to reflect on how decisions affecting the environment can impact on every stage of a construction project. A problem based learning scenario based upon an actual construction law case is used for the law assignment in the second year undergraduate course. In addition, students are required to give procurement advice as part of their second year and final year projects. Students are also asked to produce budget estimates and life cycle cost reports as part of these projects.

At Masters degree level, students investigate cost modelling in greater depth than their undergraduate colleagues. Postgraduate students are invited to critique a journal paper, for example, Worth et al's [9] exploration of life cycle costs of four alternative types of roofing systems. The life cycle costs involve a wider scope of calculation than traditionally undertaken and include such factors such as carbon emissions, embodied energy and energy conservation. In the law subject area, Masters degree students consider wider issues of sustainable procurement and explore whether some construction contractual arrangements for the procurement of buildings are more environmentally friendly than others.

3.5 Process management

Process management is the knowledge area that supports the building process, rather than the building product. This is covered in most modules of the programme. The importance and benefits of thinking about the construction process at the very start of the project is being recognised by industry and leads naturally to (recent) innovations in construction, such as partnering, joint ventures, supply chain management and special delivery vehicles. However there is still a real lack of understanding of these ideas in the construction industry and this reinforces the need for all graduates to know the underpinning ideas for these new ways of working.

A theoretical model, underpinning and explaining these newer ways of working needs to be presented to students to ensure that they do not use a cookbook style of learning, and this is provided by systems theory. Theoretical ideas from research in trust, culture and collaboration are needed to enable the new strategies to work. Systems theory can also help understand the more traditional areas such as project management – how and why they fail or succeed for example; it also provides a better explanation of more recent ideas such as lean construction and more sustainable ways of managing the construction process.

The integration of both product and process into one model will become important in the future to enable the client to make fully informed choices from the range of alternatives. We will have to develop new theoretical ideas and ways of teaching these things to both the undergraduate and postgraduate students. It is essential that Plymouth provides its graduates with the ability to cope with future changes in the sector.

3.6 Land and environmental surveying

This area of the curriculum includes learning within the fields of level surveying and measurement, the regulation of land use through the Town and Country Planning System, the issues around the effects of change of land use by development which is assessed by environmental impact assessment and the problems caused by previous uses of land which have left it at the risk of being contaminated.

In environmental terms change has taken place towards consideration of the whole sites, not just the buildings. This requires students to consider both the hard and soft landscaping as a means of improving the setting of the building in its surroundings.

The awareness of the need to obtain planning permission for a project has to be extended due to new requirements relating to the granting of permission. These relate to changes, designed to take environmental and sustainability issues into account. This has been done through changes in planning policy as well as the revisions to the Environmental Impact Assessment (EIA) regulations [10, 11] which required EIAs to be carried out for smaller projects than was required by the original regulations and to cover additional issues such the consideration of alternative sites.

To reduce the amount of green field land used for development and to encourage the redevelopment of urban areas the government has introduced a policy of re-using brownfield (i.e. previously developed land). This requires more detailed coverage of this in the curriculum as many of these brownfield sites are contaminated. The pressure to use brownfield and hence possibly contaminated land required this to be covered in the syllabus as developers were going to need to be aware of a whole range of issues - definition of what constitutes 'contaminated land', how to avoid taking an unforeseen responsibility when buying it, and an overview of the investigation and remediation processes.

All of these aspects are becoming increasingly important for setting the context within which the construction of the actual buildings takes place and therefore are of considerable importance in achieving sustainable development.

4. New curriculum directions

Sustainability is fast emerging as a central paradigm for construction education as demonstrated by The RICS inclusion of sustainability as a mandatory competency for all types of surveyor [5], the UK government and other professional bodies such as the Chartered Institute of building and the Royal Institute of British Architects [12]. While the Environmental Building Group has taken structured and active steps both to assess and enhance the sustainability content of the Environmental Building Degree Programme the implications of this new paradigm is that within ten years the curricula of ***all*** construction-related programmes will be expected to fully embrace sustainability.

In order to maintain a leading position in this changing context, the Environmental Building Group is reflecting on the long-term changes expected for its discipline of construction. In this future, the group expects a larger emphasis on safety, and the role of industry in the general future of humanity – allowing the human race to cope with a range of pressing issues like climate change, population growth, shortage of fossil fuel, and ecological problems (ecodiversity, acid rain etc). Given the scale of these problems, it seems unlikely that mitigation is going to solve all; it therefore seems paramount that the discipline starts working on resilient technologies, and response to inevitable changes in our environment. Furthermore, the group recognizes two approaches towards a ‘sustainable’ future: 1) gradual change, with a residual gap between what is needed and what is actually achieved, and 2) step change, which requires instant changes in the workings of the industry.

Preparing itself for this future, the Environmental Building Group at Plymouth has put in place a strong base for ensuring the sustainability literacy of our students, by providing them with an understanding of the set of environmental problems faced, as well by handing them the knowledge and skills to contribute to changing the industry. At the same time a new impetus is given to work that aims at helping the industry respond and adapt to change; this work has a strong research component, as this a developing field. Both these efforts align well with gradual change to a sustainable future. On a longer horizon, the team is starting to contemplate the needs of working to step change, and its impact on both the understanding, knowledge and skills this will demand from future staff, students and construction professionals. These views are depicted in figure 2.

In practical terms, the Environmental Building Group recognizes a need to increase the research base if it is to contribute significantly to resilience, responsiveness, and step change. At the same time the compact structure of the group provides a flexible starting point for steering in a novel direction.

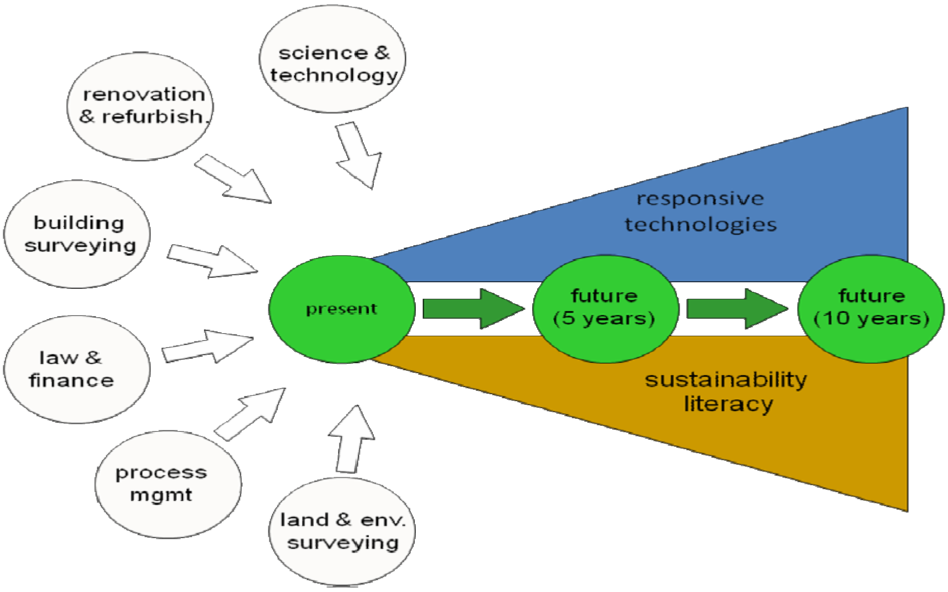

Figure 2:Curriculum development of the Environmental Building Programme at the University of Plymouth

5. Conclusions and remarks

The preceding sections underpin the following conclusions and remarks:

- ‘Environmental’ and ‘sustainability’ issues are having an increasing impact on the construction industry, and on the academia that prepare new professionals for a career in this field. Any curriculum needs a regular update, but students in this discipline also need to be made aware that Environmental Building is a rapidly developing field that is facing large changes. Students need to be equipped to take a leading role in guiding the industry into the future.

- Focussing on a developing discipline provides ample opportunity to combine teaching and research, and for growth of the programme. There are good job opportunities for graduates.

- Although the science underlying the curriculum in Environmental Building is quite stable, rapid changes are taking place in the application of these underlying principles in construction practice, building methods, and building systems.

- For the longer term future, the curriculum of the University of Plymouth will prepare for both gradual and step change. To do so, it has identified the subfields of ‘sustainability literacy’ and ‘responsive technologies’ as key enablers for what is to come.

- There remains a need to ensure that students become critical, independent thinkers, and that the programme does not slip towards what is named ‘greenwash’ in industry (a term used to denounce projects that seem more concerned with an environmentally friendly appearance than with actually addressing the underlying environmental issues).

Abstract

E-business models are emerging in many business sectors [1], although the potential has been realised, the level of implementation and penetration has not been as predicted. E-business achievements in other industries exemplify the potential for construction. However, its poor uptake (less than 2.9%) suggests the lack of usage of e-procurement in UK construction [2].

There are many drivers and barriers to e-procurement. Previous studies in the US [3,4] and Australia [5] ranked these for the general procurement of goods and services. A pilot study for this research, Eadie et.al [6] ranked the drivers and barriers to e-procurement in construction from the perspective of contractors working for the Northern Ireland public sector.

Perera et.al. [9] suggested a methodology for the production of an e-capability maturity model for construction organisations. To strengthen this methodology a Delphi process was added to the suggested methodology. This paper collates the findings on identified drivers and barriers from literature and reports on the findings of the Delphi process, confirming those that apply to the construction sector.

Keywords: Drivers and Barriers, e-procurement, e-readiness

1. Introduction

1.1 E-Procurement in Construction

Alshawi et.al. show that the increased use of e-procurement has led to the development of models in a number of business sectors [1]. E-business savings and efficiencies in other industries show the benefits that construction could potentially harness. However, Martin [2] shows, that less than 2.9% of construction work is procured in this manner, suggesting that there is less usage of e-procurement in the UK construction industry.

In order to investigate the low uptake of e-procurement in construction, it was deemed necessary to identify the drivers and barriers to e-procurement. There is only a limited amount of research reported in this area. Eadie et.al.[6] attempts to address this issue with a preliminary study into drivers and barriers to e-procurement in construction. By utilising the application of established drivers and barriers from other industries and applying them to construction, it was possible to produce a ranking of drivers and barriers for this sector.

This paper collates the findings of the preliminary study [6] into drivers and barriers to e-procurement in construction and successfully rigorously verified the applicability of drivers and barriers to construction using the Delphi methodology.

1.2 E-Procurement drivers and barriers identified from literature

The drivers and barriers to e-procurement identified through literature contain a list of 21 drivers and 31 barriers. Table 1 lists drivers to e-procurement identified from literature.

Table 1 Drivers to construction e-procurement identified from Literature

No	**Drivers from Literature**	**Referenced in:-**
1	Process cost savings -(Tender / Purchase Process)	Knudsen[10], Minahan & Degan [4]
2	Service / Material / Product Cost Savings	Minahan & Degan [4]
3	Transaction Administration Cost Savings	Davila et.al. [3],Panayiotou et.al.[13]
4	Reduced Administration Costs	Egbu et.al. [14], Hawking et.al.[5]
5	Increasing Profit Margins	McIntosh & Sloan [16], Wong & Sloan [17], Ribeiro [18]
6	Strategic Cost Savings	Knudsen [10]
7	Enhanced Inventory Management	Hawking et.al. [5]
8	Decrease in Costs through reduced staffing levels	Kong[19], Davila et.al. [3], Egbu et.al. [14]
9	Shortened Overall Procurement Cycle Times	Minahan & Degan [4]
10	Shortened Communication Cycle Times	Knudsen [10]
11	Reduction in time through greater transparency (Less objections)	Panayiotou et.al. [13]
12	Reduction in Evaluation Time	Panayiotou et.al. [13]
13	Reduction in Time through improved internal workflow	Panayiotou et.al. [13]
14	Reduction in purchasing order fulfilment time - Contract Completion	Davila et.al.[3]
15	Reduction in time through increased visibility	Kalakota et.al.[12]
16	Increased Quality through increased competition	Kalakota et.al.[12]
17	Increased Quality through Benchmarking (Market Intelligence)	Hawking et.al. [5]
18	Increased Quality through increased visibility in the supply chain	Minahan & Degan [4], Hawking et.al. [5]
19	Increased Quality through increased efficiency	McIntosh & Sloan [16], Ribeiro [18]
20	Increased Quality through Improved Communication	Hawking et.al. [5]

No	**Drivers from Literature**	**Referenced in:-**
21	Gaining Competitive Advantage	Wong & Sloan [17]

Table 2 lists barriers to construction e-procurement identified from literature.

Table 2 Barriers to construction e-procurement identified from Literature

No	**Barriers from Literature**	**Referenced in:-**
1	Upper Management Support / Lack of Leadership	Davila et.al. [3], Hawking et.al. [5]
2	Other Competing Iniatives	Kheng et.al. [19]
3	Resistance to change	Davila et.al. [3]
4	Lack of a widely accepted solution	Davila et.al. [3]
5	Magnitude of Change	Kheng et.al. [19]
6	Lack of a national IT policy relating to e-procurement issues	Carayannis et. al. [20]
7	Lack of Flexibility	Carayannis et. al. [20]
8	Bureaucratic dysfunctionalities	Carayannis et. al. [20]
9	Complicated procedures and extended relationships	Carayannis et. al. [20] examine excessive state intervention.
10	Lack of technical expertise	Davila et.al. [3]
11	Staff turnover	Kransdorff [21]
12	Slowdown in the uptake of internet services since the dotcom bubble burst	Christensen et.al. [22]
13	Company access to the internet	Smith - BBC Webpage [23]
14	Religious objections to the internet	McMullan[24] CPD Correspondence
15	Insufficient assessment of systems prior to installation	Forrest [25]
16	Security in the process - Data transmission to the wrong person	Gebauer et. al. [26], Kheng et.al.[19]- 59% of companies in Singapore cite security as the main barrier.
17	Confidentiality of information - unauthorised viewing	Gebauer et. al.[26]
18	Prevention of tampering with documents - changes to documents	Gebauer et. al.[26], Feniosky and Choudary [28]
19	Data transmission reassembly - incorrect reassembly of data transmitted in packets	Jennings [29]
20	Partial Data Display - incomplete documents provided	Jennings [29]
21	Lack of pertinent case law	Hawking et. al.[5],Price Waterhouse Coopers[30]
22	Different national approaches to e-procurement	Carayannis et. al. [20]
23	Proof of intent - electronic signatures	Rawlings J [31], Dumortier et.al. [32], Wright [33]
24	Clarity of sender and tenderer information	Wright[33],Dumortier et.al. [32]
25	Enforceability of electronic contracts	Jennings[29],CITE website[34]
26	Information technology investment costs	Irani & Love[35],Wong & Sloan [17]
27	Cost of assessment of systems to find correct system to fulfil tasks	Forrest[25],Wong and Sloan [17]
28	Internal Compatibility	Davila et.al.[3],Boeing [37]
29	External Compatibility	Davila et.al.[3], Boeing [37]

No	**Barriers from Literature**	**Referenced in:-**
30	Investment in compatible systems	Davila et.al.[3]
31	Reluctance to "buy-into" one off systems	Irani and Love [35]

2. The Delphi Process

A full Delphi process was carried out to ensure that the drivers and barriers identified from general e-procurement studies applied to construction. It was also used to identify any further drivers and barriers to construction e-procurement.

2.1 The Delphi Process definition

The Delphi process can be defined as "*A social survey technique which involves polling experts and others for their prediction on important demographic, political, economic, technological, and social trends*" [38]. The Delphi Methodology is a defined process allowing the collection of tacit knowledge from a group of experts utilising a series of questionnaires and additional controlled opinion feedback [39,40]. It is well suited as a research instrument when there is imperfect knowledge about a problem or experience [39].

The Delphi technique was regarded as the most appropriate instrument to collect data to enable the formation of a list of drivers and barriers to construction e-procurement as it allows solicitation and aggregation of informed judgement from a group of experts on specific questions or issues [27]. The identification and confirmation of drivers and barriers to e-procurement does not befit precise analytical techniques but is more suited to the collection of group opinions from experts who can contribute their experience from diverse backgrounds within the construction industry.

The 'classical' Delphi method was used, where data is collected from experts individually over a number of consultations; results are fed into the following cycle until they are stable and a consensus level of 60% is reached.

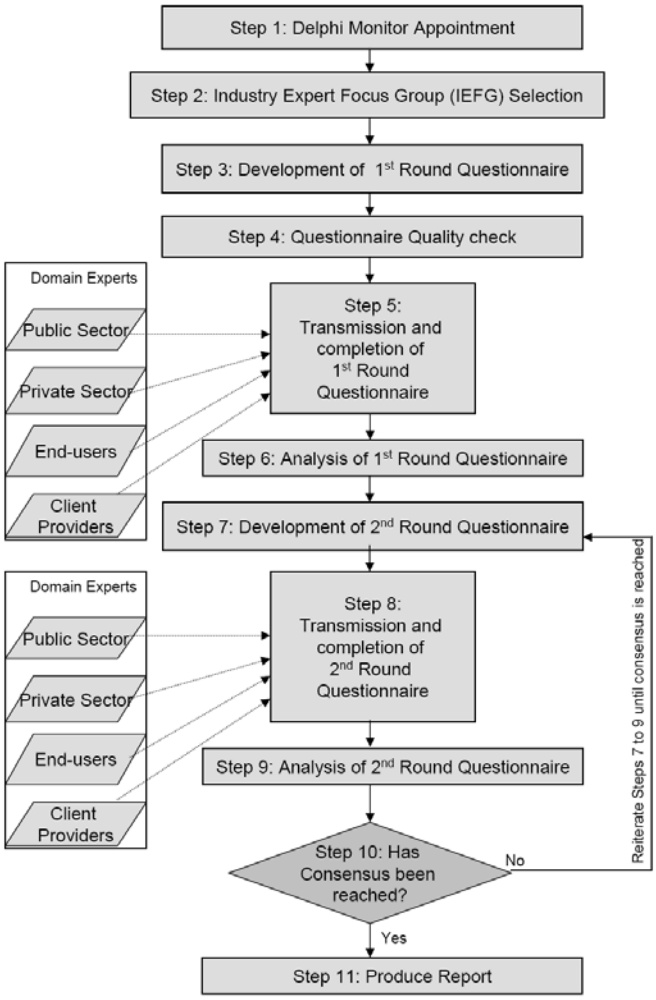

Figure 1: Schematic of the Delphi process as adapted for this study

2.2 Delphi Process Industry Expert Focus Group (IEFG) Selection

For Figure 1 Step 2 Dalkley[15] shows that "Using the expert as a surrogate for direct knowledge poses no problems as long as the expert can furnish a high-confidence estimate based on firm knowledge of his own". The entire industry expert focus group (IEFG) were stakeholders; had direct knowledge of e-procurement from a construction perspective and had used or implemented e-procurement systems within construction. This allowed the IEFG to add their extensive "everyday experience" to the incomplete data from previous studies in other fields. Linstone and Turoff [8] conclude that the selection of the expert group improves the accuracy to a greater degree than feedback or iteration. All but one of the IEFG had worked in the construction industry for more than 10 years. The final member had worked in the industry for seven years. Ludlow [7] concludes that respondents will be more receptive if the techniques are tailored to specific groups on the basis of their training and experience.

Stakeholders were chosen who had shown they were capable of acting as facilitators. As well as being directly engaged and involved in e-procurement each panel member was also chosen for his/her clarification, organisational, stimulation and analytical skills. Each panel member had written internal reports on contractual issues for their organisation.

2.3 Analysis of Representativeness of the IEFG

The IEFG for the Delphi process had to represent the entire construction industry, therefore, a list of attributes that measure representativeness was identified in Table 3. Two representatives from the public and private sector were selected to maintain a balance, with the last representative being from a wholly owned government company. All members of the IEFG had extensive experience and direct responsibility for e-procurement issues within their respective organisations.

Experiments by Brockhoff [36] and Boje and Murnighan [11] suggest that under ideal circumstances, groups as small as three or four can perform well. Brockhoff [36] also suggests that a general positive relationship between group size and group performance cannot be recognized and smaller groups perform equally as well as large. One prerequisite is that the panel must be homogeneous in its makeup. The IEFG for the Delphi process can be considered homogeneous as they are all members of the construction industry which enables the limitation of group size to five.

Table 3: Representativeness of the various panel members

Attributes necessary	Criteria	How Achieved with panel
Homogeneousness	Member of the Construction industry. Required 100% of panel	5 out of 5 **adequate**
Expertise	100% of panel require Membership of Professional Body to meet requirements of Shields et.al 1987	5 out of 5 **adequate**
Gender Balance	Male / Female - Equal number	3 – 2 **adequate**
Sector Balance	Public / Private Sector - Equal number	2 public – 2 private - 1government owned company **adequate**
Direct Responsibility	Implementation of a system of e-procurement from a client perspective	3 out of 5 – 60% of the panel had been instrumental in implementation within their organisation **adequate**
Experience	User (Formation of Documents from a client perspective) - 40% of panel – knowledge of issues relating to the use of e-procurement	4 out of 5 – 60% of panel had formed contract documents. 3 public and 1private sector. **adequate**
	User(Completion of Documents from an end user perspective) - 40% of panel – knowledge of issues relating to the use of e-procurement	2 out of 5 – 40% of panel had completed contract documents. **adequate**

Attributes necessary	**Criteria**	**How Achieved with panel**
Willing to take part in Delphi Process	100% of panel	5 out of 5 **adequate**

2.4 Delphi Process application

On the first round of the Delphi process the panel was provided with the initial list of identified drivers and barriers to e-procurement from literature (Table 2 and Table 3) in the form of a developed questionnaire (Figure 1 Steps 3 and 4). They were asked to rank these as to their importance to construction. The scale chosen was 1 – very important, 2 - important, 3 – necessary and 4 – not very necessary. IEFG members were requested to add other drivers and barriers that they felt would also impact upon construction e-procurement (Figure 1 Step 5). The results of the questionnaire were then analysed as per Figure 1 Step 6.

3. Findings

Boje and Murnighan [11] show that while confidence increased as the number of rounds increased, accuracy decreased. It is therefore important to get a consensus of opinion in as few iterations as possible. The first iteration reached a consensus level greater than 60% on all the drivers and all but three of the barriers. These were *"staff turnover"," slowdown in the uptake of internet services since the dotcom bubble burst"* and *"religious objections to the internet"*. These were forwarded to the second stage for further analysis. Eight additional drivers and four barriers were identified by the panel. However, after further contact with the panel only three drivers namely, *"Increased quality through increased accuracy (elimination of errors through computer use)"*, *"convenience of archiving completed work"*, and *"develops the Technical Skills, knowledge and expertise of procurement staff"* were added to the second round of the process and list of drivers. *"Perception of no business benefit realised", "lack of publicity / awareness of best practice solutions"* and *"a lack of a forum to exchange ideas"* were added to the list of barriers. It was agreed by those raising the additional drivers and barriers that five of the eight additional identified drivers and one of the barriers had previously been covered in the initial list.

These results were carried into the Delphi second stage questionnaire (Figure 1 Step 7). The second round questionnaires were split into three sections:-

Section A: - To get consensus as to the removal or otherwise of the three barriers identified in the first round of questionnaires. This was achieved with staff turnover being included and the other two being rejected after additional information being submitted to the panel.

Section B: - To get consensus as to the inclusion or otherwise of the additional drivers and barriers identified in the first round of questionnaires. Consensus was achieved that the following drivers and barriers would be included. *"Increased quality through increased accuracy (elimination of errors through computer use)", "convenience of archiving completed work"*, and *"develops the Technical Skills, knowledge and expertise of procurement staff"* were added to the list of drivers and *“perception of no business benefit realised”, “lack of publicity / awareness of best practice solutions”* and *“a lack of a forum to exchange ideas”* were added to the list of barriers.

Section C: - To examine if the amalgamation of the drivers and barriers identified through conversations would be acceptable to all. The amalgamation of the following drivers - Process Cost Savings - (Tender / Purchase Process), Transaction Administration Cost Savings, Reduced Administration Costs and Decrease in Costs through reduced staffing levels into "Process, Transaction and Administration Cost Savings", Shortened Communication Cycle times and Reduction in time through improved internal workflow into "Shortened Internal and External Communication Cycle times" and Amalgamation of Lack of a widely accepted solution and cost of assessment of systems to fulfil tasks into "Lack of a widely accepted e-procurement software solution" was also agreed by all the panellists.

Consensus on all items was reached after two iterations (Figure 1 Step 10).

4. Conclusions

The aim of using the Delphi process was to obtain a confirmed list of drivers and barriers to construction e-procurement that was agreed upon by representatives from all sections of the construction industry. Consensus was achieved and these findings have been used to produce an instrument for ranking drivers and barriers to Construction e-procurement (Table 4, Table 5).

