ToF-SIMS sample preparation

The samples for TOFSIMS were prepared in a glovebox under dry nitrogen (BOC Nitrogen Oxygen Free) and mounted onto the adhesive side of a piece of Sellotape that was attached to a clean stainless steel substrate *ca*. $1 \text{ cm} \times 1 \text{ cm}$ in size by a small piece of double-sided tape (3M 'Scotch Tape' grade 665). A small pile of powder was pressed onto the tape using a clean stainless steel micro spatula. Any excess powder was removed by gentle tapping and blowing using an ambient atmosphere duster. This assembly was subsequently attached to the base plate of a sample holder using a small piece of double-sided tape. The prepared sample was then sealed under nitrogen inside a container and transferred to the TOFSIMS instrument.

ToF-SIMS data analysis

TOFSIMS peaks with a peak area of at least 1000 counts for ionic species with mass up to 117 Dalton were considered in the study. This allowed limiting uncertainty below 3.3% and the number of ionic species to be analysed (a list of species considered in the study is reported in

Table S2 of the SI). The sum of all species with positive polarity used in the analysis accounted for 20.15%-29.23% of the related total counts, whereas the sum of all species with negative polarities accounted for 63.31%-77.55% of the related total counts. The raw data were corrected to take account of any instrumental drifts by dividing the counts of each ionic species by the total counts in the spectrum. To allow easier identification of peaks with highest counts, the data were normalized to the species with the highest count, after the initial correction.

Ionic ratios of similar species containing ¹⁶O and ¹⁸O were studied using the data normalized to the total counts for both, positive and negative polarity. All ionic species included in the evaluation of the ¹⁸O:¹⁶O ratio are listed in Table S3. To estimate the total ¹⁸O:¹⁶O ratio, the

normalized intensity of each specie was multiplied by the number of oxygen isotopes in the specie. Species containing both isotopes were not included in the calculations. The resulting values were summarised to allow calculation of the ¹⁸O:¹⁶O ratio.

ToF-SIMS results: analysis of the individual ionic species

Figure S1-S3 in the SI show the normalized intensities of ions containing different oxygen isotopes, over the course of the experiment. Data at time 0 refers to the analysis carried out after 3 minutes exposure to atmosphere. Results demonstrate that, within the first 24 hours, the intensity of positive ions containing both, Ca and ¹⁶O increases, whereas positive ions containing only ¹⁶O and ¹⁶OH decrease. At the same time, the intensity of most positive ions containing ¹⁸O decreases, with the exception of the $[Ca_2^{18}O_2]^+$ which shows a small increase. The intensity of negative species containing ¹⁶O increase with the exception of Ca¹⁶OH, which decreases. Conversely, the intensity of the $[^{18}O]^-$ and $[^{18}OH]^-$ ions decrease.

From day 1 to day 8, the intensity of ions with positive and negative polarity typically showed very little variation. Exceptions are the positive species $[^{18}O]^+$ and $[^{18}OH]^+$, which sharply decrease and increase, respectively. The negative the species $[C^{18}O_3]^-$ and $[HC^{18}O_3]^-$ show a significant increase.

From day 8 to day 137, the most substantial variations are related to ions with positive polarity containing ¹⁶O (¹⁶O, ¹⁶OH, Ca¹⁶OH, Ca¹⁶O₂ and Ca² ¹⁶O₂H), which varied in the range 10^{-2} - 10^{0} , the ions [¹⁶O]⁻ and [¹⁶OH]⁻ with variations within the range 10^{-1} - 10^{0} , and the ions [¹⁸O]⁻ and [¹⁸OH]⁻, which showed variations in the range 10^{-1} - 10^{-3} .

Overall, the results show a general reduction in the relative intensities of species containing ¹⁸O from time 0 to day 1 and a simultaneous increase of the intensities of species containing ¹⁶O. The most relevant variations were related to ions such as $[Ca^{16}OH]^+$, $[Ca_2^{16}O_2H]^+$, $[^{16}O]^-$ and $[^{16}OH]^-$. Species containing carbon such as $[HC^{18}O_3]^-$, $[C^{18}O_3]^-$ and $[HC^{16}O_2]^+$ show an increase from day 1 to day 137.

TOFSIMS: analysis of the ¹⁸O:¹⁶O ratio

Figure S4 shows the ratio of the different isotope species containing ¹⁸O and ¹⁶O considered in this work. Species with positive polarity showed a general reduction from day 0 to day 1, whereas from day 1 to day 8 and from day 8 to day 137 the ratio remained almost unchanged. Unlike other results, [¹⁸OH:¹⁶OH]⁺ ratio of the carbonated Ca(¹⁸OH)₂ shows an increase from day 1 to day 137, due to an increase in the intensity of the 18OH ion and a simultaneous reduction of the ¹⁶OH ions. From day 8 to day 137, the isotopic ratio [¹⁸O:¹⁶O]⁺ approaches the values of natural samples.

PHREEQC calculations

Script S1 represent the model is used to calculate OH⁻ concentration of a solution of pure water in equilibrium with air at 23°C, and of a saturated aqueous solution of CaOH)₂ in equilibrium with air. Lines 1-10 are specially designed to not allow the N₂ gas contained in the air to react with O and form NO₃, according to a model suggested by David Parkhurst¹². Absence of these lines would make the N₂ and O₂ in the air react to form NO₃ since, having a fixed partial pressures of N₂ and O₂ would generates huge amounts of NO₃, and the program would fail to converge. Lines 12 to19 are used to model a solution made of pure water at 23°C. Initial pH 7 is adjusted during calculations to achieve charge balance. Lines 21 to 25 are used to model an equilibrium phase simulating air that is made to reacted with the water solution. Lines 28 to 21 are used to model an infinite reservoir of Ca(OH)₂ to be reacted with the water in equilibrium with air. The Ca(OH)₂ is forced to be in equilibrium with the solution. Values of the OH⁻ concentration can be read at the end of each batch-reaction calculation. Values are reported in Table S5 of these SI, together with the related pH. Databases used for these calculations are the wateq4f.dat (a database suited for processing large numbers of water analyses) and the llnl.dat (a database that uses thermodynamic data compiled by the Lawrence Livermore National Laboratory). Results obtained with the llnl.dat database are in very good agreement with the experimentally verified previous calculations made with a different model and the same llnl.dat database.¹³

Table S4 - Peak positions in the Raman spectra for different phases of calcium carbonate reported in the scientific literature

 $Table \ S5-pH \ and \ OH-\ concentration \ in \ different \ aqueous \ solutions, \ calculated \ using \ PHREEQC$

| Solution | Database wateq4f.dat | | | |
|--|----------------------|--------------------------|--------------------------|--|
| Solution | pН | OH ⁻ Molality | OH ⁻ Activity | |
| Pure H ₂ O in equilibrium with air | 5.6 | 3.444E-09 | 3.438E-09 | |
| Ca(OH) ₂ saturated aqueous solution | 12.54 | 3.697E-02 | 2.988E-02 | |

| | Database llnl.dat | | | |
|--|-------------------|--------------------------|--------------------------|--|
| | pН | OH ⁻ Molality | OH ⁻ Activity | |
| Pure H ₂ O in equilibrium with air | 5.6 | 3.353E-09 | 3.347E-09 | |
| Ca(OH) ₂ saturated aqueous solution | 12.45 | 2.801E-02 | 2.321E-02 | |