Table 4 Final list of Drivers after completing the Delphi Process

No	**Drivers from Literature and Delphi Process**
1	Process, Transaction and Administration Cost Savings
2	Service / Material / Product Cost Savings
3	Increasing Profit Margins
4	Strategic Cost Savings
5	Enhanced Inventory Management
6	Shortened Overall Procurement Cycle Times
7	Shortened Internal and External Communication Cycle times
8	Reduction in time through greater transparency (Less objections)
9	Reduction in Evaluation Time
10	Reduction in purchasing order fulfilment time - Contract Completion
11	Reduction in time through increased visibility
12	Increased Quality through increased competition
13	Increased Quality through Benchmarking (Market Intelligence)
14	Increased Quality through increased visibility in the supply chain
15	Increased Quality through increased efficiency
16	Increased Quality through Improved Communication
17	Gaining Competitive Advantage
18	Increased Quality through increased accuracy (Elimination of errors through Computer use)
19	Convenience of archiving completed work

No	**Drivers from Literature and Delphi Process**
20	Develops the Technical Skills, knowledge and expertise of procurement staff

Table 5 Final list of Barriers after completion of the Delphi process

	Barriers from Literature and Delphi Process
1	Upper Management Support / Lack of Leadership
2	Other Competing Iniatives
3	Resistance to change
4	Lack of a widely accepted e-procurement software solution
5	Magnitude of Change
6	Lack of a national IT policy relating to e-procurement issues
7	Lack of Flexibility
8	Bureaucratic dysfunctionalities
9	Complicated procedures and extended relationships
10	Lack of technical expertise
11	Staff turnover
13	Company access to the internet
15	Insufficient assessment of systems prior to installation
16	Security in the process - Data transmission to the wrong person
17	Confidentiality of information - unauthorised viewing
18	Prevention of tampering with documents - changes to documents
19	Data transmission reassembly - incorrect reassembly of data transmitted in packets
20	Partial Data Display - incomplete documents provided
21	Lack of pertinent case law
22	Different national approaches to e-procurement
23	Proof of intent - electronic signatures
24	Clarity of sender and tenderer information
25	Enforceability of electronic contracts
26	Information technology investment costs
27	Internal and External interoperability of e-procurement software
28	Investment in compatible systems
29	Reluctance to "buy-into" one off systems
30	Perception of no Business Benefit Realised
31	Lack of publicity / awareness of best practice solutions
32	Lack of a forum to exchange ideas

A further detailed survey of the UK Construction Industry will be completed to rank these drivers and barriers to construction e-procurement.

Abstract

Today it is widely accepted that ICT is becoming a strategic asset for any organisation to deliver business improvement and achieve sustainable competitive advantage. However, traditionally the construction industry has approached investing in ICT with a lack of strategic focus and low level of priority to the business. The nature of such investments have been made very much in an ad hoc manner with the focus on improving specific processes predominantly driven by technology, rather than towards business improvement driven by the strategic objectives of the business. As such, this may have delivered isolated areas of improvement within the organisation but has contributed little in the context of strategic benefit. This paper presents a recent study focused on investigating the current strategic role of ICT in the Turkish Construction Industry. The study explores issues relating to the role of ICT strategy, reasoning behind ICT investments, barriers to the successful implementation of ICT and role of ICT through the lifecycle of a facility/project.

Keywords: ICT, Strategic Role, Investment, Turkish AEC Industry, Construction

1. Introduction

Over the last 30 years the evolution of ICT has led to construction organisations increasingly adopting technology in support of their businesses. ICT is now widely accepted as becoming a key element of any organisation as they strive to ensure sustainable competitive advantage. However, since the initial enthusiasm of the industry during the 70’s in their adoption of CAD applications, the investment in ICT has (in the main) been extremely ad-hoc. Traditionally, ICT investments have been driven either by demands generated at operational levels to satisfy particular needs (bottom-up) or requests issued by senior management to meet specific business requirements (top-down). This ‘Technology Push’ approach to investments in ICT results in the development of ICT-driven solutions that are unlikely to deliver real strategic benefit to the organisation. Furthermore, the nature of the industry has been such that ICT investments have not been perceived of strategic importance and a priority to the business. Although the introduction of several advanced ICT applications may have contributed to the improvement in the efficiency and performance of a number of processes, often the overall efficiency and performance of an organisation has not been realised in terms of meeting the strategic business objectives. This is a result of the development and implementation of ICT that is not part of an overall ICT strategy and/or the implementation of an ICT strategy that is not aligned to the strategic objectives of the business. Emphasis therefore in facilitating sustainable competitive advantage has to be on establishing strategic policies for ICT investment that are formulated to align with the business strategy thereby leading to more business-driven ICT solutions. The results of previous research on measuring the ICT use and trends in Turkey [1] indicated that, as similarly to many countries, the Turkish construction industry has been facing difficulties related to communication and loss of information due to fragmentation in the industry. In 2002, ICT was viewed as a strategic resource by senior industry figures in Turkey and they indicated that they were ready to spend time and effort in order to increase the ICT awareness and improve training. The overall research aimed to identify whether the Turkish construction industry currently views ICT as strategically important. The research methodology is summarised in the following section.

1.1 Research Methodology

The study began with a comprehensive literature review in the area by looking at the role of ICT in the AEC industry and the studies on evaluating the usage and benefits of ICT for AEC organisations. In the next stage semi-structured interviews were conducted with contractors and consultants in light of a questionnaire. During the interview process a range of areas such as the role of ICT strategy in the organisation, the reasons for investments on ICT and barriers to successful implementation of ICT for the organisation were investigated. The results of the literature review are summarised in the next section, followed by the findings of the interviews along with an analysis of these findings.

2. Background

2.1 The Role of ICT in the AEC Industry

The literature review identified numerous questionnaire surveys and case studies on investigating the usage and the strategic role of ICT in the construction industry. For example, Li and Wang [2] presented a “5Cs” evaluation framework to assist construction companies to predict, measure and evaluate the potential benefits that can or should be gained by the introduction of IT. Love at al. [3] presented findings of a questionnaire survey related with IT investments of SMEs in the Australian construction industry. Three findings were mentioned as (i) the different organization types significantly differ in the amount they invest in IT but this is not influenced by organisation size, (ii) strategic benefit varies with different organization types and (iii) the way in which employees adapt to change as a result of IT implementation differs with organisation size. Based on the above mentioned findings, Love *et al.* [4] proposed a pragmatic ex-ante IT evaluation framework which can be used by construction organizations to ameliorate their investment decision-making process. Peansupap and Walker [5] explored the factors influencing ICT adoption within construction organizations. As a result, researchers determined that individual and environment factors generally have a high impact upon ICT diffusion but management and technology factors have a slightly above moderate impact. Following this, Peansupap and Walker [6] stated that people-related factors are crucial in effective ICT implementation and support at the personal, workplace and organisational level is clearly needed. Hua [7] conducted an IT Barometer in Singapore and compared the results with previous IT Barometer studies on Nordic Countries. Hua [8] later conducted an industry-wide survey by adopting the IT Barometer questionnaire and applying stratified sampling to Singapore's AEC SMEs. In the study, the characteristics of ICT usage by the AEC companies were compared and the alignment of business and ICT strategies of the AEC companies was examined. Tse and Choy [9] investigated the differences in the use of IT by conducting an in-depth interview with three major quantity surveying organisations in Hong Kong. The authors found that the full potential of IT to improve organizations' efficiency, effectiveness and flexibility has seldom been reached and then they apprised that a sector to enter the IT era must employ the right sort of technology by a sufficiently large number of the supply chain and stake holders.

A significant amount of research has also been carried out related with the barriers for ICT implementation and the critical success factors to implement ICT. Stewart et al. [10] presented a conceptual framework for incorporating the impediments like operational factors, financial constraints, limited marketing and human resource management expertise, limited strategic planning and ineffective IT implementation. The authors [11] then explored the most effective coping strategies to overcome these impediments. A survey study was undertaken in Australia by Gajendran et al. [12] to identify the critical success factors that underpin the integration of ICT in supply chains. As a result, organizational commitment, organizational attitude to communication, rights and duties, investment drive and guarantee/protection/assurance were identified as critical issues to be addressed by organisations wishing to successfully adopt and integrate ICT into their supply chain operations. Ugwu and Kumaraswamy [13] identified two trajectories of IT project success and failure in construction, and the critical success factors that could be useful for IT applications, based on the research conducted over the period 2000-2004 in Hong Kong. Brandon et al. [14] identified the ingredients such as convergence, connectivity, culture, creativity, content improvement and collaborative working needed to "tip" the balance for an accelerated penetration of information technologies into the construction industry. The authors suggested that design and nD modelling, B2B and KM are the areas where current and future research may lead to a transformation of how the industry behaves.

2.2 Evaluating the Usage and Benefits of ICT for the AEC Industry

Another field of research to emerge during the literature review is that of evaluating the usage and benefits of ICT (and ICT applications). For instance, Andresen et al. [15] recommended a framework for measuring the benefits of IT implementations. Parasuraman [16] ameliorated a multiple-item scale to measure readiness to embrace new technologies in marketing.

Other recent studies in the area include El-Ghandour and Al-Hussein [17] who presented a holistic view of ICT applications in construction during the years 1992 and 2002, Rivard et al. [18] who conducted case studies about the usage of IT in Canadian construction industry, Oladapo [19] who investigated the level of use ICT usage and the factors impacting the level in the Nigerian Construction Industry, Scheer et al. [20] who sought the application experiences of IT in construction industry in Brazil, and El-Mashaleh [21] carried out a modified version of an IT Barometer survey in Jordan’s AEC industry.

In addition, [22] [23] [24] can be referred to as further studies related to the applicability and usage of ICT in Construction, while there have been other studies for determining the role of ICT in AEC which can be found in [25],[26],[27]

2.3 Background on Use of ICT in Turkish AEC Industry

The literature review in the field identified three research papers that investigated the role of ICT in the Turkish AEC industry. The first is entitled “*A survey of ICT use in the Turkish Construction Industry”* [1]. The study examined the ICT capabilities of the Turkish construction industry via 22 semi-structured interviews with senior construction professionals within government and private organizations. In the study the authors investigated the usage and applicability of current information systems and technologies and assessed priority topics for the future of ICT. As a result, ten priority areas where IT use can facilitate processes were identified. A second study entitled “*Use of Information and Communication Technologies by Small and Medium-Sized Enterprises (SMEs) in Building Construction*” [28] analysed four major research questions associated with perception of the impact of ICT, extent of investments in ICT, level of usage of ICT and the software preferences of the SMEs by conducting a questionnaire survey of 227 building construction organisations in Turkey. Finally, Tas and Irlayici, [29] investigated the current and the planned use of IT and its impact on the construction industry in the case of acquiring building product information in Turkey. The authors conducted a questionnaire with both the supply side (manufacturers) and the demand side (architects). In the paper, the supply side’s behaviour on providing building product information and the demand side’s methods of getting product information were discussed.

3. The Interview Process and Results

In the next stage of the research semi structured interviews were conducted with 21 major contractors and consulting organisations in the Turkish AEC industry in light of a questionnaire. A questionnaire was formulated consisting of 19 questions. The first group of questions investigated the role of ICT strategy in the organisation, while the next set explored the reasons behind ICT investments. Further questions focused on the role of ICT in recruitment, structure of ICT departments, barriers and facilitating factors for the successful implementation and management of ICT in the organisation and finally, the role of ICT through the various phases of the construction lifecycle.

3.1 Methodology

The semi-structured interviews were conducted generally with ICT managers by visiting each organisation. The interviews started with an informal introduction to the research which lasted around 20 minutes. The interviewees were later interviewed based on the questionnaire by two interviewers. The interview results were cross-checked by the interviewers and a copy of a completed questionnaire was reviewed by the interviewers and the interviewee in order to validate the answers given by the interviewee. The overall interview process with each organisation took between 1 and 1,5 hours. The list of interviewees is provided in Appendix 1.

3.2 Findings into the Strategic Role of ICT within the Turkish AEC Industry

Role of ICT Strategy

The first two questions investigated the general role of ICT in their organisational strategy. In response to the first question, the majority of the organisations mentioned the role of ICT as value adding (58%) and critical (38%) in order to gain advantage against their competitors. On the other hand, only a few organisations (10%) viewed ICT as simply a tool for supporting their business processes.

The second question investigated the role of ICT in order to win work, and in response more than half of the participants indicated the role of ICT as value adding (40%) and critical (20%). In fact, 40% of the participants found ICT as a non-critical resource for winning work, with30% viewing ICT as a supportive tool to win work, and the remaining participants (10%) argued that ICT does not have any positive impact for winning work.

The next set of questions was focused on the role of ICT strategy within the organisation and in the context of the organisations' overall business strategy.

The following question aimed to identify how organisations formulate their ICT strategy. The majority of the respondents (81%) indicated that their organisations' ICT strategy is formulated by focusing on their strategic business objectives. On the other hand, a few participants (19%) indicated that their ICT strategy is formulated primarily focusing on implementing the technological innovations. In response, the interviewees also mentioned that a successful ICT strategy can only be developed by focusing on both the technological aspects and the organisations' business objectives.

The fourth question asked whether the organisation has a well formulated and documented ICT strategy, i.e. an agreed set of actions to be taken in the investment in ICT and written in the form of a strategy document. The results demonstrated that the majority of the organisations (65%) do not have a documented ICT strategy while 30% mentioned that they do have a documented

ICT strategy (in the form of a written strategy report). Those organisations that do not have a documented ICT strategy indicated that their ICT vision is based on following the technological developments and advancements, while making ICT investments in parallel with their business (strategic) needs. In contrast, the actions and ICT investments of their competitors' has no influence on any of the organisations that have an undocumented ICT strategy. On the other hand, 5% of the interviewees mentioned that their organisation does not have any form of an ICT strategy.

The next question explored the role of the organisations' ICT strategy in the context of the organisations' overall business strategy. In response, 76% of the organisations mentioned that their ICT strategy is either value adding or a critical part of their overall business strategy, while 24% pointed out that their ICT strategy only supports their overall business strategy.

The sixth question investigated who engages in the formulation of the ICT strategy. More than half of the respondents (60%) mentioned that the organisations' ICT strategy is formulated by their central/core ICT department to align with the operational needs, which is dependent on the feedback from various departments. On the other hand, 33% pointed out that their central/core ICT department alone formulates the organisational ICT strategy (without input from other departments), and 7% stated that individual departments are responsible for formulating their own ICT strategy.

ICT Investment

The following group of questions focused on understanding the reasoning behind ICT investments and investments related to ICT R&D and training. The first question investigated the strategic reasoning behind the investments in ICT. In response, 42% stated that their organisation invest in ICT to reduce the cost of the processes, 39% indicated that ICT investments are made to add value to the current form of processes, while only a small percentage (19%) mentioned that their organisation invest on ICT to gain strategic advantage. In contrast, none of the respondents indicated that their ICT investments are made to avoid losing strategic advantage.

The following question asked if the organisations measure the Return-on-Investment (ROI) for their ICT expenditures. 45% of the respondents mentioned that they measure ROI, however only a limited number (15%) undertake this regularly, while 30% calculate ROI when needed. On the other hand, 30% expressed that they do not calculate ROI as they do not have a reliable method for ROI calculation for ICT investments in construction. A quarter of the respondents (25%) do not perceive ROI as an important indicator for determining their ICT investment policy, thus they do not calculate it.

The next question in this group explored the organisations' focus on investments on software and information systems development. In response, 5% of the interviewees indicated that their focus is on developing in-house software and IS, and in contrast 35% mentioned that they only outsource software development. More than half of the interviewees (55%) stated that their organisation implement a mix-and-match approach where some parts of their IS is developed in-house, while the development of some components is outsourced.

The following two questions investigated the organisations' perspective on ICT related research and development (R&D) investments. The first question was with regard to the organisations' focus on R&D activities. 47% of the interviewees mentioned that their organisation has never thought of investing on R&D. On the other hand, 48% stated that they have considered investing on R&D efforts, but only 37% actually recognise R&D as a part of their organisational vision. A small percentage of the organisations (5%) have joined an R&D effort initiated by an ICT organisation. The next question queried the organisations' willingness to participate in a national or European research project. 61% of the respondents indicated that their organisation may be interested in getting involved in a research project related to ICT. On the other hand, 39% mentioned that their organisation have no interest in joining such projects.

The next set of questions focused on whether organisations invest on ICT training along with the reasoning for investing on training activities. In response to the first question, 80% of the organisations stated that they invest on ICT training, while 20% make no investment at all. However, interviewees mentioned that even when a separate budget is not dedicated to ICT training (i.e. as 20% mentioned that they do not invest on ICT training); this does not necessarily mean that training is not provided for their employees.

The second question explored the reasoning behind the investment on ICT training. 36% indicated that ICT training is necessary to facilitate the business processes, while 25% mentioned ICT training has a strategic importance to win work. On the other hand, 19% indicated that their organisation is investing on ICT training in order to have better human resources (HR), and 19% stated that their organisation is providing ICT training as ICT is a necessity in accomplishing several tasks in their business processes.

Role of ICT in Recruitment

The following question investigated the role of ICT knowledge in employing white-collar staff for the organisation. 61% of the respondents indicated that a high level of ICT knowledge plays an important role for getting better employment opportunities. 34% mentioned that their organisation only require a certain level of ICT knowledge, which will be necessary to complete their tasks. On the other hand, 5% mentioned no importance is given to level of ICT knowledge while employing white-collar staff.

Structure of ICT Departments

The following two questions focused on the ICT department of the organisation. In response,, 86% of the respondents indicated that their organisation has an ICT department, while 14% pointed out that their organisation does not have a department dedicated to ICT. The survey results showed that 56% of the ICT department consists of only support staff, and of the remaining 44%, the staff is responsible for strategy development, systems implementation along with providing support for solving ICT (hardware/software) related problems.

Barriers and Critical Success Factors to the Successful Implementation of ICT

The next question investigated the possible barriers to successfully managing ICT in the organisation. In this question the interviewees were given a set of 'possible' barriers to which they were requested to answer whether the given issue has been a barrier for the organisation. The results are summarised in Table 1. Problems related to network and communication infrastructure, inefficient use of software and processes that are not defined successfully are indicated as the biggest barriers to preventing the efficient implementation and management of ICT in the organisation. On the other hand, the organisations state that their senior management does not underestimate the role of ICT for their processes and also indicate that no problems are due to the lack of an ICT strategy. The majority of interviewees also pointed out that as their ICT strategy is driven by their business needs, the lack of business driven ICT strategy has therefore not been a barrier.

The following question explored the critical success factors in order to implement and manage an information system (IS) within the organisation. First, the interviewees were given a set of factors which might be critical and were requested to select whether the given factor is either, not important, moderately important or critical for the successful implementation and management of IS. The results are given in Table 2. Continuous training on ICT (55%) and support from software vendors (55%) were found as the most critical factors for successful IS implementation. On the other hand, 47% of the respondents mentioned that experience gained from previous IS implementations in the organisation plays an important role on the success of future IS implementations. Another issue that 37% of the organisations found as critical was the re-design of current processes. The interviewees pointed out that their organisations faced several difficulties due to ill-defined processes. Finally, investment on new technologies has been found as an important issue by the majority of the respondents, but only 25% found technology-focused investment critical for the success of an IS, as many organisations thought that their IS should be designed towards their business objectives.

Table 1: Barriers to the successful implementation of ICT

	Has not been a barrier for successful ICT implementation	Has been a barrier for successful ICT implementation but does/did not have a direct effect on our business processes	Has been a barrier for successful ICT implementation and has/had a direct negative effect on business processes
Problems in the physical network and communication infrastructure	20%	35%	45%
Problems related to hardware	40%	25%	35%
Problems related to data storage	50%	20%	30%
Problems related to data exchange	60%	30%	10%
Inabilities of the software	37%	37%	26%
Inefficient use of software	21%	37%	42%
Not well defined processes	47%	16%	37%
The lack of ICT strategy	83%	6%	11%
Lack of Business driven ICT strategy	88%	6%	6%
The view of management that underestimates the role of ICT	85%	5%	10%
The staff with insufficient ICT skills	50%	30%	20%

Table 2: CSF for the successful implementation and management of IS

	Not important	Moderately important	Critical
Continuous ICT training	5%	40%	55%
Investment on new ICT	0%	75%	25%
Support from software vendors	5%	40%	55%
Benchmarking with competitors	55%	30%	15%
Re-design of current processes	16%	47%	37%
The feedback from previous IS implementations that failed or successfully implemented	10%	45%	45%

Role of ICT through the Construction Lifecycle

The final question investigated the role of ICT for organisations in different phases and for different aspects of the construction lifecycle. In the beginning the interviewees were given a set of lifecycle phases and processes and requested to identify the role of ICT in terms of '*not needed, supporting or critical*' for the given lifecycle phases/processes. The results are given in Table 3. The majority of the respondents indicated that ICT has a supporting role for all lifecycle phases. On the other hand, 38% interviewees mentioned that ICT is vital during the feasibility phase (for feasibility studies and sketch design), 44% pointed out that ICT is vital for architectural design and structural analysis, and 31% mentioned that ICT is vital for supply chain coordination and management. In most of the lifecycle phases, only a minority of the respondents (6%) stated that they do not use ICT in support of their business processes, i.e. most of the major LSEs in Turkey do not underestimate the role of ICT in managing AEC projects.

Table 3: Role of ICT through the construction lifecycle

	ICT is not needed/ not used within the organisation	Currently ICT are supporting the process	ICT are vital for process (task) to function
Feasibility Studies Sketch Design	6%	56%	38%
Architectural Design and Structural Analysis	6%	50%	44%
Bidding	6%	67%	27%
To manage activities in Construction Site	0%	78%	22%
Supply Chain Management / Procurement	6%	63%	31%
Time/Cost Management	0%	68%	32%
Quality Management	0%	89%	11%
Facilities Management	13%	74%	13%

4. Analysis and Discussion

The results of the first two questions demonstrated that ICT is seen as a value adding resource as a part of an overall business strategy, for gaining competitive advantage and for wining work. For example, around 1/3 of the organisations viewed ICT as a critical resource for their competitive strategy and similarly 38% mentioned that ICT strategy is a critical element of their overall business strategy. In contrast, 40% viewed ICT as non-critical in winning work. These results suggest that the strategic role of ICT is not completely underestimated among the organisations. The fact that the role of ICT in winning work is not found critical is due to customers not usually requesting a well established ICT infrastructure as one of the main requirements in the bidding process.

Most of the organisations that participated in the interviews mentioned that they do not have a properly documented ICT strategy, while the organisations that have a documented ICT strategy developed this in the requirement for standardisation reasons (i.e. ISO 9001). The findings indicate that the organisational culture in terms of ICT has not reached a level of maturity where ICT activities are planned and managed with a properly documented strategy. The majority of the organisations have chosen to follow technological developments/advancements in order to make decisions for further investments on ICT. This approach can be seen as a technology-oriented/driven approach for forming a strategy. However, the organisations are not aware of the bigger (industry) picture while formulating their strategy, as most of them are not driven by their competitors' actions and investments. The survey results highlight that business needs/objectives play an important role in forming ICT strategies. However, the organisations also follow an approach towards implementing the latest technologies possible to accomplish their business objectives.

The results indicate that in most of the organisations there is a well balance (of contribution) between ICT department and other departments of the organisation in forming the organisational ICT strategy. This well balanced contribution is necessary for the development of a successful strategy, and the results indicated that the organisational culture is mature enough in this manner.

The majority of the organisations invest in ICT either to reduce costs or add value to the current form of processes, i.e. ICT investments are not made for strategic reasons (gaining competitive advantage) but are made for supporting the processes. As previously explained, the findings indicated that the organisations do not completely underestimate the strategic role of ICT, but this has not been reflected in the organisational investments. This result raises the question if organisations recognise the strategic importance of ICT investments then why are they not investing in this manner?

The findings of the interviews showed that although not practiced as a regular activity, calculating ROI for ICT expenditures is quite evident (45%), which is an indicator that ICT investments is recognised as of critical importance in terms of the business.

The majority of organisations (90%) outsource IS development, but 55% also carry out in-house development to mainly align IS into their business needs. The organisational view in regard to this issue is towards developing and implementing systems on an 'as-needed' basis, and issues such as major changes in processes are not considered.

While half of the organisations have never considered investing in ICT related R&D, the findings of the survey indicate the willingness of 61% of organisations to participate in such activities. This raises the question of how many of these organisations would actually become involved in a research and technology development project/initiative without the recognition of a major industry-wide necessity.

In parallel with the results of a previous survey [1], training on ICT appeared as an important aspect of the overall organisational strategy. The reasoning behind ICT training was various but the main focus was towards facilitating business processes through the better use of technology.

Most of the organisations have an ICT department. However, the ICT departments are mostly composed of support staff rather than of staff responsible for strategy development and systems implementation. In contrast to the willingness of middle level management to join R&D projects, this result indicates that senior management still views ICT as a supporting resource.

The greatest barriers related to successfully implementing and managing ICT were identified as infrastructure problems and inefficient use of software. The infrastructure problems indicated are mainly related to telecommunications, e.g. low bandwidth in communications and internet access, while the inefficient use of software is mainly due to the lack of support from software vendors in Turkey. On the other hand, the importance given to ICT training and support from software vendors appeared as the most critical factors for successfully implementing ICT. The interviewees thought that ICT training acts as a road from failure to success, in parallel they also believe that without the support from software vendors a successful ICT implementation cannot be accomplished. In fact, the authors disagree with this industrial point of view, and believe that the success in ICT implementations should never heavily depend on external factors. In response to final question, the majority of interviewees mentioned the role of ICT as ‘supportive’ in different phases of the construction lifecycle; this indicates that (similar to the role of ICT from organisational point of view) ICT is also not seen as a strategic resource (by the majority of respondents) from the construction lifecycle management perspective.

5. Conclusion

There is a shift towards the recognition of the strategic importance of ICT in terms of value adding in winning work and achieving strategic competitive advantage, as opposed to simply supporting and facilitating business processes. However, although there is recognition of the strategic importance of ICT, the focus of investments in ICT is very much towards business process improvement rather than achieving strategic competitive advantage. This poses further research into exploring this gap between the ‘strategic thinking’ and the actual ‘process-focused practice’. Furthermore, the development of a well formulated and documented ICT strategy is not common practice. In such cases, the strategy is driven by business needs by focusing on technological advancements/developments, while the investments of competitors are of no concern, i.e. pointing towards an internally focused nature to investment. Organisational ICT strategy is being developed by a core/central ICT group/department, which in the main is still driven by operational business processes. However, there is evidence that some ICT departments are influencing the ICT strategic direction of their organisation.

Although not a regular activity, measuring the return on ICT investment is quite evident and further demonstrates the valuing of the critical importance of ICT investment to the business. In addition, it is the issue of the lack of a reliable method that is preventing many organisations from measuring the return/impact of their investments rather than any undervaluing of their investments. While on the other hand, measuring the return on ICT investments is still perceived by some as having no importance on their ICT strategic planning.

ICT-related R&D is still not perceived an important strategic activity by the construction industry and therefore receives very little attention and investment. Although interestingly, there is significant interest in possibly becoming involved in ICT construction related research. This raises a further question at what level of involvement would encourage their engagement?

ICT training is evidently important in terms of investment, which in the main is towards delivering the ICT strategy, i.e. business process improvement facilitated by technology. However, where the strategic importance of ICT on the business is not recognised/undervalued, the activity of training and the associated budget is not encompassed as part of the overall investment in ICT.

In terms of the successful implementation and management of ICT, the main barriers identified are predominantly technological and process related rather than associated to people and strategy. In terms of the critical success factors, these are very much aligned with the barriers in that continuous training policy, learning from previous implementation efforts, and the re-design-engineering of currently ill-defined processes were identified. Interestingly, benchmarking against other competitor organisations was not identified as important, which further substantiates the internally focused nature of organisations in their ICT strategy and investments.

Finally, overall ICT is having a supporting role throughout the lifecycle of a facility/project. However, ICT is perceived vital particularly during the design phases along with the management of time/cost and the supply chain. The role of ICT is in the main valued in the management of AEC projects in Turkey.

Abstract

IT knowledge has become increasingly essential to the success of today's construction and will become more so in the future. Ineffective IT exploitation and poor procurement practices in construction organizations often create obstacles in reaping the full potential of IT investments. This paper presents a Decision Support Model for procurement of IT for construction organizations, which uses a value-based framework drawn from value engineering. It enables the identification of best value IT procurement options for various IT solutions and requirements. The model is developed using object oriented modeling techniques providing greater flexibility in future modification and expansion. The model is implemented as a decision support system and tested using real life cases from the construction industry. An expert evaluation carried out positively verified the concept and the usability of the system. The decision support model creates a knowledge repository for IT procurement and opens the opportunity to further enhance of aspects of IT procurement. The research was carried out in Sri Lanka using the construction industry as the forum for development of the system.

Keywords: Information Technology Procurement, Value engineering, Construction industry, Procurement model, IT solutions, Decision Support System

1. Background

Rapid evolution and spread of Information Technology (IT) during last few decades has increased usage of IT in every category of business. IT can no longer be viewed as an enhancement to traditional business procedures but rather as an innovative agent that enables new and different alternatives to organizing, administrating and operating business enterprises [1]. IT knowledge has become increasingly essential to the success of today's construction engineers and managers and will become more so in the future [2]. Lack of effective IT exploitation methods in construction organizations often creates difficulty in justifying future expansion and use of IT innovations. The task of identifying best IT products, procurement approaches, costs and benefits are some reasons behind that. This problem is global and drawbacks are experienced in all types of enterprises [3]. There is only limited capital available and an IT investment must compete with other demands on capital. Companies must recognize the full benefits of an IT project which can only be achieved as a part of an overall business strategy [4]. A recent article by the Central Unit of Procurement in the UK (2003) [5] states; everybody benefits from fast, effective and transparency in procurement. It reduces supplier's cost, enables the organizations to fulfil commitments faster and more effectively and gives better value for the client's money. These underline the necessity of having a systematic approach to procurement of IT.

A survey on the usage of IT in the construction industry of Sri Lanka revealed that there is organization wide poor utilization of IT [6]. This demands the introduction of a tool to evaluate and prescribe procurement approaches and provides feedback on their probable successes or failures. In most cases, although IT investment achieves business requirements, it may not provide value for money. Simply it may not increase client satisfaction nor reduce expenditure on procurement approaches. This research hypothesizes the use of Value engineering (VE) as an appropriate methodology for providing a solution for the problem of selecting best value IT procurement option. Value engineering is an organized approach in providing necessary functions at lowest cost [7]; [8] (VE is considered synonymous to value management in this paper).

The aim of this study on IT procurement is to investigate challenges associated with and develop a decision support model for construction organizations to assist in IT procurement which is capable of increasing customer satisfaction while removing unnecessary expenditure on IT procurement through the incorporation of value engineering principles.

2. Research methodology

A comprehensive survey of the construction organizations provided a detailed account of the current status of IT procurement and the extent of usage VE in the construction industry. The findings of the survey confirmed the need for a new approach to assist IT procurement in construction organizations while expert opinion favored the development of a DSS. The approach was to review previous theoretical considerations and current industry practices and to synthesize a new approach for IT procurement. It was modeled using a value based framework drawn from value engineering. The conceptual model was then further developed using object oriented modeling techniques allowing the users to make an intelligent and informed decision on the procurement route. The model was tested with real life IT procurement scenarios and evaluated using domain experts. The evaluated model was then implemented to as a Decision Support System (DSS) prototype with the intension of providing a user-friendly guide for IT procurement in construction organizations.

3. Survey of the construction industry of Sri Lanka

A comprehensive survey of industry was conducted to establish current status in terms of use of value engineering and methods of IT procurement. The survey also served as a method to establish the need for greater guidance in IT procurement for construction organizations.

Construction organizations in Sri Lanka are primarily represented by construction contractors and consultants. The survey sample selected included over 90% of representatives of contractors and consultants. This included all the large-scale construction organizations as those represent organizations capable of significant investments in IT. Survey sample size was restricted to 100 organizations comprising of 20 consultant organizations, 60 contracting organizations (selected from among M1, M2, M3 grades and foreign contractors) and 20 IT providers. Construction Contractors in Sri Lanka are classified in to 7 grades (M1 to M7), where M1 represents the largest organisations and M7 represents the smallest. The survey was carried out by visiting the organizations and getting the person responsible for IT procurement to fill the survey responses within an interview session. This way the researchers managed to achieve a 100% response rate.

3.1 Main Findings of Survey

Following are the main findings of the survey. These are analyzed under two headings: VE related and IT Procurement related findings.

3.1.1 Use of Value engineering in the Construction Industry of Sri Lanka

Most construction organizations consider value engineering as a relatively new concept. The only reported significant application of value engineering was in the construction of the World Trade Centre (Colombo) [9]. The survey identified the following as key factors contributing to poor usage of VE [9]:

- Greater fragmentation of the industry.
- Lesser collaboration and project approach among professionals.
- Less knowledge about benefits of value engineering among clients, developers etc.
- Unavailability of standards or guide for value engineering in Sri Lanka.
- No statutory requirement or encouragement to use VE in the public sector construction projects.

3.1.2 IT Procurement Methods used in Industry

The Sri Lankan construction industry is IT backward and is no different to construction industries of most other developing countries [6]. However, Methananda [6] found that the Sri Lankan construction industry has identified the potential of IT to a reasonable degree and that it has resulted in a trend of greater investment in IT. Current practices regarding IT procurement in construction organizations reveal the following [10]:

- 97% of organizations consider IT as a strategy to improve organizational performance.

- 75% of organizations hardly adhere to any rules and regulations for procurement of IT. Only 10% of government organizations even adhere to the "Guidelines on Government Tender Procedure (1997) for procurement of material and equipment including IT".

- Only 3% had licensed software. This is in fact violation of international copyright laws.

- 20% of organizations adopted a strategic plan for development of IT within their organizations. They tend to find finances as and when the need arises rather than pre-plan.

- Approaches available for IT Procurement include: Consulting services, Off-the-shelf IT supply and maintenance, Systems supply & installation and Systems Engineering. These options were used with different methods of payment: direct purchase, hire or leasing.

- Although organizations were conscious of the value of investments, there is no evidence of use of VE techniques to evaluate IT procurement.

In addition, the survey also revealed some factors within the industry that contribute to the problems associated with IT procurement:

- Unavailability of adequate resources (finance and technical) to invest on IT.

- Poor standard of after sales services provided by the IT providers.

- Difficulty of identifying the best IT products and systems in the open market, and inability to assess suitability of such products for the organization.

- Poor regulation of the IT sector and non-availability of industry standards, independent information and customer protection.

The major causes of concern in procurement of IT were the poor levels of knowledge of professionals, unavailability of a procurement guide, and difficulty of identifying best products. All these factors underlines the need for greater guidance for IT procurement to assist professionals in the construction industry. This research aims to address some of these issues through the development of a model for IT procurement.

4. The decision support model

The main function of the model is to facilitate its users in intelligent and informed decision making on available procurement routes for the procurement of IT. It provides guidance on how to procure IT solutions. This approach was adopted as various companies have various IT requirements based on size, activities and nature of their business. The IT solutions identified shall relate with the business and consequently play a part in and be integrated with construction activities. The model is designed for senior management, particularly those without adequate knowledge of IT procurement but responsible for selection and procurement of IT. It provides a ranked list of best-valued procurement methods with details of procedures and associated merits and demerits.

Development of the DSS for IT procurement consisted of phases for design and implementation. The Design phase was again considered in two stages as conceptual modeling and information modeling. Conceptual model illustrates the principles of the IT procurement model while information model deals with the contents of it. The model was evaluated for its contents to ensure its accuracy and validity of data through industry based case studies. The evaluated model was then implemented as a DSS providing greater user friendliness and was tested with actual data for its accuracy and workability. Finally, an expert evaluation was conducted to verify the validity of the research and the model.

4.1 The Conceptual model for Best Value IT Procurement

IT requirements identified by organizations and existing IT procurement options are considered in the value engineering process to identify best-valued procurement options, which will match procurement options to IT requirements. This facilitated the incorporation of new IT procurement options, procurement requirements and opportunity to address problems identified in current practice (Figure 1 1).

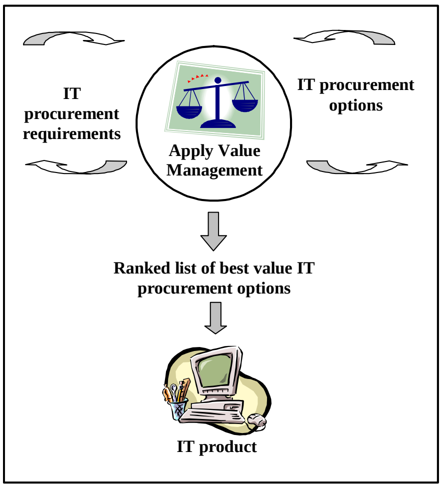

Figure 1: The Conceptual Model for IT procurement

The model assumes that IT solutions already identified have satisfied functional, financial and technical requirements of an organization. Requirements are diverse and difficult to define, highly sensitive to changing business objectives, organizational politics, and capacity of end users and are subjected to rapid technological changes over time.

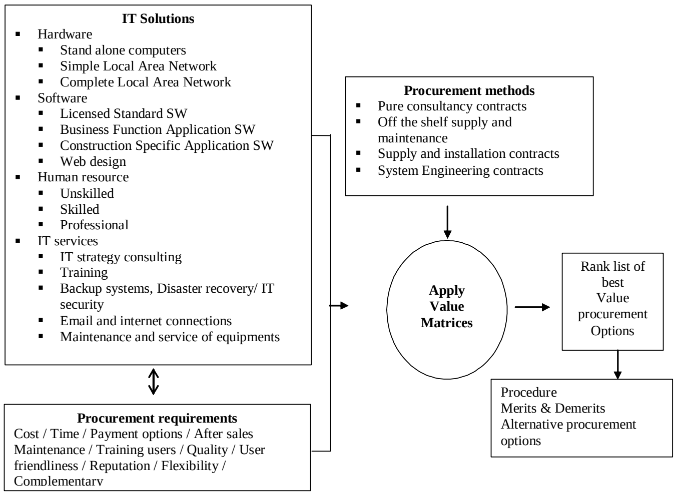

Figure 2: The Detailed Design of the Conceptual Model

Figure 2 illustrates the detailed design of the conceptual model for IT procurement. IT requirements are the inputs for the model while a ranked list of best valued procurement options are the output of the model. In addition the model knowledge base consists of all available procurement and payment options procurement procedures, their merits and demerits and alternative procurement options. The model uses value matrices as a useful technique to match and compare competing alternatives to identify the best-valued procurement routes relevant to the identified IT solutions. It initially weighs evaluated criteria according to their relative importance and then scores alternatives based on weighted criteria to determine those that are optimal. IT procurement requirements are scored against procurement options to determine the ranked list of best-value procurement options for the identified IT solutions. An example of application of value matrices to identify IT procurement route is illustrated in section 4.2.1

The model provides for the adoption of experience gained from building procurement as alternatives learned from the construction industry. This will enable to device new procurement methods for IT procurement based on the experience of building procurement. There are various theoretical models developed for selection of procurement methods for construction by various researchers [11]; [12]. These models can be adopted to provide alternative options as a further development of this IT procurement model. The conversion of this conceptual model to a workable object oriented information model is explained in detail in the next section.

4.2 The Object Oriented Information model

Information modeling is the logical representation of information identified at previous designs. Simply, it defines procedures, which must be followed, and data required to achieve user requirements. There are two main techniques of information modeling, viz: structured approach and object oriented approach [13]. The object oriented approach was used to develop the information model as it was developed to mimic a more natural way of defining systems than that is offered by the structured approach. This method provides greater flexibility and reusability, furnishing a components based programming framework [14]; [15]. The Unified Modeling Language (ULM) standard notations were used to express the content of the information model generated [16].

The object-oriented model for IT procurement is illustrated below in Figure 3.

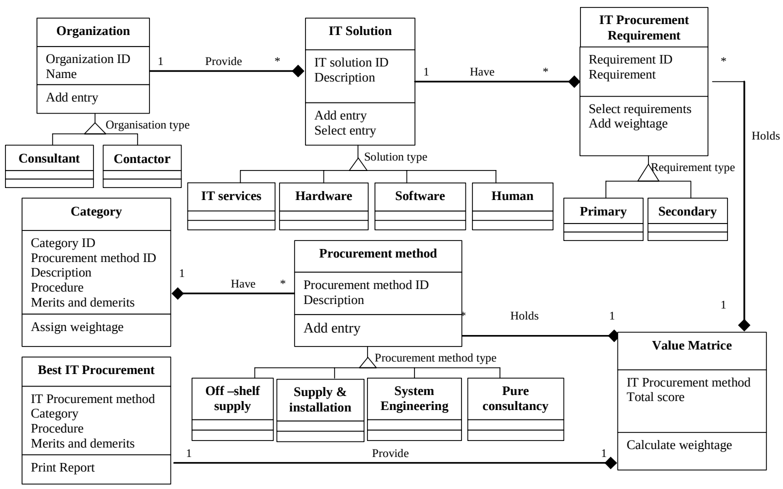

Figure 3: Object oriented model for IT procurement

The object model represents entities and their relationships. It consists of seven classes as: Organization class (containing organization. ID and name fields), IT solution class (containing IT solution ID and description), IT procurement requirement classes (containing requirement ID and requirement), Procurement method class (containing procurement method ID and description), category classes (which contains category ID, procurement ID, description, procedure and merits and demerits), Value matrices class (containing IT procurement ID and total score), best valued IT procurement class (which contains procurement description, category, procedure and merits and demerits) and their relationships. The methods “Add Entry”, “Select Entry”, “Print Report” and “Calculate Weightage” are the tasks carried out by the system. The inheritance (labeled “organization type”, “solution type” etc.) shows the categories or types belong to each class.

4.2.1 Use of Value Matrices

A value matrix is a tool that can be used to analyze complex situations when decision-making becomes hard and laborious task because of multiple variables and varying degree of influences by different factors. This method requires weighing of evaluation criteria according to their relative importance and scoring alternatives on the basis of weighted criteria to determine those that are optimal. An example value matrix for a selected IT solution (purchasing stand-alone computers) is illustrated below. (Out of fifteen IT solutions – refer figure 2)

Table 1 Weightage used for IT Procurement requirements

Procurement Requirement	Time	Cost	Payment options	After sales services	Maintenance	Quality	Reputation	Flexibility	Complementary
Code	T	C	PO	AS	M	Q	R	F	CO
Weightage	10	10	7	9	9	10	8	5	3

Application of points based on the level of satisfaction of procurement requirements (identified in Table 1 above) are given below.

Table 2 Degree of Satisfaction Points Scale

Level of Satisfaction	Non-satisfied	Poor	Average	Good	Complete satisfaction
Points	0	1	3	4	5

Table 3: Alternative analysis matrices

	T	C	PO	AS	M	Q	R	F	CO	Total	Rank
	10	10	6	10	10	10	8	5	3		
P1	5	3	1	3	3	3	3	5	1		
	50	30	6	30	30	30	24	25	3	228	3
P2	5	3	3	3	3	3	3	3	3		
	50	30	18	30	30	30	24	15	9	236	2
P3	5	5	5	5	5	5	5	1	3		
	50	50	30	50	50	50	40	5	9	334	1

Alternative procurement options;
P1 – Direct purchase (Off the shelf supply and maintenance contracts)

P2 – Through nomination (Off the shelf supply and maintenance contracts)

P3 – Calling quotation (Off the shelf supply and maintenance contracts)

The above example illustrates the use of value matrices for an identified IT solution for purchasing stand-alone computers. Initially weightage is assigned to each IT procurement requirement according to its relative importance (code denotes shorten form for IT procurement requirements). In this example cost, time, quality, and maintenance and after sales services are considered as critical factors.

At the alternative analysis matrix weighted IT procurement requirements are scored against alternative IT procurement options identified to determine a ranked list of best valued procurement options for the IT solutions identified. Application of points for each alternative is based on above criteria, which represent state of satisfaction of procurement requirements among selected alternatives where zero represents non-satisfaction and 5 points represents full satisfaction of requirements.

4.3 Decision Support System Developments

DSS development based on evaluated model consisted of three main phases: Database development, system interface development and system testing. The databases use a structure of a relational model as it provides the ability for end users to create and change records in the database in a user-friendly manner [17]. Microsoft™ Access 2000 was used to create the relational databases. Relationships among entities of the DSS were illustrated at object model in section 4.2.

System interfaces were developed using Java programming language (Beans IDE 3.6), which incorporates certain features such as polymorphism and inheritance, illustrated at object model for IT procurement. Java development environment offers benefits such as faster development, reusability, increased quality, modular architecture, better mapping of problem domain and client/ server applications [18]; [19].

4.4 Model and System Evaluation

The first stage of evaluation involved the evaluation on the model. It was then followed up by an expert evaluation using five industry experts on IT and value engineering.

4.4.1 Results of model evaluation

Model evaluation was aimed at verifying contents of model with industry practice. Thirty case studies were carried using large-scale construction and non-construction organizations within the Colombo metropolitan area. Model derived results were compared with the actual procurements occurred. The results indicated the existence of considerable variations in the selection of best-valued IT procurement options compared with the industry practice. Following summarizes the comparison.

Out of fifteen, only seven IT solutions (stand-alone computers, simple LAN, standard licensed software, web design, unskilled, skilled and professionals) represent similar results to the model derived best-valued IT procurement options. However, order of ranking of best-valued procurement options differs in most cases except in purchasing stand-alone computers and standard licensed software. Rest of IT solutions represents completely different results. This is significant as it means that industry has not been using best value procurement options.

From the model evaluation it was clear that model performance was different to the industry practice. Where differences exist, further evaluation proved that model performance was acceptable over industry practice. This was then verified using domain experts. The verification and expert evaluation process is explained in detail in the next section.

4.4.2 Results of expert evaluation

Expert evaluation was carried out as a series of semi-structured interviews, demonstrations and discussions as such methods provide openness to an interviewee to express genuine opinion, feeling at ease. It concluded that the model assists the initial decision making process and is specifically useful for less IT literate personal to procure IT in construction organizations. In addition facilitation of basic concepts of IT procurement highlighted as a shortcoming of this model. Also as the suggestions for improvement highlighted that it should be expanded to other industries and need to be flexible to accommodate future expansions.

The views expressed by the experts were considered in detail in the final phase of modification of the DSS. Following are some of the responses to the expert opinion.

- Model was designed, evaluated and developed based on results obtained by surveys and case studies obtained from construction organizations. Therefore, model is more suitable for construction organizations. However, the methodology and the conceptual model will be valid for implementation in any industry.

- Extension of the research to other industries and new areas was not incorporated due to time and resource restrictions of this research.

5. Conclusions

Organizations are continuously pressurized through evolving and demanding markets to increase productivity more than ever before. Increasing productivity has become a key to remain competitive. IT provides a means to attain greater productivity and competitive advantage to most enterprises. As a result, organizations tend to invest on IT. Although organizations have recognized adequate IT solutions to prevailing problems, identification of an appropriate approach for procurement of IT that achieves best value remains a barrier. The construction industry is not an exception to this. However, due to fragmentation and complex nature of the construction industry IT procurement has taken back stage in modern construction organizations resulting in unsatisfactory selection of IT procurement options. Through a comprehensive construction industry survey, Perera et.al, [9] identifies the adverse effects of poor IT procurement and consequent hesitation in investment on IT. This places emphasis on the need for formal guidance to assist in the decision-making process. The aim of this research was focused at the development of a IT Procurement model and implement it as a Decision Support System for construction industry organizations.

The approach was to identify and review industry practices and synthesize it with theoretical considerations. The technique of value matrices was used to identify best value procurement route. The data extracted from industry surveys and case studies were then modeled using object oriented techniques allowing users to make intelligent and informed decisions on available procurement routes. The model designed was also tested with real life IT procurement scenarios and then subjected to an expert evaluation to identify necessary improvements. Finally, the evaluated model was successfully enhanced into a Decision Support System to provide a user-friendly guide for IT procurement in construction organizations. The system and expert evaluations clearly revealed the superiority of the model and its greater industry relevance.

IT procurement model (and DSS) was designed to help understand procedures, merits and demerits of prevailing procurement methods for which IT investment can be directed. It is modeled using object oriented development methodology, developed using a relational database system and operates in a menu driven mode. Microsoft Access for databases and Java (Net Beans IDE 3.6) for system interfaces were used as development tools for the DSS.

The research makes a significant contribution in developing a knowledge base for IT procurement that facilitates the selection of best valued IT procurement option. The model serves as a knowledge repository and its object oriented nature allows it to be expanded to incorporate procurement experiences from the construction industry and to be further developed as a generic model for IT procurement. The research addressed the key issue of providing a value based framework for evaluating and selecting IT procurement options.

Abstract

Poor project monitoring and control process has been identified as one of the main reasons for construction projects not achieving project cost objectives. Other factors contribute to this condition include: lack of documentation on project lessons learned, not optimum in adopting information technology, and a long process in making decisions. Documentation of lessons learned corrective actions can help project team in identifying various project risks. It is an important feedback in the effort to achieve better project performances, to prevent occurrences of specific risks or to prepare responses to such risks. This paper discusses the development of knowledge-based corrective actions related to controlling project material cost, which includes identifying the impacts, the causes and corrective actions. A survey on various high rise building projects was selected as the research method, and structured interviews with experts on such projects was used as data collecting method. Probability matrix, statistic and simulation were used to analyse the data, and expert system was used to develop decision support system based on cost control theory and practices. The results of the research show that there are four cost performance indicators, fifty eight impacts with fifty seven causes of risks for developing knowledge based lessons learned corrective action which provides about one hundred and fourteen corrective actions

Keywords: Knowledge base, cost control, lessons learned

1. Introduction

Construction industry is highly competitive industry. To win a construction projects, many construction companies have to work with small profit margin. Many construction companies fail to get profit from their projects because of their lack of capability in developing strategy that based on effective management system [1]. This condition typically caused by limited capabilities of project personnel, which resulted in ineffective project control. For that reason, the focus of project control in most developing countries is in project cost rather than time and quality [2]. In developing countries such as Indonesia, construction project failures are caused by [3]:

- Poor monitoring and control
- Lack of documentation on project lessons learned
- Not adaptive to information technology development
- Delayed and mistakes in decision making

There are also constraints that are faced by construction companies which are caused by internal as well as external factors. These factors are considered as sources of risk that potentially resulted in cost overrun [4]. Cost overrun in construction projects in Indonesia is typically caused by poor weather condition forecast, increased material cost due to inflation, increased labour cost, and lack or project experience [5]. A good coordination among project stakeholders using a good control system tool is needed in order to achieve required project performances [6].

There are several variables that need to be controlled in order to control project cost, which include: labours, materials, equipment, subcontract and field overhead [7, 8]. Sufficient data, particularly in material costs, is required to have effective monitoring and evaluation process. To support this, a good control system tools is needed.

Improvement in construction process is required in order to have a better quality performance management. This improvement should consider factors that directly influence the quality of construction process, particularly those that are related to documenting lessons learned, management techniques and technology used [9]. Many cost control techniques using software project management system have been developed and used to support project cost control process. However, is yet to provide optimum solution, in particular to support anticipating cost overrun. Therefore, a development of a decision support system tools using an expert system approach for corrective action in controlling project cost would be very beneficial, which in the end could improve quality performance management.

Base on the above problems description, the purpose of this paper is to discuss the development of a decision support system for project material cost control based on expert system approach as well as cost control theory and practices. To develop such system, it starts with identification of source of risks that cause cost overrun, then continued with the identification of appropriate lessons learned corrective actions.

2. Research method

To achieve the research aim, the following approach has been adopted:

- Secondary data collection was based on completed project report. Primary data was collected using questionnaire surveys and structured interview to different experts and experience project personnel.

- Data was analysed using Delphi method, risk assessment techniques, and statistical analyses. These analyses have provided various knowledge that were stored in knowledge based system. Risk analysis was used to assess related risk level for specified source of risks. Correlation analysis was used to identify various sources of risks, which have been assessed to have negative correlation with project cost performance. The Delphi method was used to select recommended corrective actions based on the specific source of risks. Regression analysis was then used to perform simulation which assessed the relation between the selected corrective actions and project cost performance. This process has resulted in preliminary conclusions which were used as input for the succeeding steps.

- Using an inference engine, a knowledge structure was then developed and converted into computer language.

- The knowledge based system was further developed using a scenario decision flow diagram, which considered various conditions that are related to decision making process. This scenario was used as the basis for developing subsequent decision flow diagrams. Dependency diagram and logic diagram were used in developing the knowledge structure.

- The validation of expert system application was done to compare the results with the opinion of experts.

3. Research results

3.1 Relationship between costs overrun indicators with events and causes in project cost control

Knowledgebase for project cost control process are based on relationships between cost overrun indicators with events and causes. In the initial stage of the research, these relationships were grouped into related project cost components. Table 1 shows the number of knowledgebase indicators as well as their related events and causes.

Project material cost has four indicators, which are purchasing cost, transportation cost, storage cost and excess (waste) material cost [10, 11, 12, 13]. Survey and interview with construction experts have identified 58 events that influence these cost overrun indicators. The four cost overrun indicators and their fifty eight events makeup 225 relationships. The numbers of events that influence each cost indicators are as follows:

- Purchasing cost 57 events (98%)

- Transportation cost, 57 events (98%)

- Storage cost 54 events (93%)
- Excess (waste) material cost 57 events (98%)

Table 1 Number of Knowledgebase Cost Overrun Indicators, Event and Causes

Project cost component	Cost overrun indicators	# Event	# Causes
Equipment	5	67	52
Materials	4	58	57
Manpower	4	48	70
Subcontractor	4	31	48
Overhead	4	52	43
Total	21	256	270

Literature survey and expert interviews have identified 57 causes of project material cost overrun, which can be grouped into ten as follows: planning & scheduling (12.3%); organization & key personnel (15.8%); purchasing (12.3%); transportation (7%); QA/QC (1.8%); storage (10.5%); usage (12.3%); change order (7%); monitoring & control (10.5%); and external factors (10.5%).

The 58 events and 57 causes make up complex relationships. The results of the analysis indicated that there are eleven events and their related causes which influence the cost overrun the most. Table 2 lists the eleven dominant events and their related causes.

Table 2 - The dominant events and related causes in project material cost overrun indicators

Event	Causes	
1. Delay in project completion	- planning & scheduling related - purchasing related - usage - monitoring & control	- organisation & key personnel - transportation related - change order - external factors
2. Material shortage during construction	- planning & scheduling related - storage	- transportation related - usage
3. increased material purchasing cost	- planning & scheduling related - usage - transportation related	- purchasing related - QA/QC
4. reworks	- planning & scheduling related - purchasing related - usage - monitoring & control	- organisation & key personnel - QA/QC - change order - external factors
5. excess materials	- planning & scheduling related - transportation related - usage	- purchasing related - storage - external factors
6. delay in procurement	- organisation & key personnel	- purchasing related

7. mistake in work execution	- organisation & key personnel - monitoring & control	- change order
8. delay in work	- purchasing related - QA/QC - usage - monitoring & control	- transportation related - storage - change order
9. increased material procurement cost	- purchasing related - storage - change order	- transportation related - usage
10. delay in delivering material to site	- purchasing related - external factors	- transportation related
11. increased damaged materials	- storage - change order	- usage - external factors

Further assessment using qualitative risk analysis has provided information on the complexity of the relationship between cost overrun indicators and events, as well as between events and their causes. Cost overrun on project materials which is caused by change order, for example, has 11 sources of risks.

The sources of risks that cause the most events on material cost overrun are purchasing and material usage. Eight events that have the most influence on material cost overrun, which are related to purchasing are:

- Project delay which is caused mostly by schedule variance and materials are purchased not in accordance to specifications & requirements,
- Increased material costs which is caused mostly by delay in purchasing and poor strategy in selecting sellers
- Change orders and excess materials which are mostly due to materials that are purchased not in accordance to specifications & requirements
- Delay in material procurement which is caused mostly by shortage in the market, change in materials sources that are related to project location, delay in payment, and delay in purchasing
- Delay in project works execution which is mostly due to shortage of materials in the market, change in materials sources that are related to project location, delay in payment, and delay in purchasing
- Increased procurement cost which is caused mostly by shortage of supply in the market
- Delay in delivery of materials to project site which is mostly due to poor strategy in selecting sellers

Seven events that have the most influence on material cost overrun which are related to material usage are:

- Delay in project completion which is mostly due to repairs or reworks
- Shortage of materials during construction which is caused mostly by excess materials onsite, reworks and inefficient works
- Reworks which are mostly caused by mistakes in material use
- Excess materials that are mostly caused by inefficient usage and materials movements of materials on site, poor understanding of site characteristics, insufficient equipment for mobilisation, and mistakes in materials usage.
- Delay in works execution which is due mostly to poor understanding of site characteristics and insufficient equipment for mobilisation
- Increase in procurement cost which is caused mostly by inefficient usage and materials movements of materials on site, reworks, mistakes in materials usage, poor understanding of site characteristics, insufficient equipment for mobilisation, and mistakes in materials usage.
- Increase in defective/damage materials which are caused by inefficient materials movements of materials on site, poor understanding of site characteristics, insufficient equipment for mobilisation, and mistakes in materials usage

The cost overruns indicators that are influenced by the above events are purchasing costs, storage costs, and excess material cost.

The main objective of material cost control is to have required materials as scheduled. It is an important and integrated part of materials management. The important steps in implementing materials control are planning, executing, monitoring, analysing performance, evaluating variance and developing necessary corrective actions [14]. There is a need to plan the necessary corrective actions to anticipate the events that can cause material cost overruns.

3.2 Relationship between cost overran indicators with event, causes and corrective actions in project cost control

The second stage of the research is aimed to identify appropriate lessons-learned corrective actions related to sources and events of the cost overrun as discussed in the previous section. This part of the research provides relationship patterns for: indicators-event; event-causes; and causes-corrective actions. Table 3 shows the grouping of these relationships.

Table 3 Number of knowledge base groups for Project Cost Control

Project cost Component	#indicators	#events	#causes	#corrective
Equipment	5	67	52	104
Materials	4	58	57	114
Manpower	4	48	70	149
Subcontractor	4	31	48	94
Overhead	4	52	43	120
Total	21	256	270	581

For project cost materials overruns, there are 114 recommended corrective actions that are related to the 58 events and their 57 causes. Good understanding and experiences are needed to provide recommended corrective actions that are appropriate for a particular cause of cost overrun.

The relationship of indicator-event, event-causes, and causes-corrective actions can be summarised as shown in Figure1. It is a complex network which requires a decision making tools that can identify the most appropriate corrective action for any cost overrun problem.

Figure 1 shows the integration of the relationships between indicator-event, event-causes and causes-corrective actions. The first level, which is the highest level of the network, is the four cost overrun indicators: purchasing cost, transportation cost, storage cost, and excess (waste) material cost. The second level is the events, the third level is the causes, and the fourth, which is the lowest level of the network, is the corrective actions.

An example of the relationship as follows: there is a cost overrun on purchasing cost (I1) as a result of the event number three (E3). This event is caused by the causes number twenty one (C21). To rectify this problem, the corrective actions number two and five (CA2 & CA5) are recommended to be performed. The interesting thing here is that by performing CA2 & CA5, they do not only solve the I1 problem but may also solve, for example, I2 (transportation cost) and I3 (storage cost). This is possible because, for example, C21 is also related to I2 and I3. These relationships make a complex network which requires a computer application to provide effective problem identification and decision making in selecting appropriate corrective actions.

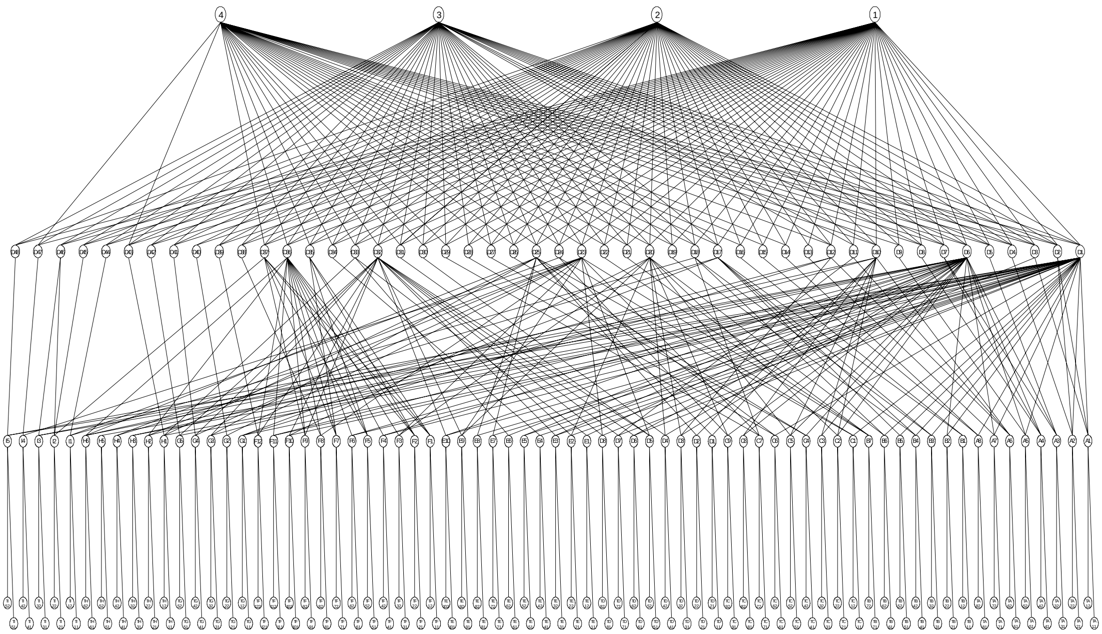

Figure 1 Relationship pattern indicators-event-causes-corrective action in Project Material cost control

From the 114 recommended corrective actions for project materials cost control, almost 90% of them tend to be preventive in nature. They are more likely lessons-learned corrective actions as they are used to prevent the similar events from happening. As an illustration, in planning & scheduling related events, materials are purchased way before they are needed which is caused by inaccuracy in materials scheduling. The recommended corrective action is for supervisor to review planning document before works execution. Another example: delay in decision (organisation & key personnel related events), which is caused by lack of support from head office, the recommended corrective action is to apply appropriate procedure.

3.3 Decision Support System Program

The use of decision support system (DSS) in selecting corrective actions can improve the effectiveness and efficiency in getting recommended corrective actions that lead to better project cost performances. The DSS developed in this research follows the algorithm as shown in Figure2.

The program starts with an introduction that explains what the program is all about and instructions to use the program. The second sub-model defines the project information, such as project type, contract type and contract value. The third sub-model consists of two modes of process, i.e. lessons learned mode and DSS mode. The fourth sub-model provides report of the process results. C++ has been used in developing the program.

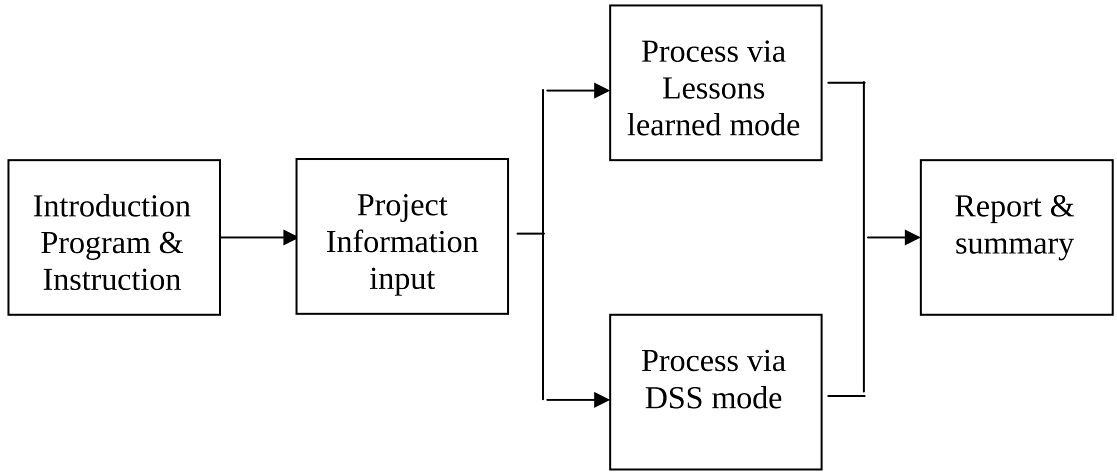

Figure 2 Algorithm for DSS Program

The validation of the program was done by conducting several trials to construction experts. These experts were asked to assess the program and the results it provides. The assessment used in the validation include: completeness of knowledgebase system, speed, user friendliness, accuracy of the results, and level of application. Most of the experts involved in the validation gave good assessments for the program. They also suggested that an improvement in design can make the program more attractive.

4. Conclusions

The paper discusses the development of a decision support system for project material cost control based on expert system approach, cost control theory and practices. In the first step of the development four cost overrun indicators have been identified. Those indicators are purchasing, transportation, storage and excess material costs. The four cost-overrun indicators have fifty eight events and fifty seven causes. To rectify these costs overrun, one hundred and fourteen corrective actions have been recommended by high-rise building construction project experts.

Relationships between cost overruns-events and events-causes are complex. The combinations of these relationships require effective and efficient corrective actions that can lead to improve project cost performances. It is very significant to document those relationships as part of project cost control system. Those relationships make up a basis for a good knowledgebase to select corrective actions The use of DSS program can support the selection of effective and efficient corrective actions.

Abstract

Governments, NGOs and International organisations must work together and contribute towards strategic disaster recovery planning process of countries [9]. Emergency management plans should be in place and tested fully well ahead of any adverse situations. Quantification of probable risks and preparedness can save time, costs and most valuably, lives in the disaster response and recovery effort. ICT system infrastructures play a significant role [15] in connecting various experts at disaster recovery centres around the world in a tactical environment. Virtualisation [8] of disaster recovery centres can provide high availability and efficient system deployment strategy for any emergency management plan. This paper proposes a systematic virtualised infrastructure and associated tools for the operation of disaster recovery centres by capitalising the state-of-the-art for leveraging its use.

Keywords: Disaster recovery centres, Virtual Data Services, Virtualisation technology, ICT infrastructure

1. Introduction

Finding a sustainable solution for facing disasters

Eliminating disasters cannot be achieved under most circumstances. Therefore efficient warning systems and preparedness at all levels must be established to minimise the aftermath. Based on the damage to the existing communication infrastructure the recovery process could be an overwhelming task. Due to collapse communication centres, antennas, power and mobile networks, transportation infrastructures, etc. recovery teams may not be able to reach the helpless. People could not survive without adequate basic needs for more than a few days or hours based on their health condition. It is clear that for recovery teams the time is the most important factor for reaching individuals affected. This is with the assumption that the recovery teams can accommodate all the necessary equipment, food, etc. in time when they reach individuals for salvation. Due to a number of reasons adequate quantities of such materials may not be able to be transported where required. With the experience of recent disasters around the world governments, organisations and researchers are aggressively seeking solutions for various aspects involved to find more sustainable solutions for facing future disasters.

Researchers are concentrating on finding the most appropriate solutions for various matters that are associated with disasters; natural or manmade. Firstly it is important to provide sufficient lead time as well as appropriate guidance based on the expected impact from the disaster in concern so that people and rescue teams take adequate precautions to minimise damage. This can be achieved by audible warnings [10], visual extrapolation of impending disaster, etc. after the disaster has been detected by the equipment and sensory devices and experts have completed the primary risk analysis of perhaps the inevitable. Such warning signals generated by the devices can be received by the disaster recovery centres through satellite networks or through global mobile network base stations via dedicated emergency channels established for such communications. Secondly after the disaster, it is vital to locate the affected people /communities for providing the required emergency assistance. Although many could assume that people can communicate for requesting emergency rescue services based on the level of disaster and the inadequate sophistication of available communication infrastructures this may not be possible. Vice versa, rescue teams and authorities (local or international) may not be able to locate or reach helpless people within an acceptable time frame. Inefficiencies of global diplomatic protocols [9] also may have an adverse effect on this matter. Standard mobile handsets are not designed to utilise the satellite communication network directly therefore they should communicate to a nearest base station and establish a connection for reaching other destinations. Lack of functioning mobile communication towers, base stations and telecommunication networks can isolate people under disaster conditions. Similarly lack of power networks can jeopardise reaching people through radio, TV, etc receives for information dissemination or provision of related advice. Specialised /switchable satellite networks that can reach ordinary mobile handsets, ample of portable GIS handsets to access detail imagery of the disaster area and globally funded automated disaster detection and recovery infrastructure armed with specialised teams that can reach any part of the world without a delay (E.g. political barriers) are some sustainable solutions for solving these matters. Finally provision of disaster relief during the most difficult period and thereafter continuing support until the civilisation recovers from the tragedy needs to be thought ahead and acted upon spontaneously until an adequate momentum of recovery to a reasonable expectation can be achieved. With the assumption that some local authorities have access to satellite phones and organisational specific wireless communication hubs it would be possible to create ad-hoc networks for people to make emergency communication via these hubs [1]. While current generation mobile handsets are capable of switching between up to four bands to accommodate various continental standards the future mobile handsets can be designed with the capability of switching into such universally accepted emergency bands via ad-hock networks.

This paper proposes a Virtualised [8] Disaster Recovery Centre (VDRC) that could be mobilised into the danger zone to assist the field workers and experts. The infrastructure proposed is built on the state-of-the-art services available to maximise their use. Recent knowledge created by European projects, Federal Emergency Management Agency (FEMA) [6] of the United States as well as research and industry contributions from experimental virtual emergency operations centre established by Telematics Lab at Simon Fraser University [7], SAR Technology [11], SAHANA Project initiated by the Sri Lankan Boxing Day tsunami [15][16], etc. drive defining the proposed infrastructure. While staff from the VDRC directly advise teams (ground, water, air based or tactical analysers) on recovery process, it captures information for mass delivery to the external parties and other VDRC's for constructive analysis. Experts around the world and staff from other centres can lively assist many scattered recovery teams with more informed manner from information received through VDRCs of the live condition. The writing is divided into three sections to expand the virtualised disaster recovery centre infrastructure proposed for emergency situations which follows onto a brief in further development works.

- Design of a system architecture for robust deployment
- Establishment of a broadband wireless communication and/or satellite system
- Provision of software services required for assisting the field workers through virtualised disaster recovery centres
- Further developments of the implementation strategy

2. Design of a system architecture for robust deployment

There are many ongoing global and continental initiatives with established infrastructures for Earth Observation (EO) focussed of meteorology, security, strategic incident management, etc. applications. World Meteorological Organisation (WMO) realised the inadequacies of the Global Telecommunication System (GTS) and its inability to address global issues and concerns in the early part of this decade. It promoted the requirement of countries within every continent to work together to collate and capture necessary EO data with a mutual effort for satisfying such matters. The definition of Future WMO Information System (FWIS) was created with the focus to disseminate the requirement of a single coordinated effort at an international level by the WMO in 2003.

The demonstration of Virtual Global Information Systems Centre (V-GISC) was considered a successful attempt to establish this definition using the SIMDAT technology. SIMDAT European Project has developed required protocols, knowledge and common infrastructure for the collection and sharing of distributed meteorological data among five dispersed organisations as a demonstrator [12]. The national weather services of France, Germany and the UK, the European Centre for Medium-Range Weather Forecasts (ECMWF) and the European Organisation for the Exploitation of Meteorological Satellites (EUMETSAT) have been working together for this invaluable outcome. The inefficiencies, incompatibilities and redundancies of the previously developed multitude of ICT infrastructures of many countries are now possible to streamline by adhering this outcome; V-GISC that will be at production level by 2008. Capitalising on these and other findings figure 1 describes the virtual data service architecture of VDRC.

Each VDRC is to be linked with other VDRCs and similar data provisioning centres via Dedicated Data Communication Infrastructure (DDCI) as briefed previously. Services are created based on the local and external resources from various sites. As figured some Global Services / Resources (GS/R) are directly linked with the related local resources while others linked to resources from other centres. The centres responsible for the provision of services are also in charge for altering the portal service for corresponding services, managing and maintaining of data gathering and cleaning process related to service provision, synchronisation of catalogue updates to other centres, etc. The resource pool is labelled as Virtual Data Services (VDS) in the figure. This VDS architecture is common for all the VDRCs and the services available are accessible via the Virtual Global Portal (VGP) by its users. The experts who advise planning and recovery teams, data and resource managers and VDRC staff are among the users of this infrastructure. Construction of the portal and its operation is detailed later.

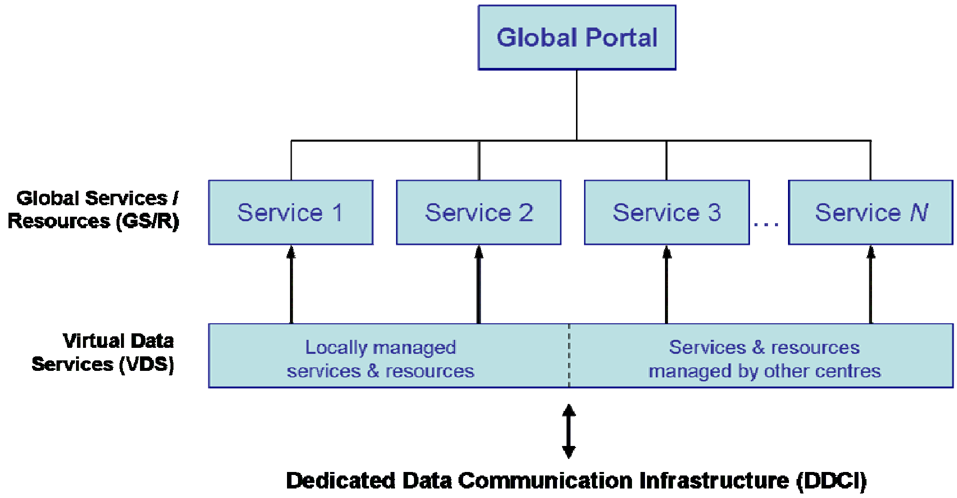

Figure 1: Virtual data services architecture

Centralisation of databases is not considered appropriate due to the sheer size of each database involved. Different VDRCs are responsible managing and maintaining of the related database resources and appropriate services based on the centre resources. However it is noted that very large databases hosted at multiple of distance sites may give adversary effect on user interrogation of services. A synchronised version of a distributed data catalogue, a synchronised global portal service and the local replication of necessary resources are used to provide prompt services to users. Figure 2 details components of proposed architecture.

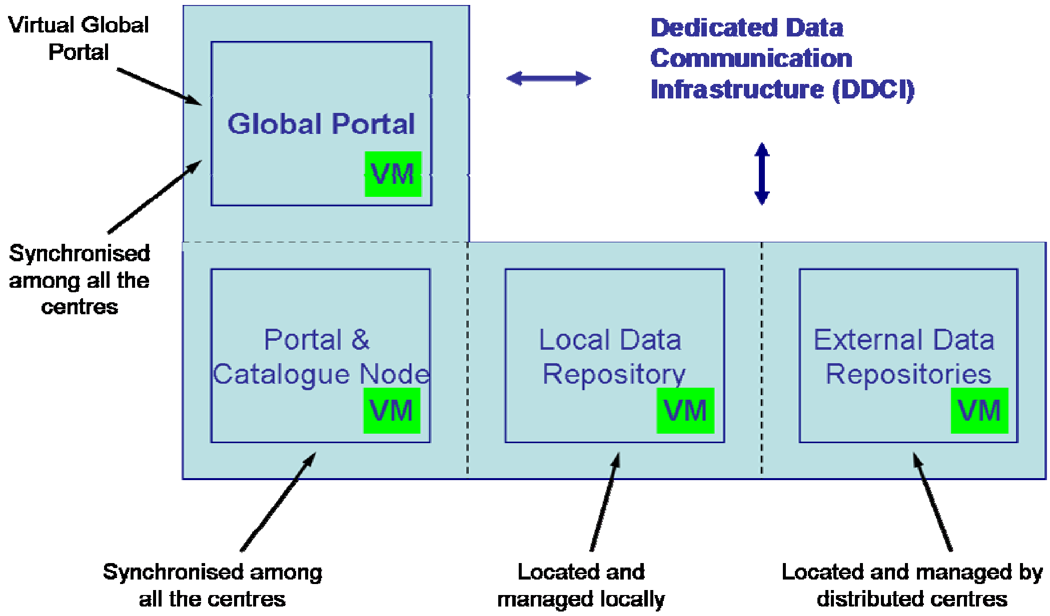

Figure 2: Component synchronisation and virtualisation

The portal and catalogue services are fully synchronised with other sites while some data repositories held locally and others dispersed within distributed centres. More importantly Virtual Machine (VM) architecture is employed to virtualise the complete disaster recovery centre infrastructure for achieving the necessary characteristics and robustness [8]. This is noted in the figure and expanded view of these components is to follow.

Virtual Global Portal

Users interrogate services via the virtual global portal. The service providers may alter this portal as needed and the synchronisation offer users with the same look and feel, streamlined functionality regardless of users' location. User authentication, security and access rights are controlled with the virtual DMZ engaged. As a first point of reference user queries and searchers are to be carried out among the synchronised catalogue VM. The system is to fetch necessary data items from the Local DR and/or External DR for displaying it to the user. Data communication within and among VDRCs are achieved by use of virtual networking where relevant. Some of this functionality is not detailed here due to lack of space.

Virtual Data Services

VDS is comprised of two parts; local data repository and external data repository. In the most circumstances data gathering process is linked with very specialise technological infrastructures that may be very expensive and somewhat complex to discuss here. Each VDRC is focussed of gathering some specialised disaster and recovery related data based on the equipment and expertise it hold. Colleted and cleaned data are saved in the data repositories (Local DR) where suitable services are created for sharing and utilisation purpose. While cataloguing of data and services available is managed within each centre the catalogue is synchronised among all the VDRCs for efficient access to services offered for their distributed users. Partial or full replication of some data repositories at the local level (Local DR) is also considered for providing the efficient service. This is very important if an External DR become unavailable for some reason such as loss of communication with that particular centre. Under this situation such

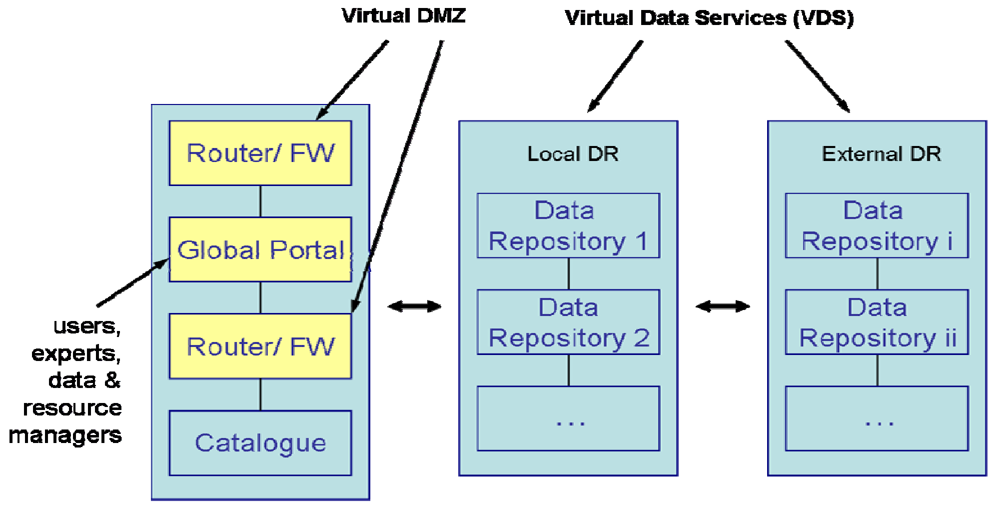

Figure 3: Virtual global portal linking VDS

Local DR could become available even for other centres. However maintenance of such data repositories could impinge on the available bandwidth adversely as replicated repositories are required to be kept current. The Virtual Global Portal links the VDS for providing services available to VDRC users as in figure 3 above. Many Local DRs are hosted and maintained as needed for efficient operation. The External DR in the figure is the consolidated view of the other data repositories available from many VDRCs.

3. Establishment of a broadband wireless communication and/or satellite system

There are many satellite based global broadcast systems (E.g. GEONETCast, EUMETCast) available for receiving the necessary data for disaster recovery process. The area of coverage may be important in some situations where the service may not be available globally. GEONETCast global data exchange program as introduced in November 2006 combines effort of FengyunCast (Asia-Pacific), GEONETCast Americas and EUMETCast (Europe-Africa) by provisioning interoperability between services offered to global communities for various applications. This is a continuing effort inspired by the 10 year implementation plan that was put forward and endorsed at the third Earth Observation Summit held in Brussels in February 2005 to create a Global Earth Observation System of Systems (GEOSS) as an essential step to undertake by a global community of nationals and intergovernmental, international and regional organisations. Dealing with disasters is high in the agenda of creating GEOSS.

> 'Disaster losses can be reduced through observations relating to hazards such as: wildland fires; volcanic eruptions; earthquakes; tsunamis; subsidence; landslides; avalanches; ice; floods; extreme weather; and pollution events. GEOSS implementation will bring a more timely dissemination of information through better coordinated systems for monitoring, predicting, risk assessment, early warning, mitigating, and responding to hazards at local, national, regional, and global levels.' [14]

NOAA Satellite and Information Service provides the user community of environmental satellite data and various products. These include analyses, blended products from polar orbiting and geostationary satellites, and interpretive services. The products and services are distributed to a diverse user community for a broad range of environmental applications [13]. This Satellite Services Division maintains an operational satellite data distribution network providing user access to real-time or near real-time environmental data and information that are suitable for disaster recovery activities.

EUMETCast is a product of EUMETSAT's Broadcast System for Environmental Data that is a multi-service dissemination system based on standard Digital Video Broadcast (DVB) technology. EUMETCast uses commercial telecommunication geostationary satellites to multicast data files and other products to a wide user community and it is the EUMETSAT contribution to GEONETCast [4]. EUMETSAT website, www.eumetsat.int provides the technical documents with details on reception station setup, programs and tools required, etc. for receiving the data from broadcast [3]. The establishment of broadband wireless communication infrastructure for VDRC is based on these and similar services offered by various global organisations.

4. Provision of software services required for assisting the field workers through virtualised disaster recovery centres

Provision of software services (GS/R) to operate the VDRC is partly based on the local and external data resources (VDS) the centres are willing to create and maintain for collaborative use. On the other part these software services must be capable of assisting the field workers carrying out their effort to engage with the disaster situation for helping the helpless. It should be noted that these services should also maintain the well-being of all the field workers and analysts involved for reaching and saving the helpless in a time critical manner.

The system architecture described in the section 2 requires the software environment to be virtualised using a suitable Virtualisation Technology (VT) [8]. The software available via SIMDAT European Project is suitable for virtualisation and provides some of the functionalities described here. This binary repository is available through the European Centre for Medium-Range Weather Forecasts website [2]. Federal Emergency Management Agency recently released IRIS V2.0 software [6] suitable for incident management applications. The National Incident Management System - Incident Resource Inventory System (NIMS-IRIS) software is designed for assisting the emergency response communities. The current version provides a basic database management tool for community's to manage 120 typed resources, which is suitable for sharing among other VDRCs by establishing as a parent host within one of the identified VDRCs. Future system functionality is expected to assist in placing and mobilising resource requests, GPS tracking of resources, and resource recovery. Since FEMA’s incident management focus is extensive; to capture different kinds of disasters, to support the recovery effort in a streamlined coherent facilitation within a large continent and nevertheless be able to secure ample resources for such developmental work than any other agency this tool captures, integrates and facilitates many disaster incident management situations. The vision for providing this tool at no cost for a wider community use is documented by FEMA as below.

> ‘The National Incident Management System provides a systematic, proactive approach guiding departments and agencies at all levels of government, the private sector, and nongovernmental organisations to work seamlessly to prepare for, prevent, respond to, recover from, and mitigate the effects of incidents, regardless of cause, size, location, or complexity, in order to reduce the loss of life, property, and harm to the environment. [5]

'Incident Commander Pro' Software developed by SAR Technology for Search, Rescue and Emergency Response is built upon the NIMS Incident Command System and provides a comprehensive set of Command, Operations, Planning and Logistic functions to manage every type of emergency response mission. It has features that are tightly integrated and tested by field workers to provide a fast and flexible response to every aspect of the recovery mission [11]. Versions of this software are available from http://sartechnology.ca, SAR Technology repositories for downloading.

5. Further developments

The components described in figures 2 and 3 were considered for integrating into a unique single VM infrastructure with the focus of targeting a simplified evaluation of the VDRC technology. Hence VGP, VDS and Catalogue node services are integrated to achieve an efficient decentralisation [2] of these services among many VDRCs with ease. The VMs in operation at VDRCs are connected securely for automated repository and catalogue updates. While each centre manages their own user base and related access policies within the node the single sign on allows users to access other centres based on the negotiations between VDRCs. Therefore with the engagement of an appropriate networking technology to connect VDRCs the users are able to receive required information via the VGP through the established VDS. The integration of this infrastructure with the other software services described in section 4 that also operates within VM environments are to be considered for establishing a baseline infrastructure for the future VDRCs. The results of such work, improvements to the system architecture and updates of the global communication infrastructure will be published in the future.

6. Conclusion

The proposed system, infrastructure and software tools that are described in this paper takes the disaster recovery process another step forward under different circumstances. It is envisaged to pilot this proposal for refining the baseline architecture suitable for ad-hock deployment in the near future. The VDRC infrastructure described which combines the above features while supporting an innovative capacity for dynamic integration of such tools within the given volatile environment. The VT allows the ability to mix and match variety of softwares and systems together that facilitate the disaster recovery effort. While the recovery communities and organisations may not have adequate resources to develop their own tools, softwares and infrastructures for this purpose it becomes very important to move with the latest global developments and capitalise on the state-of-the-art.

Abstract

The aim of this paper is to introduce a model for pre-qualification of contractors in construction projects. In the recent years huge funds has been wasted due to the inappropriate selection of contractors for the construction projects. So, the appropriate selection of the qualified contractors is one of the most important strategies in such projects. However the nature of such decision making is sophisticated. Several quantitative and qualitative factors can be employed in the assessment procedure. The assessment of Iran construction codes shows that the most important criteria in construction contractors pre-qualification are experience, quality & safety, current projects, resources and company repetitions. In the present paper the language terms will be used in contractors' evaluation. These language terms are including triangular and trapezoidal fuzzy numbers. After that, a multi criteria decision making system based on the fuzzy set theory is introduced in order to clarifying the ranks of the contractors due to their qualification. In the proposed method, after determining the fuzzy weight of each criterion using Buckley method, the fuzzy topsis method is used for ranking the contractors due to their qualification. Finally the proposed model is assessed using a numerical example and sensitivity analysis has been done.

Keywords: Pre-qualification, Fuzzy Topsis method, Fuzzy Set, Multi Criteria Decision Making

1. Introduction

Contractors play a significant role in construction projects. So it can be concluded that the contractor selection is the most important decision made by the project owners. The contractor selection process has significant risks for the project owners; consequently they try to reduce these risks [1].

In the recent years, several problems encountered in the construction projects which cause wasting of huge funds. The collected statistics shows that near 10% of these problems is due to the low qualification of construction contractors [2]. Hence, introducing a procedure to solve

such problems has its place in the owners' point of view. Firstly, the contractor selection was based on the lowest proposed price which causes some problems during the project performance. To solve the mentioned problem, the owners need a filter to prevent unqualified contractors to participate in the tender [3]. In the present paper a fuzzy method will be introduced to determine the qualification level of each contractor. After determining the fuzzy weights of criteria, the closeness coefficient for each contractor will be obtained and finally based on the owner idea limited number of qualified contractors will be invited to participate in the tender. Applying the mentioned method, assures the owner certain on the contractor's qualification and the breakage risk of the projects becomes lower.

2. Literature Review

The tender competition has a long history in the U.S.A. Hatush shows that this system has been employed in New York State since 1847. The main employment of this method was in highways and bridges tenders [4].

The main idea of this method was that awarding the tender with the minimum price, saves the public sector from the corruption and other unacceptable events. The initial demand for this system was to make owners certain on the project utilization and benefit with the minimum construction costs.

Some changes has made in this system during years. A division for proposal acceptability selection and the public tend to control the tender winner's capability has been added to the system. There were some improving elements including preparation of a list of qualified contractors and other factors in this area. Although the main idea has been remained unchanged since 19th century, but all countries do not accept the minimum price as the contract awarded [5].

Few countries including Italy, Portugal and Peru have chosen a system in which the best proposal is not necessarily the minimum financial proposal. The main philosophy used in this system is that the best proposal is the most acceptable one, not the one with the minimum price. The most acceptable proposal is near to the average price of received proposals [6].

This kind of tender's procedure has some disadvantages which influences its efficiency. Although this procedure saves the project from any political, financial and public pressures, as the decision making parameter is the proposed price it may cause some problems in time, quality and safety of project. So the multi parametric tender system has been proposed which considers other intervening parameters more than the construction costs. In the new system it is believed that the project can be completed with the highest quality if the contractor has an appropriate combination of all parameters. So the multi parametric procedure has been used in prequalification of contractors. This problem has been used in different cases by researchers. Diekmann used the multi properties applications method in a case study about contractor selection and evaluation in Cost-Plus contracts [7]. Nguyen used the fuzzy set theory in contractors evaluation based on some decision making parameters [8].

The most important person performing lots of activities in this field is J. S. Russel. Russel and his colleagues prepared a program named Qualifier-1 in 1990 which was produced from a linear model of weight factors created by the user. This program calculates the weight ratio of each contractor and each contractor's rank. Due to the systematic nature, this program is an appropriate device available for users to produce their own model considering the specific conditions. He also produced the Qualifier-2 software which is a model based on expert systems to select the appropriate proposal [9].

3. Fuzzy Set Theory

Fuzzy set theory, to treat fuzziness in data, was proposed by Zadeh in 1965. In Fuzzy set theory the membership grade can be taken as a value intermediate between 0 and 1 although in the normal case of set theory membership the grade can be taken only as 0 or 1.The function of the membership grade is called its "membership function" in Fuzzy theory. The membership function will be defined by the user in consideration of the fuzziness. In remote sensing it is often not easy to delineate the boundary between two different classes. In such cases as unclear defined class boundaries, Fuzzy set theory can be usefully applied, in a qualitative sense [10].

For the initial familiarization with fuzzy set theory some essential concepts and definitions should be mentioned. [11]

3.1. Definition of fuzzy sets: it is assumed that X is the classic set of possible space and its members are shown by x. Membership in a fuzzy subset of X is shown by μ_A identification function from X to [0,1], so that:

$\tilde{A} = \{(x, \mu_{\tilde{A}}(x)) \mid x \in X\}$	(1)

3.2. Definition: the $\tilde{A}$ fuzzy set will be convex if and only if for each x_1 and x_2 members of X:

$\mu_{\tilde{A}}(\lambda x_1 + (1-\lambda)x_2) \geq Min(\mu_{\tilde{A}}(x_1), \mu_{\tilde{A}}(x_2))$	(2)

3.3. Definition: the $\tilde{A}$ fuzzy set will be normal if and only if there is one x_i member of X for which we will have:

$\mu(x_i) = 1$	(3)

3.4. Definition: the $\tilde{A}$ fuzzy set which has been defined in the $\tilde{X}$ universal set will be named $\tilde{A}$ fuzzy number.

3.5. Definition: the cutting section set from the $\widetilde{A}$ fuzzy set is a non-fuzzy subset of X and is defined as following:

$A = \{x \mid \mu_{\widetilde{A}}(x) \geq \alpha, x \in A\}$	(4)

3.6. Definition: A trapezoidal and triangular fuzzy number $\widetilde{A}$ are shown as $\widetilde{A} = (a_1, a_2, a_3, a_4)$ and $\widetilde{A} = (a_1, a_2, a_3)$.Their shapes come below:

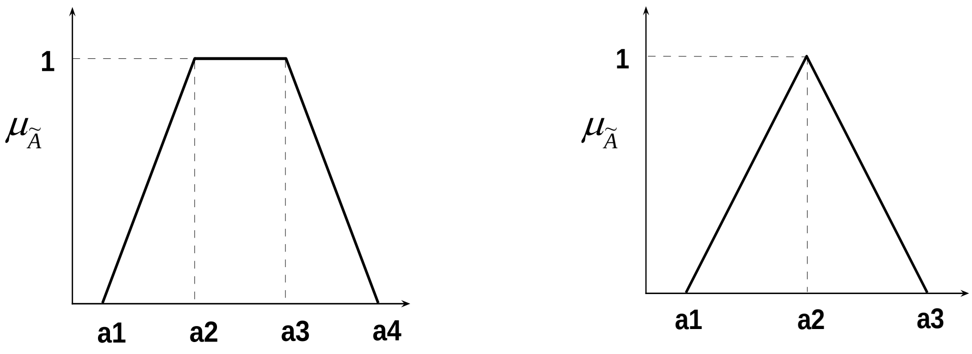

Figure1. Trapezoidal and triangular Fuzzy Numbers

If $\widetilde{A}=(a_1,b_1,c_1,d_1)$ and $\widetilde{B}=(a_2,b_2,c_2,d_2)$ then:

$\widetilde{A} + \widetilde{B} = (a_1 + a_2, b_1 + b_2, c_1 + c_2, d_1 + d_2)$	(5)
$\widetilde{A} - \widetilde{B} = (a_1 - d_2, b_1 - c_2, c_1 - b_2, d_1 - a_2)$	(6)

$r \otimes \widetilde{A} = (ra_1, rb_1, rc_1, rd_1)$	(7)
$\widetilde{A} \otimes \widetilde{B} = (a_1.a_2, b_1.b_2, c_1.c_2, d_1.d_2)$	(8)

3.7. Definition: The distance of two $\widetilde{A} = (a_1, b_1, c_1, d_1)$ and $\widetilde{B} = (a_2, b_2, c_2, d_2)$ fuzzy numbers is equal to:

$d(\widetilde{A},\widetilde{B}) = \sqrt{\frac{1}{4}\left[(a_1-a_2)^2+(b_1-b_2)^2+(c_1-c_2)^2+(d_1-d_2)^2\right]}$	(9)

4. The Proposed Model for Prequalification Based on the Fuzzy Topsis Method

The proposed model diagram for prequalification of contractors is indicated in Figure 2.

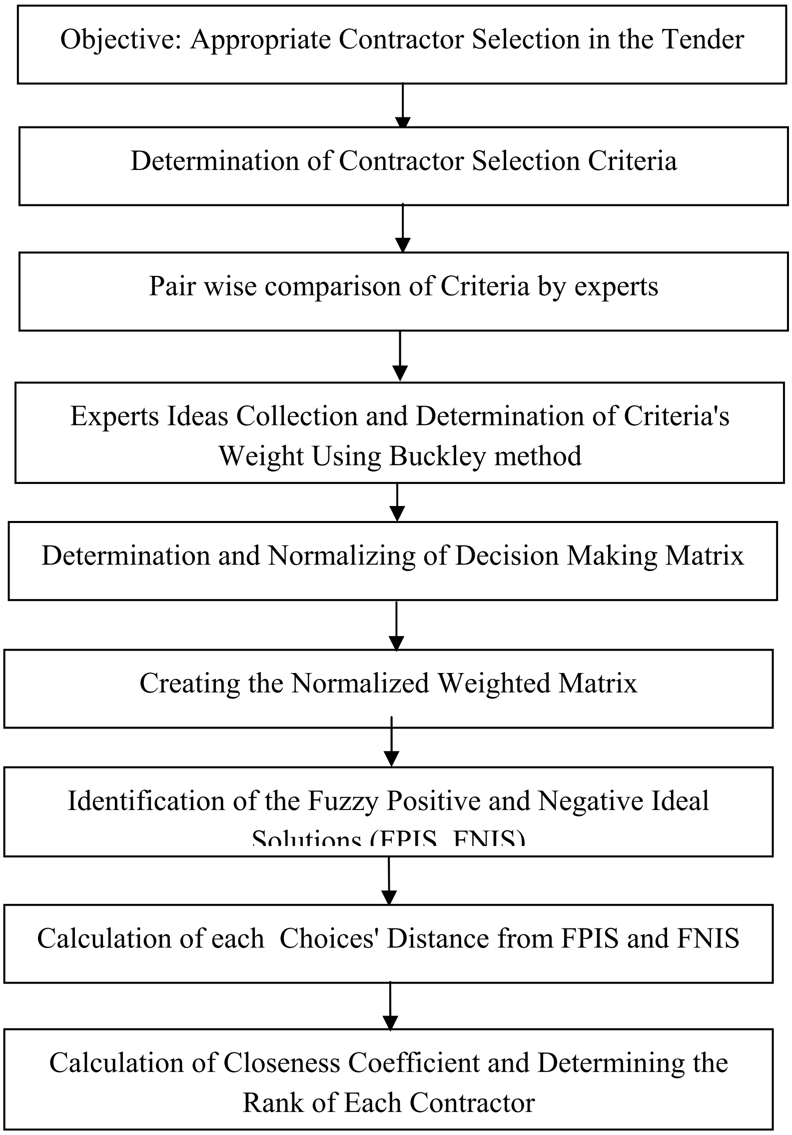

Figure 2: Proposed diagram for contractors' Pre-qualification model.

The model preparation steps are as follows:

Step 1: after careful assessment of Iranian construction codes and standards and assessing several owners' objectives, the main criteria for prequalification of contractors are mentioned below:

C1: Experience
C2: Financial Stability
C3: Company Repetitions
C4: Quality
C5: Current Projects
C6: Resources
C7: Company Management
C8: Company Technology

Step 2: To determine the weight of each criterion, the mentioned criteria were compared by experts. By application of Buckley method, the weight of each criterion will be determined considering the created pair wise comparison matrix. In this method some fuzzy numbers are used to compare the criteria priority. Figure 3 shows these numbers [12].

- Equal priority or importance: $(1,1,1,1)$
- Poor priority or importance: $(\frac{2}{3},1,1,\frac{3}{2})$
- Average priority or importance: $(\frac{3}{2},2,2,\frac{5}{2})$
- Strong priority or importance: $(\frac{5}{2},3,3,\frac{7}{2})$
- Absolute priority or importance: $(\frac{7}{2},4,4,\frac{9}{2})$

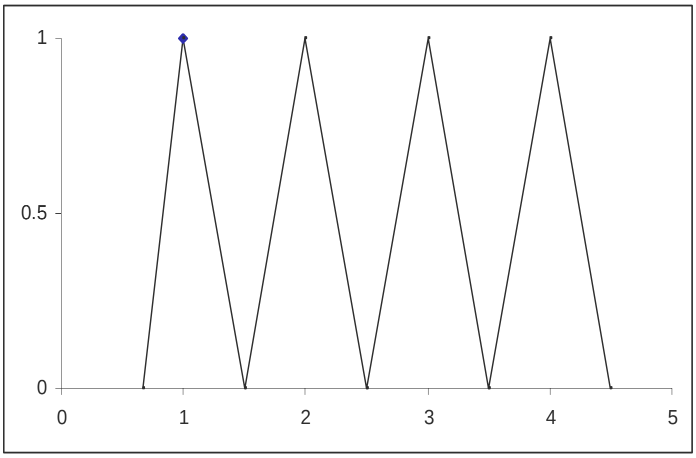

Figure 3: Fuzzy Numbers to Compare Criteria

Step 3: After completing the pair wise comparisons of criteria by experts and creating the pair wise comparison matrix, considering Buckley method the geometrical average of each line of pair wise comparison matrix will be determined using the following equation:

$$\tilde{z}_i = (\tilde{a}_{i1}.\tilde{a}_{i2}.\dots.\tilde{a}_{in}) \quad (10)$$

Then the fuzzy weight is determined by application of following equation:

$\widetilde{w}_i = \dfrac{\widetilde{z}_i}{\widetilde{z}_1 + \widetilde{z}_2 + \cdots + \widetilde{z}_n}$	(11)

If the number of decision makers were equal to k, and by using the mentioned method for each criterion a fuzzy weight has been obtained, then the total weight will be obtained as comes below:

If the weight of the J^{th} criterion for each of decision makers was as mentioned beneath:

$w_j = (w_{jl1}, w_{jl2}, w_{jl3}, w_{jl4}) \quad l = 1,2,\cdots,k$	(12)

Then the total weight will be calculated using following equations:

$w_{j1} = \dfrac{1}{k}\sum_{l=1}^{k} w_{jl1} \quad l = 1,2,\cdots,k$	(13)
$w_{j2} = \dfrac{1}{k}\sum_{l=1}^{k} w_{jl2} \quad l = 1,2,\cdots,k$	(14)
$w_{j3} = \dfrac{1}{k}\sum_{l=1}^{k} w_{jl3} \quad l = 1,2,\cdots,k$	(15)
$w_{j4} = \dfrac{1}{k}\sum_{l=1}^{k} w_{jl4} \quad l = 1,2,\cdots,k$	(16)

Step 4: Considering the ideas of experts assessing the contractors, for each criterion a quality manner is specified and finally the decision making matrix will be determined and then, using the following equations it will be normalized:

For indexes with positive aspect:

$\widetilde{n}_{ij} = \left(\dfrac{a_{ijl}}{a_{jr}^{\max}}, \dfrac{a_{ijm1}}{a_{jr}^{\max}}, \dfrac{a_{ijm2}}{a_{jr}^{\max}}, \dfrac{a_{ijr}}{a_{jr}^{\max}} \right)$	(17)

For indexes with negative aspect:

$$\tilde{n}_{ij} = \left(\frac{a_{jl}^{\min}}{a_{ijr}}, \frac{a_{jl}^{\min}}{a_{ijm2}}, \frac{a_{jl}^{\min}}{a_{ijm1}}, \frac{a_{jl}^{\min}}{a_{ijl}} \right) \tag{18}$$

Finally, after normalizing, the following decision making matrix will be obtained:

$$\tilde{N} = (\tilde{n}_{ij})_{m\times n} = \begin{array}{c} \\ A_1 \\ A_2 \\ \vdots \\ A_m \end{array} \begin{array}{c} \begin{array}{cccc} x_1 & x_2 & \cdots & x_n \end{array} \\ \begin{pmatrix} \tilde{n}_{11} & \tilde{n}_{12} & \cdots & \tilde{n}_{1n} \\ \tilde{n}_{21} & \tilde{n}_{22} & \cdots & \tilde{n}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{n}_{m1} & \tilde{n}_{m2} & & \tilde{n}_{mn} \end{pmatrix} \end{array} \tag{19}$$

Step 5: in this step, having the weights of criteria and the normal matrix, the normalized weighted matrix will be obtained using following equations:

$$\tilde{V} = [\tilde{\upsilon}_{ij}]_{m\times n} \qquad i = 1,2,\ldots,m \qquad j = 1,2,\ldots,n \tag{20}$$

$$\tilde{\upsilon}_{ij} = \tilde{n}_{ij} . \tilde{w}_j \tag{21}$$

$$\tilde{V} = [\tilde{\upsilon}_{ij}]_{m\times n} = \begin{pmatrix} \tilde{\upsilon}_{11} & \tilde{\upsilon}_{12} & \cdots & \tilde{\upsilon}_{1n} \\ \tilde{\upsilon}_{21} & \tilde{\upsilon}_{22} & \cdots & \tilde{\upsilon}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{\upsilon}_{m1} & \tilde{\upsilon}_{m1} & & \tilde{\upsilon}_{mn} \end{pmatrix} = \begin{pmatrix} \tilde{w}_1 . \tilde{\upsilon}_{11} & \tilde{w}_2 . \tilde{\upsilon}_{12} & \cdots & \tilde{w}_n . \tilde{\upsilon}_{1n} \\ \tilde{w}_1 . \tilde{\upsilon}_{21} & \tilde{w}_2 . \tilde{\upsilon}_{22} & \cdots & \tilde{w}_n . \tilde{\upsilon}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{w}_1 . \tilde{\upsilon}_{m1} & \tilde{w}_2 . \tilde{\upsilon}_{m1} & & \tilde{w}_n . \tilde{\upsilon}_{mn} \end{pmatrix} \tag{22}$$

Step 6: Identifying the fuzzy positive and negative ideal solutions by following equations:

$$A^* = \{ \tilde{\upsilon}_1^*, \tilde{\upsilon}_2^*, \ldots, \tilde{\upsilon}_n^* \} = \{ (\max_i \tilde{\upsilon}_{ij} \mid j \in J_1), (\min_i \tilde{\upsilon}_{ij} \mid j \in J_2) \quad \mid i = 1,2,\ldots,m \} \tag{23}$$

$$A = \{ \tilde{\upsilon}_1, \tilde{\upsilon}_2, \ldots, \tilde{\upsilon}_n \} = \{ (\min_i \tilde{\upsilon}_{ij} \mid j \in J_1), (\max_i \tilde{\upsilon}_{ij} \mid j \in J_2) \quad \mid i = 1,2,\ldots,m \} \tag{24}$$

Step 7: Calculation of choices' distance from the fuzzy positive and negative ideal solutions. These distances will be specified using following equations:

$d_i^* = \sum_{j=1}^{n} d_\upsilon\left(\tilde{\upsilon}_{ij}, \tilde{\upsilon}_j^*\right) \quad i = 1,2,\dots,m$	(25)
$d_i^- = \sum_{j=1}^{n} d_\upsilon\left(\tilde{\upsilon}_{ij}, \tilde{\upsilon}_j^-\right) \quad i = 1,2,\dots,m$	(26)

Step 8: The qualification degree of each contractor is determined by applying closeness coefficient (Cc) as below:

$cc_i = \dfrac{d_i^-}{d_i^- + d_i^*}$	(27)

5. Numerical Example

To evaluate the proposed model a case study was conducted. This study was performed in a real construction project in Iran. The owner of the project is Iranian ministry of road and transportation and 7 companies participated in the tender which shown as A to G. Firstly, by distributing the questionnaires among experts and apply of mentioned method the weight of each criterion has been specified as presented in Table 1.

Table 1: Fuzzy Weights of Criteria

Pre-qualification criteria	**Fuzzy weights of criteria**
C1	(0/12 ,0/19 ,0/19 ,0/28)
C2	(0/07, 0/12 ,0/12 ,0/16)
C3	(0/08 ,0/14 ,0/14 ,0/22)
C4	(0/07 ,0/1 ,0/1 ,0/16)
C5	(0/07 ,0/12 ,0/12 ,0/20)
C6	(0/08 ,0/13 ,0/13 ,0/22)

C7	(0/1 ,0/14 ,0/14 ,0/22)
C8	(0/05 ,0/08 ,0/08 ,0/12)

After that in order to rank the contractors the language terms will be used. For this reason the triangular and trapezoidal fuzzy numbers are applied. Their fuzzy numbers are mentioned below [12]:

- Very good or very important: (VG/VI), fuzzy number: $(0/8, 0/9, 1, 1)$
- Good or Important (G/V), fuzzy number: $(0/6, 0/7, 0/8, 0/9)$
- Above Average (AA), fuzzy number: $(0/5, 0/6, 0/7, 0/8)$
- Average (A), fuzzy number: $(0/4, 0/5, 0/5, 0/6)$
- Below Average (BA), fuzzy number: $(0/2, 0/3, 0/4, 0/5)$
- Poor or low importance (P/LI), fuzzy number: $(0/1, 0/2, 0/3, 0/4)$
- Very poor or very low importance (VP/VL), fuzzy number: $(0, 0, 0/1, 0/2)$

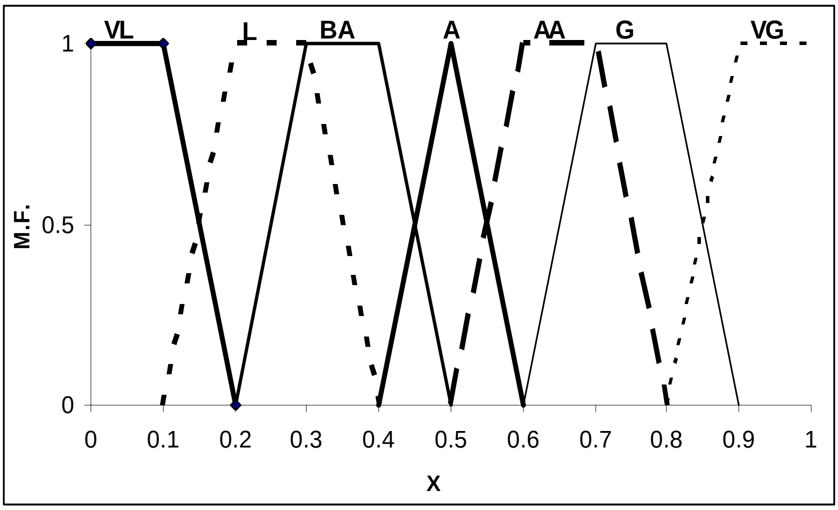

Figure 4: Fuzzy Numbers for each criterion

After determining the language terms and criteria' weight It can be assigned an especial manner for each criterion of each contractor. Considering the experts' ideas for each criterion and each contractor a language term has been assigned which is shown in Table 2.

Table 2: Assigned Language Terms

Criteria	C1	C2	C3	C4	C5	C6	C7	C8
A	G	A	VG	VG	L	G	G	AA
B	A	BA	BA	G	A	VP	BA	P
C	A	P	G	BA	H	AA	G	A
D	AA	BA	G	G	A	A	G	A
E	G	BA	BA	VG	AA	A	AA	A
F	VG	P	VP	G	VH	BA	G	VG
G	A	VP	P	G	VL	BA	G	VP

After locating the equivalent fuzzy of language terms in the above matrix, the decision making matrix will be obtained.

In the next step, by normalizing the decision making matrix using the aforementioned method, the normal matrix will be obtained. This matrix has been shown in Table 3 for the first four criteria. In the next step, by multiplying the criteria' weight by the normal matrix, the normal weighted matrix will be obtained which is shown for the first four criteria in Table 4. After determining the normal weighted matrix, the positive and negative fuzzy ideals will be obtained for each criterion. These values are shown in Table 5.

Table 3: Normalized Matrix

	C1	**C2**	**C3**	**C4**
FPIS	(0/1 , 0/17 ,0/19 ,0/28)	(0/05 , 0/1 ,0/1 ,0/16)	(0/06 ,0/13 ,0/14 ,0/22)	(0/06 ,0/09 ,0/1 ,0/16)
FNIS	(0/05 ,0/1 ,0/1 ,0/17)	(0, 0 ,0/02 ,0/05)	(0, 0, 0/01 ,0/04)	(0/01 ,0/03 ,0/04 ,0/08)

Table 5 (Continue): Fuzzy positive and negative ideal solutions for each criterion

	C5	**C6**	**C7**	**C8**
FPIS	(0/05 ,0/1 ,0/1 ,0/16)	(0/05 ,0/1 ,0/12 ,0/22)	(0/07 ,0/11 ,0/12 ,0/22)	(0/03 ,0/05 ,0/06 ,0/4)
FNIS	(0/07 ,0/12 ,0/12 ,0/2)	(0 ,0 ,0/01 ,0/05)	(0/02 ,0/05 ,0/06 ,0/12)	(0, 0, 0/01 , 0/1)

In the next step, having FPIS and FNIS for each criterion, for each contractor the distances form the mentioned boundaries will be calculated. After that the summation of these distances is determined and finally the closeness coefficient for each criterion is calculated. Table 6 shows the closeness coefficients for each contractor. Finally after grading the contractors based on these coefficients, the sensitivity of this kind of grading to each criterion's weight should be investigated. To achieve this goal the sensitivity analysis will be done in the following section.

Table 6: Closeness Coefficients for Contractors

CONTRACTOR	A	B	C	D	E	F	G
Cc	0/79	0/275	0/55	0/61	0/59	0/69	0/22

6. Sensitivity Analysis

For evaluating the effect of criterion's weight on the closeness coefficients and contractor's ranking the weights of criteria will be changed .Figures 5, 6 and 7 shows the effect of changing weight of first three criteria on the contractor's ranking.

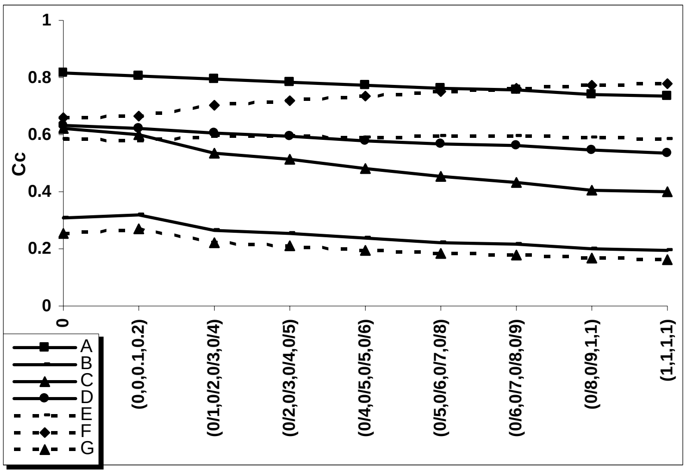

Figure 5: Experience Criterion – Fuzzy Topsis

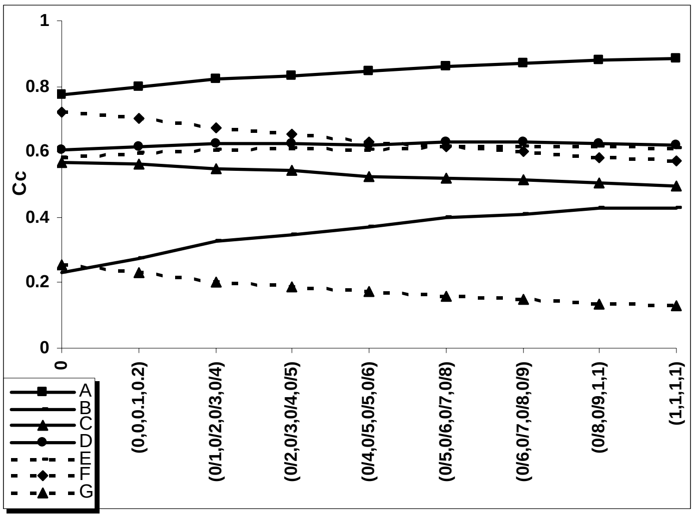

Figure 6: Financial Stability – Fuzzy Topsis

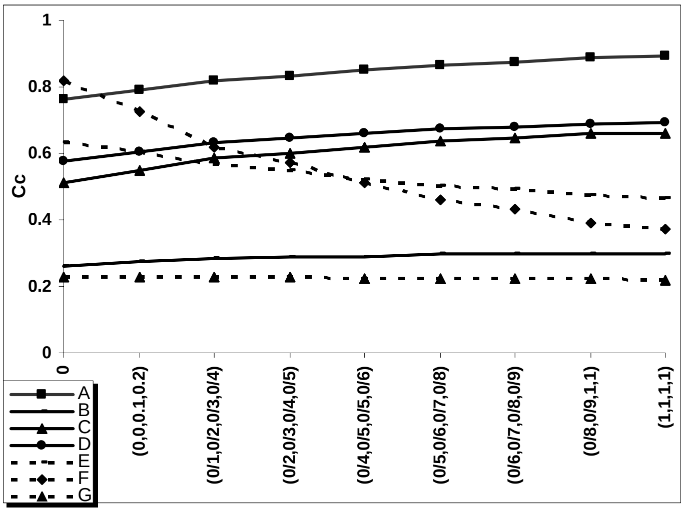

Figure 7: Company Repetitions – Fuzzy Topsis

7. Conclusion

In the present paper by introducing a fuzzy decision making method for prequalification of the contractors considering the appropriate criteria, the contractors were pre-qualified sensitivity analysis done on the model. The presented model is valuable and useful for owners plan to qualify the contractors. Considering the sensitivity results shown in the charts the following conclusions can be obtained:

- The contractor's ranking by means of Fuzzy Topsis method is too sensitive to criterion's weights. So determining the relative weight of each criterion has a significant importance in this method.

- The presented method is not appropriate for careful decision makers accepting low risks in their decisions.

Abstract

The paper aims to explore the knowledge value creation capability and maturity of a high-tech organisation in Thailand. The research adopts an interpretive stance and employs a survey and a case study approach involving multiple data collection methods. The paper is based on one of the author's personal expertise and involvement in the selected case study organisation for over a decade. The results indicate that (a) the selected organisation has demonstrated its readiness to migrate to a value creation culture underpinned by knowledge sharing and creation practices, (b) the distinctive collective characteristic of Thai culture engenders a strong human and social sense of community, which in turn promotes knowledge-friendly practices, and (c) a knowledge culture requires essential socio-organisational ingredients, including trust, confidence, motivation, continuous learning. This empirical study provides a foundation to further the research to: (a) explore the role of knowledge management systems in promoting value creation, and (b) investigate the key distinctive features of Thai culture which underpin and influence knowledge management perceptions and practices of Thai employees.

Keywords: Knowledge management, Value creation, Interpretive case study, Information Systems, Thailand

1. Introduction

The increasing popularity of knowledge management (KM) has been reinforced by the quest for innovation and value creation [1, 2]. Because of this, it is perceived that the future of KM tends to focus on value creation [3]. Value creation, as reported in Rezgui [4], is grounded in the appropriate combination of human networks [5], social capital [6], intellectual capital [7], and technology assets [8], facilitated by a culture of change [9]. In fact, the concept of Community of Practice (CoP) [5] was introduced as an effective social activity to share tacit knowledge. This had the effect of promoting and nurturing *human networks* which in turn motivate people to share and create knowledge. In this context, the *social capital* of an organisation emerges as an essential ingredient to help employees develop trust, respect, and understanding of others. Because of its (*social capital*) emphasis on collectivism and co-operation rather than individualism, distributed community members will be more inclined to connect and use electronic networks when they are motivated to share knowledge [6]. KM environments may foster social capital by offering virtual spaces for interaction, providing the context and history of interaction, and offering a motivational element (e.g. reward) to encourage people to share knowledge with each other [6]. The intellectual capital of an organisation encompasses organisational learning, innovation, skills, competencies, expertise and capabilities [10]. Liebowitz and Suen [7] suggest a strong and positive relationship between the value creation capability and Intellectual Capital of an organisation, pointing to factors such as training, R&D investment, employee satisfaction, and relationships development. Focusing on technology, the majority of KM initiatives involve, to a lesser or greater degree, information technology (IT) [11]. Alavi and Leidner [8] suggest that technology, including knowledge management systems (KMS), is an essential asset to sustain value creation. The use of technology in the context of KM has traditionally focussed on three common applications: (a) the coding and sharing of best practices, (b) the creation of corporate knowledge directories, and (c) the creation of knowledge networks. Lastly, change management plays an increasingly important role in sustaining “leading edge” competitiveness for organisations in times of rapid change and increased competition [9, 12, 13], and the future has only two predictable features – ‘change and resistance to change’ and the very survival of organisations will depend upon their ability not only to adapt to, but also to master these challenges.

KM solutions, including environments supporting information exchange, knowledge sharing and integration, and virtual communities, present a high and promising potential for developing countries [14]. However, very few articles have reported KM implementations and strategies in third world/developing countries, including South East Asia. Harris [15] argues that ICT adoption and deployment in South East Asian developing countries (Thailand, Malaysia, Philippines) are much effective than other developing countries (e.g. Pakistan and Bangladesh). Thailand, perceived as a new Asian Tiger economy [16], is successfully transforming itself into a knowledge-based economy. This confirms the perceived value of knowledge in Thailand and its crucial role in promoting a knowledge-based economy.

The aims of the paper are to (a) investigate overall KM practices and (b) explore value creation capabilities in a Thai Hi-Tech organisation, covering technical, cultural, and organisational aspects. The paper is organised into five main sections. Following this introduction, the paper presents the research methodology employed in this study, which involves a survey and a case study approach. This is followed by a brief overview of KM practices trends in Thailand that have emerged from the survey. A description of the case study data collection procedures and results is then given. The results are then discussed in the context of the research. Finally, the paper is summarised and various conclusions are drawn.

2. Research methodology

The research context used for the investigation is a case study, BETA (a pseudonym), a Thai Hi-Tech Research and Development (R&D) organisation which conducts research in Information Technology. A case study approach is well suited to Information Systems research [17]. It is widely used in qualitative information systems studies and can be applied in positivism and anti-positivism investigations [18, 19]. The case study aims to provide in-depth analysis of the selected organisation (BETA) for which KM is perceived as essential. The selected research units involve a number of knowledge-intensive production departments, which comprise several high-profile research teams. The two following research questions form the focus of the research:

- Have employees from BETA adopted a culture of knowledge sharing and creation across their organisation?

- What kind of perceived value is created out of existing knowledge practices across the organisation?

An interpretive stance is adopted as one of the researchers has worked in the organisation for over a decade. Indeed, the researcher has, over the years, acquired substantial personal knowledge of the organisation's culture and work environment.

The case study involves the use of five instruments: survey questionnaires, interview, process mapping, direct observation, and documentation. These instruments are employed in sequence from conducting a statistically analysed case study survey questionnaire then following up with in-depth interviews, observation and process mapping to better understand and interpret the results [20-22]. Therefore, the case study employs a combination of methods embodying quantitative and qualitative paradigms [23, 24]. There are two main reasons for supplementing quantitative with qualitative data: (a) to develop contextual richness that is valuable in model building, and (b) to improve internal validity and interpretation of quantitative findings through triangulation [25]. Data triangulation is chosen to analyse data collected from multiple sources, and corroborate qualitative with quantitative results [26].

3. Survey of Thai knowledge practices: key findings

Prior to conducting a case study approach, the researchers have surveyed 28 organisations, selected using the stratified random sampling technique, to build an overall understanding of KM practices in Thailand [27]. The main findings of the survey indicate that Thai organisations use information technology as a strategic instrument to address their communication and collaboration needs. Groupware has been identified as a common technology used by a limited number of leading organisations to create shared workplaces to support team work over space and time, and facilitate knowledge sharing. The results suggest that traditional face-to-face methods of interaction, such as formal and informal meetings, are essential in sharing experiences and tacit knowledge. These are complemented with virtual means through groupware functions, including e-mail, and telephone. Thai people expect reward for sharing and creating knowledge. While there is a distinct preference for monetary reward, Thai employees do also value recognition and praise. Overall, most Thai organisations attempt to increase their employees' awareness of the importance of knowledge, and various means are employed to motivate them to share, create, and use knowledge. The survey indicates a strong willingness of Thai organisations to adopt knowledge-friendly practices and become part of knowledge networks. From a socio-cultural perspective, the survey has identified the distinctive collective nature of Thai society underpinned by trust and strong social relationships. Overall, the following key findings have emerged: (a) there is an established knowledge sharing culture supported by a corporate KM strategy, amongst high-tech organisations, as well as a preparedness for change to migrate to a knowledge creation culture; (b) a number of Thai international organisations exhibit ad-hoc knowledge sharing practices as well as a growing awareness about the value of knowledge sharing and what can be termed as intangible assets; (c) there is a clear lack of any knowledge-oriented practice within ministry and departments of public sectors.

4. Case study data collection procedures and results

BETA was founded over 20 years ago. It employs more than 600 people, a majority of which is highly educated and works in R&D production departments. It has initially acted as a research supplier to Thai industry for over a decade. Following an increasing demand for R&D, BETA has transformed itself from a supply-driven to a demand-driven organisation. This demand-focused strategy has helped BETA address and meet the needs of Thai organisations more effectively. In the late nineties, the management initiated a large KM programme. In the first stage, a groupware (KMS) was deployed and adopted to help staff collaborate more effectively while promoting knowledge-friendly practices. Also, physical and virtual social spaces have been provided for sharing knowledge. Later, the management deployed a knowledge repository system to encourage staff codify tacit knowledge and experience into a re-usable form. A number of incentives have been introduced, including monetary rewards and recognition to motivate people share and create knowledge. This section provides an overview of the case study data collection procedures as well as a summary of key findings from each collected data source (survey questionnaire, interview and observation, and process mapping).

4.1 Survey questionnaire

One hundred and thirty anonymous survey questionnaires were sent to the R&D production departments. Seventy one completed questionnaires were returned and analysed, representing a response rate of 55%. The analysis is structured into four parts: work environment and teamwork, KM, requirements for ICT support, and barriers. The survey involves both open-ended and scaled-response questions.

In terms of work environment and teamwork, the results indicate that more than 95% of the respondents work in a team and almost 60% are involved in more than one team at a time. A majority of respondents perceive their teamwork culture as bureaucratic but promotes employees' participation. Virtual and face-to-face means (including E-mail, telephone, formal and informal meetings) are used to communicate within and across teams. Employees have raised a number of factors that inhibit team working, including: (a) lack of effective communication, (b) lack of contribution, and (c) conflicting cultures (or co-existence of several school of thoughts) reflected in working procedures (staff have been educated in various parts of the world).

In terms of KM practices, over 90% of the respondents rely on knowledge to carry out their tasks and processes. More than 60% of the respondents describe "knowledge" as the fact of knowing and understanding through experience and study, and materialises as objects to be stored, shared and maintained. Over 75% of the respondents express a preference in sharing knowledge in informal (traditional face-to-face) as opposed to virtual contexts supported by technology. This is perceived by a majority of respondents as a generalisable knowledge-sharing pattern. An interesting proportion (more than 75%) of the respondents exhibits a positive attitude to knowledge sharing as they perceive that knowledge sharing within and across organisations is very important in work. Simple knowledge sharing methods, such as storing knowledge items on the corporate intranet, represent some of the important needs expressed by the respondents, as opposed to any other methods involving extensive or advanced use of technology. However, some respondents have expressed strong concerns about sharing their knowledge arguing about confidentiality implications. Rewards, including in the form of staff development and empowerment, recognition, and financial incentives, have been suggested as effective factors that can contribute to improve staff level of motivation to share knowledge.

In terms of ICT usage, the results show that the respondents use computers mainly for (a) office automation purposes (including word-processing), (b) groupware-related needs (e-mail and some limited form of workflow support), and (c) web access. The survey indicates that 70% of the respondents often use groupware to support collaboration for intra-organisational purposes. Most respondents have expressed a preference to access information, knowledge, and services over the web, including access to document management functionality, e-learning and e-training systems to support self-learning over space and time. The introduction of solutions supporting ubiquitous access to information and knowledge resources has been appreciated by most respondents.

Finally, the gathered data helped identify barriers preventing employees to share / create knowledge in their organisation. These include: non-supportive organisational structure, lack of personal incentives, Intellectual Property Rights (IPR) concerns, reluctance to contribute (due to the fear to loose one's expert status), software limitations, and hardware / software prohibitive cost. A majority of respondents have also raised concerns about the management push to use open source software (e.g. OpenOffice word processor) motivated by software cost reductions. They feel that this constitutes a real barrier to personal and organisational development as ICT gradually play an important role in BETA's business processes.

4.2 Interview and direct observation

Twelve interviewees (including heads, sub-heads, and staff) drawn from four production departments, an IT department, and a KM department have been interviewed. These were complemented by direct observation. The analysis of the gathered data involved (a) producing interview transcripts, (b) generating pattern codes, and (c) drawing a checklist matrix [28].

Overall, interviewees are satisfied with their KM initiatives and the strong support they receive from their executives. This results in an increasing KM awareness and interest in the organisation, reflected in the effective use of existing in-house knowledge services. There is a strong belief that in-house knowledge repositories do provide great value for the organisation, in particular in the context of staff loss (although when an employee quits the organisation, his / her knowledge is not lost as it is already documented and stored in the system, and can therefore be used as best practice by other staff). Moreover, the interviewees believe in the self-development potential of in-house knowledge repositories. They suggest that employees should be encouraged to share knowledge within the organisation, and should be less concerned about inhibiting factors such as IPR and confidentiality issues. However, they do feel that these concerns are legitimate when knowledge is exposed externally.

Formal and on-the-job training, and learning from documentation are interviewees' preferred methods, respectively, to promote knowledge sharing. Knowledge sharing approaches in informal contexts such as discussion forums and coffee breaks are highly valued. They argue that these methods not only bridge the barrier between staff and managers, but also help staff practice their presentation skills, given the cultural reluctance of Thai people (due to a shy behavioural nature) to speak in public.

Interviewees have described their organisational structure as flat and participatory. This, in their opinion, has helped minimise teamwork problems. Employees tend to communicate with one another using informal face-to-face means. This promotes, as argued above, good relationship building between employees and managers. Although the prevailing participatory culture provides a strong working team spirit, potential problems may occur due to the desire of employees to be seen as being helpful by getting involved in several tasks, even when these can be achieved by one employee. Promoting appropriate teamwork environment and atmosphere help staff reduce their shyness and fears by encouraging them to contribute effectively through constructive comments to managers or team leaders. Interviewees have also mentioned a cultural problem where employees seem to have more respect for older employees regardless of their work performance and job status. This becomes an issue when a young manager is appointed. They have noted that this is non-changeable feature of Thai culture.

Reward systems have recently been introduced to motivate staff to share and create knowledge. The rewards offered include monetary rewards, promotion, recognition, and praise. They have noted that monetary reward and salary revision seem to be slightly resisted in the form they are currently implemented. One interviewee argues that monetary reward should be granted on an annual basis in the form of a special bonus. This is motivated by the fact that a salary revision has a permanent and definite effect (and is carried over in subsequent years) even when no further knowledge-friendly practices are demonstrated. Some categories of staff, including administrators, feel that this reward system is unfair and not suited to their jobs, as they do not involve a great deal of knowledge-friendly activities. Interviewees feel that this can be addressed through staff training and education.

In terms of technology adoption, interviewees reported that a minority of employees still resist the introduction of new IT systems to support teamwork and enhance organisational processes. This results in data redundancy and an unnecessary increase in helpdesk workload. In particular, this minority has complained about open source software that has recently been introduced, arguing that these are more difficult to use than similar commercial solutions. However, they follow these open source policies although such policies seem to generate resentment to anyone who disagrees. This is because they want to avoid any risks, conflicts, and unexpected problems such as punishment.

In terms of perceived limitations and barriers to KM, interviewees have raised several issues, including, financial implications, lack of adapted human resources, and limited knowledge of IT.

4.3 Process mapping

Process mapping is defined as a visual aid for picturing work processes which illustrate how inputs, outputs and tasks are linked [29]. Process maps do provide a clearer understanding of the business context than text [30] and are extensively used in re-engineering projects [31]. The purpose of process mapping in this research is to identify existing knowledge-related practices and structures across targeted departments. The resulting process maps, expressed in IDEF0 [32], were analysed and interpreted based on the data gathered from interview and observation.

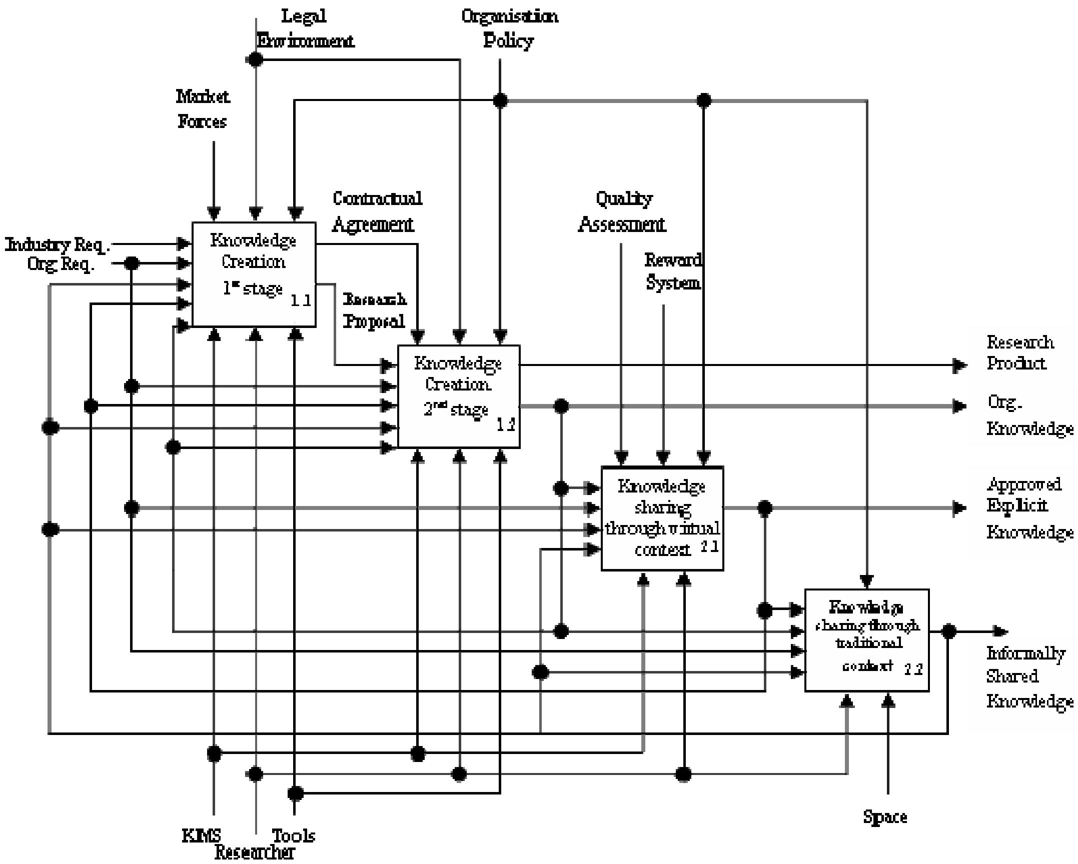

Figure 1: Process of Knowledge Sharing and Creation in BETA.

Figure 1 shows that industrial needs or market forces drive research in BETA, as it strives to be a “demand-driven” organisation. It helped identify two knowledge creation stages: *the 1st Stage* involves knowledge creation in the context of the commissioned research to support the development of a research proposal / brief, while the *2nd Stage* involves fulfilling the research proposal by producing research outputs, hence creating new knowledge. It also helped identify two knowledge sharing patterns: *Knowledge Sharing through Virtual Context*, which involves the process of knowledge sharing within virtual spaces through groupware using knowledge repository systems; whereas *Knowledge Sharing through Traditional Context* involves the process of knowledge sharing in physical contexts such as face-to-face formal or informal meetings. Researchers can share project / research knowledge through an internal and informal forum that all members of the department can attend. The forum aims to practice both research and presentation skills. Moreover, knowledge can be shared through dedicated project meetings that only project members are allowed to attend and discuss within the project team. During or after the research, the researchers are required to produce documents related to the ongoing or completed research, such as technical reports, papers, patents, and prototypes, and to upload these to the organisational knowledge repository system (BETA's Knowledge Management System). This is the mechanism used to acquire and store knowledge and also to claim rewards (monetary reward or promotion). The reward system was initiated based on the organisation policy to motivate employees to share and create knowledge. All documents uploaded to the system have to pass a quality assessment approved by a dedicated committee.

5. Discussion

Data gathered from these multiple qualitative and quantitative sources are triangulated to address the two research questions that form the basis of this investigation, supported by existing western as well as eastern (including Thai) literature.

Starting with the first research question, gathered primary sources of evidence confirm that a knowledge sharing and creation culture is in place in BETA. The results indicate an overall good awareness of, and cultural receptivity to, KM changes introduced in BETA over recent years. The authors argue in the context of the research that to promote KM, an organisation needs to meet four broad KM objectives [33] mentioned earlier in the paper: (a) creating knowledge repositories, (b) improving knowledge access, (c) enhancing cultural support for knowledge use, and (d) managing knowledge as an asset. The gathered data suggest that the introduction of a knowledge repository system has been welcomed, as the system promotes documenting and archiving of best practices across the organisation. In fact, the coding and sharing of best practice is one of the common initiatives employed to initiate organisational KM [8], and knowledge sharing can take place only once a corporate knowledge repository is made widely accessible to staff [34]. These have helped improve knowledge connectivity, access, and transfer across BETA. The research also confirms the role of information technology in general, in facilitating knowledge sharing and creation, as reported elsewhere [33, 35]. Moreover, the research has identified the role of Thai culture and values in the adoption and deployment of KM practices. This corroborates findings related to the adoption of IT in similar contexts [36]. Building a casual environment adapted to Thai culture, such as informal forums and personal connections, leads to positive KM practices [37], as trust and social relationships form the foundation of Thai society [36]. Also, the research acknowledges the impact of the change initiatives introduced by BETA over the years to increase staff KM awareness. This is exemplified by the introduction of reward systems to encourage people to contribute to KM activities, and establish an environment conducive to more effective knowledge practices, facilitated by the provision of physical and virtual spaces to share knowledge and help build knowledge communities. The change process involved (a) building awareness and cultural receptivity to knowledge, (b) changing behaviour relating to knowledge perception and practices, and (c) improving the KM process.

Overall, the gathered evidence suggests that BETA has achieved the four [33] KM objectives and has developed a true knowledge sharing and creation culture. This can help answer the second research question (What kind of perceived value is created out of existing knowledge practices across the organisation?). The four key value creation assets identified previously including human networks, social capital, intellectual capital, technology assets, and change processes [3] are used to support the discussion.

The gathered evidence shows that formal and informal communication using face-to-face (including scheduled meetings) and virtual (synchronous / asynchronous) means (e.g. telephone and e-mail) are perceived as effective to promote knowledge sharing and creation. As such, the research acknowledges the pivotal and strategic role that human networks play in promoting KM in the particular context of the collective characteristic of Thai culture, as reported in related literature [36, 38]. This has resulted in increased awareness, knowledge quality, and business intelligence which have triggered a value added dimension that did not exist prior to initiating the change processes. Human networks are facilitated and nurtured by providing informal forums that can be assimilated to communities of practice. These are complemented with virtual spaces to share knowledge (including sensitive information) protected by a role access control system. The collective characteristic of Thai society is exemplified by the dimension given to team working. However, it has been shown that human networks can only be effective if the social conditions that underpin collaboration are met (including trust). This emphasises the role that social capital plays in creating organisational value underpinned by strong human networks. A participatory culture helped employees develop trust, respect, and understanding for others at different levels in BETA. This, as reported in Kayworth and Leidner [39] and Soliman and Youssef [40], contributes to improving employees' overall satisfaction and job effectiveness.

The results confirm the usefulness of KMS to store best practices, and indicate a good enthusiasm for learning by doing, formal training or learning from documentation, facilitated by the wide introduction of technology. Knowledge is now perceived as a real asset, and gathered data highlight the importance of the ability to access internal and external knowledge. Hence, concerns raised by staff in terms of IPR and confidentiality issues. The level of awareness that exist amongst staff in relation to the power and politics of knowledge has developed remarkably over the years. This emphasises the positive perception and appreciation of BETA's corporate intellectual capital and direct influence on KM practices. In this context, the introduction of KMS (through knowledge repositories and dedicated groupware services) has been welcomed, as the system encourages staff to store and share best practices. Collaboration through groupware is overall highly valued, and is described as important to nurture knowledge sharing, as confirmed in related literature [41]. The incremental development and introduction of technology seem to have worked, as an acute sense of knowledge value is gradually emerging.

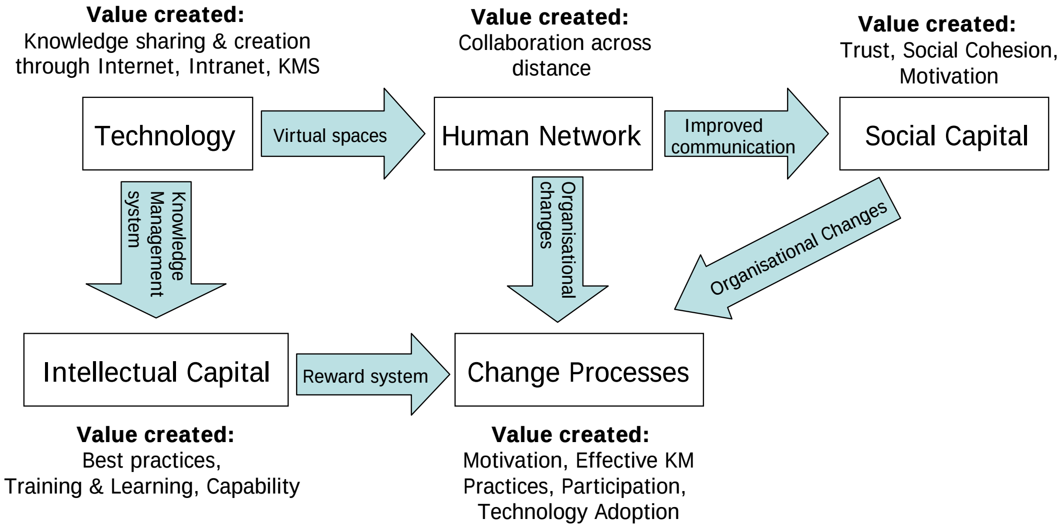

Figure 2: Factors to Sustain Value Creation in BETA

Thus, as illustrated in Figure 2, the value creation 'equation' in BETA is grounded in human networks underpinned by strong social structures facilitated by technology. Socio-cultural factors, including trust and confidentiality must be blended successfully toward the shared KM vision. Therefore, the migration path to value creation is grounded in human and cultural elements and is an exercise in change, which requires new mechanisms to enable participation and communication. The research reveals that the management have tried to adopt reward systems to motivate employees to share and create knowledge, and the employees have responded positively to the introduction of monetary and non-monetary rewards. There is a strong awareness amongst executive staff that managing the change process should not be overlooked to sustain this knowledge sharing and creation culture.

6. Conclusion

The research has investigated the KM capabilities in BETA, a Thai Hi-Tech organisation. It has also explored the perception about the value that is created out of knowledge. The results indicate that (a) BETA has demonstrated its readiness to migrate to a value creation culture underpinned by knowledge sharing and creation practices, (b) the distinctive collective characteristic of Thai culture engenders strong human and social networks, which in turn promote knowledge-friendly practices, and (c) a knowledge culture requires essential socio-organisational ingredients, including trust, confidence, motivation, continuous learning. BETA, as any other knowledge-based organisation, needs all of its employees to adopt a culture that promotes the virtues of knowledge sharing and creation. The culture of a company is the set of values, norms and attitudes shared amongst the members of the organisation. A knowledge-based culture requires a number of essential attributes, including:

- A culture of confidence and trust in which people are willing to share the information and knowledge they have.

- A culture that recognises that much knowledge is tacit and nurtured in social networks. This recognition places an emphasis on promoting open dialogues between staff so they can develop social links that can promote shared understandings.

- The support for human networks where members continuously strive to increase their shared understanding of their collective tasks and to seek continuous improvements in their practice.

The research confirms that Thai employees are full of perceptive insights into creating value out of knowledge and KM practices. Human networks, social capital, intellectual capital, and change process emerge as essential conditions to enable value creation. Focusing on social capital, the research identifies the collective capabilities derived from social networks facilitated by a supportive Thai culture. The higher the level of social capital, the more distributed communities are stimulated to connect and share knowledge [6]. Social capital can be applied to create value for organisations and end-users [42]. It has been shown that end-users in BETA are organised into teams with a strong social community dimension. Moreover, members of these teams and communities will be more inclined to use adapted KMS when they are (a) motivated to share knowledge with others, (b) able to share knowledge, and (c) have the opportunity to share knowledge. KMS that embed social awareness can play an important role in addressing these requirements, and promote social capital within and across teams.

Clearly more empirical research is needed to explore the role of KMS in promoting value creation in Thailand. A potential research avenue is to measure KM performance in organisations. It is hoped that the paper will stimulate this debate and trigger further research.

Dynamic management models for simulation of construction company development

Dalibor Vytlačil,
Faculty of Civil Engineering, Czech Technical University in Prague
(email: vytlacil@fsv.cvut.cz)

Abstract

This paper presents models that are used for the prediction of the development of construction sector companies. These models are used for teaching management in the Czech Technical University. The models are based on the system dynamics method. The process of the model development and the usage is described in the paper. The first model describes the behaviour of the complex system representing the future development of a residential building market. The main subsystem is the stock of houses under development and stock of finished houses. The simulation program for hypothesis testing has been developed. The output parameters can be investigated from the investor, developer, construction company point of views. The second model calculates the amount of finished work in the projects that depend on the resources used in the project. It is an important issue nowadays in states with fast growth of the construction sector where a large worker shortage exists. The topic of the paper is more the description of the model development and learning process than a detailed description of the problem situations.

Keywords: System dynamics model, Dynamic behaviour, Housing market trends, Learning process

1. Introduction

1.1 Construction industry trends

We can observe in the Czech Republic the fast development of a construction industry production, see Figure 1. This industry comprises of 2355 companies with more than 20 employees that completed in the half year 2007 the construction works of 55.6 billion CZK (3 billion US$). It was more by 28.7 % than in the half year 2006 [1].

The changes in the economic environment caused important problems: construction companies suffer from worker shortage and from material shortage (e.g. bricks, thermal insulation materials). This development evoked new issues concerning the management methods in the companies as well as new tasks for the teaching processes in the universities. Project management and resources management subjects deal with the above described problems. This paper is focused on the presentation of system dynamics models that help to understand the dynamic behaviour of the systems reflecting real problems.

1.2 System dynamics methodology

The models are based on system dynamics. System dynamics method allows us to understand the dynamic behavior of the complex system [2]. This method can be used for the simulation of any system - hard as well as soft systems. Most applications are focused on socio-economic systems at the company level.

The main elements of the models are the stocks that represent the level of the parameter (e.g. amount of the water in the tank, the number of existing buildings, account balance, number of workers) and the flows that influence the level of the stock (e.g. financial flows, building construction flow). An example of the model is depicted in Figure 2. Auxiliary elements are connections and converters that ensure information transfers and the calculation of the secondary parameters [3]. The elements create loops in the systems, see Figure 3. The existence of the back-loops considerably influences the dynamic behaviour of the investigated system [4].

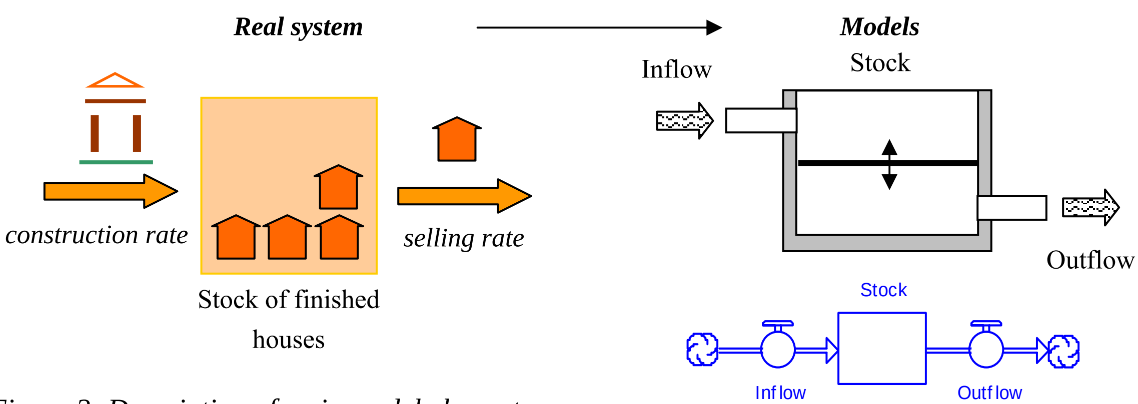

Figure 2: Description of main model elements

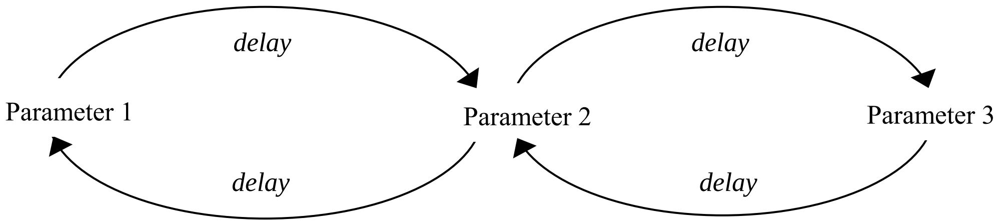

Figure 3: Causal loops in system

The equation that describes the stock changes for all kinds of parameters is Equation 1.

$$d\,(Stock)\,/\,dt = Inflow\,(t) - Outflow\,(t) \tag{1}$$

1.3 Teaching system dynamics

System dynamics models are used at the Czech Technical University, Faculty of Civil Engineering in subjects concerning management of the construction companies. There are different kinds of problem solving using system dynamics:

- From understanding system behaviour to the model - using ready-made system dynamics games, e.g. Beer game and deriving model for observed behaviour

- From the model to the proposal of the requested changes - using models for the design of input parameters or model structures with the goal to obtain the requested values of the output parameters

- Development of model for certain problem situation – understanding the dynamic behaviour and the development of the model

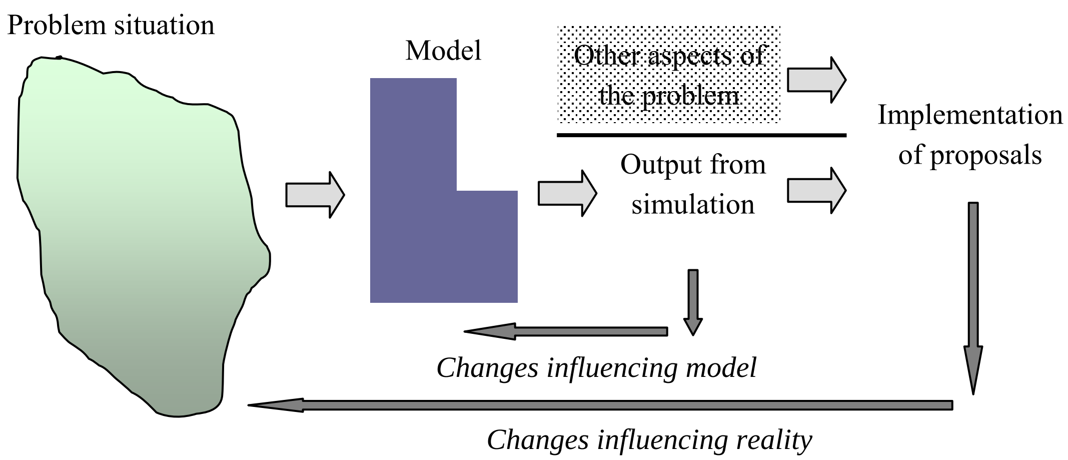

Figure 4: Relationship between problem situation and model

The students can practise all the described kind of problem solving. The whole process of the model design includes the steps of model construction, hypothesis development, hypothesis testing and conclusion writing. The students are trained to choose the relevant elements that have important influence on the behaviour of the real system and to consider also other aspects of the problem, see Figure 4.

2. Examples of models

The examples of two models developed for finding the desired parameters in the system are presented. Both models have been developed in the simulation program Stella [3].

2.1 Residential building market

The main subsystem is the stock of houses under development and stock of finished houses in a certain region. The starting rate is influenced by the efforts of the developers for new project launching. The number of finished houses depends on the capacity of building construction companies and on the demand for new houses.

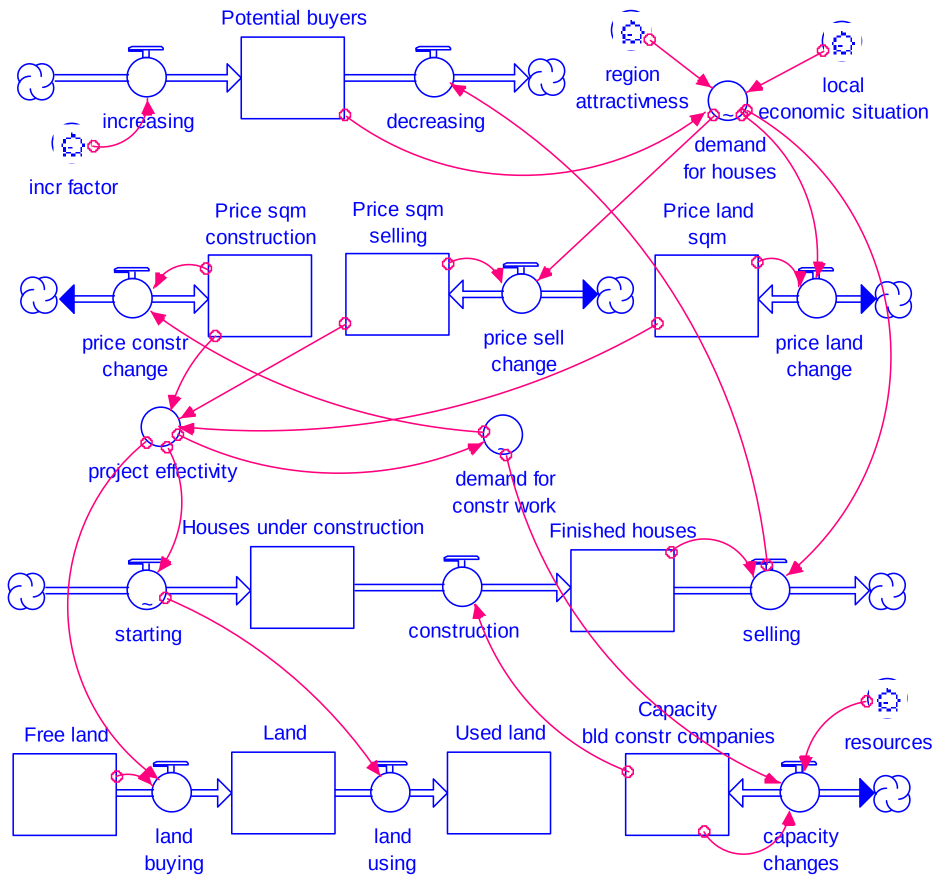

Figure 5: System dynamics model – residential buildings market

The objective of the class is to find the output parameters (finished houses during the next ten years) for actual input values and consequently to perform sensitivity analysis with goal to find the combination of input parameters that can ensure the growth of the market. The resultant values are shown in Figure 6.

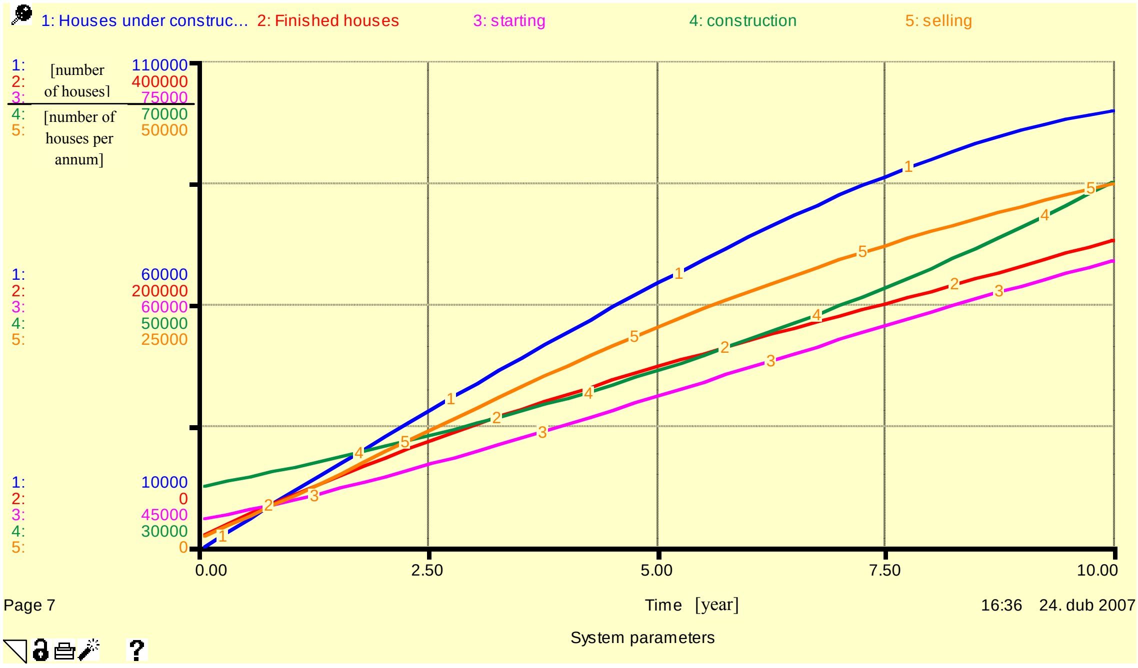

Figure 6: Output parameter values

2.2 Resources in project management

This model deals with the problem of project management. Students investigate the influence of the amount of the workers, their productivity and improvement time (Figure 7).

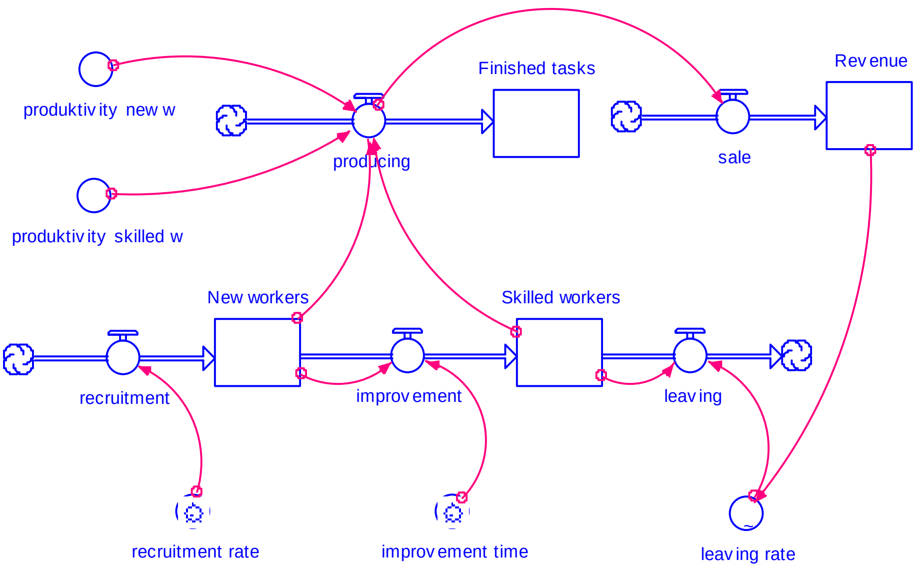

Figure 7: System dynamics model – project management

The main output parameter is *Finished tasks*. It is the amount of the accomplished tasks in the project during a time period. The model is suitable for all project-oriented companies but in this case the investigation is focused on solving problem of the key parameter - workers. The first stage is the presentation of the model as a simple line graph *recruitment – New workers – improvement – Skilled workers* and consequently other elements are added to the model. Students try to find the recruitment rate and the improvement time for the increase of the finished task and revenue. They also have possibility to design an improved structure of the model e.g. to introduce the element *cost of labour force*. The final recommendation is based on the simulated outputs together with the consideration of other influences.

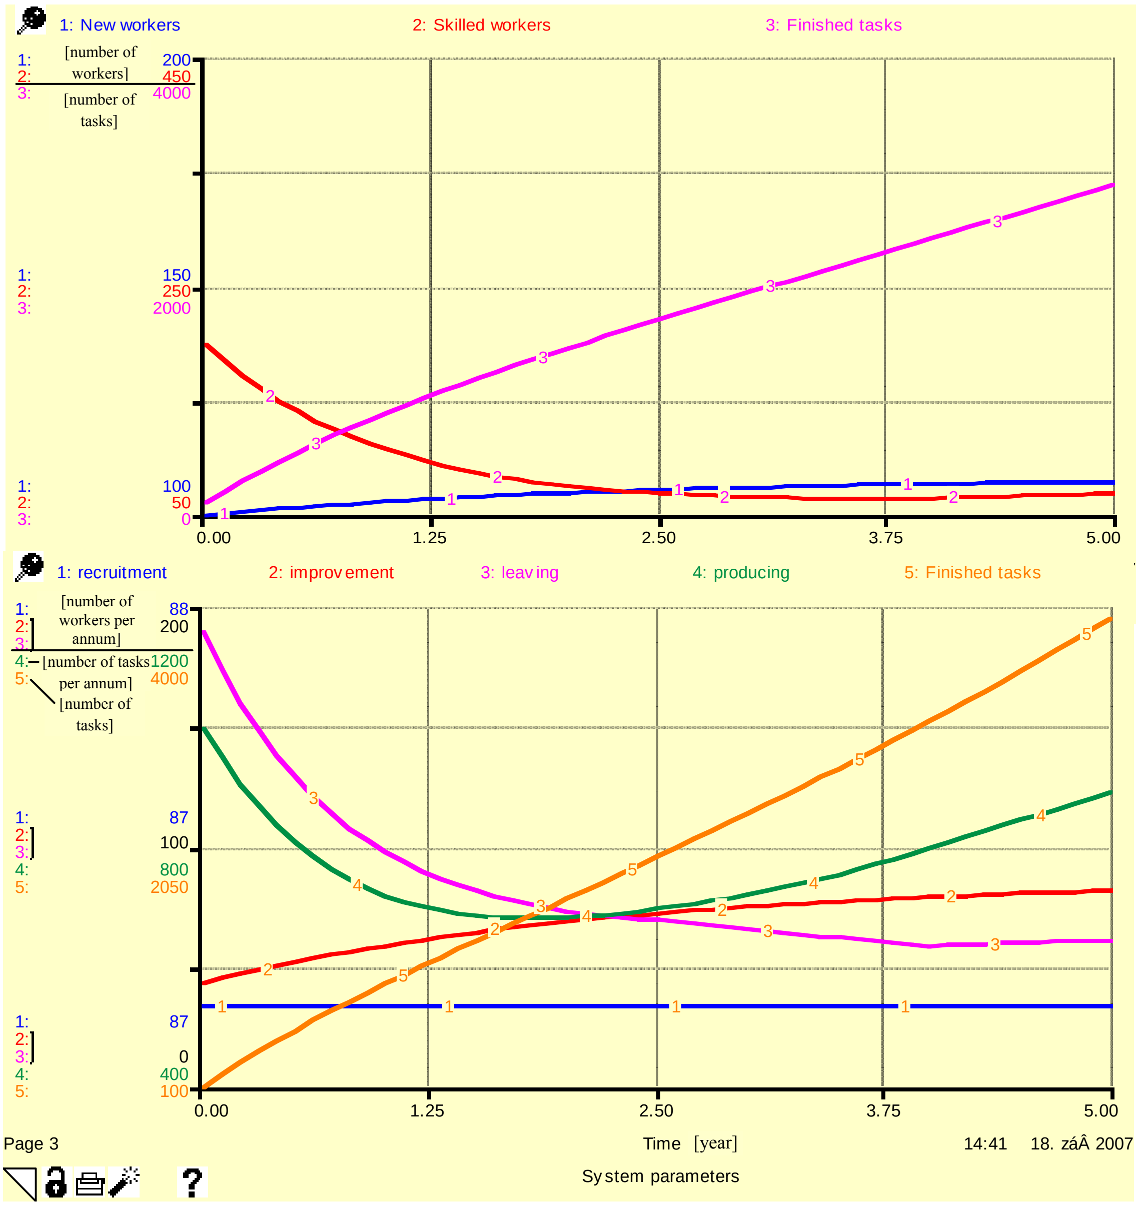

Figure 8: Output parameter values- initial values, Recruitment rate 47.0, Improvement time 2.3

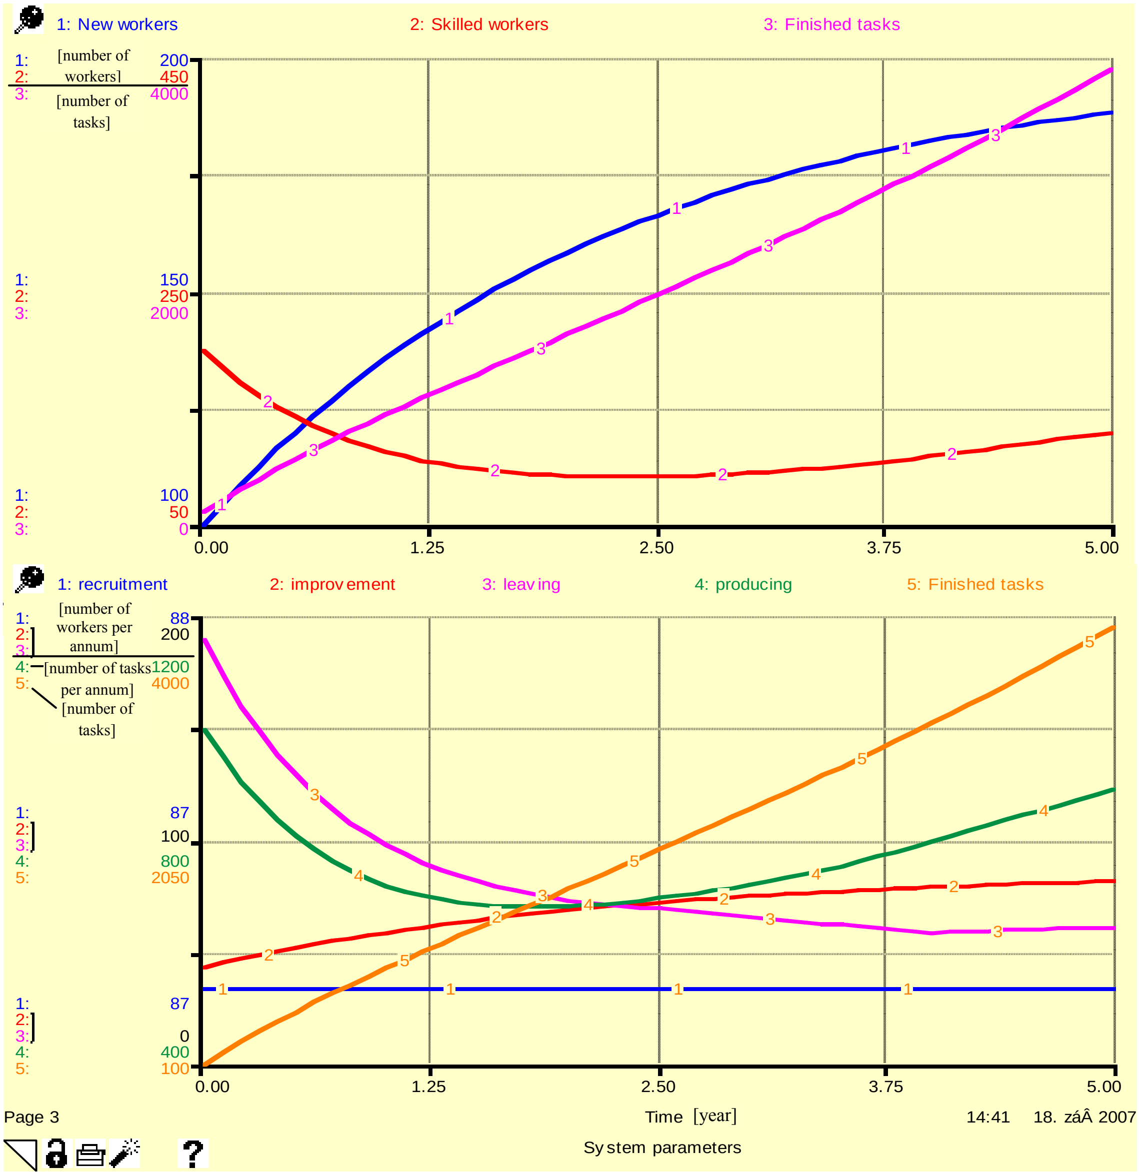

Figure 9: Output parameter values – improved values, Recruitment rate 87.0, Improvement time 2.3

Students write in the end of classes a document including their understanding of the problem situation, the goals of the simulation (what they wanted to obtain from the simulation) and their proposals for improving the problem.

The process of knowledge gathering and proposal making explained by means of system dynamics elements is described in Figure 10.

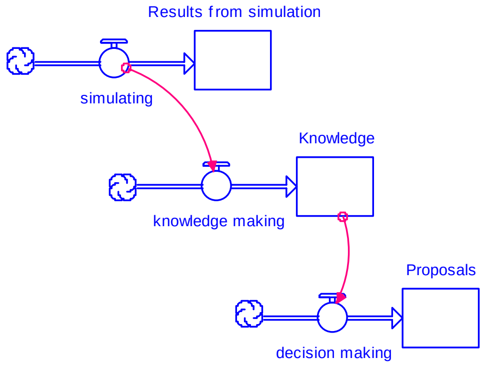

Figure 10: Process of knowledge and proposals development

3. Conclusions

Two models regarding the market prediction and the project management were presented. The usage of system dynamics models improves the learning process. The experiments in real world are very expensive and can caused serious problems in companies. The problem also is the impossibility to train all students in existing companies in the building sector.

The simulation in the virtual world brings new experiences for students. They can practise decision making without any apprehension. The students like to perform experiments in ready-made models and also to design their own models for a defined problem situation. Another advantage of using computer models is the possibility to compress time because students or any model designer can obtain many outputs in a very short time. The learning outcome is therefore very significant.

Next research will be focused on the development of the models that describe the problems in the building material supply. The discrepancies in the supply chain strongly influence the production of the companies in the construction industry.

This research has been supported by MSMT grant 6840770006.

Author Index

Building Resilience brings together contributions to the CIB W89 Building Education and Research Conference that was held at Kandalama in Sri Lanka on 11th – 15th February 2008. It includes approximately 160 executive summaries by scholars from around the world.

The content of the papers reflects the research interests of several working commissions and task groups that operate within CIB, the International Council for Research and Innovation in Building and Construction, which is the world's foremost organisation for construction researchers and practitioners. The CIB working commissions and task groups are W098 (Building Education and Research), W113 (Law and Dispute Resolution), W116 (Smart and Sustainable Built Environment), TG53 (Postgraduate Research Training in Building and Construction), and TG63 (Disasters and the Built Environment). A major cross-commission and task group theme of the conference was to promote built environment related education and research to address the complex and global problems associated with anticipating and responding to unexpected events that damage or destroy an infrastructure project.

The conference was held in conjunction with the EURASIA project (European and Asian Infrastructure Advantage), a three year International research initiative funded under the EU's Asia-Link Programme. The project is working to improve capacity in training, teaching and research activities required for the creation and long-term management of public and commercial facilities and infrastructure. The project comprises partner Institutions from the UK (University of Salford), Estonia (Tallinn Institute of Technology), Lithuania (Vilnius Gediminas Technical University), and Sri Lanka (University of Moratuwa and University of Ruhuna).
